9. During the evaluation phase, what specific indicators should the nursing team assess to determine Mr. Najarian's progress in his recovery from the broken leg? Consider his medical history in your answer.
10. How can the nursing team utilize the evaluation phase as a system to define, explain, and measure the effectiveness of Mr. Najarian's care, especially in relation to his chronic conditions?
11. How can the evaluation phase promote continuity of care for Mr. Najarian, especially considering his transition back home?
12. Reflect on the importance of comparing the planned activities (such as physical therapy sessions and wound care) with the identified outcomes (such as improved mobility and wound healing) in Mr. Najarian's case. How would this comparison impact future care decisions?
13. Mr. Najarian's recovery is on track, but he still requires pain management. How should the nursing team analyze the conclusions regarding his care plan? What decisions might they need to make?

You are a nurse in a medium-sized hospital's general medical unit. Recently, the hospital has implemented a new quality assurance program focusing on enhancing patient care and safety. One of the changes includes a new protocol for administering and documenting medications to reduce errors. Despite initial training, you notice that several nurses in your unit are struggling with the new system, leading to delays in medication administration and increased stress among the staff. The unit's patient satisfaction scores have also shown a slight decline, particularly in areas related to timely medication and effective communication.

14. In this scenario, how might structure and process evaluations be used to identify and address the issues arising from the new medication protocol?
15. How might a quality improvement initiative be designed to help the nursing staff adapt more effectively to the new medication protocol? Consider what data should be collected and how it should be used.
16. What changes could be implemented to improve the declining patient satisfaction scores? How would you use patient feedback to guide these changes?
17. Reflect on the National Database of Nursing Quality Indicators (NDNQI). What indicators might be most relevant in this scenario to monitor over time to ensure the new medication protocol is improving patient care and safety?

In a hospital setting, a patient, Mrs. Kalani, who recently underwent hip replacement surgery, is recovering in a postoperative unit. The nursing team is aware that she is at an increased risk of developing deep vein thrombosis (DVT) due to her surgery and limited mobility. To mitigate this risk, the team has implemented several interventions, including administering anticoagulants, encouraging leg exercises, and using compression stockings. Despite these measures, Mrs. Kalani complains of increasing pain and swelling in her left calf.

18. Considering the risk of DVT, what specific details should the nurses document in Mrs. Kalani's medical record to effectively manage this risk?
19. How should the nurses document their evaluation of Mrs. Kalani's condition in response to the interventions for DVT prevention?
20. In the context of this scenario, why is it crucial for the nursing team to maintain accuracy in their documentation, and what might be the consequences of inaccurate or incomplete documentation?
21. Choose a problem-oriented documentation method. Describe how a nurse might use this method to document an aspect of Mrs. Kalani's care in the given scenario.

## Competency-Based Assessments

The nurse is considering the following nursing interventions:

- Administering oral medications to a patient with hypertension
- Assisting a postoperative patient with ambulation
- Educating a patient about proper wound care techniques
- Monitoring a patient's blood glucose levels and administering insulin as prescribed
- Performing sterile dressing changes on a surgical wound
- Collaborating with the dietitian to develop a customized nutrition plan for a patient with diabetes
- Providing emotional support to a patient experiencing anxiety
- Initiating intravenous (IV) fluid therapy for a dehydrated patient
- Facilitating family communication and decision-making during end-of-life care discussions

- Assessing a patient's pain level and administering pain medication as prescribed
1. Identify if the interventions are direct or indirect.
  2. Identify if the interventions are independent, dependent, or interdependent.
  3. Identify if the interventions are based on actual or potential problems.
  4. Identify which interventions can be delegated to a CNA.

Markie, a nurse on a medical-surgical unit, is caring for a patient recovering from a surgical procedure. The goal of pain management is established, with the aim of achieving a pain level of 3 or below on a scale of 0 to 10. After administering pain medication as prescribed and implementing nonpharmacological pain relief measures, Markie assesses the patient's pain level and finds it consistently at a level of 2.

5. How does the evaluation of interventions determine a patient's progress?
6. How would the nurse evaluate the plan of care in this situation?
7. Is the goal met or unmet? How do you know?
8. Should the plan of care be continued, revised, or terminated? Why?

Take a look at the following HCAHPS sample questions and then answer the questions:

- How often did nurses communicate well with you?
  - How often did hospital staff respond quickly to your requests for help?
  - Did you receive information about what to do during your recovery at home?
  - Did the hospital staff explain the purpose of your medications in a way you could understand?
9. How do these questions assess quality of care?
  10. Determine strategies that could be used to provide quality care for each of the survey questions.
  11. Write a SOAP note documenting a nursing intervention for a patient experiencing impaired mobility following surgery.

## CHAPTER 15

# Evidence-Based Research, Quality Improvement, and Collaborative Practice

**FIGURE 15.1** Though distinct processes, evidence-based research and quality improvement together provide a solid foundation for competent, collaborative practice. Poster presentations are an excellent venue to share information about these processes, which are crucial to the growth of health care. (credit: modification of work by U.S. Department of Defense, Public Domain)

### CHAPTER OUTLINE

- 15.1 Evidence-Based Research
- 15.2 Evidence-Based Clinical Decisions
- 15.3 Quality Improvement in Nursing
- 15.4 Nursing Standards of Delegation
- 15.5 Collaborative Practice
- 15.6 Interprofessional Approach to Health Care

**INTRODUCTION** It is 1854, and Florence Nightingale has just arrived in Crimea, a peninsula in the Black Sea, with a group of thirty-eight English nurses ([Figure 15.2](#)). They have come to provide care for the sick and wounded men of the British forces who are fighting in the Crimean War. Nightingale is astounded by the filth and disease rampant in the hospital. Contaminated water is everywhere, and she sees the wounded lying in their own waste as bugs and mice scamper around them. She puts her nurses and the strongest patients to work with soap and scrub brushes. They clean the hospital from bottom to top, caring for patients as they go. The death rate in the hospital drops by two-thirds, and Nightingale—known today as the mother of modern nursing—has brought evidence-based practice to health care (Alexander, 2019).

**FIGURE 15.2** Florence Nightingale and another nurse care for a soldier in the now-clean Crimean hospital. (credit: “Florence Nightingale. Coloured lithograph” by Wellcome Collection Gallery, CC BY 4.0)

Research and evidence-based practice have been inextricably tied to modern nursing since its inception. Nurses are expected to continually seek out and learn better and more effective ways to care for their patients. In the process, they see immediately what works and what does not, giving them invaluable insight into the work of improving unit, group, and facility protocols. Agencies today recognize the value of nursing research, and many provide incentives, such as bonuses for publication of original research, and encourage research-supported quality improvements as an essential component of their promotion process. Since the days of Florence Nightingale, to be a true nurse is also to be a researcher or, at a minimum, a research user.

## 15.1 Evidence-Based Research

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe how nursing research has evolved
- Identify the steps for translating evidence-based research into evidence-based practice
- Understand various models for implementing evidence-based practice

Nurses do not stand alone. They work alongside a wide range of other healthcare providers, ranging from assistive personnel to medical professionals to environmental staff. All these positions, and the organizations that employ them, base decisions regarding their practice on evidence derived from research.

An **evidence-based practice (EBP)** is an ongoing decision-making strategy that integrates high-quality research with clinical experience and with patients’ preferences and beliefs (American Nurses Association [ANA], 2021; Polit & Beck, 2021). Evidence-based practice is considered one of the five core competencies of healthcare professionals (ANA, 2021). Thus, it is used by nurses and in all other fields of health care. For example, the Trendelenburg position (tilting a patient backward until their head is lower than their feet) was used for generations to manage hypotension immediately. However, studies have proven that while it may work for some patients, it is statistically not beneficial for the general population (Schnur, 2018). Additionally, using the Trendelenburg position has several health risks, including increased pressure on the brain and decreased respiratory ability (due to the pressure of abdominal organs on the lungs). Thus, because of research, current EBP discourages using the Trendelenburg position to manage hypotension.

The many types of research can be organized into two main categories:

- A **basic research** seeks to answer questions about current conditions without changing them. For example, basic researchers might ask, “What happens when a patient is placed in the Trendelenburg position?” Or, “How does giving patients glucose tablets rather than a cup of juice impact their blood sugar?”
- An **applied research** uses answers from basic research questions and other sources of current knowledge to evaluate changes to practice. For example, applied researchers might contrast the efficacy of a nurse-driven protocol for managing low blood sugar using glucose tablets (which may require a physician’s order) with the use of juice to manage low blood sugar within the bounds of nursing practice.

## Evolution of Nursing Research

Nursing research was in its infancy between Florence Nightingale’s work and the end of World War II, in 1945. The first journal dedicated to nursing research, *The American Journal of Nursing*, began publication in 1900, and the first doctoral program for nurses opened its doors in 1923 (Polit & Beck, 2021). Most of these early activities focused on nursing education, not patient care. However, in the 1950s, more journals began being published, nursing research centers started opening, and foundations to fund nursing research began to appear.

In the 1960s, as professional nursing organizations recognized the lack of nursing scholarship regarding patient care, they began developing research priorities that included nurses’ viewpoints, which are informed by nurses’ close connection to direct patient care. By the 1970s, quality improvement in patient care had become more important for all healthcare workers, and the expansion of nursing research reflected these needs.

By the early 1980s, at least six major nursing journals were publishing original nursing research, the ANA was holding nursing research conferences, a National Center for Nursing Research (NCNR) operated at the U.S. National Institutes of Health (NIH), and guidelines had been established to assess the quality of research for its usability in practice. Internationally, twenty-five European nurse associations had also joined forces to improve patient care there (Polit & Beck, 2021).

In the 1990s, nursing research continued growing in the United States and abroad. The United States established the Agency for Health Care Policy and Research, now known as the Agency for Healthcare Research and Quality (AHRQ), and the NCNR became the National Institute of Nursing Research. International nursing research groups and journals were also established in Europe, Australia, and Canada. Since the early 2000s, nursing research has come fully into its own, as nurses have become valued partners in the healthcare industry. Nurses have claimed their seats at national and international policy tables, and an army of nurse researchers has conducted and published high-quality research projects.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Generate Solutions: Using ANA Practice Standard 14: Scholarly Inquiry

ANA’s fourteenth practice standard for registered nurses states: “The registered nurse integrates scholarship, evidence, and research findings into practice” (ANA, 2021, p. 100).

Registered nurses should be able to perform several competencies relevant to this standard:

- Identify concerns that may be answered or informed through research.
- Combine evidence-based information with personal experience and patient preferences.
- Engage in evidence-based research.
- Use research to improve their knowledge, skills, abilities, and judgment.
- Share evidence-based knowledge with others to improve everyone’s practice.
- Incorporate research to improve the quality of patient care.
- Explain the value of research to the nursing profession.
- Encourage ethics in research endeavors.
- Review research for appropriateness within given settings and situations.

Today, nursing research is flourishing globally. The World Health Organization (WHO) designated 2020 (the 200th anniversary of Florence Nightingale’s birth) as the International Year of the Nurse and the Midwife (Wakefield et al., 2021). That same year, however, the onset of the COVID-19 pandemic brought to light many issues concerning the

nursing workforce and patient care. In 2021, the National Academy of Medicine (NAM) published a report on nursing over the next decade: *The Future of Nursing 2020–2030: Charting a Path to Achieve Health Equity*. The NAM report explores the unique position of nursing, including nurses' ability to work with all disciplines and to assist in improving health equity (Wakefield et al., 2021). It also offers research priority suggestions for nurses based on the population's most pressing needs. These include the following:

- Health equity: How can nursing and nurse-led interventions advance the equality of good health and health care across all patient populations?
- Emergencies: How can nurses better prepare for natural disasters and public health emergencies? Where are the gaps in education? What strategies will enable nurses to respond—and care for themselves—more effectively?
- Paying for health care: How can nurses quantify their value in terms of dollars saved by producing nursing-led interventions that improve patient outcomes versus the dollars spent in performing those interventions?
- Nursing education and workforce development: How can both processes be improved? What changes need to be made to improve workforce retention? What do nursing students need to be fully prepared for?
- Nurse well-being: How can nurses be supported more effectively by their agencies, the community, and each other? How can issues of lateral violence and incivility be managed?

## LIFE-STAGE CONTEXT

### Kangaroo Care for Newborns

Kangaroo care ([Figure 15.3](#)) provides an excellent example of EBP in action. Kangaroo care is the use of skin-to-skin contact—typically between an adult's bare chest (usually that of a parent) and a baby in only a diaper—for babies in neonatal intensive care units. Beginning kangaroo care immediately after the birth of a premature or low-birth-weight baby can dramatically improve their chance of survival, decreasing death rates by over 40 percent. Numerous studies have shown its effectiveness in helping premature babies regulate their body temperature, improving cardiorespiratory stability, decreasing pain and the chances of infection or severe illness, and facilitating bonding. It is cost effective and can be used exclusively in places that do not have available incubators. This practice was studied first in the 1970s but barely used until the late 1990s. Today, at least one hour of kangaroo care a day is considered best practice for premature but stable babies and recommended as a basic standard of care (Campbell-Yeo et al., 2015; WHO, 2021). Instances like these, in which nurses are firsthand witnesses to clinical behaviors that improve patient outcomes, provide a multitude of topics for nursing research.

**FIGURE 15.3** This mother provides kangaroo care to her babies in a neonatal intensive care unit. (credit: “Born too soon and too small - Edith's twin boys” by Lindsay Mgbor/Department for International Development, CC BY 2.0)

### Protection of Human Rights in Nursing Research

In a position statement about the nurse's role in ethics and human rights, the ANA highlights the need for nurse researchers to protect the human rights of research participants (ANA, 2016). Nurses taking part in research are specifically expected to do the following things:

- Ensure patients provide uncoerced agreement to participate in research or treatment. This informed consent must clearly explain the purpose, risks, and benefits of the research, as well as the intended use of patients' personal information.
- Continually evaluate the risks of the research versus the potential benefits of the outcome and stop research that is clearly harmful to the participants.
- Prevent harm to research participants.
- Engage in research that is relevant and will benefit the participants or people like them.

Everyone who seeks to perform research on a human subject, wants to receive grants or funding, or intends to publish their findings in a reputable journal must protect human rights. Per the NIH, a **human subject** is a living individual whom a researcher wants to interact with to collect information or specimens. Human subjects also include participants with whom the researcher does not interact directly if the researcher nevertheless plans to use their information or specimens in a way that may make them identifiable (NIH, 2018). Consider a case study of a 45-year-old Black man with a communicable disease such as HIV. In a large urban area where many people of all genders and races have the disease, simply removing the patient's name from the data may well make them unidentifiable to others. However, in a small community, simply removing the name may not be enough, and patients who are at risk of being identified based on the way their information is presented have the right to human subject protections. [Figure 15.4](#) provides more information about how the NIH defines research on human subjects.

Human Subjects Research		
<b>Research involving a living individual about whom data or biospecimens are obtained/used/studied/analyzed through interaction/intervention, or identifiable, private information is used/studied/analyzed/generated</b>		
<i>Examples of human subjects research include:</i>		
<ul style="list-style-type: none"> <li>• Collecting blood</li> <li>• Conducting a survey</li> <li>• Changing participants' environment</li> </ul>	<ul style="list-style-type: none"> <li>• Administering medicine</li> <li>• Interviewing</li> <li>• Administering a psychological test</li> </ul>	<ul style="list-style-type: none"> <li>• Collecting data</li> <li>• Conducting a focus group</li> <li>• Testing a new educational technique</li> </ul>
Included in the NIH application: Protection of Human Subjects attachment.		
If funded, grantees will need:		
<ol style="list-style-type: none"> <li>1. An Institutional Federal-Wide Assurance (FWA) with The Office for Human Research Protections (OHRP)</li> <li>2. Institutional Review Board (IRB) approval or determination of exemption</li> <li>3. Human Subjects education</li> </ol>		

**FIGURE 15.4** Human subjects research can include a variety of types of research. (credit: modification of work "Human Subjects Research-NIH Infographic" by National Institutes of Health, Public Domain)

Nurse researchers must consider rules for protecting human subjects when developing research questions and proposals. Generally, researchers take some type of education regarding the use of human subjects. The Office for Human Research Protections (part of the U.S. Department of Health and Human Services) offers extensive, web-based educational modules that meet the requirements for human subjects noted in [Figure 15.4](#). Researchers who want to publish or seek funding for their work must also go through their facility's **institutional review board (IRB)**, a group of people who monitor and approve medical research that will be performed and protect the agency's employees from engaging in unethical research practices.

## LINK TO LEARNING

The horrendous treatment of 600 Black men in the Tuskegee Study of Untreated Syphilis in the Negro Male (now called the USPHS Syphilis Study at Tuskegee) was the driving force behind the development of many of today's rules regarding human participants in research. Check out this [video on the Tuskegee syphilis study \(https://openstax.org/r/77TuskSyphStudy\)](https://openstax.org/r/77TuskSyphStudy) to learn more about this dark time in medical research and the need for strong protections for human subjects.

### Methodology of Nursing Research

When a nurse works with patients on a day-to-day basis, they learn through **experiential learning** (or learning by doing). This process is not linear or structured; rather, it is based on the lived experience of the practicing nurse. In contrast, **nursing research** is structured inquiry designed to obtain and evaluate information related to a clear, specific question (Polit & Beck, 2021). The nature of the research question structures the methods used to achieve the answer. The **research methods** are the strategies and techniques used for gathering and analyzing information. In this context, there are two primary types of research: qualitative and quantitative.

#### Qualitative Research

A **qualitative research** is often complex and based on individual experience. It is generally open ended, allowing the participants to guide the research rather than specifying one or two options up front to study. It is descriptive and looks to answer questions about what and how a research participant thinks and feels. The focus is on the participant's perspective and experience, not the researcher's. Qualitative research is often basic research rather than applied. However, researchers can use the information obtained from qualitative research to identify questions that can be further studied quantitatively.

In qualitative studies, researchers develop questions based on the desired outcome and narrowed to a specific population, situation, or other relevant characteristic. For example, a researcher might study the factors that influence whether young immigrant mothers choose Western forms of health care for their children or healthcare traditions from their country of origin. The information received from such research will not be clear-cut. Each mother might have a variety of motives, beliefs, and values; individuals immigrating from different places may give completely different reasons for their choices. However, the researcher will look for patterns, relationships, or themes in the data that help deepen their understanding of the situation.

Most of the time, qualitative research in health care is performed through interviews, focus groups, or case studies. An **interview** is a one-on-one conversation between the researcher and the participant. Interviews can be formal and led by a series of predetermined questions, or informal. For example, a researcher might begin with a few set questions but allow the participant to lead the conversation. Regardless, qualitative research generally uses **open-ended questions**, which require more information than *yes* or *no* responses—often including an explanation of the answer. (An important exception is if the interviewer wants to clarify a point.) A **focus group** is essentially a group interview, usually ten or fewer people, in which participants interact with each other and the researcher. A **case study** is an in-depth exploration of all aspects surrounding a complex issue as experienced by one or two individuals.

Qualitative research is an excellent way to explore some issues; indeed, nurses ask their patients qualitative questions daily even when they are not performing research. However, qualitative research has some drawbacks. For example, it is very easy for researchers to introduce bias into the process. A **bias** is a type of research error that researchers introduce by leading interviewees or suggesting one type of answer over another. Consider again the example study of young immigrant mothers. Suppose one of the interviewers asked, "Please tell me why you do not like pediatricians." However, this is a leading question: the interviewees may never have said they do not like pediatricians; they may have any number of other reasons for their healthcare choices. Anything they say in response to this question—or even to others that follow—may be invalid because the interviewees may have been influenced by the researcher's false assumption.

Qualitative research is also immensely time consuming. In general, an interview or focus group lasts one to two hours. The responses must then be transcribed before they can be analyzed. As a result, these studies are generally

small. A project that interviews fifty participants is considered very large.

## PATIENT CONVERSATIONS

---

### Asking Patients Open-Ended Questions

**Scenario:** Sharon is a 65-year-old White female with a higher weight from a small rural town in Mississippi. She recently moved to Queens, New York; she is at a new doctor’s office for an intake appointment and is speaking with a new nurse. Sharon has a thick accent and low health literacy, and she uses some terminology with which the nurse is unfamiliar. The nurse and Sharon are struggling to understand each other.

**Nurse:** Do you have any preexisting illnesses or medical conditions?

**Patient:** I have the sugar.

**Nurse:** I wasn’t talking about candy. I meant do you have any health concerns the physician should know about, such as hypertension or asthma?

**Patient:** No.

**Nurse:** Do you take any medicine?

**Patient:** Yes, I take shots for the sugar.

[Nurse looks annoyed and frustrated.]

**Scenario follow-up:** Sharon’s nurse becomes frustrated because they are not communicating, excuses herself briefly, and asks a more experienced coworker for help managing the situation. The older nurse offers to perform Sharon’s intake as the original nurse observes. They begin the assessment over again.

**Nurse:** Do you have any medical conditions we should know about?

**Patient:** I told that other nurse that I have the sugar.

**Nurse:** Can you explain what you mean by “the sugar”?

**Patient:** You know, the sugar diabetes. I take shots for it.

**Scenario follow-up:** The more experienced nurse used open-ended questions, did not make assumptions, and identified that Sharon has diabetes. (“The sugar” is a common way of referring to diabetes in the Deep South, though nurses in other parts of the country may be unfamiliar with the term.)

---

### Quantitative Research

A **quantitative research** tests the validity of a reasonable idea in a given setting. It is based on deductive reasoning, a logical approach that moves from general ideas to specific conclusions and seeks to obtain **empirical evidence**—evidence that can be measured (Polit & Beck, 2021). As the term suggests, quantitative research is grounded in numerical data, like percentages or rates. It is observational, exploring what can be measured through the senses or quantified in individual responses to questions. Quantitative researchers often use statistical analysis to prevent bias within their research and to evaluate the strength of relationships between variables. A **variable** is a factor that is measured or studied in research: anything from a subject’s age or level of reported pain to the number of times a patient gets up at night to use the bathroom, the efficacy of a particular pain medication, or the history of illness in a family.

When planning for quantitative studies, nurses and other evidence-based practitioners frequently use the PICOT framework to develop testable questions (Polit & Beck, 2021):

- P: What is the population or patient group? What characteristics bind these individuals together?
- I: What is the intervention that is being tested?
- C: What is the comparison, or the group receiving the current treatment rather than the intervention?
- O: What is the desired or expected outcome?
- T: What is the time frame for the study? How long will subjects be followed?

Here is an example of a potential PICOT question: In adult inpatients, aged 50 to 70 years, with diabetes who experience low blood sugar [Population], how does fruit juice [Intervention] compared to glucose tablets [Comparison] affect patients' blood sugar levels [Outcome] over the course of a twenty-four-hour period [Time Frame]?

Once the question is defined, the flow of quantitative research generally follows a fairly linear process, as shown in [Table 15.1](#).

Step	Description
Review the literature	Do journal research to see what is known about the question, determine why new research is important, and develop a hypothesis.
Develop a research plan	Answer questions such as: How will the research be conducted? How will data be gathered? How will it be analyzed? How will human subjects be protected? How will participants be chosen? How will they provide informed consent?
Collect the data	Run the study and gather evidence. Very large studies may be preceded by a sample study to ensure the correct data are being collected.
Analyze the data	Perform statistical analysis to compare variables and outcomes.
Interpret the results	Make sense of the results and what they mean in relation to the research question. Is there clinical importance to the results?
Present the information	This can be done in a group or presentation format or through publication.
Evaluate the results	Determine what if anything has been learned that can be used in clinical practice to improve patient care, working conditions, or other outcomes.

**TABLE 15.1** Quantitative Research Process

There are several ways to design quantitative research. Here are a few commonly used designs (Winston-Salem State University, 2023):

- A **descriptive research** approach uses one or more variables. For example, a study might seek to determine what types of pain medications are ordered on a medical-surgical unit, how frequently they are ordered, how often they are given, and what types of patients are most likely to receive them. Most research will include some descriptive statistics.
- A **correlational research** approach uses statistical analysis to explore relationships between two or more variables. For example, a study might investigate whether different physicians on a medical-surgical unit are more likely to order pain medication to be given as needed or to require patients to adhere to a schedule. Another study might investigate whether there are patterns in the timing of when certain nurses give pain medication.
- A **quasi-experimental research** approach explores cause-and-effect relationships but does not apply new interventions. For example, a study might investigate how different amounts or types of pain medication affect patients' length of stay in a facility, chances of acquiring a nosocomial infection, functional ability upon discharge, or overall mortality.
- An **experimental research** approach studies the effect of a new intervention on a known concern and evaluates its effectiveness. For example, a study might seek to determine the efficacy of alternative

therapies—such as trigger point massage, dry needling, or physical therapy—at decreasing the amount of pain medication given on the medical-surgical ward.

Regardless of the design, quantitative researchers should ask **close-ended questions**, which have a limited range of answers (such as yes/no or 1–5). Each answer should be assigned a value, enabling measurement and comparison. [Figure 15.5](#) gives examples of each type of question: qualitative, or open ended, and quantitative, or close ended.

Qualitative questions	Quantitative questions
<ul style="list-style-type: none"> <li>• Please describe what you do when your blood sugar is low.</li> <li>• How did you choose your child’s doctor?</li> <li>• Please explain what you mean by “the sugar.”</li> </ul>	<ul style="list-style-type: none"> <li>• Do you have diabetes? (Answer limited to yes, no, or unknown)</li> <li>• Please rate your pain between 0 and 10 with 0 being no pain at all and 10 being the worst pain you can possibly imagine.</li> <li>• How many times a week do you have difficulty falling asleep?</li> </ul>

**FIGURE 15.5** Qualitative questions aim to understand a patient’s experience and narrative. Quantitative questions focus on obtaining measurable and numeric data. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Quantitative studies are excellent for numerically evaluating the value of interventions and the success of treatments. They can also be easily scaled up to large numbers. Quantitative studies with large data sets may include thousands of participants. However, there are possible issues that can affect the data. For example, if individuals do not use the specified responses, their answers cannot be properly evaluated. Furthermore, because the responses are close ended, important information may be missed. Consider a researcher collecting information regarding insomnia in a particular population. They may ask participants, “How many times do you have difficulty falling asleep or staying asleep in a week?” Answers to this question are limited to 0 through 7. This misses people who perhaps have difficulty falling or staying asleep once every few weeks or only when they are worried about something. If researchers do not find other ways to capture these responses, they will lose an entire segment of the group they want to study.

## REAL RN STORIES

### Application of Nursing Research

**Nurse:** Cho, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 3

**Facility location:** Urban VA hospital in Kentucky

I conducted a small quantitative research project on my unit to improve patient care as part of my professional development. We did not like the type of needleless syringes that we were using with our patients. Several nurses complained they were too tight and difficult to attach to the Luer-locks on patients’ IV catheters. It often hurt patients because we pulled on the catheter or the tape holding it to the patient’s skin as we tried to attach the syringes. The Luer-locks also caused more than one of us to rupture a vein and then stick patients additional times.

I went to my nurse manager and discussed the issue with her. She told me that several different types of syringes were available for VA use but that our supply people only purchased one type. She encouraged me to research the possibility of changing syringes. After talking to the supply department, they agreed to get us a couple of new types to try out.

I spoke with my colleagues and explained the research project. All the nurses on the floor tried each type (there were three, our current one and two others) for one week each, starting with the new ones and ending with our current one. At the end, I gave the nurses a survey where they rated the different syringes using a Likert scale from 1 to 4, with 1 being the worst and 4 the best.

When I counted surveys and added up the results, one of the new types was a clear winner. I wrote up my findings

and took them to our nursing practice board to request a permanent change to the new syringe. I presented my findings and received approval from the board. Then I worked with the supply department to switch our unit over.

### Mixed Methods Research

Today, many researchers use **mixed methods research**, combining both qualitative and quantitative components to create more nuanced findings (Polit & Beck, 2021). This approach works well because qualitative and quantitative research are complementary; they help manage the complex phenomena that make up human health and well-being, and they offer greater validity for research. [Figure 15.6](#) offers some examples of how mixed methods research can be achieved.

<b>Research Aim</b> Understand the experience of workplace bullying by nurses with less than 1 year experience	
<b>Quantitative data</b>	Survey sent to all nurses in 3 states with less than 1 year of experience Survey data is close ended based on Likert scale
<b>Qualitative data</b>	Individual interviews with 15 nurses (5 from each state) exploring their experiences with workplace bullying
<b>Combining qualitative and quantitative data</b>	Use the qualitative data to explain the quantitative results

**FIGURE 15.6** Combining quantitative and qualitative methods in research can be the best of both worlds and ensure the highest quality results possible. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Understanding the Parts of an Article

Being able to read a **research article** effectively is an essential piece of being able to evaluate research. Most high-quality articles include several main parts (Polit & Beck, 2021):

- The **abstract**, placed at the beginning of the article, briefly describes the rest of the paper. Abstracts vary in length depending on the journal but generally range between 200 and 350 words. Some are structured, using specific subject headings; others are narrative, more like a descriptive paragraph of the work.
- The **introduction**, sometimes called the background, explains why the research was needed and conducted. It usually includes a brief **literature review** that synthesizes what other researchers have learned about the topic and explores what information still needs to be determined by future research. It may also include definitions of some key terms, an explanation of why the research is needed, and the question(s) the study aims to answer.
- The **methods** section provides all the details about how the study was conducted, including the patient population, the setting, and the specific variables studied, as well as how those variables were studied and how the data were analyzed. Most methods sections also include the human rights protections used, the way informed consent was obtained, and the approval information from the IRB that evaluated the research plan.
- The **results** section describes what was learned from analyzing the data. It often includes the demographic statistics of the participants, charts or graphs illustrating the results, and findings from statistical analyses, including how statistically significant the results are. A **statistical significance** describes the relative chance that results are reliable and would be reproducible with a different group of similar patients. The language used to describe the significance of a specific bit of research might look like this: Given the same parameters, there is an 80 percent likelihood that 75 percent of patients will experience a 5 to 10 percent decrease in their blood pressure.
- In the **discussion** section, the authors compare their results to other research that has been done related to the question. They should include information regarding the consistency of their results related to other research, the potential clinical importance of their research, any possible implications for clinical practice, suggestions for additional research, and the study's limitations.
- Some journals require a **conclusion** separate from the discussion; others add it to the end of the discussion section. Generally, it is a concise statement about the importance of the research and what it brings to the larger research community.
- Articles typically end with a **references** section that lists all the sources the authors cited when writing the

paper.

Other than these central components, an article may present additional information that readers should examine, particularly before considering any of the article's recommendations. In particular, look for these three pieces of information, which generally appear either in the front matter (everything before the abstract) or the back matter (everything between the conclusion and the references):

- If the Methods section does not provide information about informed consent and human rights protection, it should appear in either the front or back matter. If not, the research may not have been conducted ethically.
- Sometimes, how a study was funded will answer many questions about its potential value. Product manufacturers often fund research, but their biases should be obvious. Making an evidence-based decision to use new products based solely on research paid for by the manufacturer can result in a poor decision.
- One of the values of sharing research is the ability to reproduce that research in various populations. Most journals today require a statement regarding data availability so that other researchers in different places can attempt to reproduce the research to see if the findings will be the same for their population.

### Types of Research Articles

Research and research articles come in a variety of formats. For a nurse seeking to expand their knowledge base and improve their practice, the best sources of research are typically **peer-reviewed journals**. As a condition for publication, these journals require several (usually three) reviewers to thoroughly read the information and evaluate its value. Journal articles come in a variety of formats. Each type of article has value and can be meaningful for practice. [Table 15.2](#) offers a few examples of the types of articles one might find in nursing or other healthcare journals.

Article Type	Explanation
Research	These articles describe original research performed by the authors.
Literature review	These articles discuss what other original researchers have said about a topic, attempt to synthesize the information, and explore what information still needs to be determined by future research. They are narrative, do not use statistics, and often do not include a methods section.
Systematic review	The authors of these reviews systematically retrieve all research articles written on a given topic. Additionally, they often evaluate individual articles for the quality of the research.
Metareview	These systematic reviews include a statistical strategy to analyze and combine the results from many studies and evaluate their usefulness.
Guidelines	These are specific statements from large organizations, such as the ANA, that provide standards of practice for specific populations of patients. These are usually based on the most up-to-date and well-validated EBP available. Guidelines may be published in journals when major changes to a discipline's guidelines are introduced; they may also appear on association websites.
Editorials	These are generally short opinion articles, also known as commentaries, written by subject-matter experts to discuss an issue of concern.

**TABLE 15.2** Types of Research Articles

### Translating Research into Practice

An **evidence-based research (EBR)** is incorporated into EBP when healthcare providers use the research findings to improve their day-to-day care of patients, and it can be a dynamic tool for that purpose. However, a large body of EBR has not been implemented into routine patient care because moving from research to practice can be extremely complicated. Translation science is a branch of research dedicated to improving how EBP becomes

standard care (Titler, 2018). EBP can be used for individuals or patient groups (Bell, 2023). When an individual patient has a concern, need, or question with which a nurse is unfamiliar, the nurse can use the steps of EBP to seek relevant research and find an answer that aligns with the nurse’s experience and the patient’s preferences and values. [Figure 15.7](#) is a Venn diagram representing these relationships in EBP.

**FIGURE 15.7** This Venn diagram shows the interconnected relationships—between scientific evidence, clinical experience, and patient values—that form the core of EBP. (credit: modification of work from *Psychiatric-Mental Health Nursing*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

In contrast, a hospital, unit, or clinic may have several patients with similar concerns that could be managed more effectively with alternative interventions. Some nursing staff members may then decide to explore the issue using the steps of EBP to determine whether a practice or policy change should be made at the level of the agency or unit.

### Steps of Evidence-Based Practice

There are defined steps for performing EBP that aim to successfully implement a new intervention with patients, while EBR aims to determine the success or failure of an intervention (Titler, 2018). There is some disagreement between researchers regarding the number of steps in EBP. However, most scholars set the number at five or six (Bell, 2023; Capili, 2020). Here is a typical list:

1. Ask a question.
2. Find information about the topic.
3. Evaluate the evidence.
4. Align the evidence with clinical experience and patient preferences, determining what specific practice changes to make.
5. Make the changes.
6. Evaluate the outcomes.

Depending on the situation, additional steps may include planning to make the change sustainable over time, developing or revising policies and procedures, or determining how to share the information within units, hospitals, agencies, or even professional organizations.

### LINK TO LEARNING

This short video offers a quick [introduction to EBP \(https://openstax.org/r/77IntroEBP\)](https://openstax.org/r/77IntroEBP) and sets the stage for our continuing inquiry.

#### Ask a Question

The questions you ask and how you ask them will affect the value of the information you receive. Questions that are too broad will return more results than are needed or desired. Questions that are too narrow may not return the information necessary to evaluate the issue. The first rule of thumb is to ask a searchable question (Bell, 2023), one that uses clear and specific keywords enabling you to find what you are looking for. Consider looking for information about “preterm labor” (early pregnancy delivery). The searcher would receive far more titles and websites than they will be able to review. Here is a more searchable and specific question: “What is the survival rate for preterm labor before twenty weeks in the United States?”

## LINK TO LEARNING

The Oncology Nursing Society has several excellent resources regarding evidence-based practice. They provide a [worksheet with questions \(https://openstax.org/r/77EBPQuestions\)](https://openstax.org/r/77EBPQuestions) that can help staff members generate possible topics and ask questions in a way that facilitates research.

### Find Information about the Topic

Several search engines focus specifically on peer-reviewed journal articles on nursing, medical, and allied health topics, including MEDLINE and CINAHL, which can be accessed through most libraries. PubMed and Google Scholar can be accessed through any search engine. Most search engines will bring back many results that must then be explored to ensure they offer appropriate information about the question. The abstract portion of journal articles will generally provide enough information to know if the article pertains to the question and provides quality evidence.

Whether you use journal search engines, Google Scholar, or a general search engine such as Bing or Google, you must use keywords effectively to find the evidence you need. For an individual patient, look for keywords specific to that patient's situation (Bell, 2023). For example, suppose you were working with a 45-year-old, female, Black patient with prediabetes who wants nutritional guidance to prevent becoming fully diabetic. In that case, you might use these keywords: "female," "Black," "prediabetes," "middle-aged," "nutrition," and "patient education." When working with an individual, even a simple Google search can yield high-quality information from reputable sources, which can frequently be tailored specifically to that individual.

However, suppose you are searching for information that might lead to a practice or policy change for an entire group of patients. In that case, the keywords should be less refined (Bell, 2023). For example, suppose you were working to develop a patient education handout regarding nutrition for patients with prediabetes. In that case, you might search "prediabetes," "nutrition," and "patient education" as keywords. The resulting evidence would be less specific for any single patient but more generalizable for all patients.

### Evaluate the Evidence

Not all sources are equally reliable, and no search can ensure only high-quality results. Therefore, once a search has been completed, the nurse must assess the quality of the information they received (Bell, 2023). Stricter criteria may be necessary to support a policy change than to treat an individual patient. Consider the following questions when evaluating evidence.

*From where did the information come?*

High-quality information comes from reputable sources:

- peer-reviewed journals
- practice guidelines from national-level practitioner governing bodies, such as the ANA or the American Association of Critical-Care Nurses
- condition-related organizations, such as the American Diabetes Association or the American Heart Association
- laws and applicable governmental bodies, such as the Centers for Disease Control and Prevention (CDC) or the AHRQ
- reputable websites, which may be more likely to end in .gov, .edu, or .org

Nurses should consider the credentials of the authors of information to determine if it comes from a reliable and reputable source. Lower-quality information typically comes from consumer websites and blogs. It is important to look for references in any article you find. If the authors do not list their sources, you cannot determine the validity of the information. Encyclopedias also do not typically make good sources for research. While they provide excellent overviews of topics, they are usually too broad and may not be current with the most recent data. Even online encyclopedias, such as Wikipedia, which are regularly updated and often supply references, are not necessarily peer reviewed and therefore should not be considered as authoritative sources.

*When was the information written?*

Research is written and published daily, and the nursing and allied health community is dynamic, constantly

changing and continually improving. As a result, *when* the research was published can be as important as *who* published it. A general rule of thumb is only to consider research published in the preceding three to five years (if at all possible), unless it is a **seminal article** meaning it continues to influence research and practice.

*Where does the research fall in the hierarchy of evidence?*

The **hierarchy of evidence** is a classification of evidence into categories based on the type of research represented. It is one way to evaluate the strength of research. Examine [Figure 15.8](#). At the bottom of the pyramid (level VII) is the weakest evidence, and at the top (level I) is the strongest. Researchers disagree on how to structure the middle levels, but they generally agree that expert opinion is the lowest quality of evidence, while systematic and metareviews offer the highest quality (Curtis & Keeler, 2022; Oncology Nursing Society, 2023).

**FIGURE 15.8** The quality of evidence increases as researchers move up the hierarchy. At higher levels of the pyramid (such as I, II, and III), more data are available, and greater generalization is possible. (Based on Curtis & Keeler, 2022; Oncology Nursing Society, 2023). (credit: attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Align the Evidence and Determine What Practice Changes to Make

Once the best evidence has been gathered, it must be aligned with the other parts of EBP—the clinical experience of the nurse and the patient’s values—to establish a change moving forward (Capili, 2020; Bell, 2023). This strategy can be straightforward for the individual nurse with a single patient. If the change does not violate current hospital policies or procedures, if the nurse believes in the value of the intervention, and if the patient accepts the intervention, an individual nurse can introduce evidence-based changes to their practice (Bell, 2023).

In contrast, translating knowledge into practice and implementing EBP for more than a few patients require planning and strategies to overcome potential barriers (Curtis et al., 2017). Planning for sustainable change at an agency or even a single unit level may involve multiple disciplines. It can quickly become complicated because the environment in which the EBP will be performed already has a set of rules and procedures that nurses follow, as well as budgetary and other limitations (Titler, 2018). For example, suppose the evidence says that behavioral health therapies could help prevent depression in patients following cardiac surgery; however, if a facility lacks the

funds to pay for behavioral health providers, it may be impossible to implement the change there. So, with a group of practitioners or a patient population, it is crucial to initiate evidence-based changes that the agency can sustain over time (Capili, 2020; Titler, 2018).

### Make the Changes

Once the decision has been made to implement an evidence-based change, nurses should begin to use the new intervention in daily practice. Depending on the change, it may be used with all patients or only with patients who meet specific parameters (such as age range or condition type). Implementing larger-scale initiatives may require changes to existing policies or procedures or restructuring of resources (Bell, 2023). Proper documentation of the responses to the intervention is necessary for the next stage, evaluation, to take place.

### Evaluate the Outcomes

Finally, evaluate the EBP change. Did it work? Was it effective for the individual patient? Did it work for the target population? Is it sustainable for the group? How does it improve patient outcomes and satisfaction? When these questions are answered, nurse scientists can make the thoughtful decision to continue with the practice, change back to the old way, or develop an alternative intervention—always with the foremost goal of improving patient care and outcomes.

## Understand Models for Implementing Evidence-Based Practice

When considering EBP initiatives at a facility or unit level, multiple **stakeholders** (individuals or groups who have some type of interest or concern regarding practice changes in an area), usually from several disciplines, must be engaged in the process and assisting with the initiative. Whereas an individual nurse can make a personal practice change for a specific patient, larger-scale projects take time to develop and implement. Several well-respected models are used to develop EBP initiatives for group or population-level changes, including the Iowa Model, the Joanna Briggs Institute model, and the Evidence-Based Public Health model (Dusin et al., 2023).

To better understand the EBP framework, let's focus on one model. The Johns Hopkins Evidence-Based Practice (JHEBP) model was developed at the Johns Hopkins Medicine Center for Evidence-Based Practice. It is commonly taught in research courses and used by other large research hospitals and academic institutions such as Vanderbilt University and Medical Center (Dang et al., 2022; Dusin et al., 2023; Vanderbilt University Medical Center, 2018). The JHEBP model includes three core components, known as the PET process: practice question, evidence, and translation (Dang et al., 2022). Each component has several associated steps, with twenty steps for the entire process. The process incorporates agency needs and resources, stakeholder input, best evidence, and information dissemination.

### Practice Question

The JHEBP model's first component involves forming the EBP workgroup and developing the practice question. This happens over seven steps, as follows (Dang et al., 2022):

1. Recruit the interprofessional team, using care to involve members who will be impacted by any changes made. These individuals will likely be more invested in the process.
2. Decide on the leadership of the project. All projects need a knowledgeable leader to help others stay on track.
3. Schedule meetings. The leader should establish a time and quiet place for meetings and ensure that members are involved in keeping minutes, working on a timeline, and managing the project resources and information.
4. Clarify and describe the problem. Discuss the differences between what is happening and what participants would like to be happening. Clarify why the current practice is a problem.
5. Develop and refine the EBP question. The JHEBP uses the PICOT framework described in [Evolution of Nursing Research](#).
6. Determine the need for an EBP project. Before continuing, the group members should explore the literature to determine whether a body of evidence related to the problem exists. The preferred evidence is high-quality systematic reviews published within the last five years. If there is not enough research evidence for an EBP, group members can explore other options, such as initiating quality improvement projects, conducting original research, or verifying that they are using the current standards of their community, agency, or specific disciplines.
7. Identify stakeholders who will be impacted by the project and who should be involved or kept informed during

the process. Any disciplines that will be directly impacted by any EBP changes should be invited to be team members.

### Evidence

Evidence provides support that an intervention is needed and works: for example, data may show that one drug is more effective than another at treating a particular condition. The evidence component of the JHEBP model includes five traditional EBP steps focused on acquiring and evaluating evidence (Dang et al., 2022):

1. Search for evidence. Team members should be assigned to various research components, including evidence internal to the agency and external. Journal articles, specifically systematic and metareviews, are essential. Additional evidence will be found in clinical practice guidelines, community standards, position statements from professional organizations, quality improvement data, and safety and regulatory information.
2. Evaluate the quality of each piece of evidence. The JHEBP has its own hierarchy of evidence (similar to the evidence pyramid shown in [Figure 15.8](#)) that researchers use to rate sources and evidence as high, good, or low. Evidence that is rated as low is not used to make EBP decisions.
3. Summarize individual evidence. Each piece of evidence is summarized and documented based on several factors, including quality, evidence level, findings, population, and limitations.
4. Synthesize findings. The team examines the entire body of evidence and integrates the findings as a group.
5. Develop recommendations. The team determines the value of the overall findings and the evidence level. Then they recommend moving forward, stopping the process, or performing additional investigation.

### Translation

The final component of the PET process is translation of the EBP team's recommendations into practice in the target setting(s). This component involves eight final steps (Dang et al., 2022):

1. Identify practice setting-specific recommendations. Work with stakeholders, leaders, and frontline staff to determine if recommendations are actionable and feasible, given the agency's culture, willingness to change, and resources.
2. Create an action plan. Develop any policies or specific procedures reflecting the change, a timeline for implementation, and evaluation processes. Encourage feedback from stakeholders, leaders, and frontline staff.
3. Secure stakeholder support and necessary resources. The best projects and interventions can be fumbled if unit and department leadership do not support them.
4. Implement the action plan. Ensure everyone impacted receives the education and resources necessary to make the change. The team should be prepared to answer questions and assist with problems.
5. Evaluate the change. Has the change created the desired outcomes? Have unexpected outcomes occurred? Evaluate the actual versus expected outcomes and determine if the change should be retained.
6. Report the results. Use local presentations to ensure all stakeholders, leaders, and impacted frontline staff know the project's outcomes.
7. Identify the next steps. Review the process and results. Should additional research be undertaken? Are additional changes needed for the process? Have new questions emerged?
8. Disseminate the findings. Report the results to the organization, at a minimum. Also, consider other venues for disseminating the results, such as journal articles and conferences.

### LINK TO LEARNING

The JHEBP model has been used extensively in nursing projects for almost two decades. Read this article about a [quality improvement project that used the JHEBP model \(https://openstax.org/r/77JHEBPQImpProj\)](https://openstax.org/r/77JHEBPQImpProj) to decrease surgical site infections. It is an excellent example of translating research into action.

## 15.2 Evidence-Based Clinical Decisions

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the foundations for evidence-based decision-making
- Apply the Institute for Healthcare Improvement (IHI) bundles to evidence-based nursing practice

Most nurses do not spend their day-to-day lives engaging in evidence-based research (EBR). However, all nurses make evidence-based clinical decisions daily as part of the ordinary course of their work. An **evidence-based decision-making (EBDM)** involves using evidence-based practice (EBP) when making decisions about caring for individual patients (Belita et al., 2020). Examples of EBDM include preventing falls by encouraging a patient to call before getting up to use the bathroom, asking a physician to order a medication in a liquid rather than pill form to make it easier for a patient to swallow, and determining what kind of dressing to put on a new wound. EBDM draws on the nurse's experience, intuition, understanding of EBP, and knowledge of the patient (Nibbelink & Brewer, 2018).

### Foundations for Evidence-Based Decision-Making

EBP and EBDM look similar because they both rely on the EBP triad of scientific evidence, clinical experience, and patient values [Figure 15.7](#). However, EBDM must also include an understanding of the setting and environment in which the decision is made. The practical consequence of this understanding is that nurses always have a limited number of options to choose from (Nibbelink & Brewer, 2018). For example, even if the gold standard of care has excellent evidence to support it, aligns with a nurse's clinical expertise, and meets a patient's preferences, it still may be impossible to provide based on the agency's policies, procedural concerns, or resource limitations. Thus, decisions must be made based on the EBP triad and the situational reality of what is possible within a given setting.

The EBP movement has decreased gaps between what nurses and other healthcare professionals do in practice and what they should do based on the best evidence. As a result, several tools are now available to bring the best EBPs to the bedside and make them easily accessible for clinicians and agencies. One commonly used tool is the ISBAR (sometimes abbreviated to SBAR) strategy for communicating information between healthcare team members. ISBAR stands for introduction, situation, background, assessment, and recommendation. It has been implemented effectively in many agencies throughout the United States as a way to communicate necessary patient information rapidly and succinctly among healthcare workers in a variety of situations (such as end-of-shift reporting and transferring patients between units or facilities). [Figure 15.9](#) shows an example of an ISBAR communication between an emergency room nurse sending a patient to a unit and the nurse who is receiving the patient.

<p style="text-align: center;"><b>ISBAR</b> <b>EVIDENCE-BASED PRACTICE MODEL OF COMMUNICATION</b></p>	<p><i>PATIENT NAME:</i> _____</p> <p><i>DOB:</i> _____</p> <p><i>Department:</i> _____</p>
<p style="text-align: center;">INTRODUCTION <b>I</b></p>	<p>Who the speaker is and their reason for communicating</p> <ul style="list-style-type: none"> <li>• Hello, this is Kita from the ER.</li> <li>• I need to give report on Ms. Fernando, a 53-year-old Hispanic female, going to room 187.</li> <li>• She is being admitted for 24-hour observation and telemetry.</li> </ul>
<p style="text-align: center;">SITUATION <b>S</b></p>	<p>Explains what is happening right now</p> <ul style="list-style-type: none"> <li>• Ms. Fernando came to us today complaining of chest pain which resolves upon resting for one day.</li> <li>• She also has a one week history of fatigue and complains of discomfort in her upper back and left upper arm.</li> <li>• Blood pressure is 140/95 which she states is high for her and pulses is 104. EKG shows normal sinus rhythm. Troponin is 1.0.</li> </ul>
<p style="text-align: center;">BACKGROUND <b>B</b></p>	<p>Brief and relevant history of the illness</p> <ul style="list-style-type: none"> <li>• She denies history of cardiac issues.</li> <li>• She has a history of hypertension and morbid obesity.</li> </ul>
<p style="text-align: center;">ASSESSMENT <b>A</b></p>	<p>Individual assessment of the situation or background</p> <ul style="list-style-type: none"> <li>• Ms. Fernando is alert and oriented and speaks good English, however she is upset about being admitted and may need some extra attention.</li> <li>• She had several people with her in the emergency room and they seem to make her anxious.</li> </ul>
<p style="text-align: center;">RECOMMENDATION <b>R</b></p>	<p>Request needs or specify suggestions</p> <ul style="list-style-type: none"> <li>• She is a difficult needle stick, so try to draw all of her labs at once.</li> <li>• They've ordered telemetry so you might want to get a box ready for her.</li> <li>• You might consider trying to limit the people in her room to see if that will help with her anxiety.</li> </ul>

**FIGURE 15.9** The ISBAR is an example of a standardized EBP communication tool used to improve clinician communication about patients. (credit: attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

It can be confusing to apply the EBP triad in practice. Let's further explore this process for each component of the triad.

### Patient Preference

The importance of honoring patient preferences is a key tenet of both patient-centered care and shared decision-making. Patient-centered care (PCC) is the inclusion of patient preferences, values, and needs in healthcare activities. Nursing is always patient centered because our standard of practice encourages partnering and working

collaboratively with our patients and considering their culture, beliefs, and values when making decisions (American Nurses Association, 2021). Thus, incorporating patient preferences and values into EBDM is a natural behavior for nurses and an expected standard of practice.

What does it mean to include patient preferences and values in decision-making? It may be as simple as asking patients what they want or need and hearing what they say and do not say (Nibbelink & Brewer, 2018). Alternatively, it may consist of learning about the expectations of a patient's culture or ensuring the presence of a certified medical language translator when discussing their preferences or providing education. Some patients may have religious beliefs that influence their preference for one intervention. Others may have difficulty accessing outside resources, so decisions must include only resources the nurse can provide at the point of care. In short, incorporating patient preferences and values into EBDM requires assessing and understanding what matters to the patient (American Speech-Language Hearing Association, 2021).

## PATIENT CONVERSATIONS

---

### How to Identify Patient Preferences

**Scenario:** Nurse enters the patient's room shortly after the medical team has made their rounds. The patient is frowning and has balled his hands into fists.

**Nurse:** Mr. Hernandez, are you okay? You seem distressed.

**Patient:** Dr. Colling wants me to stay in the hospital for two more weeks for IV antibiotics. I don't understand it. I'm feeling much better and can move around without pain. Why do I need to be here for that long?

**Nurse:** I know that staying here longer is disappointing. You have a bad case of cellulitis on your leg that has spread quite far. That takes a long time to heal.

**Patient:** My leg is starting to look better. Why can't they switch me to an oral medication?

**Nurse:** In my experience, cellulitis is challenging to treat. IV antibiotics are stronger than oral ones because the medication goes directly into the bloodstream.

**Patient:** Oh, I didn't realize that. But I really can't stay here that long. I need to get back to work, and I help my mom out a lot. She doesn't drive anymore, you know. She lives alone, and I don't like her being alone for so long.

**Nurse:** Oh, I do understand that won't be easy. Did you discuss any of these concerns with Dr. Colling?

**Patient:** No, he just seemed too busy today.

**Nurse:** Well, why don't I call him and ask him to stop by again later? We can explain your situation and see if there are any other options.

**Patient:** Thank you. I would appreciate it. Can you help me talk to him? He makes me nervous.

**Nurse:** Of course I will.

**Scenario follow-up:** Dr. Colling came and spoke with Mr. Hernandez. When he realized the issue, he offered an additional treatment option, going home with a central line and having home health come daily to give the IV medication. While he was unwilling to have Mr. Hernandez return to his construction job due to the danger posed by having a central line in place, he agreed that Mr. Hernandez could provide his usual care for his mother.

The process of **shared decision-making (SDM)** empowers patients to actively make decisions and state their needs and limitations in conjunction with healthcare providers rather than passively receive care (Skelly et al., 2020). SDM should involve clear, comprehensible education and encouragement of patients and their families to be open and accurate about their abilities and skills in self-management (Nibbelink & Brewer, 2018). For example, sending a patient home with the expectation that they will give themselves shots mandates that the nurse supply thorough education about the process and evaluate the patient's ability to perform the task satisfactorily. Failure to do so sets up the patient for a poor healthcare outcome.

The Agency for Healthcare Research and Quality (AHRQ) has developed a SHARE decision-making model to guide SDM. Many of the components are similar to those of other decision-making models; however, the SHARE model emphasizes the inclusion of the patient in the process (AHRQ, 2023a; Skelly et al., 2020). As [Figure 15.10](#) shows, the SHARE model is a five-step process.

<b>SHARE MODEL OF SHARED DECISION MAKING</b>	
SEEK <b>S</b>	<ul style="list-style-type: none"> <li>• Seek patient participation</li> </ul>
HELP <b>H</b>	<ul style="list-style-type: none"> <li>• Help patient explore and compare options</li> </ul>
ASSESS <b>A</b>	<ul style="list-style-type: none"> <li>• Assess patient values and preferences</li> </ul>
REACH <b>R</b>	<ul style="list-style-type: none"> <li>• Reach a decision that aligns with patient's values and preferences</li> </ul>
EVALUATE <b>E</b>	<ul style="list-style-type: none"> <li>• Evaluate the decision</li> </ul>

**FIGURE 15.10** The SHARE model is one strategy to ensure patients are involved in the EBDM process. (credit: attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LINK TO LEARNING

The AHRQ offers extensive resources for using the SHARE model, including a video showing the [SHARE Approach \(https://openstax.org/r/77SHAREAppVideo\)](https://openstax.org/r/77SHAREAppVideo) in action.

### Best Evidence

One of the pitfalls nurses can fall into when seeking best evidence is an unconscious bias toward information that aligns with their clinical experience, regardless of the evidence for it (Nibbelink & Brewer, 2018). Locating high-quality evidence can be difficult and time consuming, but systematic and metareviews are excellent starting points (Pubrica, 2020). As discussed previously, these reviews are generally at the top levels of evidence hierarchies. Because they are rigorous in their methodology and provide an in-depth exploration of a given topic, they can be both a high-quality and quick resource—a one-stop shop, so to speak, of the best evidence compiled from many other researchers.

### Clinical Expertise

Several components make up **clinical expertise**. In addition to critical thinking, it includes a nurse's ability to recognize patterns based on their experiences over time and to evaluate those patterns and extrapolate alternative solutions or appropriate interventions based on similar but not identical experiences (Nibbelink & Brewer, 2018). Nurses must recognize their limitations and know when to ask for assistance if they do not have the clinical experience to make an informed clinical decision (Nibbelink & Brewer, 2018). Asking for help is never a flaw. It is a

sign of a strong, self-confident nurse who recognizes their limitations, and it protects their patients—and their nursing license.

It has been previously mentioned that a nurse’s ability to make decisions about most issues becomes almost second nature. Nurses make many daily clinical decisions that become part of the muscle memory of nursing—practically automatic, like driving a car or riding a bike. However, other situations require reflection to determine the best course of action. Even with the decisions that nurses make every day, they must guard against **cognitive bias**: an unintentional error in judgment due to incorrect thought processes (The Joint Commission, 2016; Thirsk et al., 2022). Nurses must be aware of their own biases and seek to avoid them by engaging in regular self-reflection, particularly in situations that felt uncomfortable. Also, nurses must be willing to change, as nursing, medicine, and health care are constantly changing.

### Clinical Decision Support and the Institute for Healthcare Improvement (IHI)

Due to the time-consuming nature of EBR and the structural difficulties associated with changing the practices of all healthcare workers within an agency, several **clinical decision support tools** are available to help nurses and other healthcare professionals access information about best practices more quickly (Pubrica, 2020). These tools combine evidence about specific best practice into an organized body of knowledge that is easily accessible. Many are electronic and integrated into electronic medical records or point-of-care informatics tools to enhance decision-making (HealthIT, 2018). Others are integrated into care pathways in different ways. The key advantage is that they provide a structured approach that is reproducible and repeatable across practice settings and patients.

The Institute for Healthcare Improvement (IHI), a not-for-profit organization, has been at the forefront of developing clinical decision support tools, particularly care bundles, to allow all patients in all environments to have the same high-quality level of care. For over three decades, the IHI has been working to improve the quality and safety of health care, both in the United States and globally (IHI, 2017).

#### Evidence-Based Practice Bundles

The **evidence-based practice bundles** are like nursing toolkits: small sets of evidence-based interventions that are used together to improve patient outcomes. They are rooted in EBR and have been shown to positively impact patient care (IHI, 2017). The IHI pioneered these bundles to address some common causes of hospital-based morbidity and mortality, such as ventilator-associated pneumonia (VAP), central line–associated bloodstream infections (CLABSIs), catheter-associated urinary tract infections, and surgical site infections. The use of bundles has expanded to other groups and even individual institutions. Bundles do not include all possible interventions for given situations or conditions; instead, they recommend a subset of highly effective interventions easily integrated into most hospitals (IHI, 2012a). All elements of a bundle should be used regardless of the specific situation: for example, a bundle for patients on ventilators in the intensive care unit should be used for all such patients, and all the components that make up the bundle should be used each time. Otherwise, the staff cannot count the bundle as complete. It is an “all-or-none measurement” (IHI, 2017).

## REAL RN STORIES

### New Bundle Implementation

**Nurse:** Becky, RN

**Clinical setting:** ICU

**Years in practice:** 20

**Facility location:** Rural community hospital in Tennessee

We introduced the ICU Liberation bundle a few years ago. The ICU Liberation bundle has six parts—A to F—designed to improve our outcomes. My ICU is small, with many nurses entirely set in their ways, so it was an uphill struggle. We were asked to do things differently than we ever had. Some of us were intrigued because we had the opportunity as nurses to be part of a huge change in the treatment of our patients.

Six of us volunteered to be champions of the bundle for our unit, each taking one piece of it. The pieces of the bundle include A (assess, prevent, and manage pain), B (both spontaneous awakening trials and spontaneous

breathing trials), C (choice of analgesia and sedation), D (prevent and manage delirium), E (early mobility and exercise), and F (family engagement and empowerment). I took piece F: family engagement and empowerment.

My part of the bundle encouraged a deeper relationship with the patient's family. So often in the ICU, we had limited visitation and patient disruption to a minimum. By implementing the bundle, we encouraged families to be involved and present with patients in their rooms during rounds and many aspects of patient care. We could still ask family members to leave if it was clear they were bothering the patient or disrupting care, but the bundle reminded us to view families as our partners. Their presence usually helped the loved ones in our care. I learned all I could about my part of the bundle and taught it to the other nurses on the unit. While it brought many changes, implementing the ICU Liberation bundle helped our patients a lot. I am glad we did it.

---

### **Institute for Healthcare Improvement Ventilator Bundle**

The IHI collaborated with thirteen Veterans Health Administration (VHA) ICUs to develop a bundle to decrease the risk of VAP in ICU settings. VAP is a healthcare-associated infection (HAI)—it is caused by medical treatments—that occurs as a new finding after a patient has been placed on a ventilator. Characteristics of VAP include abnormal chest x-ray findings, fever, leukocytosis (elevated white blood cell count), and thick tracheal secretions (Roch et al., 2017). Ventilator-associated pneumonia is the leading cause of death from HAIs. For patients who survive, it often increases the length of stay in the ICU, the length of time on the ventilator, and the overall costs of care (Roch et al., 2017). One incidence of VAP causes an estimated \$40,000 in additional healthcare costs (IHI, 2012a).

The VAP bundle includes five elements of care (IHI, 2012a):

1. Maintain the head of the bed elevated between 30° and 45°.
2. Perform daily sedative interruption and assessment of readiness to extubate.
3. Provide peptic ulcer prophylaxis (such as a proton pump inhibitor) to intubated patients.
4. Provide deep vein thrombosis prophylaxis (such as sequential compression devices) on the lower legs.
5. Provide daily oral care with chlorhexidine.

Using a daily checklist, maintained at the bedside, in the patient's paper chart, or in their electronic health record ensures completion of these steps.

Even though VAP continues to be a problem in health care, the VAP bundle has been proven to reduce the incidence of VAP by 45 percent or more, resulting in improved patient outcomes and lower overall costs (Taplitz et al., 2017).

### **LINK TO LEARNING**

To learn more about VAP and the Ventilator bundle, explore this [How-to Guide \(https://openstax.org/r/77VAPHowToPrev\)](https://openstax.org/r/77VAPHowToPrev) from IHI.

---

### **Institute for Healthcare Improvement Central Line–Associated Bloodstream Infection Bundle**

A central line is a catheter with a tip that ends (terminates) in a major vessel such as the aorta, superior vena cava, or femoral vein. While their use has become increasingly common in the last few decades, they are also the source of many HAIs and a great contributor to hospital-associated mortality rates. In the early 2000s, CLABSIs caused over 30,000 deaths yearly in U.S. hospitals (IHI, 2012b). In response, IHI developed a bundle to reduce the number of CLABSIs in the hospital setting; the bundle includes hand hygiene, barrier precautions, optimal catheter site selection, and daily review of need. Hospitals that have implemented this bundle have seen up to a 65 percent decrease in their rates of CLABSIs (IHI, 2012b; Taplitz et al., 2017).

### **LINK TO LEARNING**

The AHRQ provides [guidelines to prevent CLABSIs \(https://openstax.org/r/77CLABSIPrevGui\)](https://openstax.org/r/77CLABSIPrevGui) in their CLABSI bundle.

### Surviving Sepsis Campaign and Bundles

Sepsis is a life-threatening inflammatory condition in which the body starts attacking its tissue and organs in response to an infection. Historically, the fatality rate of sepsis has been very high (van der Poll & Wiersinga, 2017). In the early 2000s, the IHI began to work on the Surviving Sepsis Campaign (SSC) in conjunction with the Society of Critical Care Medicine (SCCM) and the European Society of Intensive Care Medicine (ESICM) (SCCM, 2021). (SCCM and ESICM have subsequently taken over the SSC entirely.) Two sepsis-related bundles were initially developed from their work. However, as of the 2020 revision of the SSC guidelines, only one is being used: the Hour-1 bundle, for initial resuscitation for sepsis and septic shock (SCCM, 2021).

The Hour-1 bundle should be initiated immediately upon recognition of sepsis or septic shock (SCCM, 2021). The hour begins when providers recognize sepsis or septic shock (SCCM, 2021). While all components may not be completed within an hour, they should begin in the first hour. There has been some pushback concerning using this bundle, particularly from emergency room physicians concerned about unnecessary antibiotic treatment. However, the data strongly suggest that the sooner treatment begins, the better chances patients have of survival (SCCM, 2021).

### LINK TO LEARNING

Here are resources produced for the Surviving Sepsis Campaign (SSC):

- This [video about the SSC \(https://openstax.org/r/77Hour1VidHelp\)](https://openstax.org/r/77Hour1VidHelp) illustrates how practitioners should use the Hour-1 bundle to help patients survive sepsis.
- This [Hour-1 bundle infographic \(https://openstax.org/r/77Hour1Infograp\)](https://openstax.org/r/77Hour1Infograp) illustrates how to provide initial resuscitation for sepsis and septic shock.

## 15.3 Quality Improvement in Nursing

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Understand the role of the quality improvement nurse
- Identify benefits of quality improvement in nursing practice
- Recognize different quality organizations for nursing practice

In 2016, an earth-shaking article noted that if medical errors were classified as diseases are, they would be the third-largest cause of death in the United States (Makary & Daniel, 2016). It is estimated that there are over 110 safety events for every 1,000 hospitalizations. Over 11 percent of hospitalized patients will experience such an event, adding thousands of dollars to patient stays and costing too many lives (Finkelman, 2022).

For healthcare providers, the core focus of quality improvement is to decrease errors (Sherwood & Barnsteiner, 2022). An **error** is a failure to carry out a planned healthcare action or to complete the action correctly, with the result that the patient is harmed or experiences a less favorable outcome. An **adverse event** is one in which a patient is harmed or killed due to care that is being delivered, not to their underlying health condition. A **preventable adverse event** is related to human error, such as errors of diagnosis, medication administration, treatment delays, and lack of follow-up (Sherwood & Barnsteiner, 2022). A **sentinel event** is an adverse event that happens in a healthcare setting, based on an accident (such as fall) or the actions of healthcare workers and results in patient death or permanent disability. Note that deaths related to the progression of a patient's illness are not sentinel events.

The Institute of Medicine defines quality health care as the provision of health services that improve the chances of preferred outcomes, decrease the chances for error, and are consistent with current evidence and knowledge. **Quality improvement (QI)** is a framework used to improve patient care and outcomes systematically and continuously. It incorporates the expectation that no matter how good a system's quality is, it can be improved upon; thus, quality improvement is a continuous, ongoing endeavor.

The American Nurses Association (ANA) considers quality improvement, like evidence-based practice (EBP), to be one of the five core competencies of all healthcare professionals (ANA, 2021). It also expects all nurses to meet the

standard of quality of practice. Quality of practice includes several competencies focused on performing safe, effective, efficient, and person-centered care; in addition, several other competencies are directly related to QI in nursing and health care overall (ANA, 2021). They include the following:

- incorporating EBP into practice to improve outcomes
- enhancing nursing through creativity and innovation
- recommending strategies to leadership to improve quality of nursing practice
- engaging in data collection to monitor care quality
- participating in QI initiatives
- collaborating with other disciplines to implement QI

These standards apply to all nurses at all levels of practice. Nurses are responsible for consistently improving their practice and patient care (Finkelman, 2022). In fact, all nurses and healthcare providers must actively engage in ongoing and continuous improvement projects to improve health care for our patients and communities. Hospitals also have standards of practice for nursing staff to encourage QI at the local level.

## LINK TO LEARNING

---

Quality improvement is a huge undertaking, continuously occurring across all of medicine. The Institute for Healthcare Improvement (IHI) provides a [video on the evolution of QI in health care \(https://openstax.org/r/77EvolutionQI\)](https://openstax.org/r/77EvolutionQI) and a quick snapshot of QI, including many of the concepts covered in this section.

---

### Role of the Quality Improvement Nurse

As with EBP, QI happens both with individual nurses in their practice and at the level of larger systems. Most healthcare systems today have a QI program office that manages ongoing QI systemwide. Often these are staffed with **quality improvement (QI) nurses**—experienced RNs or advanced practice nurses with a special interest in QI who, by receiving extra education and passing a subject-matter examination, may have undergone the process of **certification** to become an expert in QI. Quality improvement nurses work with individual nurses, unit leadership, and facility leadership to ensure consistent quality related to current policies and procedures; they engage in the QI process across the agency, department, or facility.

## LINK TO LEARNING

---

This [video features a QI nurse at Cincinnati Children's \(https://openstax.org/r/77QINurseCinChi\)](https://openstax.org/r/77QINurseCinChi) hospital. Her story provides an example of how nurses move into QI through their nursing practice and interest in quality and safety.

---

### Quality Assurance

One component of a quality program is **quality assurance (QA)**, the provision of oversight to ensure that, across a department or agency, the staff is receiving education and support to maintain the current quality standards. Quality assurance nurses review the data on errors and poor patient outcomes at the facility. They look for trends and create opportunities to improve nursing care by identifying where additional education, staffing, or equipment are needed or where new policies and protocols should be implemented. Their work seeks to improve patient outcomes and increase the standard of care by relying on data for problem identification and EBP for interventions.

### Quality Assurance and Performance Improvement Programs

**Quality Assurance and Performance Improvement (QAPI)** is the dual use of QA and performance improvement (PI), specifically in post acute care environments such as rehabilitation centers and nursing homes. The Affordable Care Act (2010) mandated QAPI for all post acute healthcare environments, and the necessary roles are often filled by RNs. The Centers for Medicare and Medicaid Services (CMS) developed the framework to reinforce legal statutes regarding how these facilities perform and how they are accountable for QAPI activities (CMS, 2021). Through the American Association of Post-Acute Care Nursing, nurses seeking to be a QAPI subject-matter expert can earn a QAPI certification.

to be a systemic issue, the QI nurse may develop a QI intervention to deal with the problem. If it is unique to the nurse who made the error, the QI nurse may instead be involved in retraining that nurse to prevent the error from reoccurring.

## Benefits of Quality Improvement in Nursing Practice

Quality improvement should improve patient outcomes. The AHRQ notes that healthcare quality includes these six domains (AHRQ, 2022):

- safe
- effective
- patient centered
- timely
- efficient
- equitable

Quality improvement in nursing practice is always engaged in solving problems or bettering outcomes. As such, QI activities should improve one or more of these domains in an effort to fix broken processes or integrate new practices that are based in local reality combined with the best evidence (Grys, 2022). Further, QI activities should offer measurable outcomes to clearly show their value (or their failure to achieve the expected value) (O'Donnell & Gupta, 2023).

### Maximizes Use of Resources

Resources in health care include time, staff, equipment, facilities, and other tangible and intangible resources used to provide patient care. When professional nurses are trusted and included in QI efforts, processes affecting resource allocation and use typically become more effective. Nurses know what they need and do not need in their supply cabinets; when performing procedures, they know how many staff they need on different shifts; and they know how much time they spend performing their daily tasks. Using nursing knowledge to develop QI initiatives can allow for realistic identification of necessary resources versus superfluous ones. Such engagement can ensure that nurses have the resources they need available when they are necessary and discourage the presence of unnecessary ones.

### Promotes Innovation of Team Members

The development of new ideas, methods, and procedures, or **innovation**, is where the future of quality improvement lies. Nurses are perfectly positioned as healthcare innovators thanks to their direct role in patient care and advocacy. They see processes in action daily. Engaging frontline nurses in addressing quality concerns and performing QI activities has the added benefit of encouraging innovation among staff members and during staff development. Quality improvement should encourage nurses to improve their practice and discuss their concerns with leadership and management (Drew & Pandit, 2020). It provides opportunities for nurses on the front lines to clarify their understanding of what causes problems and engages them in developing solutions.

### Reduces Unnecessary Tasks

Nurses perform many tasks daily, but these tasks are often redundant or not performed efficiently. The QI method of Lean helps to find and reduce waste: tasks or behaviors that have no value for the system (Kelly, 2022, O'Donnell & Gupta, 2023). For nurses, waste can be found in a variety of locations, such as unnecessary transportation of patients or duplicate tasks; waste also happens when units are laid out inefficiently, necessitating additional time and motion to gather items, or when people are unable to work at the height of their licenses and abilities. Quality improvement strategies can be used by and for nurses to streamline their work, resulting in increased time at the bedside and higher-quality care (Kelly, 2022).

## Quality Organizations for Nursing Practice

Nurses can turn to several resources for answers to QI questions or guidance for their practice. As previously mentioned, the ANA provides standards for quality in nursing practice. Additionally, most specialty professional nursing associations, such as the Oncology Nursing Society, have some information relevant to quality or QI on their websites. Nurses can also use several other agencies and programs to advance the quality of their practice, including national and international organizations.

### American Nurses Association

The ANA is the primary overarching organization for nurses in the United States. The ANA establishes the Scope and Standards of Practice and Code of Ethics for all RNs and advanced practice nurses, lobbies for nurses with government, seeks to ensure that nurses have safe and ethical workplaces, provides continuing education, and establishes the goals of professional nursing (ANA, 2017). The ANA further provides position statements to help nursing practice and supports nurses to lead change (ANA, 2017). Though affiliated with other specialty nursing organizations, such as the American Association of Critical-Care Nurses, the ANA remains the body that represents all nurses no matter their specialty or job location. The ANA also manages the Nursing Alliance for Quality Care, an organization that seeks to improve healthcare quality among nurses and agencies alike.

### Agency for Healthcare Research and Quality

The AHRQ has been discussed several times previously in this text. It is the U.S. Health and Human Services agency tasked with improving the quality, safety, efficiency, and effectiveness of health care for everyone (Finkelman, 2022). The agency provides extensive toolkits and best practice evidence for healthcare professionals at all levels.

For example, in 2005, the AHRQ and the Department of Defense developed the TeamSTEPPS curriculum to improve communication and collaboration within interprofessional healthcare teams in various settings. TeamSTEPPS is now in its third version, TeamSTEPPS 3.0 (AHRQ, 2023b). TeamSTEPPS has been released into the public domain so that all medical agencies can use it to improve their collaboration and team management, regardless of their ability to pay for it (AHRQ, 2019).

### Magnet Recognition Program

The American Nurses Credentialing Center has created the Magnet Recognition Program to recognize healthcare organizations that provide high-quality nursing care. Magnet recognition requires several components, including involvement in research, EBP, and QI (Polit & Beck, 2021). There are five components to the Magnet model:

- transformational leadership
- structural empowerment
- exemplary professional practice
- new knowledge, innovation, and improvements
- empirical quality outcomes

The program encourages and rewards hospital systems that place emphasis on QI and actively recognize nurses engaging in QI projects (Finkelman, 2022). Since 2014, one requirement for hospitals seeking Magnet status has been the inclusion of clinical nurses who perform leadership roles on collaborative teams and in shared decision-making (Hughes-Rease, 2015). Today, the ANA also encourages using evidence-based team strategies, such as TeamSTEPPS, to improve patient outcomes and care quality (ANA, 2021).

### The Joint Commission

The Joint Commission is an agency that offers accreditation, or official recognition, to membership hospitals that meet their quality and safety standards (Sherwood & Barnsteiner, 2022). It also provides annually updated national patient safety goals for many hospital settings. These goals are set for areas that are considered at risk and include guidance for process and QI initiatives that member agencies can use. Other goals are available for settings such as nursing care centers, behavioral health clinics, ambulatory care centers, and critical access hospitals. Additionally, to promote collaboration between disciplines, The Joint Commission requires its member agencies to have codes of conduct defining appropriate and inappropriate communication and behavior between team members and disciplines (Sherwood & Barnsteiner, 2022).

### National Coordinating Council for Medication Error Reporting and Prevention

The focus of the National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) is safe medication use and awareness of medication errors (NCCMERP, 2023). The council promotes open communication, error reporting, and QI to prevent medication errors. It uses national reporting systems to evaluate the root causes of medical errors and develop recommendations to prevent such errors. A senior policy adviser for the ANA sits on the council to lend the voice of nurses to policy development.

### Quality and Safety Education for Nurses

Quality and Safety Education for Nurses was created in 2005 as a response to the demand from nursing leaders for

an increase in nursing safety. The goal of the QSEN project, which was initially funded by the Robert Wood Johnson Foundation, was to discover a way to change nurses' mental outlook and education. On the topic of nursing education, QSEN identifies four goals (Sherwood & Barnsteiner, 2022). Student nurses should be taught to:

- enter their nursing practice expecting to be involved in inquiry and QI
- use and engage in evidence-based practice and research
- consider outcomes and critical incidents from a system's perspective
- work effectively in interprofessional care management teams

The QSEN model has also adopted the essential competencies offered by the Institute of Medicine as critical for nursing practice: patient centered, evidence based, teamwork and collaboration, QI, safety, and informatics (Sherwood & Barnsteiner, 2022).

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Generate Solutions: Understanding the Differences between Research, Evidence-Based Practice, and Quality Improvement

There are several similarities between research, EBP, and QI. Indeed, they are complementary endeavors that build off each other. However, it is important to recognize the differences between them to use them most effectively in practice. [Table 15.3](#) summarizes these differences.

Activity	Qualities
Research	Purpose: Generate new knowledge or validate existing knowledge Methods: Scientific method Process: <ol style="list-style-type: none"> <li>1. Begins with a question about an event and proceeds systematically</li> <li>2. Data are collected</li> <li>3. Results are disseminated as evidence informing an associated body of knowledge</li> </ol>
Evidence-based practice	Purpose: Translate evidence into practice and integrate it into clinical decision-making to improve safety, quality, and systems Methods: PICOT, etc. Process: <ol style="list-style-type: none"> <li>1. Begins with a clinical question and proceeds systematically</li> <li>2. Evidence is collected, appraised, and integrated into a practice change</li> <li>3. Results of the practice change are evaluated and disseminated</li> </ol>
Quality improvement	Purpose: Improve processes or patient outcomes Methods: Lean, PDSA, etc. Process: <ol style="list-style-type: none"> <li>1. Begins with an outcome that needs to be improved and proceeds systematically</li> <li>2. Identifies how improvement will be measured and plans interventions</li> <li>3. Collects baseline data before interventions and collects data again afterward</li> <li>4. If improvement occurs, determines how to sustain the improvement over time</li> </ol>

**TABLE 15.3** Differences between Research, EBP, and QI (Sources: Grys, 2022; Hain, 2017.)

## 15.4 Nursing Standards of Delegation

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify nursing standards for delegation
- Recognize nursing principles for delegation

The act of requesting staff members to perform tasks or procedures that are outside of their normal job but within the limits of their job description is called **delegation**. Nurses delegate tasks and procedures to other staff members daily to cope with the constantly changing needs of patients in an active healthcare setting. Per the National Guidelines for Nursing Delegation, delegation happens when a registered nurse (RN) asks either a licensed practical nurse (LPN)/licensed vocational nurse (LVN) or **assistive personnel (AP)**—such as nursing assistants, certified nursing assistants, patient care technicians, or surgical technicians—to perform a task on the nurse’s behalf. RNs do not delegate to other RNs. If an RN asks another RN to perform tasks for them, it is considered a transfer of care, and the new RN becomes responsible for the patient (American Nurses Association [ANA]-National Council of State Boards of Nursing [NCSBN], 2019). While charge nurses, managers, and supervisors give assignments to other RNs, this is not considered delegating but rather assigning job tasks.

Delegation is a critical nursing skill that reflects directly on the nurse doing the delegating (NCSBN, 2016). Inappropriate delegation can cause harm to a patient and result in disciplinary action for the nurse who sets it up. Delegation is governed by nursing practice standards from the ANA, nursing practice guidelines from the ANA and the NCSBN, local and state laws regarding delegation, and individual agencies or facilities (NCSBN, 2016). All nurses must understand what they can and cannot do per the relevant guidelines and laws.

## Nursing Standards for Delegation

The ANA offers basic delegation competencies in two nursing standards:

### Standard 5: Implementation

- RNs can delegate based on the needs of the healthcare consumer.
- RNs can delegate “after considering the circumstance, person, task, direction or communication, supervision, evaluation, as well as the state nurse practice act regulations, institution, and regulatory entities while maintaining accountability for the care” (ANA, 2021, p. 82).

### Standard 12: Leadership

- RNs demonstrate “authority, ownership, accountability, and responsibility for appropriate delegation of nursing care” (ANA, 2021, p. 97).

Consider those statements for a moment. They emphasize the idea of accountability: an RN who delegates a task to another staff member is responsible for that choice and answerable for its consequences.

## Five Rights of Nursing Delegation

When an RN designates a job to another staff member (the **delegatee**), that RN is still responsible for ensuring the job is performed appropriately (ANA-NCSBN, 2019). The five “rights” of nursing delegation specify when and how to delegate nursing duties (ANA-NCSBN, 2019): right task, right circumstance, right person, right communication, and right supervision. Each of these rights should be considered when delegating a task to another staff member.

### Right Task

Any activity delegated to a delegatee must be included in their job description or established through the written policies and procedures of the given setting (ANA-NCSBN, 2019). However, delegated tasks can fall outside of the delegatee’s normal duties. Agencies must ensure that written policies or procedures describe the abilities and limitations of different AP (NCSBN, 2016). Facilities must provide training for any skilled competencies (such as drawing blood or using equipment) that AP may be required to perform.

### Right Circumstance

Patients must be in stable condition with expected outcomes before a nurse can delegate care responsibilities (ANA-NCSBN, 2019). If the patient’s condition changes, the RN must reassess the patient to determine whether the delegation is still appropriate. For example, it is very unusual for critical-care areas to staff large numbers of AP and LPNs/LVNs because they are limited in how much assistance they can provide to unstable patients without direct, constant supervision.

### Right Person

The RN is responsible for ensuring the delegatee has completed any required education and has the necessary competencies to perform the care (ANA-NCSBN, 2019). For example, a staff member must be educated in how to

use patient transfer equipment, such as ceiling lifts for moving patients between surfaces, before they can be delegated tasks involving that equipment. An RN asking an AP to transfer a patient to a stretcher would have to be sure the AP had received the necessary education and was competent to perform the transfer when making the request.

## REAL RN STORIES

---

### Delegating Care

**Nurse:** Mai C., RN

**Clinical setting:** Inpatient psychiatric unit

**Years in practice:** 30

**Facility location:** Urban psychiatric facility in Tennessee

I remember one time when I was working the night shift. We did not often have blood draws ordered on the night shift, but that night, two of them had to be completed in the early morning. I was the charge nurse and was making patient care assignments for the unit. I delegated the blood draws to one of our AP. The AP was fairly new but had been with us long enough that I thought he had completed all his competencies.

At about 2 a.m., he came to me to tell me that he could not do the blood draws because he had not been checked off on them by our lab. All staff members had to receive education and perform three successful lab draws in our outpatient lab before they could draw blood on the unit. Since he had started on night shift and never worked on days, he had not done his blood draws for check-offs.

I found another AP who could do the blood draws that night. Then I spoke with our nurse manager to be sure that the AP had the opportunity to do his check-offs in the outpatient lab one morning before he left work. The next time I asked him to draw blood labs, he could without difficulty.

---

### Right Communication

When RNs delegate to other employees, they must provide appropriate instructions, and the delegatee must have the opportunity to ask questions (ANA-NCSBN, 2019). Clear communication must be provided to ensure the delegatee understands the specifics of the assignment. The delegatee must also agree to perform the assignment. The delegatee cannot make any decisions regarding care changes without consulting the delegating RN (NCSBN, 2016).

### Right Supervision

The RN must provide supervision to ensure the activity is performed correctly and evaluate patient outcomes. The delegatee must communicate patient information accurately to the RN. If the performance of the task is inadequate, the RN must intervene as necessary. Consider this example. An RN has asked an AP to take a patient's vital signs. When the AP gives the information to the RN, the patient's blood pressure is substantially higher than expected, representing a considerable alteration over previous readings. The RN then returns to the patient's room to verify the elevated blood pressure by taking it himself.

### Delegation versus Assignment

There is a difference between being delegated a task and being given a patient assignment. An **assignment** consists of the routine activities and procedures that are part of a staff member's normal job and taught in either a degree or certificate program or as part of on-the-job training (ANA-NCSBN, 2019). RNs may still be responsible for supervising other staff as they complete their assignments, but not to the same degree as with delegation. For example, an LPN/LVN with a patient assignment who gives their patients medication, takes their vitals, draws their labs, and documents their responses to care is functioning within the capacity of their degree and scope of practice; they should be able to complete these tasks with limited to no supervision. In contrast, an LPN/LVN whose patient goes into respiratory arrest would reasonably expect a code team to manage the patient's care when they arrive. With the proper supervision, however, the code team could delegate a task to the LPN/LVN, such as providing bag-mouth ventilation—that is, helping the patient breathe by squeezing a bag connected to an oxygen supply and the patient.

## Principles for Delegation

The ANA and NCSBN have developed principles for delegation. These fundamental principles are strategies to protect the patient's well-being, health, and safety, and they must be considered along with the five rights of delegation discussed previously (ANA, 2013). They include the following:

- While elements of nursing care may be delegated, the nursing process cannot.
- Decisions to delegate must be based on the nurse's judgment and consideration of the patient's complexity and care needs and the ability of the RN to provide appropriate supervision to the AP.
- Delegation should always be respectful of both the delegate and patient.

### LINK TO LEARNING

---

The ANA has a [booklet that explores the principles of delegation \(https://openstax.org/r/77DelegBooklet\)](https://openstax.org/r/77DelegBooklet) and provides a decision tree to assist nurses in knowing when delegation is appropriate.

---

#### Authority

Facilities use the nursing scope and standards of the ANA and the state's nurse practice acts to determine the authority and practice capacity of RNs within their agencies (ANA-NCSBN, 2019; Barrow & Sharma, 2022). Under this authority, nurses are expected to complete their job duties. These duties include delegating tasks to AP and LPN/LVNs based on the needs of the patient population, the stability of training, the training of delegates, and the nurse's ability to provide appropriate supervision.

#### Accountability

Nurses are legally and ethically liable for their patient care actions, known as **accountability**, including decisions to delegate activities to APs and LPN/LVNs. Even when care is delegated to other personnel, the RN remains accountable for the care provided. If nurses are concerned about delegating a task, they should perform it themselves (ANA-NCSBN, 2019). Once a delegate has accepted the responsibility of a delegation, they are accountable for completing that activity correctly, timely, and per facility protocol (ANA-NCSBN, 2019).

#### Responsibility

All RNs are responsible for acting within their states' nursing practice acts and performing reliable and dependable patient care tasks (Barrow & Sharma, 2022). When delegating tasks, RNs are responsible for providing high-quality communication and clearly explaining the delegated responsibility. Further, they are responsible for ensuring that delegated tasks are completed appropriately (ANA-NCSBN, 2019).

Delegates are responsible for delegated activities they accept and should only accept activities for which they have been appropriately trained (ANA-NCSBN, 2019). They are also responsible for maintaining their competencies—reviewing and renewing educational modules or skill check-offs on an ongoing basis—for activities they may be required to perform if delegated. [Figure 15.12](#) outlines the responsibilities of all parties involved in the delegation of nursing tasks.

**FIGURE 15.12** This Venn diagram shows how the responsibilities of the employer, nurse, and delegatee are different and where they overlap (ANA-NCSBN, 2019). (credit: attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## 15.5 Collaborative Practice

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define collaborative practice
- Understand the components of an effective team structure
- Recall core competencies for collaborative practice

A patient hospitalized for four days may meet fifty different healthcare providers, including a variety of doctors, nurses, assistive personnel (AP), and many additional staff members (O’Keefe, 2020). Each member of this large team must **collaborate**, or work effectively together, to ensure the patient has the best outcomes possible. No matter a nurse’s role or working environment, every nurse will collaborate with other healthcare workers, stakeholders, patients, and their families. Collaboration is impossible without communication. The two are inextricably intertwined.

Collaboration is so essential to nursing practice that it is the eleventh standard in the American Nursing Association’s (ANA) scope and standards of practice (2021). There are several collaboration competencies expected of all RNs (ANA, 2021, p. 96):

- Work with patients and stakeholders to advocate for and make changes that improve patient outcomes and healthcare quality.
- In every interaction, treat others with dignity and respect.
- Recognize the value of what other stakeholders and professions bring to the table.
- Encourage all team members to contribute their knowledge, skills, and abilities to achieve goals.
- Describe the role of the nurse on interprofessional teams.
- Use tools and informatics to facilitate team processes while maintaining patients’ dignity and respect and

following the Health Insurance Portability and Accountability Act protections to ensure their privacy and confidentiality.

- Encourage consensus and conflict management.
- Encourage team-building strategies to improve team or group performance.
- Engage with all stakeholders to develop, execute, and assess plans.
- Role model exemplary team building, leadership, and management when working with teams.

As a new nurse, it can be both reassuring and daunting to realize how important collaboration is to nursing practice. Effective collaboration improves patient outcomes and teamwork between healthcare professionals.

## Definition of Collaborative Practice

A **collaborative practice**, also known as interprofessional or interdisciplinary practice, results from healthcare workers from different professions working and communicating effectively to provide patient care and improve healthcare quality and patient safety. It involves mutual respect and trust, shared decision-making, and effective working relationships (McLaney et al., 2022). It can occur between two or more individuals within the same setting, within and between disciplines, and even over hundreds of miles. Successful collaboration between physicians and nurses improves patient outcomes such as length of stay, mortality, and patient satisfaction (McLaney et al., 2022). It is also linked to increased nurse perception of quality of care.

A 2013 report by The Joint Commission noted that communication issues were the top cause of mortality related to treatment delays (O’Keefe, 2020). Also, communication was found to be the third most common cause of sentinel events. Unfortunately, many healthcare settings have long resisted open and honest communication between all staff. This is mainly because healthcare settings have historically been structured hierarchically, with physicians at the top, creating power imbalances that have negatively impacted communication and, as a result, collaboration. Nurses and other healthcare professionals avoid speaking up and calling out problems for fear of losing their job or experiencing revenge or other forms of discomfort in the workplace (O’Keefe, 2020).

## LINK TO LEARNING

---

In 2020, as a response to infection-control issues raised by the COVID-19 epidemic, the Centers for Disease Control and Prevention (CDC), ANA, and over seventy other professional, public health, and educational organizations collaborated in Project Firstline. They aimed to improve the accessibility of infection-control education for all frontline healthcare workers. Explore [the website for Project Firstline \(https://openstax.org/r/77ProjFirLinWeb\)](https://openstax.org/r/77ProjFirLinWeb) to see how organizations can collaborate together to address healthcare quality.

---

## Components of Effective Team Structure

A **team** is a coordinated group of two or more people, each with a specific role, who interact to achieve a common goal. A team structure is the makeup of a single team or a multiteam system, including identification of a team leader and other members. Healthcare teams can be small or large, all at one location or spread out (Agency for Healthcare Research and Quality [AHRQ], 2019). Their goals may be short-term goals: for example, a **patient care team** forms to provide care for a specific patient and disbands when the patient leaves the organization. In contrast, teams such as quality improvement committees typically have long-term goals.

In the case of patient care teams, team members include anyone involved in that patient’s care. Members of the patient care team are accountable to each other for their actions on the team. They must stay informed and engaged in the process to ensure effective team functioning (AHRQ, 2019). When all members of a care team are present during rounds, for example, patient safety and healthcare quality increase, as does communication between nurses, physicians, and other healthcare team members (Rosen et al., 2018).

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Recognize Cues: Including the Patient and Family in Team Structure

While no patient care team can be complete without including the patient and their family, as applicable, it is often difficult to know how to involve these crucial members effectively. Try some of these strategies to encourage their participation in team processes:

- Ask how involved they want to be in the patient's care.
- Ask about their concerns before beginning discussions of their status, to ensure they can best listen when needed.
- As much as possible, speak in plain language without the use of medical jargon, and explain jargon that cannot be avoided.
- Encourage family members to ask questions.
- Provide additional education and resources for relevant information.
- Ask patients for feedback and encourage them to participate.

Patient responsibilities differ from those of clinicians. Patients are accountable for being honest and accurate when providing information, speaking up if they are concerned about a proposed plan of care, complying with a plan of care if they agreed to it, and reporting any change in their condition in a timely fashion.

(Adapted from AHRQ, 2019.)

Most nurses are members of multiple teams every time they come to work. For each of their patients, they are members of a patient care team that also includes the patient and their family, their provider or prescribing staff member, and additional providers and healthcare workers as needed. Nurses are also members of contingency teams that come together for specific, often emergent, events such as codes, disasters, or rapid response issues.

Healthy teams have a clear structure and work together to enhance patient safety and healthcare quality. High-performing teams also share some important principles that bind them together, including the following (AHRQ, 2019; McLaney et al., 2022):

- role clarity
- shared goals and vision
- mutual respect, trust, and support
- effective communication
- measurable outcomes and processes

### Effective Leadership

Teams cannot hold together without effective leadership (AHRQ, 2019). Any professional member of a healthcare team can serve as the team leader if they have the knowledge and skills to achieve the team's goals (AHRQ, 2019). On the best teams, no matter who the leader is, all members are skilled collaborators adept at encouraging each other to share their expertise.

Team leaders do need to perform a few specific tasks. Leaders must ensure all members are familiar with their roles and responsibilities, set up and monitor the care plan, keep the team on task, model appropriate behavior, and hold members accountable for performing their roles (AHRQ, 2019). Leaders also need to be able to run a team meeting and ensure everyone has the opportunity to be heard. Leaders also need to be able to help members get the resources they need, provide feedback to team members, ensure a strategy to communicate is in place, and assist with conflict resolution.

### Interdependent and Adaptive Interactions

Teams interact in a variety of ways. Internally, team members and their roles shift occasionally; even the leadership may change based on the group's needs (AHRQ, 2019). In a high-functioning team, the team member with the skills most closely aligned to the task at hand will often lead the team while that task is performed. Team members should be able to openly share information within a team without criticism. Regardless of who leads, each member should feel comfortable monitoring the situation and sharing their insights with the entire team, without fear of

criticism.

Team members should recognize each other's limitations and provide support when needed, each from the framework of their respective expertise (AHRQ, 2019). Teamwork failures occur when individuals fail to share information with the team, do not ask for information they need, or fail to include the patient or their family in discussions (AHRQ, 2019). Other failures occur when teams do not adequately use available resources or plan based on unavailable resources, or when individuals do not know and understand the plan or are not told that the plan has changed.

### Clear Roles and Responsibilities

Each team member should perform their job on the team and trust the other members to perform their jobs (American Association of Critical-Care Nurses, n.d.). This requires team members to have clear roles and responsibilities and complementary skills that are similar enough to work well together but not identical (McLaney et al., 2022). Each member must also be aware of their role and the roles and responsibilities of the other team members. The larger the team, the more difficult it may be to manage. However, if each member is aware of their own roles and responsibilities, then ongoing team management is easier.

### Desire for Common Goals

A shared vision and common goals are characteristics of high-performing teams. When working with patients, the team's work must be organized around the patient and their family's goals (American Association of Critical-Care Nurses, n.d.). This patient-centered approach to setting goals allows the healthcare team to align its goals with the needs and abilities of the patient rather than the wishes of the healthcare professionals. At the same time, it allows the healthcare team to be sure the patient is aware of the various strategies the team can use to assist in their care.

As teams work toward their goal, they should regularly evaluate the situation to determine whether they are still heading in the correct direction or if the goal needs to change (McLaney et al., 2022). Consider again the example of a patient care team. When a patient is in the hospital, the patient care team typically meets daily to determine their progress toward meeting their goals, explore any new information that has come up, and ensure all team members remain focused on the goals that matter to the patient.

## PATIENT CONVERSATIONS

### Using Shared Decision-Making and Collaboration with a Patient

**Scenario:** Mr. Rosenberg, a 50-year-old, has been admitted to the hospital with a diabetic foot ulcer and possible osteomyelitis on his right heel. He is meeting with his care team, including Dr. Blalock, Dr. Eboko, and Nurse Rosa.

**Dr. Blalock:** Mr. Rosenberg, I'm Dr. Blalock, the attending in charge of your case. Do you understand why they wanted to admit you to the hospital?

**Patient:** I came in because of this sore on my right heel. I can't get it to heal, and it's getting hard to walk so I can't work. I don't feel my feet very well, because of my diabetes, and apparently it was worse than I realized.

**Dr. Blalock:** Yes, you have a diabetic foot ulcer. It's fairly common for people with diabetes to have injuries to feet that don't heal well. Yours has gotten quite bad and become infected. We are concerned that the infection has spread to the bone of your heel.

**Patient:** The doctor downstairs in the emergency room said something about that infection. He had a name for it. . . . I don't remember. Anyway, how can we fix it? I need to be able to work.

**Dr. Eboko:** I'm Dr. Eboko, I work with Dr. Blalock. It's called osteomyelitis, which is a fancy way of saying a bone infection. I will be honest with you: it is difficult to treat and may take some time.

**Patient:** I don't have a lot of time, but I guess I have to have this treated. My father lost both of his feet by the time he was sixty. What is the best thing to do, doc?

**Dr. Blalock:** Well, I would like to run some additional tests and take a couple of wound cultures so that we know we are using the right antibiotics. Then I would like to start you on antibiotics and wound care. You will need to stay

here for two weeks to see if the antibiotics work. If all is well, we should be able to discharge you then.

**Patient:** And if the antibiotics do not work?

**Dr. Blalock:** Then, assuming you do have osteomyelitis, we would have to consider a surgical option to cut out the infected pieces of your bone.

**Patient:** Would I lose my foot?

**Dr. Blalock:** I am not sure. Hopefully not. The surgeon would do their best to leave enough intact bone that you could still walk if possible. But we are not ready for the surgeon yet. Are you okay with running some tests and starting the IV antibiotics?

**Patient:** Yes. My daughter is getting married in two months, and I need to walk her down the aisle.

**Nurse:** Oh, that is exciting, Mr. Rosenburg! I will be back in just a few minutes to draw those labs, swab that wound, and dress your foot. Dr. Blalock, are you also going to order some imaging, and could you please put in some orders for wound care and maybe a consult for the wound care nurse?

**Dr. Blalock:** I sure will. Mr. Rosenburg, you're in great hands with Nurse Rosa. Do you have any other questions for me right now?

---

### Personal Accountability

Accountability is one reason why effective teams outperform individuals (Zajac et al., 2021). Rather than one individual managing everything, each team member handles their role within the team and is accountable to the other members when they do not (McLaney et al., 2022; Zajac et al., 2021). At the same time, team members must be able to ask questions and request help if needed. Communication must be transparent, and members must serve with honesty and discipline. Teamwork requires members to recognize that personal accountability involves a willingness to be open about what is owed to others and to practice self-management in meeting one's obligations as part of the team (Peteet et al., 2023).

### LINK TO LEARNING

This [video about using TeamSTEPPS \(https://openstax.org/r/77STEPPTeamVid\)](https://openstax.org/r/77STEPPTeamVid) from the AHRQ's TeamSTEPPS page offers an example of how teams work. It shows clear communication and roles and illustrates how the team can expand or shrink based on the patient's needs.

---

### Core Competencies for Collaborative Practice

Moving healthcare culture from hierarchical to collaborative practice has taken substantial planning and careful execution. Historically, schools of health professionals, such as nursing schools, have been governed solely by their own national associations (such as the American Association of Colleges of Nursing, the Association of American Medical Colleges, and the American Dental Education Association). These national associations lead the development of curriculum standards and competencies for professional healthcare provider education. For example, the 865 nursing schools that belong to the American Association of Colleges of Nursing use the association's curriculum standards to develop their own nursing programs (American Association of Colleges of Nursing, 2023). This level of coordination creates consistency across programs, allowing all RNs to use the same NCLEX examination for licensing.

#### Interprofessional Education Collaborative

In 2009, the Interprofessional Education Collaborative (IPEC)—a partnership between the American Association of Colleges of Nursing and associations for medical, dental, public health, osteopathic, and pharmacy education—was established to develop collaborative education competencies for all healthcare professionals. These became the IPEC Core Competencies for Interprofessional Collaborative Practice (McKearney, 2022). Their aim is to ensure that everyone earning a degree from a healthcare program can perform in collaborative teams immediately upon graduation. Today IPEC has twenty-one association members; it published the third version of its core competencies in 2023.

### Interprofessional Education Collaborative Core Competencies

The IPEC core competencies fall into four categories: values and ethics, roles and responsibilities, communication, and teams and teamwork (IPEC, 2023b). Keep in mind that IPEC’s definition of teams includes patients, caregivers, community members, advocacy groups, and other interested parties, and was influenced by team science, a collaborative effort to address a scientific challenge by engaging the strengths of team members with different areas of expertise. IPEC also emphasizes the importance of cultural humility, which encompasses both the ability to self-reflect on one’s background and culture and the willingness to learn from team members of other cultures. [Table 15.4](#) explores the IPEC competencies further.

Competency Category	Explanation	Examples
Values and ethics	These eleven competencies emphasize the need for all healthcare professionals to “maintain a climate of shared values, ethical conduct, and mutual respect” as they collaborate.	<ul style="list-style-type: none"> <li>• Promote the values and interests of people and populations in all aspects of health care.</li> <li>• Advocate for social justice and health equity across the life span.</li> <li>• Respect individuals’ dignity, privacy, identity, and autonomy and maintain confidentiality.</li> <li>• Value diversity and cultural differences.</li> </ul>
Roles and responsibilities	These five competencies emphasize the need for all healthcare providers to use their professional expertise and that of their team members to improve health outcomes.	<ul style="list-style-type: none"> <li>• Include all team members’ knowledge, skills, and attitudes to provide person-centered, safe, cost-effective, timely, efficient, effective, and equitable health care.</li> <li>• Collaborate with others inside the agency as well as in the community and across different agencies to improve health outcomes.</li> <li>• Delineate each team member’s role, scope of practice, and responsibility in promoting health outcomes.</li> </ul>

**TABLE 15.4** IPEC Core Competencies (Source: Adapted from IPEC, 2023b.)

Competency Category	Explanation	Examples
Communication	These seven competencies emphasize the need for respectful, responsible, and compassionate communication between all team members.	<ul style="list-style-type: none"> <li>• Be genuine and authentic in communication, practice cultural humility, and avoid jargon that all team members may not understand.</li> <li>• Be constructive in providing feedback to bring the team to consensus.</li> <li>• Be aware of power structures, including one's own position, and use them to improve communication and decrease conflict.</li> </ul>
Teams and teamwork	These ten competencies emphasize the need to collaborate and engage the strengths of team members with different areas of expertise.	<ul style="list-style-type: none"> <li>• Recognize all team members for their diverse positions, cultures, and experiences to improve team function.</li> <li>• Use group brainstorming to solve problems and make decisions.</li> <li>• Use shared leadership strategies to improve team effectiveness.</li> <li>• Hold the entire team accountable for both positive and negative outcomes.</li> <li>• Openly discuss issues that may limit or benefit the team, such as organizational structure, procedures, resources, and policies.</li> </ul>

**TABLE 15.4** IPEC Core Competencies (Source: Adapted from IPEC, 2023b.)

## LINK TO LEARNING

Check out [Core Competencies for Interprofessional Collaborative Practice \(https://openstax.org/r/77IPECCoreCompe\)](https://openstax.org/r/77IPECCoreCompe) to find out more about the IPEC competencies.

## 15.6 Interprofessional Approach to Health Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine interprofessional team members and their roles
- Recognize the benefits of an interprofessional approach
- Identify ways to improve interprofessional teamwork

In any healthcare organization, no nurse works in isolation, not even when working from home or other remote locations. As previously discussed, all nurses work with other nurses, health professionals, and administrative staff, and they collaborate in teams with other healthcare professionals, stakeholders, patients, and family members. This can be difficult for new nurses, who must learn and remember numerous interprofessional relationships, teams, interactions, people, and roles. Sometimes it may even feel a bit like there are too many cooks in the kitchen. Thus, it is important to understand who the potential team members are and how to work effectively with them.

## Interprofessional Team Members and Their Roles

Interprofessional team members fall into a wide array of healthcare categories. While most have standard roles and responsibilities, some may shift between roles. Additionally, just like nurses, all members of interprofessional teams are bound by state regulations that govern the scope of their practice. So, while the following descriptions are true for most professionals in most environments, they may not be universally accurate.

### Provider

A **provider** is generally the only team member who can write patient care orders, particularly for medications and treatments (Pistoria, 2022). They make medical diagnoses and often provide supervision for patient care teams. A team may include several types of providers. They are most often physicians; however, advanced practice registered nurses and physician assistants also have prescriptive authority.

### Registered Nurse

Registered nurses (RNs) provide patients with skilled care, such as medication administration, procedures, and wound care. Patients in hospitals will likely see their RN more than any other interprofessional team member. RNs are often the first to detect condition changes and advocate for patient needs and desires. RNs may also be charge nurses (posting assignments and acting as points of contact for the unit), nurse managers, nurse supervisors, care managers, quality improvement specialists, or discharge coordinators, as well as additional roles throughout the healthcare system.

### Licensed Practical Nurse/Licensed Vocational Nurse

A licensed practical nurse (LPN) has different educational requirements and fewer advanced skills than an RN and provides basic nursing care under the supervision of an RN or provider. Some nursing boards call these professionals licensed vocational nurses (LVNs), but LPNs and LVNs have essentially identical scopes of practice. In most agencies, LPN/LVNs manage basic patient care and provide medications under the supervision of RNs. They often have restrictions on the level of patient assessment and education they are licensed to provide. For example, in a hospital system, LPNs/LVNs may be unable to give IV push medications, hang blood, or perform full daily patient assessments. However, they may be the primary nursing staff on duty in a nursing home or skilled nursing facility.

### Assistive Personnel

The category of assistive personnel (AP) includes a wide range of staff, such as nursing assistants (certified or not), home health aides, scrub techs, and medical assistants. These team members help nurses provide patient care. Their duties may include taking vital signs; transferring, bathing, feeding patients; and otherwise providing patient comfort. AP may be trained in more complicated procedures in some locations and circumstances. For example, many community living homes for people with disabilities employ medical technicians who have received additional training to assist patients with their medications. But these circumstances are based strictly on the laws of the state.

### Respiratory Therapist

A **respiratory therapist** provides daily respiratory care such as breathing treatments and supportive care for many patients experiencing respiratory conditions. They also work closely with patients who are intubated and on mechanical ventilation or who use breathing machines for sleeping, and they participate on code and rapid response teams for patients who are experiencing distress or going into respiratory or cardiac arrest. They may also be called upon to evaluate if a patient needs to be discharged on oxygen, and they may assist in setting up home oxygen.

### Physical Therapist

A **physical therapist** evaluates and treats patients who have difficulty moving. For example, a patient may struggle to walk, change positions, or move from chair to bed. Physical therapists often see patients who have become deconditioned due to bedrest or who have had orthopedic injuries or surgery. They work with patients on endurance and strength and help the team identify whether patients can stay safely at home after discharge or need physical therapy at a rehabilitation facility.

### Occupational Therapist

An **occupational therapist** works with patients on activities of daily living. For example, occupational therapists may help patients who have had strokes or head injuries relearn to feed and dress themselves, bathe or toilet, and sometimes even cook or clean. They also assist the team in determining whether a patient is safe to be in their own home—particularly if they live alone.

### Speech Therapist

A **speech therapist** works with patients on speech and communication and helps manage issues that occur with swallowing. Many patients develop difficulties in swallowing and with oral communication. Speech therapists conduct studies to determine if patients can safely eat different textures of food to prevent aspiration into the lungs. They also help to determine if patients have any other issues—such as neurological injury, brain damage, anxiety, or fear—that are affecting their speech.

### Social Worker

A **social worker** provides the team with support and information and the patient with education about meeting their social needs. Social workers frequently help with discharge planning by identifying community services or resources for families and home health needs. They are often the clinician who liaises between an acute hospital setting and a skilled nursing or rehabilitation facility.

### Pharmacist

A **pharmacist** does more than simply fill prescriptions. They reconcile medications and ensure patients are not ordered new medications incompatible with their current ones. Their presence saves time and reduces medication errors by increasing the chance for the correct medication and dosage to be ordered the first time. Additionally, they fill an integral role in patient and family education regarding medications and treatment plans. Pharmacists field inquiries regarding dosing, available formularies, and administration of medications, making them an excellent educational resource for healthcare providers.

### Chaplain/Spiritual Care Provider

A **chaplain**, or spiritual care provider, is available in most care settings. Their role is to meet patients' spiritual needs and ensure that a patient's regular spiritual adviser is notified of their presence in the facility (if the patient wants them to know). Chaplains also provide spiritual care for family members as well as members of the healthcare team.

### Other Team Members

This section has identified some of the most common healthcare team members, but the list has not been exhaustive. Nurses will encounter many others, such as patient advocates, laboratory personnel, radiology technicians, dietitians, and interpreters. Each member has their own roles and responsibilities—all in service to the goal of achieving the best patient outcomes possible.

## Benefits of an Interprofessional Approach

This chapter covers a lot of topics—from research to decision-making to collaboration. At times you might have wondered, “How does all of this fit together?” The interprofessional care management approach provides holistic, engaged care from a team that includes healthcare professionals, the patient, and their loved ones. Through transparency, shared decision-making, evidence-based practices, and quality improvement, the interprofessional approach impacts patient safety, resource allocation, care coordination, care quality, and patient outcomes.

### Resource Allocation

A **resource** is anything required to perform effective patient care: both tangible items (such as supplies, patient rooms, financial resources, and staff) and intangible items (such as time and knowledge). While it may seem counterintuitive, interprofessional care frequently decreases the costs of the resources used by individual patients. In one study of over 110,000 primary care patients, team-based care patients were less likely to be seen in an emergency room or admitted to a hospital (Reiss-Brennan et al., 2016). They were also less likely to be seen by their primary care physicians, as other team members could often manage their concerns. Thus, by using resources more efficiently, team-based care ends up decreasing overall costs of care.

Additionally, organizations that foster highly collaborative healthcare teams frequently find that team members report greater job satisfaction and engagement, leading to lower turnover rates (Morley & Cashell, 2017). It is very expensive to replace staff, so organizations with low turnover rates often can allocate resources into other areas.

### Improved Adherence to Plan of Care

There are two ways to explore the idea of improved adherence to plan of care: from the perspective of healthcare professionals and from the perspective of patients. For healthcare professionals, having a collaborative practice is likely to improve the team's adherence to the patient's care plan. Team members are accountable to the team for

performing their roles effectively and appropriately. This improves patient care by increasing the likelihood that plans of care will be maintained. Additionally, the extra communication and collaboration provided by the team structure decreases opportunities for confusion or error.

For patients, there is evidence that having a care team improves the patient's chances to participate in their own self-care (Morley & Cashell, 2017). Collaborative teams increase patient education and engagement by being responsive to patients and respectful of their wishes, which in turn increases the patient's participation in making care decisions, including the creation of a self-care plan to which they can adhere when the care team is not present.

### Improved Quality of Care

Team-based care models have been shown to improve patient safety and quality of care. In the primary care study mentioned previously, patients in team-based care practices were substantially more likely to be screened for depression, be seen for an annual wellness exam, and participate in self-care plans for chronic illnesses than their counterparts in traditional practices (Reiss-Brennan et al., 2016).

### Improved Outcomes

Interprofessional care teams have also been shown to improve overall patient outcomes. Many studies have shown improved outcomes on performance measures such as mortality, morbidity, and postoperative complications (Schmutz et al., 2019). For example, one study looked at high-risk patients who experienced frequent emergency room visits and hospitalizations or had elevated hemoglobin A1c levels (an indication of glucose control over a three- to six-month period for people with diabetes) (Guck et al., 2019). Each of these measures improved with an interprofessional, collaborative team approach to their care.

### Improving Interprofessional Teamwork

Root cause analyses show that over 50 percent of adverse events are related to ineffective teamwork (Zajac et al., 2021). Effective teamwork requires two separate types of functioning: the actions from team members necessary to reach goals and the ability of team members to combine their knowledge, skills, and attitudes to make the team sustainable and successful. While teamwork is imperative in today's healthcare culture, it also has challenges and should be continuously and intentionally improved upon.

### Setting Clear and Attainable Goals

Effective teams have clear purposes with attainable and measurable goals. There are a variety of strategies to develop attainable goals. When a group finds they are struggling with goal setting, they might first try a more focused approach. Consider a quality improvement team of nurses who want to improve the use of a patient care bundle for diabetes management (currently at 25 percent). They have a goal to improve the use of the patient care bundle but no clear strategy of how to get there. The team might consider using a strategy known as SMART to determine how to set a clearer goal and achieve it (see [2.3 Effective Communication](#)) (Centers for Disease Control and Prevention, 2020). SMART is an acronym that represents five characteristics of strong goals:

- **Specific:** The goal must identify exactly what will be done and who or what will be involved and impacted.
- **Measurable:** The goal must state how the desired change will be measured and what amount of change is expected.
- **Attainable:** The goal must be possible to attain given the resources available and time allotted.
- **Relevant:** The goal must be reasonable to expect under the given circumstances.
- **Timely:** The goal must set a time frame for completion.

In the case of the diabetes management care bundle, the SMART goal might be the following: By January 31, 2024 [Timely], care managers will complete patient care bundles for patients with diabetes [Specific] at least 75 percent of the time [Measurable]. Assuming the circumstances make this improvement possible, the goal is also attainable and relevant. Once the SMART goal is set, the team can develop its strategy for ensuring the improvement occurs.

### Improving Interprofessional Training

Interprofessional training and continuing education are important for all healthcare professionals. As previously discussed, agencies such as the Interprofessional Education Collaborative, which provide curriculum standards for schools of healthcare professions, have already established a critical niche in educating up-and-coming healthcare

professionals. In addition, interprofessional continuing education has its own set of joint accreditation standards, determined by a collaboration between nursing, medical, and pharmacy groups (Joint Accreditation for Interprofessional Continuing Education, 2023). Hospitals and agencies can send staff to interprofessional continuing education opportunities to learn or maintain skills.

### Providing Leadership Training

Leadership training is another possibility to improve nursing team performance. The TeamSTEPS 3.0 program (see [Quality Organizations for Nursing Practice](#)) has a leadership training module that can be used to help leaders improve and that can be taken as self-study or used in classroom settings (Agency for Healthcare Research and Quality [AHRQ], 2023). The program recommends strategies such as ensuring the team is coordinated, monitoring plans, and communicating changes; encouraging team members to assist each other; and modeling effective teamwork. It also recommends that leaders employ strategies such as a “brief checklist” at the beginning of a project and a “debrief checklist” at the end to assist in continuous leadership improvement (AHRQ, 2023). See [Figure 15.13](#) for examples provided by the AHRQ.

○

Brief Checklist

- \_\_\_ Who is on the team?
- \_\_\_ Do all members understand and agree upon goals?
- \_\_\_ Are roles and responsibilities understood?
- \_\_\_ What is our plan of care?
- \_\_\_ What is staff and provider availability throughout the shift?
- \_\_\_ How is workload shared among team members?
- \_\_\_ What resources are available?
- \_\_\_ What matters to you related to the focus of the briefing?

(a)

○

Debrief Checklist

- \_\_\_ Was communication clear?
- \_\_\_ Were roles and responsibilities understood?
- \_\_\_ Was situation awareness maintained? (Did you know the plan?)
- \_\_\_ Was workload distribution equitable?
- \_\_\_ Was task assistance requested or offered?
- \_\_\_ Were errors made or avoided?
- \_\_\_ Were resources available?
- \_\_\_ What went well?
- \_\_\_ What one thing should improve?
- \_\_\_ What is one thing that could be done differently next time?

(b)

**FIGURE 15.13** (a) The Brief Checklist can be used at the beginning of a project to ensure that all team members understand the plan. (b) The Debrief Checklist can be used at the end of a project to give team members an opportunity to reflect on the successes and struggles and provide feedback for continuous improvement. (credit a: modification of work “Brief Checklist” by Agency for Healthcare Research and Quality; Public Domain; credit b: modification of work “Debrief Checklist” by Agency for Healthcare Research and Quality; Public Domain)

### LINK TO LEARNING

The AHRQ offers a variety of strategies and tools to help teams perform more effectively. Take a few minutes to explore the AHRQ [TeamSTEPS 3.0 pocket guide \(https://openstax.org/r/77TeamSTEPSGui\)](https://openstax.org/r/77TeamSTEPSGui) Consider how you could implement some of the strategies in your own teamwork at school or in your workplace.

## Summary

### [15.1 Evidence-Based Research](#)

Research has been an essential component of nursing since the days of Florence Nightingale. It is codified into our practice acts and ethical standards and has evolved over the decades into a vibrant field of nursing researchers. Today every nurse should be able to use research, even when they are not conducting it themselves. With individuals or small groups, using research involves translating EBR into EBP through several steps that integrate the best scientific evidence with the nurse's clinical experience and the patient's values and needs. On larger scales, changes to implement EBP must be planned and negotiated with multiple stakeholders based as much on resources and institutional values as on the value of the research. Several models can facilitate these changes, including the JHEBP model.

### [15.2 Evidence-Based Clinical Decisions](#)

Operationalizing EBP into EBDM involves the EBP triad of the patient's preferences, the clinical expertise of the nurse, and the best available evidence. While effectively combining all three can be complicated, they have the greatest impact on patient outcomes. However, the nurse must also understand the available resources and limitations of their work setting and be able to develop alternatives when limitations prevent the first choice from being feasible. Clinical decision support tools such as bundles, checklists, and standardized processes have been developed to assist nurses and other healthcare workers in their decision-making. One type of tool, EBP bundles, has been shown to provide excellent results in acute care and ICU settings.

### [15.3 Quality Improvement in Nursing](#)

As with research and EBP, QI is integral to nursing care and should be performed continuously because care can always be improved. Because nurses directly care for patients and work on the "front lines" of health care, they are involved in all aspects and levels of QI; regardless of their role or specialty, all nurses engage in some QI activities. In addition to causing better patient outcomes, QI can promote innovation and professional development, decrease unnecessary tasks, and improve resource allocation. There are many organizations and initiatives that facilitate improvements to quality in health care, such as The Joint Commission, the Magnet Recognition Program, and the educational focus on QSENs.

### [15.4 Nursing Standards of Delegation](#)

Under their practice acts with individual states, nurses have the ability and responsibility to delegate certain tasks to other staff members. Nurses use the nursing standards of delegation to ensure the right task, circumstance, person, communication, and supervision for any tasks they delegate. They also use the principles of accountability, authority, and responsibility to ensure that tasks are performed appropriately while maintaining patient safety in all aspects.

### [15.5 Collaborative Practice](#)

Collaborative practice is a core standard for nurses and all healthcare professionals, who are expected to work in interprofessional teams that also include patients and their families. The importance of collaboration and teamwork is codified in our standards of practice, encouraged by national and international regulations, and taught in healthcare professional programs. High-functioning collaborative teams share common goals, mutual respect and support, and effective communication. Additionally, each member has clearly defined roles and aims to produce measurable outcomes. The IPEC core competencies for effective collaboration in health care are taught nationwide to ensure that all new healthcare professionals are skilled at collaborative practice.

### [15.6 Interprofessional Approach to Health Care](#)

The healthcare team consists of a wide array of team members with unique roles and responsibilities. Working together well must be a purposeful goal. Many professionals, from ministers to dietitians to respiratory therapists, may be important members of the healthcare team. A well-built team can lead to improved patient outcomes, higher-quality care, and greater likelihood that care plans will be fully implemented and adhered to. Setting clear goals, utilizing a curriculum for interprofessional training, and supporting leadership training with SMART goals and tools such as TeamSTEPPS 3.0 are a few strategies to create a strong, dynamic team of healthcare providers.

## Key Terms

**abstract** a brief description of the content of an article

**accountability** the responsibility of being answerable to oneself and others for one's choices

**adverse event** an event that results in injury or death to a patient due to care that was not appropriately delivered rather than to their health condition

**applied research** research that applies answers from basic research to current knowledge, testing it to evaluate changes in practice

**assignment** the routine activities and procedures that are part of a staff member's normal job and that they were taught in either a degree or certificate program or as part of on-the-job training

**assistive personnel (AP)** people who work to help nurses and other providers, including nursing assistants, certified nursing assistants, patient care technicians, and surgical technicians

**basic research** research intended to answer questions without changing the current conditions

**bias** a research error due to encouraging one response over another, usually unintentionally

**case study** an in-depth exploration of all aspects surrounding a single, complex issue as experienced by one or two individuals

**certification** the process of receiving extra education plus passing a subject-matter examination to become a recognized subject-matter expert

**chaplain** a spiritual adviser or minister working with an agency or hospital to meet patients' spiritual needs

**clinical decision support tools** resources available to help nurses and other healthcare professionals access best practice information more easily

**clinical expertise** the combination of a nurse's experience, critical thinking, and ability to recognize patterns and extrapolate alternatives based on similar experiences

**close-ended questions** questions with a limited range of answers, each of which can be assigned a variable for statistical evaluation

**cognitive bias** an unintentional error in judgment due to incorrect thought processes

**collaborate** to work effectively with one or more others

**collaborative practice** the process of healthcare workers from multiple professions working and communicating effectively together with patients and their families to provide patient care and improve healthcare quality and patient safety; also called interprofessional practice

**conclusion** the section of an article that discusses any deductions that can be made from the research

**correlational research** research that uses statistical analysis to explore relationships between two or more variables

**delegatee** the staff member being delegated to complete a task or activity

**delegation** the act of requesting staff members to perform tasks or procedures that are outside of their normal job but within the limits of their job description

**descriptive research** research that describes one or more variables

**discussion** the section of an article that explores the results of the research in relation to what else is known about the topic

**empirical evidence** evidence that can be measured and quantified

**error** the failure of a planned action to be carried out correctly

**evidence-based decision-making (EBDM)** the use of evidence-based practice (EBP) when making decisions about caring for individual patients

**evidence-based practice (EBP)** the responsible and thoughtful use of current and best evidence in conjunction with clinical expertise and patient values to guide healthcare decisions

**evidence-based practice bundles** small sets of evidence-based interventions that have been proven to improve patient outcomes when used in specific settings and groups

**evidence-based research (EBR)** when healthcare providers use research findings to improve their day-to-day care of patients

**experiential learning** learning by doing

**experimental research** research that studies the effect of a new intervention on a known concern and evaluates its effectiveness

**focus group** group interview in which participants interact with each other and the researcher

**hierarchy of evidence** classification of evidence into categories based on the type of research represented

- human subject** a living individual whom a researcher wants to interact with to collect information or specimens
- innovation** the development of new ideas, methods, and procedures
- institutional review board (IRB)** a group of people who monitor and approve medical research that will be performed within a given agency and protect the agency and its employees from engaging in unethical research practices
- Interprofessional Education Collaborative (IPEC)** partnership between the American Association of Colleges of Nursing and associations for medical, dental, public health, osteopathic, and pharmacy education, which was formed to develop collaborative education competencies for all healthcare professionals
- interview** a one-on-one conversation between the researcher and the research participant
- introduction** a brief discussion at the beginning of an article detailing the history, relevant literature, and rationale for the research conducted; sometimes called the background
- literature review** a synthesis of what other researchers have learned about a topic and what information still needs to be determined by future research
- methods** the section of an article detailing how the study was conducted
- mixed methods research** research that combines components of qualitative and quantitative methods into a single study
- nursing research** structured inquiry to obtain and evaluate information related to a specific nursing question
- occupational therapist** a healthcare worker who specializes in providing therapies to regain or prolong the ability to perform activities of daily living such as dressing and cooking for oneself
- open-ended questions** questions that lack a specified answer, such as yes or no, and that require explanation on the part of the participant
- patient care team** a group of people, including the patient and their family, responsible for providing care for a specific patient
- peer-reviewed journals** publications that require several reviewers to thoroughly evaluate articles and their value to the overall body of knowledge as a condition of publication
- pharmacist** a healthcare worker who specializes in filling prescriptions and reconciling medications to ensure patients are not prescribed incompatible medications
- physical therapist** a healthcare worker who specializes in manual treatment of physical injury or disease with methods such as exercise and massage
- Plan-Do-Study-Act (PDSA)** a quality improvement strategy to make changes through a PDSA strategy
- preventable adverse event** an adverse event related to human error
- provider** a physician, nurse practitioner, or physician's assistant tasked with diagnosing patients and ordering treatments such as medication and therapies
- qualitative research** complex, open-ended research that is based on the lived experience of participants and suitable for identifying areas of concern
- Quality and Safety Education for Nurses (QSEN)** a collaborative effort to advance and promote the integration of quality and safety competencies into nursing education and practice
- quality assurance (QA)** oversight to ensure that current quality standards are being met across a department or agency and that staff are receiving the education and infrastructure support to maintain that quality
- Quality Assurance and Performance Improvement (QAPI)** the dual use of quality assurance (QA) and performance improvement (PI), specifically in post acute care environments such as rehabilitation centers and nursing homes
- quality improvement (QI)** a framework to improve patient care and outcomes systematically
- quality improvement (QI) nurses** experienced RNs or advanced practice nurses who have a special interest in QI and may have taken a certification to become a subject-matter expert
- quantitative research** research that uses deductive reasoning, empirical evidence, and numerical data to test the validity of a reasonable idea in a given setting
- quasi-experimental research** research that explores cause-and-effect relationships without testing new interventions
- references** sources used within the body of an article to provide background information and support for analysis and discussion of the findings
- research article** a formal, written description of original research performed by the author(s)
- research methods** strategies and techniques used for gathering and analyzing data

- resource** a tangible or intangible item used in patient care, including time, staff, supplies, and space
- respiratory therapist** a healthcare worker who specializes in maintaining patient airways and providing advanced respiratory care
- results** the section of an article explaining what researchers learned or concluded from the data
- root cause analysis** a structured process to determine factors that underlie errors and adverse events
- seminal article** an article that strongly influences research conducted in the future and thus retains its value past the time when most research is generally considered obsolete
- sentinel event** an unexpected occurrence involving death or serious physiological or psychological injury, or the risk thereof; like a never event but is not necessarily preventable
- shared decision-making (SDM)** the practice of empowering patients to make healthcare decisions and state their needs and limitations
- social worker** a healthcare worker who specializes in helping patients meet social needs such as housing or rehabilitation upon discharge
- speech therapist** a healthcare worker who specializes in speech and language issues as well as the identification and management of swallowing concerns
- stakeholders** individual with an interest in the success of an organization, such as an investor in a business or a nurse in a hospital
- statistical significance** the relative chance that a study's results are reliable and similarly reproducible in a different group of similar patients
- team** a coordinated group of two or more people, each with a specific role, who interact to achieve a common goal
- team science** a collaborative effort to address a scientific challenge by engaging the strengths of team members with different areas of expertise
- team structure** the makeup of a single team or a multiteam system, including identification of the team leader and other members
- translation science** a branch of research dedicated to improving the movement of evidence-based practice from recommendations to normal care
- variable** a factor that is measured or studied in research

## Assessments

### Review Questions

1. A nurse is concerned that she has not been fully meeting the cultural needs of some of her Muslim patients. She conducts research into culturally appropriate care for Muslim patients and integrates a few ideas she learns into her practice. Which type of research is she most likely using?
  - a. basic research
  - b. applied research
  - c. evidence-based research
  - d. quasi-experimental research
2. Six months ago a medical-surgical unit established a series of rules for staff and patients regarding noise and patient interruption between 10 p.m. and 6 a.m. Several nurses want to evaluate the impact of these rules to ensure the changes have met the patients' needs and perform some EBR into these outcomes. Some nurses want to use a survey with all the patients. However, others think that better data might be captured by interviewing a few patients. Which research methods would be best for this situation?
  - a. qualitative methods
  - b. quantitative methods
  - c. mixed methods
  - d. All methods are equally appropriate for this situation.
3. A nurse is considering integrating some new evidence into her practice. She has explored several sources. Which sources have the highest quality information?
  - a. an article from Wikipedia
  - b. a blog post from the American Diabetes Association

- c. a clinical practice guide from the American Association of Critical-Care Nurses
  - d. a 15-year-old systematic review
4. What are the three components of the PET process in the JHEBP model?
- a. population question, evidence, and treatment
  - b. practice question, evidence, and treatment
  - c. population question, evidence, and translation
  - d. practice question, evidence, and translation
5. Ensuring a patient's preferences involves incorporating which two strategies?
- a. patient-centered care and shared decision-making
  - b. patient education and health literacy
  - c. patient-first care and group decision-making
  - d. patient-centered care and family engagement
6. How do EBP bundles work?
- a. They provide all intervention options in a single place for the nurse to choose from.
  - b. They provide equipment sets packaged together to make it easier to manage procedures.
  - c. They provide a set of a few interventions that should always be used in given situations.
  - d. They create performance templates to use when providing all patient care.
7. Nurses are informed during a staff meeting that a patient on a different unit recently died because a nurse gave them an insulin overdose. What kind of an event is this?
- a. adverse happening
  - b. preventable error event
  - c. preventable adverse occurrence
  - d. sentinel event
8. Nurse Shelly has just completed her nursing degree and is trying to choose which facility to work for. She has offers from several hospitals. Which facility probably provides the best environment for their nursing staff?
- a. Hospital A is accredited by The Joint Commission.
  - b. Hospital B is accredited by the IHI.
  - c. Hospital C is designated a Magnet facility.
  - d. Hospital D is designated a critical access facility.
9. A charge nurse is trying to determine whether they can delegate an LPN to give blood to a patient. Which sources should she explore?
- a. the state's nurse practice acts and the LPN job description for her facility
  - b. the ANA website and the guidelines given in the *American Journal of Medicine*
  - c. the RN's job description and the clinical decision tool in the electronic health record
  - d. another nurse and the agency's policy for blood transfusion
10. An RN is trying to determine whether she can delegate some lab draws to an AP from a different unit with whom the RN is familiar. Which reason prevents the RN from delegating the labs?
- a. The AP has completed the competencies for drawing labs but does not do them regularly.
  - b. The RN is unable to provide adequate supervision to the AP.
  - c. The RN is able to obtain the lab draws without delegation.
  - d. The RN has not worked directly with the AP before.
11. A nurse is conducting walking rounds with a patient's care team. Which action, if performed by the team leader, would most likely surprise the nurse?
- a. making eye contact with the patient and speaking with plain language
  - b. stating they do not want to do rounds if the patient's spouse is in the room

- c. encouraging a patient to ask questions
  - d. ensuring each team member addresses issues or concerns if needed
- 12.** Collaborative practice is characterized by healthcare professionals from different disciplines working together. What else is a characteristic of collaborative practice?
- a. adhering to a rigid leadership structure
  - b. assigning roles based on the group's needs rather than member knowledge
  - c. treating others with dignity and respect
  - d. limiting one's communication to weekly meetings
- 13.** Which member should a patient care team always include?
- a. a patient
  - b. a chaplain
  - c. a social worker
  - d. a medical student
- 14.** The nurse is assisting a patient with their lunch and notices they seem to be having difficulty swallowing. She communicates this new concern to the patient care team and suggests they place a consult for a specialist. Which type of interprofessional team member should evaluate the patient for this issue?
- a. occupational therapist
  - b. physical therapist
  - c. speech therapist
  - d. respiratory therapist
- 15.** TeamSTEPPS® encourages continuous leadership improvement through the use of tools such as:
- a. debrief checklist
  - b. surgical checklist
  - c. problem checklist
  - d. error reporting

### Check Your Understanding Questions

1. Explain the difference between qualitative and quantitative research.
2. What is the difference between the research conducted by an individual nurse for use in their practice and that conducted by a group for use with a population of patients?
3. Describe the components of the CLABSI bundle.
4. Describe the difference between QI and quality assurance.
5. Explain at least one benefit of QI and list three domains that are included in healthcare quality.
6. Describe the difference between delegation and assignment.
7. Why is collaborative practice important in health care?
8. What is IPEC, and why is it important?
9. Briefly explain how interprofessional care can improve the allocation of resources and the outcomes for population health.

### Reflection Questions

1. Discuss your feelings about human rights protections and their importance in nursing research. How do these protections align with nursing ethics and standards of practice?
2. Consider your decision to enter nursing school through the lens of the decision-making process. Describe the data you included in your decision as well as your judgments and those of anyone you consulted as part of the

process. While the final outcomes are not available yet, are there any initial outcomes that either help to validate your decision or that have caused you to question it?

3. What types of behavior do you think constitute mutual support in team settings?
4. Consider the various interprofessional roles discussed in this section. Many of these professionals perform roles that nurses also perform. Why do you think healthcare teams should include these additional professions?

### What Should the Nurse Do?

Members of the nursing staff on the Rose Unit of Sunshine Hospital are concerned there have been more falls than usual on the unit over the last six months. They would like to determine if there are better interventions they can use as a group to prevent falls. They bring it up to their nurse manager during a staff meeting. The nurse manager agrees it is a good project idea and suggests they use the JHEBP model. Answer the following questions regarding this case study and the JHEBP model:

1. What is the first step the nurses should take when beginning their project?
2. Suppose the nurses determine there is not enough available evidence to make a full EBP project. What alternatives might they have to reduce falls on the unit?
3. The nurses eventually determine there is sufficient available evidence, so they are moving forward with their project. However, when it is time to use the rating worksheets to evaluate the evidence, they note that a lot of it rates as low quality. What should they do?
4. The nurses have identified several recommendations they would like to implement on the Rose Unit. How should they proceed?
5. The action plan has been implemented for six months, and the outcome measures have been established. Not only did the number of falls decrease on the Rose Unit, but there is also a lower percentage of injuries from falls—and unexpectedly, the patients’ length of stay also decreased over the same time frame. What should the nurses do next?
6. Nurse Rosen is caring for an older adult patient with pneumonia who wants their adult child to stay the night. While this is not technically against the unit’s rules, usually staff allow family to stay only if patients are expected to pass away soon. Otherwise, families are encouraged to leave at 9 p.m., when visiting hours end for the day. Nurse Rosen knows several other hospitals in the area allow visitors overnight. What should Nurse Rosen do?

Mr. Rodriguez has been admitted to the ICU with a five-day history of high fever and cough. His English is quite poor, and he is very anxious. The nurse is trying to perform the initial assessment and evaluate his needs, but there is a real communication barrier.

7. Mr. Rodriguez takes a turn for the worse, and the physician is concerned for sepsis. What should the nurse expect to do?
8. A decision is made to establish a central line for Mr. Rodriguez. What can the nurse do to prepare the supplies?
9. Mr. Rodriguez does have sepsis and goes into respiratory failure. He is placed on a mechanical ventilator. What additional care should the nurse expect to provide?

Nurse Sa’ad has a patient requesting to go to the bathroom. The patient has not been out of bed for five days and has physician orders for bed rest, but they are insistent that they will be fine to walk and want to use the toilet. Nurse Sa’ad walks them to the bathroom and returns to the nursing station after asking the patient to pull the cord when they are ready to return to the bed. Ten minutes later, a nursing assistant finds the patient lying unconscious on the floor between the bathroom and their bed. Upon assessment, the patient has a head wound and a fractured hip but will recover fully. The nurse manager contacts the quality and safety department with an incident report.

10. What type of event is this?
11. When the quality nurse arrives, what kind of investigation can Nurse Sa’ad expect to be conducted?
12. Scenario update: The root cause investigation determines that the patient was not wearing nonslip socks (a unit standard), had a broken call light in their bathroom, and had been taking narcotics for pain, which might have contributed to their fall. Given this update, how should Nurse Sa’ad act to prevent a similar event from happening again?

13. Nurse Gomez has delegated a task to a member of her unit's AP staff, Glenda. She has ensured Glenda has completed the necessary training. Glenda has a competency on file, and Nurse Gomez is comfortable with Glenda's ability to perform the task. After Nurse Gomez finishes explaining what she needs Glenda to do, Glenda states that she does not feel comfortable accepting the delegation. What should the nurse do?

Consider again the scenario of Mr. Rosenberg, the 50-year-old with the diabetic foot ulcer who was discussed earlier in this chapter. Reread that conversation and answer the following questions.

14. Name one strategy that Dr. Blalock used to engage Mr. Rosenberg initially.
15. How did the team encourage Mr. Rosenberg to determine his goals?
16. Nurse Rosa asks for the wound care nurse to be consulted for Mr. Rosenberg's foot wound. Was this an appropriate request for her to make?

## Competency-Based Assessments

1. Read through this [worksheet on developing PICOT questions \(https://openstax.org/r/77JPICOT\)](https://openstax.org/r/77JPICOT) by the Oncology Nursing Society. Once you have read the material, use the format suggested to write two full PICOT questions about topics that interest you. They do not have to be related to oncology.
2. Using one of the PICOT questions developed in question 1, begin conducting EBR for information addressing your issue. Locate at least five high-quality resources, at least three of which must be from peer-reviewed journals. You must also include at least one systematic review. Give the information for each resource, copy and paste the abstract information into your document, and detail why you believe each source to be high quality.
3. Explore the information about the [Teach-Back Technique \(https://openstax.org/r/77DecisionTool\)](https://openstax.org/r/77DecisionTool) offered on the AHRQ's website. It is commonly used to aid in shared decision-making. Work with a partner. Each partner should prepare to briefly educate their partner, using the Teach-Back Technique, on a topic of their choice.
4. Goal 6 of the 2023 National Patient Safety Goals from The Joint Commission is to reduce patient harm associated with clinical alarm systems (NPSG.06.01.01: Improve the safety of clinical alarm systems). Explore the rationale and elements of performance for this goal in [the 2023 National Patient Safety Goals \(https://openstax.org/r/77SafetyGoals\)](https://openstax.org/r/77SafetyGoals); then, describe three elements you can envision incorporating into your own practice.

Consider the following scenario. You are a newly graduated nurse in Texas participating in a nurse residency program and learning about delegation. Your residency supervisor asks you to use the [delegation resource from the Texas Board of Nursing \(BON\) \(https://openstax.org/r/77TXBoard\)](https://openstax.org/r/77TXBoard) to answer the following questions.

5. Which chapter of the Texas BON's rules describes delegation responsibilities in acute care settings?
6. Can LVNs delegate care in Texas? Please explain the answer.
7. Can RNs be required to delegate? Please explain the answer.
8. When nursing students are employed to work as AP in healthcare settings, can tasks they have learned in school be delegated to them? Please explain the answer.
9. Conduct internet research and provide a URL for at least one other state's laws regarding delegation (preferably your own state unless you are Texan).

## CHAPTER 16

# Legal and Ethical Considerations

**FIGURE 16.1** Ethical and legal issues in nursing can have profound consequences, both personally and professionally. (credit: “registered nurse assigned to the 959th Medical Group” by Master Sgt. Helen Miller/U.S. Air Force, Public Domain)

### CHAPTER OUTLINE

- 16.1 Value Considerations of Care
- 16.2 Ethics in Nursing Practice
- 16.3 Legal Dimensions of Care
- 16.4 Advocacy in Nursing Practice

**INTRODUCTION** Consider the following scenarios:

- A patient recently signed a do not resuscitate order and has a living will stating they do not want any extreme lifesaving measures; however, when they cease breathing, their adult children demand they be placed on life support.
- A provider has asked a nurse to facilitate understanding of the informed consent documents with a patient before surgery; however, based on their confusion about the procedure and aftercare expectations, it is apparent the health literacy of the patient and family is low, and they do not understand what the patient was asked to sign.
- A teenager has been brought in with multiple traumatic injuries following a motor vehicle accident. They require blood transfusions and surgery to survive; however, the family refuses to consent to the procedures, citing religious conflicts.
- An older patient from a skilled nursing facility has been brought to the hospital in a coma after a fall. They have no family, no living will, and no chance of recovery; however, they have no one to make decisions for them since they are incapacitated.

What is the nurse’s role in these types of situations? These scenarios offer real examples of why a clear

understanding of values, ethics, laws, and advocacy is critical for nurses. Every nurse will face these or similar scenarios and ethical and legal questions in their careers. For this reason, entering practice with a solid moral and ethical foundation is vital for all nurses and healthcare workers.

## 16.1 Value Considerations of Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize how values are developed
- Describe the values of professional nursing
- Identify the process of structuring values for patient care

How do humans figure out what is good or bad? Right or wrong? Why do some people feel a strong need to care for others who are less fortunate and other people feel that everyone should be fully responsible for making their own way? What is the difference between an individual who regularly breaks the law by selling illegal drugs and someone who will not even go through a red light because it is against the law? Often, these questions boil down to values. Everyone has them, everyone uses them, and everyone experiences them differently.

A **value** is a central, guiding principle in an individual's life. Values help people establish priorities, plan for their futures, choose their careers, and determine how they want to live (Weiss et al., 2019). Values are central to individual identity, allow for common communication within groups, help set up goals and ideals of behavior, and assist individuals in responding to questions and ethical situations (Sagiv & Schwartz, 2022).

### Development of Values

People develop their values throughout their lifetimes, with much development occurring early in life. Recent studies of twins have shown that both nature (innate, hereditary tendencies) and nurture (socialization and environment) impact value development (Sagiv & Schwartz, 2022). Much like culture, values tend to be shared among individuals living, working, and worshipping in proximity. Caregivers are the first teachers of values, sharing their values and attitudes with their children (Weiss et al., 2019). Caregivers are often among the strongest sources of values, probably due to the inherited and environmental aspects of value transmission. However, children are also influenced by the values of peers, teachers, and religious systems (Sagiv & Schwartz, 2022).

Professional values also develop throughout a person's lifetime. Nurses learn professional values in school and the workplace (Kosmidis et al., 2021). Developing a solid sense of values increases professional and patient satisfaction.

### Value System

A **value system** is the sum of an individual's or group's values. Just like individuals, groups have sets of values, often clarified as codes of conduct, tenets, commandments, or simply value statements (Sagiv & Schwartz, 2022). The factors that bind individuals as a group can also influence their value system. Multiple factors can bind such groups, including religion, profession, interest, economics, business location/facility/company, and ethnicity.

Individuals' value systems are often personal and created from their experiences, environment, and genetics. By contrast, groups' value systems are generally thought-out principles created to guide group members in their behaviors and actions (Poorchangizi et al., 2019).

### LINK TO LEARNING

The World Health Organization (WHO), the health agency of the United Nations, is an international healthcare agency focused on global health care. The [WHO Values Charter \(https://openstax.org/r/77WHOchart\)](https://openstax.org/r/77WHOchart) discusses values for human rights, life, and healthcare equity. They state their group value system to guide the values with which WHO employees are supposed to perform their jobs.

### Professional Nursing Values

Like most professions, nursing has a highly formative system of values. In a concept analysis (an exploration of

meaning) of nursing professional identity, 62 percent of the sixty-eight articles analyzed cited shared values and ethics as definitive characteristics of the nursing profession (Fitzgerald, 2020). These values reflect how nurses should conduct themselves and behave toward patients, other healthcare workers, and even themselves (Poorchangizi et al., 2019). Professional values such as altruism, autonomy, integrity, social justice, and human dignity are core components of nursing beliefs and practices. Furthermore, nurses are bound by the Code of Ethics for Nurses (discussed in [16.2 Ethics in Nursing Practice](#)) and the standards of nursing practice. Nurses learn these values and ethical codes and how they are practiced (Fitzgerald, 2020). Additionally, as the single largest group of healthcare workers, nurses must adhere to their core professional values, acting as role models for other professional disciplines (Kosmidis et al., 2021).

### Altruism

Working for the well-being of others, or **altruism**, is one of the core values of nursing practice ([Figure 16.2](#)). It is inherently connected to the understanding that nursing is a profession of caring for others. The foundation of nursing practice and decision-making is rooted in altruism, which frequently plays a role in the decision to pursue nursing as a profession (American Nurses Association [ANA], 2021; Chen et al., 2022). Altruism affects the nurse/patient relationship and the willingness of the individual nurse to fully embrace other nursing values (Chen et al., 2022). It is easy to lose sight of altruism in today's modern healthcare settings, which are often driven by business models rather than models of human caring (Chen et al., 2022). However, nurses must continue to embrace altruism because caring for others is central to the profession.

**FIGURE 16.2** Altruism in nursing means making the well-being and care of others the primary goal. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

While altruism is core to nursing, it is sometimes difficult to maintain. Patients may present challenges in their demeanor, exhibiting emotions such as anger, confusion, or manipulation. Occasionally, these circumstances can pose difficulties in providing care with a compassionate and tender approach. Keeping an altruistic attitude through difficult times is essential for nurses to learn (Kubsch et al., 2020). Remembering that all patients are vulnerable, even the “difficult” ones, and providing care for them all with kindness and respect supports the altruistic, caring core of the nursing profession.

### Autonomy

The value of **autonomy** reflects the individual's ability to make decisions and decide on a course of action based on being well informed, giving consent, and volunteering, all without coercion. There are two prongs to autonomy: patients' right to self-determination and nurses' right to act autonomously. The value of autonomy is built into the ANA Code of Ethics and runs through many nursing standards (ANA, 2015).

Ensuring patients' inclusion and participation in the decision-making process about their diagnosis and treatment is key to preserving their autonomy. Patients have the right to accept or refuse treatment, understand the implications of their choices, and be supported throughout the decision-making process. The nursing value of autonomy supports patients in those choices, ensures that patients receive the information they need, aids in determining whether a patient can understand what they are agreeing to, and supports the entire process (ANA, 2015, 2021).

The value of autonomy is as significant in research as in treatment decisions. Research participants have the autonomy to make their own decisions, and nurses must value that autonomy and ensure it is respected by other members of research teams (ANA, 2015). Nurses must use their involvement at all stages of the research process to

protect patient autonomy. “Patients’/Participants’ welfare [and autonomy] may never be sacrificed for research ends” (ANA, 2015, p. 28).

Nurses also share the value of autonomy for their own practice (ANA, 2021). Within the bounds of their professional practice acts, nurses have the right to perform their duties autonomously. Nursing leaders at all levels have championed nurses’ ability to have stronger voices within the healthcare arena and be allowed their autonomy. Thus, nurses are allowed to make decisions, truly advocate for their patients, and deeply engage in the entire process (ANA, 2021).

### Integrity

The value of **integrity** presents as honesty, moral consistency (supporting what is “right” even when it is not popular), and commitment. Nurses must hold themselves accountable for the value of integrity in all their activities. The patient’s interests must always be primary (ANA, 2015). Further, nurses must maintain their integrity and behave within the bounds of their nursing professional values. Nurses must have the integrity to protect patients from incompetent, illegal, unethical, and/or impaired practice, even when others are unwilling to speak. Most agencies have processes for reporting concerns, and nurses must be willing to use them to keep their own integrity and that of the profession (ANA, 2015).

In healthcare environments, there are times when the value of integrity is threatened. Situations may present a **conflict of interest** when a nurse cannot hold the patient’s interests as primary. The nurse must “address such conflicts in ways that ensure the patient’s safety and that promote the patient’s best interests while preserving the professional integrity of the nurse and supporting interprofessional collaboration” (ANA, 2015, p. 5). Conflicts of interest that can negatively impact a nurse’s integrity might include caring for a family member, friend, or enemy, being asked to bill for services not provided, withholding information from a patient, falsifying records, and/or being asked to act outside of the patient’s best interest. When conflicts arise, nurses must seek guidance from their leadership in deciding the correct actions. Nurses must continuously work to support integrity in the workplace and expect it from themselves and other healthcare professionals.

When a nurse refuses to perform an action that violates their personal sense of integrity, the refusal is known as **conscientious objection**. Nurses can preserve their integrity and refuse to act as long as they are not refusing based on personal prejudices such as bias and/or convenience (ANA, 2015). If a nurse chooses to use conscientious objection to refuse to violate their professional integrity, they may face consequences. For example, a nurse who holds strong ethical or religious beliefs against participating in certain medical procedures, such as abortion or assisted suicide, may refuse to take part in such procedures, due to conscientious objection. As a result, they might face consequences, such as disciplinary action or a negative performance evaluation. However, many agencies have policies that allow nurses the autonomy to express conscientious objection, provided that the nurse ensures patient safety and does not leave a patient without someone providing for their care (ANA, 2015).

### Human Dignity

The belief that every individual has worth based on being human is called **human dignity**, and all humans share this worth equally. A belief in the value of human dignity is fundamental to the nursing system of values. It should underline every interaction a nurse has with patients, healthcare workers, family members, and community members (ANA, 2015). The importance of human dignity is closely linked to autonomy, as both uphold an individual’s right to make their own decisions. Even if the nurse disagrees with the patient, human dignity allows an individual patient to make their own decisions and be supported by the nurse.

The nursing profession is also committed to championing human dignity beyond the bedside. Nurses are involved in human rights campaigns and collaborative strategies to ensure equality in health care for all people (ANA, 2015). Nurses involved in human subjects research must remember to value the human dignity of research participants and that a human being is being studied; it is important to protect at-risk populations from being disrespected or devalued.

### Social Justice

An inherent belief that all people deserve equal treatment and access to health care is called **social justice**. This value encourages nursing professionalism and influences organizations to work toward health equity for patients and communities (ANA, 2021). Social justice means that nurses supply the same high-quality treatment for all patients, regardless of socioeconomic status. From a nursing standpoint, it does not matter if a patient has

insurance, can speak the dominant language of the location, or has racial, ethnic, gender, religious, or political differences. All patients should be treated equally, with dignity and respect (ANA, 2021).

## LINK TO LEARNING

Nurses have many opportunities to engage in social justice activities locally, nationally, and internationally. Explore some ways [members of National Nurses United involve themselves with social justice \(https://openstax.org/r/77membNNU\)](https://openstax.org/r/77membNNU) issues.

A belief in social justice develops naturally from other nursing professional values such as altruism, integrity, autonomy, and human dignity. Together these values represent the social contract for the nursing profession that extends beyond hospital walls and physician offices and into the heart of the community (ANA, 2021). Nurses must look beyond personal biases to fight for the rights of all people to have fair and equal access to health care, both in daily nursing practice and in nursing research. This value is inherent in four of the five current research lenses supported by the National Institute of Nursing Research ([Figure 16.3](#)).

### RESEARCH LENSES

**FIGURE 16.3** See how the value of social justice is inherent in research foci of health equity, social determinants of health, population and community health, and prevention and health promotion. (credit: “2022-2026 Strategic Plan” National Institute of Nursing Research, Public Domain)

### Process of Structuring Values

Nursing values are the principles upon which the nursing profession is built. Nursing values become internalized in nurses and throughout the profession. They are structured into nursing standards of practice, codes of ethics, nursing organizations, agency departments of nursing service, and even the nursing process (Habeeb, 2022).

For most nurses, the values of the nursing profession also align with their personal values. Why else would they choose this profession? However, if the personal values of most nurses generally align with the values of the nursing profession, then why do some nurses behave differently? Studies have shown that individual nurses’ emphasis on different nursing values is directly linked to their own personal values (Habeeb, 2022). Since everyone’s personal experiences are different, so are their interpretations of nursing values and their applications to nursing practice.

### Assessing Values

There is great benefit in assessing values. Professional values can be taught in classes or textbooks or learned through observing role models. However, understanding one’s personal values is always useful. Some agencies include personality and values inventories before hiring staff members. Some schools also use these inventories to help their students make determinations about ideal professions.

Several values assessment inventories are available to explore values in oneself or others (Chowdhury, 2023). For example, the Personal Values Assessment is one values measurement tool. It focuses specifically on personal, social, and universal values. It provides a basis to understand one's own beliefs about right and wrong (Chowdhury, 2023). There is also a Nurses Professional Values Scale-3, written using the ANA's Code of Ethics to measure nursing values. It has been validated in English and several other languages (Weis, 2017).

## LINK TO LEARNING

There are [suggestions to use in considering your own values \(https://openstax.org/r/77corevalue\)](https://openstax.org/r/77corevalue) and knowing your core values. Check some of them out and consider how your own values align with those of the nursing profession.

### Application of Values in Clinical Practice

Once professional nursing values are established and learned, how are they applied? How do nurses use these values in clinical practice? How are they recognized by patients, colleagues, leadership, and even friends or family? It would be easy to simply state that they should be obvious based on an individual nurse's actions and behaviors. However, this response does not provide clarity or concrete discussions of how values are applied or show how they are structured into the fabric of nursing. Instead, let us explore the nursing process, assessment, diagnosis, outcomes/planning, implementation, and evaluation, to see how principles of nursing values are integrated into the strategies that nurses use in clinical practice ([Table 16.1](#)).

Process Step	Description	Examples
Assessment	The nurse collects and analyzes objective and subjective information about their patient.	<ul style="list-style-type: none"> <li>• Preserving patients' human dignity by remaining professional and offering respect and privacy throughout the process</li> <li>• Offering culturally competent care and assessing patients' cultural needs without judgment</li> <li>• Fostering autonomy by including shared decision-making and ensuring patients understand why questions are being asked and how their information will be used</li> <li>• Showing honesty and integrity during assessments by coming back when they told the patient they would be back, answering questions and admitting when answers are unknown, and finding answers for questions the nurse does not have ready answers to</li> </ul>
Diagnosis	The nurse uses clinical judgment to determine the patient's needs regarding nursing care.	<ul style="list-style-type: none"> <li>• Recognizing how patients' health is dictated, to some extent, by the social determinants of health (SDOHs), the conditions in and under which people live and work, such as economics, education, and social environment</li> <li>• Ensuring every patient with chronic pain receives a nursing diagnosis reflecting their pain regardless of the underlying circumstances or the patient's background, also speaks to integrity, human dignity, and social justice</li> <li>• Refusing to allow personal prejudices to interfere with the nursing diagnosis process, which is another way to show altruism, integrity, human dignity, and social justice</li> <li>• Taking responsibility for one's role in the diagnostic process, which also shows integrity</li> </ul>

**TABLE 16.1** Nursing Values Expressed in the Nursing Process (Sources: American Association of Colleges of Nursing, n.d.; ANA, 2021; International Council of Nurses, 2021; Royal College of Nursing, 2023.)

Process Step	Description	Examples
Outcomes/ Planning	The nurse identifies desired outcomes and develops nursing plans to help achieve those outcomes.	<ul style="list-style-type: none"> <li>• Ensuring patients have a role in the decision-making process for determining outcomes and safeguarding their informed consent fosters autonomy</li> <li>• Completing all planning while providing culturally appropriate care and understanding, which respects human dignity</li> <li>• Encouraging interdisciplinary teams to develop plans that patients can maintain once they are discharged, which speaks to both autonomy and social justice</li> <li>• Advocating for equal treatment for all patients with similar conditions, demonstrating human dignity and social justice values</li> </ul>
Implementation	The nurse puts various interventions and plans into action to help the patient gain/regain the desired outcomes.	<ul style="list-style-type: none"> <li>• Ensuring patients receive the care they need in all areas, which involves altruism and deep caring for the patient as an individual</li> <li>• Reporting concerns or seeking additional guidance in situations that appear hazardous or unethical, which reflects professional integrity</li> <li>• Guaranteeing patients and their families receive appropriate information and education regarding interventions, providing informed consent, and using language interpreters when necessary, which all show the nursing values of autonomy, social justice, and human dignity</li> <li>• Advocating for all patients to have the same access to interventions, which reflects social justice</li> </ul>
Evaluation	The nurse evaluates progress toward outcomes.	<ul style="list-style-type: none"> <li>• Providing all patients with the opportunity to respond to their perceptions of how well outcomes have been met (such as with pain), which embraces the values of autonomy, human dignity, and social justice</li> <li>• Ensuring that if the original set of interventions does not result in desired outcomes, new interventions are introduced, which reflects altruism and integrity</li> </ul>

**TABLE 16.1** Nursing Values Expressed in the Nursing Process (Sources: American Association of Colleges of Nursing, n.d.; ANA, 2021; International Council of Nurses, 2021; Royal College of Nursing, 2023.)

## 16.2 Ethics in Nursing Practice

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the role ethics plays in nursing
- Identify different theories of ethics
- Recognize ethical conduct and decision-making in nursing

Ethics are embedded in everything nurses do. They are intertwined with nursing values and intertwined in nursing standards of practice. They underlie nursing principles. Further, there is a well-defined ethical code of conduct for nurses to use when questions regarding right and wrong arise. All nurses must understand nursing ethics and use them daily in their professional practice.

## Nursing Ethics

A branch of philosophy, **ethics** is a set of moral principles, virtues, or ideals that guide behavior and help distinguish right from wrong, and **nursing ethics** provide a moral base from which nurses work. The most recent version of the *ANA Code of Ethics for Nurses* (also known as The Code) was published in 2015 and reaffirmed in the fourth edition of the *Scope and Standards for Nursing Practice* published in 2021. The Code and the corresponding documents lay an ethical blueprint for all nurses in the United States to follow.

### Nursing Ethical Virtues

A character trait or habit that is considered morally good is called a virtue. They are learned behaviors and attitudes and can be taught in school and through experiences, such as caring for older relatives, siblings, or pets. Many consider virtues, such as caring, compassion, discretion, trust, integrity, and consciousness, fundamental to nursing practice and ethics (Kosmidis et al., 2021). Note that virtues can also be values; however, a value is an internal belief in a concept, while a virtue is the execution of that belief. Consider the concept of integrity. The *value* of integrity is a belief in honesty, moral consistency, and commitment. The *virtue* of integrity is acting on that belief with honesty and clarity, even in the face of one's failure. For example, a nurse who goes to their nurse manager after making an error and informs the nurse manager of their error is acting with the virtue of integrity (Kosmidis et al., 2021). In this sense, nursing virtues are the outward expressions of inner nursing values. Another example of a nursing ethical virtue is **moral courage**, the willingness to stand up for what is moral and ethical even when it may negatively impact the nurse (Pajakoski et al., 2021). Moral courage helps to safeguard patients and protect nursing standards.

### Ethical Principles in Nursing

The background concepts that underlie the essence of ethics and can also guide behavior are known as **ethical principles** (Weiss et al., 2019). As with values and virtues, there is some overlap between principles, values, and virtues. The main ethical principles that underpin the nursing Standards of Practice and Code of Ethics for Nurses are as follows (Weiss et al., 2019):

- **Autonomy:** Patients should have the right to make their own decisions.
- **Justice:** As an ethical principle, **justice** is somehow both the same and yet bigger than the value of social justice. It is a principle that requires nurses to treat all people equally and judge them on the same criteria, no matter who they are, what their illness is, or how much money they have.
- **Confidentiality:** The principle of **confidentiality** focuses on maintaining patient privacy in terms of both health and personal information. It is both an ethical principle and a legal issue (discussed in [16.3 Legal Dimensions of Care](#)).
- **Accountability:** The principle of accountability means that nurses accept responsibility for their own actions. Standards of care, policies, and procedures help maintain accountability by ensuring that there is a template of what should have been done to compare against what was done.
- **Nonmaleficence:** The principle of **nonmaleficence** means that nurses should do no harm either intentionally or unintentionally. They are expected to protect those who cannot protect themselves.
- **Fidelity:** A principle of faithfulness and loyalty is **fidelity**. Nursing requires fidelity to the profession and patients and is an underlying principle in accountability.
- **Beneficence:** The principle of **beneficence** is that nurses should do good for the benefit of others. Beyond simply providing competent care, nurses should truly care for their patients and seek to meet their physical, social, or emotional needs.
- **Veracity:** The principle of truthfulness is **veracity**. Nurses are expected to be honest with their patients. Veracity is also an underlying principle behind integrity.

## UNFOLDING CASE STUDY

### Unfolding Case Study #3: Part 1

The nurse is caring for a 58-year-old female with metastatic lung cancer who is a patient on the oncology unit of the hospital. The patient's health has been deteriorating for the last few months, and she has expressed an interest in discussing palliative care options.

Past Medical History	<p>Patient has been receiving chemotherapy intermittently over the last two years. She reports one brief period of remission six months ago; however, the cancer returned shortly after.</p> <p><b>Medical history:</b> Chronic obstructive lung disease, one pack/day smoker for over thirty years, gastroesophageal reflux disease.</p> <p><b>Social history:</b> Three adult children, no known medical conditions. Husband of thirty-five years passed away five years ago in a car accident.</p> <p><b>Family history:</b> Both parents deceased from natural causes.</p> <p><b>No current medications and no known allergies. Last chemotherapy round ended two months ago.</b></p>
Nursing Notes	<p><b>0900: Assessment</b></p> <p>Patient reports she does not wish to receive another round of chemotherapy and is ready to discuss palliative care options. Consult placed to palliative care team who plans to round on her this afternoon. When asked about family, patient reports: “They will want to keep me alive and change my mind about chemo, but I just can’t do it anymore. Please don’t contact them. I don’t want them to know about this.”</p>

1. Recognize cues: What cues does the nurse recognize as being the highest priority at this time?
2. Analyze cues: Which ethical principle is most relevant to the patient’s current situation?
3. Prioritize hypotheses: Why do you think the patient is requesting for her family to not be contacted regarding her decision to pursue palliative care? Does this request require follow-up or intervention by the nurse?

### Standards of Professional Nursing Practice

The **Standards of Professional Nursing Practice** are statements of functions and conduct that all nurses, in every setting, are expected to execute capably (ANA, 2021). They are not, in and of themselves, ethical statements. However, they are informed by nursing professional values, virtues, and morals. Further, their proficiency requires an understanding and appreciation of the body of nursing ethics. Each set of standards includes several competencies registered nurses are expected to meet upon graduation from nursing school and additional competencies expected of advanced practice and graduate level–prepared nurses.

There are two sets of nursing standards (ANA, 2021). The first set, the **Standards of Practice** (referring to ANA’s *Nursing: Scope and Standards of Practice*) is based on the nursing process. The Standards of Practice form the basis of rules regarding decision-making, care provision, and practice behaviors. They include the standards of assessment, diagnosis, outcome identification, planning, implementation, care coordination, patient education, and evaluation. Similar to how nursing values become incorporated into practice through the nursing process, nursing ethics are interwoven throughout the Standards of Practice despite not being explicitly about ethics.

The second set of professional standards is the **Standards of Professional Performance**. These standards represent professional nursing behaviors and mindsets. The Standards of Professional Performance include advocacy, respect, communication, collaboration, leadership, research, and environmental health. As with the Standards of Practice, the Standards of Professional Performance are informed by and grow out of the nursing professional values. One additional standard of professional performance, the Code of Ethics for Nurses, is a set of specific provisions registered nurses are expected to use to guide their practice (ANA, 2021).

### The Code of Ethics for Nurses

Values, ethical virtues, and ethical principles are all related to the development of nursing professional practice and practice standards. Now, let us look at the Code of Ethics for Nurses. [Table 16.2](#) provides the nine Code of Ethics for Nurses provisions and a brief discussion of each provision’s interpretation.

	Provision	Brief Interpretation
1	The nurse practices compassionately and respects every person's inherent dignity, worth, and unique attributes.	<ul style="list-style-type: none"> <li>• Respect human dignity and all human rights no matter the nature of the illness.</li> <li>• Establish therapeutic relationships based on trust and compassion.</li> <li>• Recognize the right to autonomy.</li> <li>• Practice respect in all relationships.</li> </ul>
2	The nurse's primary commitment is to the patient, whether an individual, family, group, community, or population.	<ul style="list-style-type: none"> <li>• Address conflicts of interest to preserve patient safety first, then professional integrity.</li> <li>• Collaboration with patients is critical.</li> <li>• Set boundaries in therapeutic and collaborative relationships to protect everyone's safety.</li> </ul>
3	The nurse promotes, advocates for, and protects patients' rights, health, and safety.	<ul style="list-style-type: none"> <li>• Protect the privacy and confidentiality of patients.</li> <li>• Protect human participants in research.</li> <li>• Engage in continuing education to perform with the most current practice.</li> <li>• Participate in a culture of safety.</li> <li>• Take action immediately when faced with incompetent, unethical, illegal, or impaired practice.</li> </ul>
4	The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and provide optimal care.	<ul style="list-style-type: none"> <li>• Make decisions with authority and are accountable and responsible for those decisions, judgments, and actions.</li> <li>• Be responsible and accountable for assigning and delegating nursing tasks.</li> </ul>

**TABLE 16.2** The Code of Ethics for Nurses (Source: ANA, 2015.)

	Provision	Brief Interpretation
5	The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.	<ul style="list-style-type: none"> <li>• Respect human dignity, including respect for self.</li> <li>• Be responsible for caring for themselves as they care for patients, as well as modeling the behaviors they teach to patients.</li> <li>• Recognize professional identities impact personal ones, and vice versa.</li> <li>• Hold the right to expect integrity will be respected.</li> <li>• Maintain their competency and seek professional growth.</li> </ul>
6	Through individual and collective effort, the nurse establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality health care.	<ul style="list-style-type: none"> <li>• Use nursing virtues when caring for patients to guide behavior and actions.</li> <li>• Support and foster moral and ethical work settings.</li> <li>• Contribute to ethical communication with colleagues and patients.</li> </ul>
7	In all roles and settings, the nurse advances the profession through research and scholarly inquiry, professional standards development, and nursing and health policy development.	<ul style="list-style-type: none"> <li>• Contribute to research and scholarly inquiry while maintaining respect for autonomy and human participants.</li> <li>• Participate in and develop policies and standards grounded in professional nursing ethics.</li> </ul>

**TABLE 16.2** The Code of Ethics for Nurses (Source: ANA, 2015.)

	Provision	Brief Interpretation
8	The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.	<ul style="list-style-type: none"> <li>• Believe health is a universal right and commit to collaborating with others to achieve human rights and health equity.</li> <li>• Fight for human rights in the face of complex practice settings such as human trafficking and war.</li> </ul>
9	The profession of nursing, collectively through its professional organizations, must articulate nursing values, maintain the integrity of the profession, and integrate principles of social justice into nursing and health policy.	<ul style="list-style-type: none"> <li>• Espouse professional nursing values and ethics.</li> <li>• Affirm the same values across all types and areas of nursing.</li> <li>• Build social justice into the fabric of health policy and nursing service.</li> </ul>

**TABLE 16.2** The Code of Ethics for Nurses (Source: ANA, 2015.)

## LINK TO LEARNING

The ANA provides the [Code of Ethics for nurses \(https://openstax.org/r/77codeethic\)](https://openstax.org/r/77codeethic) in an online version, which explores the entire Code in great depth, including interpretive statements to assist in understanding them and internalizing their meaning.

## Theories of Ethics

One of the earliest theories of ethics, **virtue ethics** was introduced by Aristotle around 2,600 years ago (Rozmus & Spike, 2018). It is based on the idea that people make decisions and perform actions based on their character, and those with good character will behave in a fashion that is consistent with their character (ANA, 2021). Virtue ethics have been widely used in nursing to explain nursing conduct and establish ethical boundaries. The underlying concept is that the virtues important to nursing supply a framework for nursing ethics by encouraging nurses to do what is right and moral.

Immanuel Kant developed **deontology** in the 1700s. The underlying assumption of deontology is that ethical decisions or actions are right or wrong because they meet a moral law or principle (ANA, 2021). People do right because it is the right, rational, and dutiful thing to do. Further, people should only behave as they want everyone to behave (Rozmus & Spike, 2018).

A third classic theory of ethics that influences nursing is **utilitarianism**, also known as consequentialism. Developed by John Stuart Mill in the 1800s, utilitarianism ethics focus on what will do the greatest good for the most people and the least amount of harm for others (ANA, 2021; Rozmus & Spike, 2018). What makes utilitarianism so powerful is that it counts all people as equally important. All three of these classical theories of ethics are still embedded in nursing ethics and have been expanded and incorporated into the ethical systems, approaches, and decision-making strategies used in nursing today.

### Principle-Based Approach

The **principle-based approach**, also called principlism, draws strongly from deontology and is perhaps the most dominant approach to ethical decision-making in nursing (ANA, 2021). This approach assumes that ethical principles can guide all actions and decisions for nurses (De Panfilis et al., 2019). Refer to provision two of the Code

of Ethics for Nurses (Table 16.2), and consider it in terms of the principle-based approach. The primary commitment of the nurse is to the patient, and the patient can be an individual, group, family, or community. When providing nursing care, the guiding principles should be based on the needs of the patient (De Panfilis et al., 2019). For example, engaging in conversations about risks and benefits or ensuring patients have name or alert bracelets to reduce medical errors are all ways to support principles of ethical decision-making (Vearrier & Henderson, 2021).

### Care-Based Approach

The **care-based approach** combines the action of offering physical care for another human being and the value of caring about the individual, recognizing their frailty and vulnerability (De Panfilis et al., 2019). It carries an underlying assumption that as a species, human beings are mutually dependent on each other and need respect, protection, and caring. It further recognizes the state of being ill and the experience of being ill are connected, and patients are treated both through physical care and therapeutic relationships between providers and patients (De Panfilis et al., 2019).

The care-based approach draws a strong sense of morality in action from virtue ethics. A nurse using the care-based approach employs virtues such as respect to actively build their therapeutic relationships with patients. They also use deontology for many of the same reasons, because actively supplying care in all ways is morally right (De Panfilis et al., 2019). The care-based approach also requires authenticity and genuineness—legitimate care for the individual patient, not one that is faked by the nurse.

### Feminist Ethics

Over 90 percent of the international nursing workforce is female, and nursing has been a dominantly female occupation since the days of Florence Nightingale. Feminist ethics arose out of a desire to provide a feminist lens to the male-dominated field of philosophy and ethics and to relocate an understanding of women's roles in health care as careers (Kohlen & McCarthy, 2020). As a result, feminist ethics arose out of a need to critically appraise the gendered nature of traditionally held theoretical perspectives: to challenge the status quo and explore ethics from a female perspective. Because, historically in Western societies, men and male-dominated professions have had more power than women and female-dominated professions, feminist ethics in nursing initially sought to shine a light on how distorted and institutionalized understandings of male/female differences impacted health care (Kohlen & McCarthy, 2020). Thus, from its earliest beginnings, feminist ethics explored relationships and power, with an underlying recognition that society has internalized understandings of gender that marginalize and disempower women.

In the four plus decades since feminist ethics initially arose, the overarching understanding of internalized prejudices inherent in areas such as institutionalized racism, sexism, ageism, and classism, have become cornerstones of what began as simple feminist ethics. It seeks to unpack the social, cultural, economic, and even political issues that impact healthcare affordability, accessibility, equity, and even justice (Kohlen & McCarthy, 2020). No longer simply focused on gendered roles, today's feminist ethics could perhaps more accurately be called the ethics of social justice. Today's feminist ethics draws on its history to situate nursing care in relation to oppression and power, not only of male versus female, but in all healthcare relationships where a difference in power impacts the individual's ability to receive the care they need.

### Ethical Conduct and Decision-Making

Behaving in a manner aligned with the Code of Ethics for Nurses, nursing values and virtues, and nursing ethical principles, is known as **ethical conduct** and is expected of nurses in all situations (Figure 16.4). However, behaving ethically is not always easy, and nurses are often forced to engage in decision-making strategies, alone or as part of the healthcare team, to determine what action is ethically appropriate.

**FIGURE 16.4** Nurses face a variety of ethical dilemmas when they make decisions in their daily practice. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

There are several strategies that can assist nurses in appropriate ethical decision-making. The ANA discusses some of them in the *Nursing Scope and Standards of Practice* (2021). For example, the MORAL model of ethical decision-making encourages the user to “massage” (explore) the situation, “outline” the possible decisions, “review” the ethical criteria, “affirm” (choose) an option, act on it, and “look” back to assess the appropriateness of the decision (ANA, 2021).

### Moral Distress

Knowing an ethically correct action but being unable to perform it, due to either internal or external forces, or being forced to act outside one’s personal and professional values is known as **moral distress** (Weiss et al., 2019). It is a sign of moral attentiveness in nurses, an indication of how important the nurse holds the values and ideals of the nursing profession (Rushton, 2023). Nurses are in a unique position when it comes to moral distress. They may be directed to act in ways they perceive as immoral based on orders from providers (Kennedy et al., 2023). Also, as part of the healthcare workforce that spends the greatest amount of time with patients, nurses immediately observe the impacts of ethically questionable decisions.

Nurses experiencing moral distress often report emotional and physical problems such as headaches, abdominal upset, anger, frustration, and depression (American Association of Critical-Care Nurses [AACN], n.d.). Some nurses leave the profession as a result (Weiss et al., 2019). During times of crisis, nurses are more likely to experience moral distress as they are exposed to breakdowns in the system and resource difficulties (AACN, n.d.). For example, many nurses experienced substantial moral distress during the COVID-19 pandemic as facilities were forced to ration care, were forced to work with dangerously low staffing levels, and found it difficult to uphold their duty to care. Nurses and other healthcare workers knew what patients needed but were unable to provide that care. In many instances, the conditions faced during the pandemic lasted long enough to cause moral injury (Čartolovni et al., 2021). If an individual cannot manage that distress or if it is sustained over time, it can become **moral injury**, in which they are psychologically harmed by being forced to act outside of their value system, resulting in conditions such as major depression and post-traumatic stress disorder (British Medical Association, 2021).

The AACN offers a position statement on moral distress during times of crisis (2020). The statement offers several strategies nurses can use to prevent and manage moral distress, including the following:

- Paying attention to your internal compass to recognize when you are being asked to perform outside of your comfort zone
- Expanding your knowledge of ethics through reviewing the various Codes of Ethics for nurses as well as your facility's ethics policies
- Recognizing the signs and symptoms of moral distress in yourself and your coworkers
- Seeking out trusted mentors to talk through issues with
- Using resources such as employee assistance programs and/or counseling to work through moral distress
- Maintaining one's work-life balance and leaning on loved ones

## LINK TO LEARNING

The [Moral Distress Education Project \(https://openstax.org/r/77morldistr\)](https://openstax.org/r/77morldistr) is a documentary presenting information about moral distress (developed by the University of Kentucky's Bioethics Program). Explore some of the various themes and resources offered to help understand and manage moral distress.

### Conscientious Objection

The inner feeling or voice inside an individual's head that tells them whether actions, thoughts, or behaviors are right or wrong, is called one's **conscience** or moral compass. A related concept is conscientious objection, the act of voicing an objection or refusing to act or behave in a manner that is allowable by one's practice act but which the nurse finds objectionable or moral on religious grounds (ANA, 2022). The right of nurses to act on their conscience is internationally recognized (Lamb & Pesut, 2021). Most professional organizations, including the ANA, agree that a clinician should not be forced into performing therapies and interventions they find morally unacceptable (Kennedy et al., 2023). Thus, while nurses should always respect and value the autonomy and values of their patients, they also have the right to act in ways that are morally affirming for themselves (Lamb & Pesut, 2021).

When determining whether to raise a claim of conscientious objection, a nurse's first consideration must be the patient. How will the patient be impacted by their claim? How will the rest of the healthcare team be impacted? When experiencing a conscientious objection, it is critical to disclose it as soon as possible to someone with the authority to change assignments in order to mitigate any potential compromise to patient care (Anderson & Henriksen, 2019). In the same vein, it is essential to never make a conscientious objection against a person. A conscientious objection is objection against an action, intervention, or therapy, never an individual (Anderson & Henriksen, 2019). Further, nurses must never abandon a patient without ensuring another nurse has assumed their care, as doing so is considered abandonment and is an ethical violation, contrary to the fundamental principles of nursing (Anderson & Henriksen, 2019; Kennedy et al., 2023). When a nurse leaves or abandons a patient's care without making sure another qualified nurse is ready to take over and continue providing necessary medical attention and support, that is called **abandonment**. Beyond the immediate impact on patient well-being, abandonment carries serious consequences for the nurse, such as legal ramifications (including potential lawsuits), disciplinary actions from regulatory bodies, and termination of employment.

## LIFE-STAGE CONTEXT

### Medical Aid in Dying

Medical aid in dying laws allow adult individuals who are competent, have terminal illnesses, and meet state criteria to administer medication to themselves that will end their lives. There are currently ten U.S. states that allow medical aid in dying: Maine, New Jersey, Vermont, New Mexico, Montana, Colorado, Oregon, Washington, California, and Hawaii, as well as Washington, DC. Providers are responsible for prescribing the medications, and nurses are legally and ethically prohibited from administering them. However, nurses must still be able to engage with patients in end-of-life conversations, are often the initial point of contact for a medical aid in dying conversation, and must understand the ethics and laws around this controversial topic.

There are two ethical sides of medical aid in dying. Individuals who believe medical aid in dying laws are right cite ethical issues of autonomy and self-determination, prevention of suffering, and ensuring all patients have access to all care options. Those who are uncomfortable with the ethics cite the violation of the sanctity of life and the conflict with professional values to do no harm. Nurses should be knowledgeable about the laws in their states and remain objective when working with patients considering this option. They must protect the confidentiality of their patients as well as other healthcare professionals involved in the process.

Nurses have a right to conscientious objection to assisting and working with patients who choose to end their lives. However, nurses living in states where medical aid in dying is legal and who have a conscientious objection to medical aid in dying must notify their employers before the situation arises and cannot abandon such patients or refuse to provide appropriate nursing medical care (ANA, 2019; Haring, 2023).

Common causes for conscientious objection include medically assisted dying, abortion, and gender-affirming surgeries (sex reassignment surgery). Nurses in organizations in which conscientious objection is unacceptable show higher levels of stress and burnout (Lamb & Pesut, 2021). By contrast, some agencies request information from staff about situations in which some may experience conscientious objections in advance of such situations occurring. This decreases the risk of having to negotiate last-minute staffing changes and potentially compromise patient care (Anderson & Henriksen, 2019). For example, a nurse manager on a palliative care unit might ask staff members how they feel about medical aid in dying (in a state in which it is legal), to determine which nurses may not be willing to participate in these procedures.

## REAL RN STORIES

### Conscientious Objection to Chemotherapy

**Nurse:** Chantrell, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 10

**Facility location:** Large Veterans Affairs (VA) hospital in Kentucky

Our unit has a variety of patient types. We do not have an oncology wing in our hospital, so it is not uncommon to get oncology patients on the unit. Intravenous chemotherapy may only be administered by RNs who have undergone specialized training and are certified to administer these drugs. Most of the RNs on the unit who have been there for at least one year have completed the training.

We do have one nurse, Mirlande, from Haiti. She had a conscientious objection to giving chemotherapy. I never quite understood why she was unwilling to give it, but she was adamant. Mirlande has been on the unit since before the time when we began giving chemotherapy. When we started doing chemotherapy treatment, she went to the nurse manager to request agreement that she not have to provide chemotherapy based on conscientious objection.

I did not even know that we were allowed to make such a request, but we are, and Mirlande does not take chemotherapy patients on days on which chemotherapy infusions will be given. If staffing does not allow her to have an entirely different assignment, then she will take a chemotherapy patient if another nurse manages the chemotherapy infusion. It can make staffing difficult, but we all respect her for standing up for her beliefs.

### Ethical Considerations

Most of the day-in and day-out decisions a nurse makes are very clear-cut in terms of their ethics. However, all nurses will have occasions when they must consider the ethics of a situation. A circumstance that causes a nurse to stop to think through the ethics of a situation is called an **ethical consideration**. The choices are not necessarily difficult ones; however, they are ones for which the nurse must think about whether one decision is more ethical than another. A nurse may find themselves unable to keep the provisions of the Code of Ethics for Nurses equally and must decide how best to manage a situation.

## REAL RN STORIES

---

### Ethical Considerations

**Nurse:** Amy, MSN

**Clinical setting:** Intensive care unit (ICU), night shift

**Years in practice:** 8

**Facility location:** Rural area in Tennessee

While we generally do not keep terminal patients in the ICU, a few years ago, we had a 45-year-old male, Bruce, dying of terminal cancer that had been diagnosed after his admission due to pneumonia one week earlier. Bruce had been approaching end of life for two days. He had made his peace with his impending death and said goodbye to his adult children. However, he had one teenage son whom he kept asking for. His wife, Maria, told all of us that she wanted their son to remember his father as he had been before getting sick. During our shift report, the day shift nurse told me she thought he was only hanging on to see his son but that she also respected Maria's decision. When I assessed him that evening, Bruce was in a great deal of pain but told me that he refused to die without seeing his child.

The situation upset me and made me so sad. I had a responsibility to care for both Bruce and his family in their time of grief and had to consider the ethics of the situation. I had been debating approaching Maria with my concerns, and then she came to me in tears, asking how to help Bruce let go and pass so he did not have the pain anymore. I took the opportunity and gently suggested that he was holding on to say goodbye to his son. She asked me if I truly believed that, and I said I did. She also said again that she wanted her son to remember Bruce as being healthy, not as sick and dying. I reminded her that children are resilient, and that her son might always hurt worse that he had not been able to tell his father goodbye. I was able to meet my obligation to Bruce by advocating for his needs.

Later that evening, Maria brought the son in to see Bruce. Bruce chatted with his son for a little while and was able to say goodbye. He died peacefully shortly after. I will admit that I cried a bit with my coworkers because the situation was so very sad, but I was also proud that I had handled the situation the way I had.

---

### Ethical Dilemmas

A **dilemma** is a choice between two or more potentially correct answers. An **ethical dilemma** occurs when there *must* be a choice between two or more or more actions, both of which are equally good, both of which are equally bad, or for which the benefits of both actions are unknown (Rich, 2023; Weiss et al., 2019). They also occur when members of the healthcare team have different ideas concerning what is ethical or unethical in treatment situations (Manderius et al., 2023). Dilemmas are more complicated than considerations. In an ethical consideration, the nurse must consider the ethics of a situation, whereas in a dilemma, the nurse must practice some decision-making strategies to determine the most appropriate course of action. When faced with ethical dilemmas, nurses should always keep in mind the nursing values, standards, and Code of Ethics to guide them (Kosmidis et al., 2021). The MORAL model of ethical decision-making is a helpful option for managing ethical dilemmas ([Figure 16.5](#)) (ANA, 2021; Center for Public Health Practice, 2022).

<b>MORAL MODEL OF ETHICAL DECISION-MAKING</b>	
MESSAGE THE DILEMMA  <b>M</b>	<ul style="list-style-type: none"> <li>• Collect all data</li> <li>• Identify related laws, ethics, and policies</li> </ul>
OUTLINE OPTIONS  <b>O</b>	<ul style="list-style-type: none"> <li>• Identify options and consequences</li> <li>• Try to have at least three options</li> </ul>
REVIEW CRITERIA AND RESOLVE  <b>R</b>	<ul style="list-style-type: none"> <li>• Recognize best- and worst-case scenarios</li> <li>• Find applicable ethics and laws for each option</li> </ul>
AFFIRM DECISION AND ACT  <b>A</b>	<ul style="list-style-type: none"> <li>• Make a decision</li> <li>• Act on the decision</li> </ul>
LOOK BACK  <b>L</b>	<ul style="list-style-type: none"> <li>• Evaluate success, values, and ethics</li> <li>• Identify what should be different in future</li> </ul>

**FIGURE 16.5** The MORAL model of ethical decision-making can be used by individuals or groups. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## UNFOLDING CASE STUDY

### Unfolding Case Study #3: Part 2

Refer back to [Unfolding Case Study #3: Part 1](#) for a review of the patient data. The nurse is experiencing moral distress about the patient's situation. The nurse is concerned because she has previously interacted with the patient's children before and knows they will be upset if they are not updated on their mother's condition and decision to pursue palliative care. But on the other hand, the nurse knows she must respect the patient's autonomy and her wishes not to contact her family. The following conversation takes place between the nurse and patient:

**Nurse:** Are you sure you don't want to contact your children about the palliative care decision? It might be nice to have them here with you when the team comes to discuss your options. This is a hard decision to make on your own.

**Patient:** No, I don't want them involved. I love my kids, but I know them well. They will want me to keep fighting, and I just don't have it in me. I don't want to tell them no and let them down.

**Nurse:** I understand your concerns. I'm not trying to pressure you or change your mind, but I just want to make sure you are certain about what you want.

4. Generate solutions: Thinking about the "O" of the MORAL model of ethical decision-making, what options does the nurse have at this time?
5. Take action: Of the options identified in the previous question, which is the best action for the nurse to take at this time?

- Evaluate outcomes: What findings would indicate the nurse's moral distress has improved? What findings would indicate that it has worsened?

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Generate Solutions: The Four Topics Method

The MORAL model of decision-making is not the only common strategy for ethical decision-making. Another is the Four Topics Method, also known as the Four Quadrant Approach. This strategy works very well with teams. In this strategy, an ethical issue is explored through four separate lenses:

- Medical indications use the principles of beneficence and nonmaleficence to explore the problem, the treatment goals, and how to best benefit the patient while avoiding harm.
- Preferences of the patient use the principle of autonomy. This piece explores the patient, their health literacy, their understanding of the situation, their ability to make decisions for themselves, and their concerns.
- Quality of life embraces the principles of beneficence and nonmaleficence and the value of autonomy to explore how different options will affect the patient's quality of life and ability to return to their baseline.
- Contextual features employ the principles of justice and fairness. This part explores any implicit bias on the part of providers or family members, any sociocultural or legal issues that may impact decisions, and any resource allocation issues.

Often, once the team explores a given situation from each of these angles, the correct decision becomes clear (ANA, 2021; Rich, 2023).

#### Ethics Committees

There may be times when an individual or healthcare team is unable to make an appropriate ethical determination. In these situations, a facility's **ethics committee**, a group that works together on a regular basis to address ethical issues within the organization, might be able to help. These committees usually include employees such as providers, nurses, and chaplains, as well as the facility's legal representation and perhaps even community members (Rich, 2023). Ethics committees can assist with clarification when there is confusion about ethical solutions, or they can become involved in making ethical decisions when teams are unable to come to a resolution. Additionally, when patients do not have a surrogate to speak for them and cannot speak for themselves, it is generally an agency's ethics committee that acts on their behalf. Nurses should use their agency's ethics committee when they have questions or concerns about whether situations are appropriate and fully ethical.

## 16.3 Legal Dimensions of Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the legal concepts for professional nursing
- Recall different legal regulations for nursing practice
- Describe various types of legal actions in nursing practice

The first nursing practice act (NPA) was passed by the New York state legislature in 1938 (Guido, 2020). Since that time, the nursing profession has been bound to laws and legislation that govern health care and the scope of nursing practice. Laws, including those related to nursing and health care in general, change, contract, and expand based on the needs of culture and society. Understanding the legal dimensions of care is critical for all nurses because those dimensions impact daily nursing practices.

#### Legal Concepts for Professional Nursing

Formal rules, or **laws**, for conduct—professional, political, social, or otherwise—govern behavior and are created and sanctioned by various governing bodies, such as Congress and states. Nurses are bound to work within laws established nationally and locally, by agencies and professional associations and by state boards of nursing (SBONs).

A requirement that healthcare providers must inform a patient or their surrogate of the potential benefits, risks, and alternative treatments for a procedure or treatment that is being offered is called **informed consent** (Weiss et al., 2019). Informed consent is a legal concept, typically memorialized in a specific document within a patient's chart. Nurses should not be providing the details of the documents, such as risks, benefits, and alternatives; that is the provider's responsibility. However, the process often includes nurses, particularly as witness to the signature and to confirm that informed consent was obtained prior to beginning procedures or interventions.

The nurse holds the responsibility of ensuring the person signing the consent is of legal age, competent, and voluntarily providing informed consent. The patient must possess sufficient knowledge about the procedure, risks, and alternatives, and their consent should be free from coercion. Generally, consent can only be obtained from mentally competent adults; however, exceptions exist for minors, developmentally disabled adults, emancipated minors, and those with appointed healthcare decision-makers. In cases where the patient is unable to consent, legal representatives, including parents, guardians, or court-appointed individuals, may provide consent on the patient's behalf.

Nurses can be held legally liable if they know appropriate consent has not been obtained and do not inform supervisors or providers (Rich, 2023). Further, when acting as witness, nurses are still responsible to the patient to act as advocate, preserve dignity, ensure concerns receive adequate responses from providers, and ensure patients understand what they are being asked (Weiss et al., 2019). Not getting informed consent from a patient is considered negligence (breach of duty). Further, performing procedures on patients without consent may be considered **battery**. The exception to the informed consent requirement is emergency situations, when implied consent is assumed (Weiss et al., 2019).

#### Sources of Law

The United States Constitution and the Bill of Rights are the foundation of all U.S. laws (Weiss, et al., 2019). Together they outline the types and limitations of governmental power as well as the rights of citizens. Subsequent laws may not be written that violate these basic rights provided by the constitution. State governments can further expand the rights of individuals; however, they are unable to limit the rights provided by the U.S. Constitution and its amendments. See [Table 16.3](#) for a summary of the types of laws that impact nursing: **constitutional law, statutory law, administrative law, common law, civil law, and criminal law.**

Type of Law	Definition	Example
Constitutional law	Laws written into the U.S. Constitution and its amendments	This ensures the safeguarding of medical records and that healthcare professionals do not disclose patient information without appropriate consent or a legal basis (protected by the Fourth Amendment to the United States Constitution).
Statutory law	Established by legislative bodies, such as Congress, state legislatures, and local governments	Examples of statutory law include the following: <i>Federal:</i> Health Insurance Portability and Accountability Act (HIPAA), Americans with Disabilities Act, Affordable Care Act (ACA) <i>State:</i> Nursing practice act

**TABLE 16.3** Types of Laws Impacting Nurses (Sources: Guido, 2020; OCR, 2021; Weiss et al., 2019.)

Type of Law	Definition	Example
Administrative law	Policies and procedures established by governments (federal, state, and local), which detail rules and procedures for statutory laws; determines how laws are administered and enforced, and by whom	<i>Federal:</i> The U.S. Department of Health and Human Services administers statutory law of HIPAA and developed the specific standards, rules, policies, and strategies with which all agencies must abide to ensure HIPAA is upheld. <i>State:</i> State boards of nursing write the rules to enforce the nursing practice acts and manage professional licensure and also act as an enforcement arm for violations of practice acts or professional licensure requirements.
Common law	Based on the tradition of unwritten law that is grounded in the principles of justice, reason, and custom; assumes court decisions set precedents that can be used to decide other cases.	Most civil and criminal law is based on common law.
Civil law	Related to people, things, and the relationships between them	Civil lawsuits, such as malpractice, are brought by an individual or individuals against a healthcare provider, group of providers, or institution; based on the idea that expected care was not provided appropriately and the patient suffered or died as a result; they generally result in fines or monetary awards.
Criminal law	Define crimes and the punishments for people perpetrating them	Criminal charges, such as negligent homicide, are brought by the state based on care (or lack of it) that is so egregious that it rises to a crime; they generally result in punishment, such as jail time,

**TABLE 16.3** Types of Laws Impacting Nurses (Sources: Guido, 2020; OCR, 2021; Weiss et al., 2019.)

## LINK TO LEARNING

The [Affordable Care Act \(ACA\)](https://openstax.org/r/77ACA) (<https://openstax.org/r/77ACA>) is an important healthcare law signed into legislation. It is designed to ensure access to affordable health insurance to a larger percentage of the population, including those with preexisting conditions.

## Legal Regulation of Nursing Practice

Legal regulation of nursing practice occurs at a state level, via SBONs. These SBONs set standards and expectations of nursing practice for the state and strategies to decide when correct care has been provided (Boehning & Haddad, 2022). Legally, nurses are evaluated based on their adherence to the applicable laws of their state as well as their experience and position.

### Nurse Practice Act

Each state government sets the **nursing practice act (NPA)**, the statutory law guiding nursing, for their state. The NPAs give authority for nurses to practice as nurses within a given state or given group of states (if a multistate license) (Guido, 2020). The NPAs also define the specific activities that different types of nurses are allowed to perform, scopes of practice, nursing school standards, licensure processes, causes of disciplinary actions, and the legal rights nurses have if complaints are filed against them (Boehning & Haddad, 2022). The SBONs administer the

NPA established by the state legislature and enforce the applicable laws.

### Standards

Professionally developed criteria, or **standards**, provide the minimal level of acceptable practice for all individuals within a profession. The ANA established nursing standards to guide the expected behavior of individual nurses. Various nursing specialties, such as perioperative nurses, have additional standards that nurses working in that specialty are expected to meet. State boards of nursing and professional organizations establish practice standards and define the responsibilities of nurses (Boehning & Haddad, 2022; Weiss et al., 2019). Institutions also establish internal standards of practice or policy based on, ideally, current evidence-based practice and the availability of resources within a given agency. Individual nurses have a responsibility to meet the standards of practice for their agency and state.

### Credentialing

A process that agencies use to ensure that their clinical staff (all healthcare professionals) meet the necessary and legal criteria to practice is called **credentialing**. It involves the verification of a healthcare worker's credentials (qualification such as academic degree, license, expert knowledge) (Health Resources and Services Administration [HRSA], 2023). To complete the credentialing process, a healthcare agency will verify several pieces of information, some of which will be provided by the nurse (Table 16.4).

Type of Activity	Examples of Documentation for RNs
Verification of identity	Government-issued picture identification
Verification of licensure	Must be obtained directly from the state boards of nursing licensing agency
Verification of education/training	Generally, through transcripts and/or diplomas; if a nurse has certifications, that may occur through the American Nurses Credentialing Center
Verification from the Drug Enforcement Administration (DEA) that there are no known issues with a nurse's ability to give medication	Retrieved through the DEA by the agency
Verification of Basic Life Support (BLS) and/or Advanced Cardiovascular Life Support training	Copy or certificate of training completion or active BLS card

**TABLE 16.4** Verification and Credentialing Documentation (Source: HRSA, 2023.)

### Accreditation

Schools of nursing seek accreditation from agencies recognized by the U.S. Department of Education. Accreditation means that a school is teaching a curriculum that meets state and national standards of nursing education (Gaines, 2023). It sets a standardized level of uniformity and consistency across programs, instilling confidence in the comparability of like-degree programs nationwide. This ensures every student is well prepared to provide competent patient care upon graduation (Gaines, 2023).

### Licensing

State boards of nursing are fully responsible for providing and managing nursing licenses (Boehning & Haddad, 2022). They set fees and ensure applicants for licensure have completed the requisite education and board testing. They additionally perform criminal backgrounds checks for licensure, if required by law. Further, SBONs ensure nurses renewing their licenses have completed any required continuing education. Finally, they are responsible for revoking or suspending nursing licenses and other disciplinary actions against nurses shown to have conducted themselves inappropriately in terms of the law (Boehning & Haddad, 2022). Licenses for nurses can be tracked through their SBON, which also maintains records regarding actions against an individual nurse's license.

In response to the dynamic nature of health care and the increasing demand for nursing services across state

borders, the **Nurse Licensure Compact (NLC)** has emerged as a solution to facilitate the mobility of nurses. The NLC is an agreement among certain U.S. states to recognize and accept a single nursing license that allows nurses to practice in multiple participating states. This innovative approach aims to enhance healthcare accessibility while maintaining rigorous regulatory standards and prioritizing patient safety. Nurses holding a multistate compact license must adhere to the rules and regulations of the respective state in which they are practicing at any given time. It is essential for nurses to be aware of the specific states participating in the compact and the associated regulations.

### Certifications

A certification allows healthcare practitioners to become specialized in one or more subjects as subject-matter experts (edX.org, 2023). Certifications generally require some education (in person, online, or self-study), and the passing of an examination focused on a specific subject area. Many certifications also require a minimum number of practice hours within the area of the requested clinical specialty. In some cases, practice hours within the area of the specialty replace added educational requirements. Many different certifications are available for RNs to obtain, including (but not limited to) medical-surgical nursing, critical care, case management, informatics, occupational health, and addictions.

### Laws Affecting Nursing Practice

Numerous laws influence nursing practice both in the workplace and during nonworking hours. One of these is the **Good Samaritan law**. There is a general expectation in most states that healthcare providers will respond and offer voluntary assistance during emergency situations because it is the moral and ethical thing to do. However, many healthcare workers became hesitant to provide such assistance because so many were sued by the very people they were trying to assist. As a result, many states have passed Good Samaritan laws (Weiss et al., 2019). These laws protect healthcare professionals from civil liability in emergency situations as long as they are acting in a way that is expected, reasonable, and prudent for someone with the same background. Another law affecting nursing practice is the Health Insurance Portability and Accountability Act (HIPAA) passed in 1996. The HIPAA developed standards so that patients could understand how their health information was used (see also [Chapter 2 Communication](#) and [Chapter 9 Safety and Security](#)).

### Occupational Safety and Health Administration

The Occupational Safety and Health Administration (OSHA) is a division of the U.S. Department of Labor. The OSHA is an administrative services agency established to ensure the safety and health of workers in all industries in the United States (OSHA, 2021). OSHA sets regulations for healthcare facilities to follow to protect workers. Their regulations for nursing include topics as wide ranging as workplace violence, safe patient handling, infectious diseases, chemical and pharmaceutical hazards, and enforcement standards.

### LINK TO LEARNING

The OSHA has [eTools to make it easier for hospitals to identify some of the most pertinent OSHA regulations](https://openstax.org/r/77etool) (<https://openstax.org/r/77etool>) for hospital settings. Explore some of the common topics to see how facilities should ensure the safety of their workers.

### National Practitioner Data Bank

The National Practitioner Data Bank (NPDB) is part of a law passed by the U.S. Congress in response to increases in medical malpractice, medical insurance fraud, and the need to be able to restrict and track incompetent healthcare workers (U.S. Department of Health and Human Services, 2018). The NPDB is a national clearinghouse that provides information on medical malpractice payments and adverse actions against the licenses of physicians, dentists, and some other healthcare providers. It also includes information on medical insurance fraud, actions by other federal agencies, and actions healthcare plans take against providers. The information maintained in the NPDB can be requested by hospitals, state licensing agencies, law enforcement agencies, and individuals requesting the file for themselves. Agencies can then use the information to inform decision-making regarding hiring of staff, offering licenses to individuals moving from other areas, and even law enforcement when there is concern for a pattern of behavior (U.S. Department of Health and Human Services, 2018).

## Reporting Obligations

When a nurse or other healthcare professional suspects a patient of being abused or neglected, they may be legally required to report their suspicions to the correct authorities. It is sad but true that (1) a case of child abuse is reported every ten seconds, (2) a high percentage of victims of human trafficking see healthcare providers, and (3) millions of men and women are abused annually by their intimate partners (Carlson, 2024). A nurse is a **mandated reporter**, an individual required by law to report suspected or known abuse against children, older adults, people with disabilities, and between intimate partners. Other mandated reporters include other healthcare workers, law enforcement, teachers, and even clergy (Thomas & Reeves, 2022). Failure to report suspected abuse may result in fines or criminal charges against healthcare staff.

Most of the time, reporting will be made to either law enforcement or agencies, such as child protective services or adult protective services. The specifics of where and how to report vary by state; however, all nurses have a legal and ethical responsibility to report suspected abuse (Carlson, 2024). Mandatory reporting laws generally cover neglect as well as physical, sexual, emotional, and financial abuse (Thomas & Reeves, 2022).

In addition to mandatory reporting of suspected abuse or neglect, there are three other areas of mandatory reporting that are pertinent to nursing. First, there are many infectious agents that require mandatory reporting to health departments for tracking purposes. These diseases include several sexually transmitted diseases, the various types of hepatitis, measles, tetanus, tuberculosis, and many others (Centers for Disease Control and Prevention, 2023). Second, most states have duty-to-warn and protect laws. In these states, nurses and other healthcare providers are required to notify third parties, such as spouses, work groups, or anyone against whom a patient has threatened physical harm.

The final area of mandatory reporting is reporting against other members of the healthcare professions. Most states have laws requiring individuals with healthcare licenses to report (usually to their state boards of health or their state's licensing agency, such as the SBON). While these laws also vary by state, they are generally focused on recognizing and reporting healthcare professionals who are impaired by drugs, alcohol, or other conditions or are practicing in a fashion that is dangerous to patients.

## LIFE-STAGE CONTEXT

---

### Abuse of Older Adults

Abuse can happen to any older adult; however, it is most common among women, those without friends or family, and those with disabilities, memory problems, and/or dementia. It is most common for older adults who require help with activities of daily living, such as toileting, bathing, dressing, and managing their medications.

Abuse is surprisingly common among older adults and includes several types of abuse:

- Physical abuse includes both bodily harm and restraining an older adult against their will (such as tying them to furniture or locking them in spaces).
- Emotional abuse (also known as psychological abuse) includes yelling, threatening, and ignoring an older person as well as isolating them from friends and relatives.
- Neglect is characterized by the failure to address the needs of an older individual, which may encompass withholding essential elements such as food, medication, or necessary health care. Abandonment occurs when an older individual is left alone without the necessary assistance and support they need.
- Sexual abuse includes forcing an older adult to watch or engage in sexual acts.
- Financial abuse includes stealing or misusing a patient's belongings or money, such as taking Social Security checks, withholding money, and changing names on wills or home titles without permission.

Nurses and other healthcare professionals should monitor older adult patients for signs and symptoms of abuse that include the following:

- being withdrawn, violent, or agitated
- showing signs of trauma, such as rocking back and forth
- having unexplained wounds, bruises, or scars

- experiencing preventable conditions, such as pressure ulcers
- having poor personal hygiene and dirty clothing
- not having necessary assistive items, such as eyeglasses and mobility devices (National Institute on Aging, 2023)

---

### Patients' Bill of Rights

In the 1970s, the American Hospital Association (AHA) recognized the need for guidelines to support ethical patient care in U.S. hospitals and published the first Patients' Bill of Rights, now known as the Patient Care Partnership (Hunt, 2023). While it is not legally binding, the AHA encourages their member hospitals to tailor the information contained within to meet the needs of their patient populations, and to inform patients of their rights and responsibilities in each hospital system. The Patient's Bill of Rights from the AHA provides a recommended blueprint for member hospitals to use with their own patient populations (Hunt, 2023).

Patients have rights to the following:

- considerate and respectful care
- clear, relevant, and accurate information about diagnosis, treatment, and prognosis
- informed consent and shared decision-making unless incapacitated
- ask questions and receive honest answers, particularly about risks and alternatives
- know caregivers' identities, and when caregivers are students, residents, or trainees
- know treatment cost, both immediate and long-term, as the information is known
- refuse treatment
- have an advanced directive or surrogate decision-maker and expect the agency to honor the designations
- privacy when their information is being discussed between healthcare workers
- confidentiality of communications and records
- access their medical records
- medically indicated care based on urgency
- address conflicts of interest, particularly financial ones between providers and commercial interests
- refuse to participate in research studies
- receive continuity of care and be informed of upcoming care changes
- be informed of hospital policies and practices as well as dispute and grievance resolution

## PATIENT CONVERSATIONS

---

### How to Provide a Patient with Information about Their Rights

**Scenario:** Nurse walks into a newly admitted patient's room. The patient is a 45-year-old Latina female, and she is sitting gently on the bed, looking anxious. A male family member is standing near her with a hand on her shoulder. He looks sternly at the nurse; the patient looks down.

**Nurse:** Hello Ms. Hernandez, my name is Martika. I will be your nurse this afternoon. Is everything all right? You look troubled.

**Patient:** Yes, I am worried.

**Nurse:** Ms. Hernandez, I'm sorry that you are worried. I know you are anxious about being admitted to the hospital. I need to discuss a few things with you and ask you some questions, would you like me to come back since you have company?

**Patient:** No, this is my husband, Mario. I would like him to stay with me if that is okay.

**Patient's husband:** She was in another hospital last month. They wouldn't let me stay with her and were mean. When they sent her home, we didn't understand about her medications and follow-up appointment, so she got sick again. I am staying with her to be sure she is cared for better.

**Nurse:** Oh, Ms. Hernandez, I'm so sorry you had that experience. Let me reassure you that you will receive excellent care here. I brought you a folder with information about our hospital. In it, right here, is a discussion of your rights

and responsibilities as a patient. This copy is in English; however, we do have it available in multiple languages. What is your preferred language for receiving educational materials?

**Patient:** We both read and speak English, so this version will be just fine. I don't think they had anything like patient rights at that other hospital. Thank you for showing us.

**Nurse:** You are very welcome. You have the right to be treated with dignity and respect and to understand your treatment, both here and for what you will need after you leave. If you have any concerns about the care you receive from me or any others working here, here are the people with whom you can speak. They will ensure that any concerns you have are addressed.

**Scenario follow-up:** With the information about their rights in hand, the patient and her husband relaxed, and the nurse was able to complete the admission.

---

### Bill of Rights for Registered Nurses

Registered nurses are the largest group of healthcare workers in the United States. Further, nursing is consistently listed as the most honest and ethical profession in the country (ANA, 2022). However, nursing jobs are complex and occur in a wide variety of settings and locations, from level 1 trauma centers to death row prisons and everywhere in-between. As a result of the registered nurse's value to society, health care, science, and all communities, the ANA developed a Bill of Rights for all registered nurses. These rights are expected to be nonnegotiable and provide nurses with the rights they need to meet the needs of their patients while caring for themselves as well (ANA, 2022). The Nurses Bill of Rights includes a variety of clauses designed to allow nurses to practice in safe environments that allow for psychological and physical safety and respect, ethical and legal practices, and the autonomy to advocate for patients and practice at the top of their licenses. The Nurses Bill of Rights is not a legal document; however, it can assist professional organizations, state legislatures, and healthcare agencies in developing laws and regulations related to nursing practice and organizational policies (ANA, 2022).

### LINK TO LEARNING

Take a look at the most recent version of the [Nurses Bill of Rights \(https://openstax.org/r/77NurseBOR\)](https://openstax.org/r/77NurseBOR) from the ANA. Consider how items in the bill can improve nurses' experiences and work environments.

---

### Legal Actions in Nursing Practice

While nurses may be involved in legal proceedings that have no interaction with their SBON, the SBON is the only agency that can revoke or suspend a nurse's license or ability to practice. The SBONs can receive complaints about nurses providing substandard care from their agencies, other healthcare workers, other nurses, and patients. After complaints are made to a SBON, they are investigated to determine whether the nurse was providing substandard care. If the nurse has acted against their state's NPA, the SBON can assign disciplinary actions including fines, remedial education, required supervision for practice, and/or suspension or revocation of a nurse's license (Boehning & Haddad, 2022).

Legal actions come in a couple of different forms through either a **criminal charge** or a **civil action**. Criminal charges are brought against an individual who has allegedly perpetrated a crime by acting against a specific statute or common law principle in a way that is harmful (Guido, 2020). Individuals found guilty of criminal charges face penalties that can range from fines and imprisonment to the possibility of the death penalty. Civil actions are brought in the form of lawsuits, in which one individual or group ("**plaintiff**") sues another ("**defendant**") for violating a social or legal contract or the rights of others. If the court or jury finds in favor of the plaintiff, the defendant may be required to pay monetary damages to the individual or group they harmed. It is possible for an individual to be sued civilly and charged criminally for the same action (Guido, 2020).

## LINK TO LEARNING

---

The [conviction of RaDonda Vaught \(https://openstax.org/r/77RaDonda\)](https://openstax.org/r/77RaDonda) for criminally negligent homicide provides an example of ethical and legal considerations of nursing, as well as criminal charges, civil suits, and actions to remove a nurse's license. (RaDonda Vaught was a former RN at Vanderbilt University Medical Center in Nashville, Tennessee.)

---

### Crimes in Nursing Practice

As previously noted, criminal laws are focused on conduct that is offensive or harmful to others. They can be statutory or common laws. When an individual violates a criminal law by performing a prohibited act, it is a **crime**. There are two main categories of crimes: misdemeanors and felonies. A **misdemeanor** is a typically less severe criminal act, for which perpetrators are generally fined less than \$1,000 and/or jailed for less than one year. A **felony** is a more serious criminal act for which perpetrators are generally fined more than \$1,000 and/or jailed for more than one year.

There are a variety of ways in which a nurse can act in a criminal fashion (Guido, 2020):

- falsifying records, which are legal documents (including backdating)
- narcotic theft/diversion
- patient maltreatment/abuse
- patient murder
- failing to protect at-risk populations, such as failing to report child abuse
- inadequate nursing care
- working or driving under the influence of drugs or alcohol (nurses have lost their nursing licenses for driving under the influence)

## LINK TO LEARNING

---

Read through the press release detailing the [criminal activities of an Iowa nurse \(https://openstax.org/r/77Crimenurse\)](https://openstax.org/r/77Crimenurse) that included fraud, narcotic theft, and violation of HIPAA. In addition to the legal ramifications of her actions, consider the ethical implications. This case highlights the connection between the legal system and ethical considerations.

---

### Torts

A **tort** is the harm that results when an individual or organization breaches their duty to another individual or organization. The duty may be general or specific. Torts are civil laws and include both intentional and unintentional actions (Guido, 2020; Weiss et al., 2019). The underlying assumption behind tort law is that people are responsible for their actions (Ronquillo et al., 2022).

#### Intentional Torts

An **intentional tort** is an action that an individual knew or should have known was incorrect or inappropriate (Ronquillo et al., 2022). Intentional torts include **assault** and **battery, false imprisonment**, breach of privacy or confidentiality, **slander** and **libel**, and **fraud** (Table 16.5). For example, giving a blood transfusion without obtaining consent would be battery, which is an intentional tort. Many intentional torts can also incur criminal charges.

Type of Intentional Tort	Definition	Example
Assault	Intentionally putting another individual in fear of being hurt or touched in an offensive fashion	Threatening to withhold or forcibly give a patient medication as a way to make them behave
Battery	Intentionally causing harm or touching an individual offensively without their consent	Forcibly administering medication to a patient without their consent (Emergency situations to prevent harm to the patient or others do not count.)
False imprisonment	Restraining another person or causing them to be restricted to a specific area	Using chemical restraints (medications) to restrict the movement of a patient with Alzheimer disease to prevent them from wandering
Privacy and confidentiality	The right of an individual to have their dignity protected and their personally identifiable medical information protected and kept private	Discussing a patient, including their name and medical information, in an elevator containing individuals without a reason to know the information
Slander and libel	Making negative, malicious, and/or false remarks about another person to damage their reputation; can be either oral (slander) or written (libel)	Telling a patient the nurse they had on a previous shift is known to be a bad nurse and that you will attempt to get them a good nurse for the following shift
Fraud	Deceiving an individual or group for personal gain	Altering documentation to cover up an error in patient care

**TABLE 16.5** Types of Intentional Torts

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety and Legal Use of Behavioral Restraints in a Psychiatric Setting

**Definition:** Restraints can be used to protect patients from harming themselves or others when other interventions are ineffective; however, inappropriate use of restraints is illegal and constitutes false imprisonment.

**Knowledge:** Restraints include mechanical devices, chemical restraints (medications), and seclusion. Behavioral restraints are used with psychiatric patients who are attempting to harm themselves or others and for whom no other type of de-escalation has been possible. Restraining patients is a legal action, as it is also imprisonment, and it can only be done in specific circumstances. The following are Medicare and Medicaid guidelines:

- Restraints should only be used as a last resort.
- There must be a physician's order written within one hour of their initiation.
- They must be discontinued as soon as possible.
- Restraints can never be a standing or PRN order.
- Patients must be assessed frequently, and mechanical restraints must be removed, and the patient's skin inspected every hour.
- Orders for behavioral restraints or seclusion must be discontinued or rewritten every four hours for adults, every two hours for children between the ages of 9 and 17 years, and every hour for children under 9 years of age.

**Skills:** When using restraints, nurses should do the following:

- Demonstrate effective use of restraint devices and risk reduction strategies.
- Ensure complications or unexpected issues are communicated promptly to the healthcare team and are reported as required to institutional restraint monitoring sites.

**Attitude:** When using restraints, nurses should do the following:

- Value standard procedures for restraint management per facility policy and manufacturer directions.
- Understand the importance of maintaining restraint safety through vigilant monitoring of restraints while in use.

### Unintentional Torts

An **unintentional tort** involves causing harm to someone without intending to do so, often due to a lack of care or awareness of potential risks. Unintentional torts still harm the patient, so nurses and other healthcare workers can still be liable for the damage caused as a result even when the harm was unintentional (Rich, 2023). A type of unintentional tort called **negligence** results from individuals not acting in a way that would be reasonably expected of someone in the same position (Ronquillo et al., 2022). While the harm itself was not intended, negligence might be the result of either an action or inaction (Table 16.6).

Problem	Prevention Strategies
Falls	Identify at-risk patients. Ensure fall risk notices are easily visible. Maintain beds in lowest position and use caution with side rails.
Injuries from equipment	Ensure appropriate education is provided for new equipment. Evaluate thermostats and temperatures if providing hot or cold therapies.
Inappropriate patient monitoring	Regularly assess IV sites, vital signs, urinary output, cardiac status, and so on. Evaluate laboratory values and ensure providers are aware of abnormal values.
Poor communication	Ensure status changes are reported. Document status changes and communication of status change with providers.
Medication errors	Follow the Rights of Medication Administration. Follow agency medication policies. Monitor patients after medication administration. Never give an unknown drug without looking it up to determine action, contraindications, and side effects.
Not following orders	Always ensure provider's orders are followed in a timely manner. If orders appear inappropriate or inaccurate, communicate that clearly to the provider, and document. If there is a conscientious objection to following an order, communicate that clearly to the appropriate member of leadership immediately.

**TABLE 16.6 Preventing Negligence in Nursing** (Sources: O'Neill, 2021; Weiss et al., 2019.)

### Steps in Litigation

The process of resolving disputes or legal conflicts through the court system is called **litigation**. There are several stages to the litigation process. In the *initial phase*, a lawsuit must be filed by a plaintiff or plaintiffs against a defendant or defendants. In the case of malpractice, it is most commonly an individual plaintiff against multiple defendants including nurses, doctors, and agencies altogether (Guido, 2020). Following this, the defendant is served with the complaint and a **summons** (a formal notice issued by a court or other authorized entity, informing an

individual that a legal action has been initiated against them). The discovery phase ensues, incorporating mechanisms such as interrogations (formal questioning), depositions (formal out-of-court testimony), and requests for documents to gather relevant information. Pretrial motions may be filed, including a **motion to dismiss** a case before going to trial. A **settlement**, an agreement between the parties to not go to trial, may be negotiated in which a payment to the plaintiff may be requested in exchange for no admission of guilt or liability for the defendant.

If a settlement is not reached, the case proceeds to trial. A **verdict** will be made as the formal decision rendered by a judge or jury at the conclusion of a trial. It serves as the legal determination of guilt or innocence in criminal cases and establishes liability and potential damages in civil cases. An **injunction** may also be issued by a court to require defendants to refrain from or carry out particular actions or procedures in the future. Ultimately, the enforcement of the judgment involves actions like collecting damages or ensuring compliance with the court's orders. It is important to note that the specific steps may vary based on jurisdiction, legal systems, and the nature of the case at hand.

[Figure 16.6](#) offers an example of how litigation flows from initial complaint to conclusion in a malpractice case.

**FIGURE 16.6** Scenario: Jane Doe died thirty days after discharge from the hospital where she had a gastric bypass. Her family is suing the hospital and physicians for malpractice. Follow the flow of litigation events for this case. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Cases of different nature demand distinct levels of evidence to establish the guilt or liability of defendants (Guido, 2020). For example, civil cases frequently use a preponderance of the evidence, in which one set of facts is more likely than not to be true. Conversely, criminal cases use beyond a reasonable doubt, the highest **level of evidence** (an indication of how much proof is required to find a defendant liable for an event). In these cases, the government must prove that no reasonable person would doubt the prosecution has proved that a crime occurred and that the defendant committed it; however, it does not mean the absence of all doubt.

### Nurse as a Defendant

Professional negligence on the part of a service provider who must have specialized education to fulfill the designated complex assistance expected of someone in the same position is called **malpractice**. Nurses are

involved in malpractice suits for a variety of reasons (O'Neill, 2021; Weiss et al., 2019):

- inadequate/inappropriate assessment
- not reporting status changes appropriately
- not documenting appropriately
- falsifying documentation/altering a patient record
- not reporting coworker negligence
- not providing necessary education
- violating standards of practice or practicing outside or beyond one's scope of practice
- inappropriate delegation
- not recognizing inappropriate orders and/or order errors

Much of the time, malpractice cases are brought against the employer rather than the employee because employers are considered responsible for the actions of every employee. There are four criteria needed to prove malpractice. A jury will assess community standards, institutional policies, expert opinions, and literature/research to determine the level of care that is the standard for a nurse in the defendant's position (Weiss et al., 2019).

### **Nurse as a Witness**

Nurses are often called on to be witnesses in court proceedings. They may be called on as witnesses for or against coworkers or as independent experts (Weiss et al., 2019). In this capacity, a nurse is considered a **lay witness** and allowed only to speak to the facts of the case—what they saw or did not see (Guido, 2020). In the capacity of lay witness, nurses are involved in the case because they have pertinent information but are not direct defendants to the case.

A second way in which nurses are called to testify at trials is as an **expert witness**. When called as expert witnesses, their job is to describe the applicable standards and their opinion of whether a nurse in each situation would have been reasonably expected to behave/perform in a particular way (Guido, 2020). Expert witnesses also explain, in plain language, the various issues associated with nursing actions, performance, and medical technology, to make it easier for judges and/or juries to understand the case (Guido, 2020). Nurse expert witnesses must be able to show they have the knowledge and expertise required to speak with authority about the specific issues being considered in a given court proceeding.

### **Prevention of Liability for Nurses**

Unfortunately, it is impossible to guarantee a nurse will never be sued for malpractice. Perhaps the best strategy to prevent being named in a criminal or civil liability case is through personal **risk management**. Risk management includes a variety of practices that agencies utilize to reduce the likelihood of injury to patients and others. Individuals can also employ risk management strategies. Always practice within the bounds of your state's NPA and agency's policies and practices (Nurses Service Organization and CNA Financial Corporation, 2021). Keep files of documents that can be used to show your character. Include documents such as letters of recommendation, performance evaluations, and continuing education certificates. When in doubt, follow the chain of command of your agency in terms of notifications and seeking advice. All nurses should consider investing in malpractice insurance, which will provide financial support and, in some cases, legal representation in the case that they are sued.

## **CLINICAL SAFETY AND PROCEDURES (QSEN)**

**QSEN Competency: Safety, Avoiding Legal Problems**

**Definition:** Decrease the chance of being a defendant in a legal proceeding by providing high-quality, safe, and person-centered care, and carefully following standards of practice.

**Knowledge:** Understand the safety issues that most frequently lead to malpractice claims, as well as common errors and care hazards.

**Skill:** Employ these strategies to decrease the chances of being called as a defendant in a legal case:

- Always provide authentic and person-centered care when working with patients. People are less likely to sue

people they know genuinely care for them.

- Regularly review new evidence-based research and practice in your specialty.
- Encourage leadership to ensure staff are educated when policies, procedures, and technology change.
- Always follow the agency's policies and procedures.
- Delegate appropriately.
- Ensure clients who are at risk of injury from falls, elopement, pressure ulcers, and so on, have appropriate care plans and are provided with appropriate levels of care.
- Always document objectively, precisely, and clearly using only approved abbreviations.
- Ensure incident reports are detailed and provided to the appropriate departments.

**Attitude:** Value your role in preventing errors.

---

### Factors Affecting Competent Practice

There are a variety of intrinsic and extrinsic factors that can negatively affect the practice of the best nurses, making them more prone to errors. Studies have shown that competent practice can be impacted by a wide range of factors, including staffing ratios, work schedules, fatigue, physical health, and mental health. For example, in one survey of 771 critical care nurses, over 60 percent of nurses reported suboptimal physical health, and over 50 percent of nurses reported suboptimal mental health (particularly depression and anxiety) (Melnik et al., 2021). The same nurses with less than perfect physical or mental health reported between 30 and 60 percent greater chance of making medical errors than their healthier coworkers.

For example, **presenteeism** is coming to work but not being able to perform fully and competently due to illness or job stress that impacts the safety of patients through increased patient falls, medication errors, and missed care (Rainbow et al., 2019). Another common factor impacting nursing practice is nursing fatigue and scheduling. Most nurses work in shifts, often 12-hour shifts, and frequently rotate between days of the week and sometimes even times of the day (between day, evening, and/or night). Shift work impacts nurses' ability to concentrate and communicate at work and increases the chances of work-related injuries, illnesses, burnout, and errors (Peršolja, 2023). A third issue is the impact of nursing staffing levels on errors, patient mortality, and nursing burnout, which have been known for over two decades. Studies have shown that for hospital nurses working on inpatient units, for every additional patient a nurse cares for in a given shift, there is an increased risk of patient mortality, burnout, and job dissatisfaction (Aiken, 2023).

## 16.4 Advocacy in Nursing Practice

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the role of nurses as advocates
- Recognize the importance of nursing advocacy
- Identify barriers to nursing advocacy

Publicly lending one's voice and/or support to a cause, person, or policy is called **advocacy**. Florence Nightingale is the first nurse advocate we know of. Not only was she a fierce advocate for her patients, fighting hard to ensure cleanliness within hospitals, but she was also a tireless crusader for nurses themselves. She fought hard for respect and improvement of the nursing profession. Today, advocacy is a core component of professional nursing and a cornerstone of nursing practice.

### Role of Nurses as Advocates

Nursing advocacy seems, on the surface, to be a simple concept: be vocal to support what is right. However, upon closer examination, it is a rather complex concept. Advocacy involves ensuring excellent care for patients and respect for their rights, as well as advocating for the nursing profession. Nurses advocate for what is ethically sound in their interactions with and provision of care to patients and their families. They also advocate for their patients with other healthcare providers and for all patients as well as the profession of nursing through activism and engagement at local, state, and national levels.

### Advocacy for Patients

There are several different behaviors associated with patient advocacy ([Figure 16.7](#)). Nursing advocacy includes

protecting patients from unintentional or intentional harm. Further, advocacy involves teaching patients and their families so they can understand their conditions and care for themselves. Simply caring and ensuring patients feel respected and as if they matter as a human, not only a sick body, is another way to show advocacy. Nurses are also well positioned to act as mediators to ensure that the patient's wishes and needs are understood by all. Finally, nurses are excellent champions and advocate for their patients by speaking out against injustice (Abbasinia et al., 2019).

<b>Protecting</b>	<ul style="list-style-type: none"> <li>• Track medical errors</li> <li>• Speak out against incompetency and misconduct</li> <li>• Protect autonomy</li> </ul>
<b>Educating</b>	<ul style="list-style-type: none"> <li>• Provide education for diagnosis and treatment</li> <li>• Educate about discharge or home care</li> </ul>
<b>Caring</b>	<ul style="list-style-type: none"> <li>• Maintain patient privacy and dignity</li> <li>• Ensure patient's preferences and cultural needs are met</li> </ul>
<b>Mediating</b>	<ul style="list-style-type: none"> <li>• Liaison between patients, families, and other healthcare professionals</li> <li>• Help patients speak for themselves and speak for them when they are unable</li> </ul>
<b>Championing</b>	<ul style="list-style-type: none"> <li>• Speak against injustice and inequality in the healthcare system</li> <li>• Assist with access to community services and outreach</li> </ul>

**FIGURE 16.7** Nurses function as patient advocates in a variety of ways. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LINK TO LEARNING

A snapshot of [nurses' voices about the varied expressions of patient advocacy \(https://openstax.org/r/77advocate\)](https://openstax.org/r/77advocate) is presented in this brief video.

### Promoting Self-Determination

The ways individuals control their lives and surroundings and express their autonomy is called **self-determination**. Increasing numbers of patients have complex chronic conditions, many with multiple comorbidities, which require sophisticated self-management on the patient's part. Encouraging patients to be engaged and involved in their own care by implementing shared decision-making strategies and healthcare environments in which patients can ask questions, state their limitations, and feel safe and understood supports patient self-determination (Dineen-Griffin et al., 2019). Several strategies to help patients develop greater self-determination and management skills have proven effective with a variety of complex medical conditions, such as type 2 diabetes mellitus, asthma/COPD, and heart failure (Dineen-Griffin et al., 2019). Examples of effective strategies include the following:

- Educating patients regularly about their conditions, allowing patients to better manage their own health
- Improving patients' ability to solve problems and make decisions regarding symptom changes
- Developing written action plans with patients including strategies for managing situations and exacerbations when they arise
- Encouraging active symptom awareness on the part of patients, such as maintaining blood pressure journals

Each of these strategies require patients to be engaged with healthcare providers on a one-to-one basis with enough frequency to develop the tools needed for effective self-determination (Dineen-Griffin et al., 2019). The most effective interventions to promote patient self-determination involve ensuring patients feel supported and informed about their own healthcare conditions, encouraging them to believe they have the right to act

autonomously, motivating them to act on their own behalf, and encouraging healthy behaviors for both physical and psychological health (Ntoumanis et al., 2020).

### Self-Advocacy

The act of speaking up for oneself and one's needs is **self-advocacy**. While nurses are excellent at speaking up for their patients and for at-risk populations, they are not always good at speaking up for themselves and ensuring they are providing the same care for themselves that they do for others (Eaton, 2021). Consider the instructions that airlines provide: in case of an emergency, put on your own oxygen mask before helping others. Otherwise, you may not be able to help others. It is the same for nurses. Nurses must remember to take care of themselves so that they can take care of others. Otherwise, they can become exhausted, burned out, and unable to supply the high level of quality and skill their patients need.

Safe Harbor is one mechanism for expressing self-advocacy. Safe Harbor in nursing is a legal and ethical concept designed to empower nurses to refuse specific patient assignments under circumstances where carrying out the assignment would compromise patient safety or violate professional standards. When a nurse identifies a situation that raises concerns about patient well-being or adherence to nursing standards, the Safe Harbor process is initiated. The nurse assesses the situation, promptly notifies the appropriate supervisor, and collaborates to find a resolution that addresses the identified issues, such as redistributing assignments or providing additional resources. If an acceptable resolution cannot be reached, the nurse may refuse the assignment without fear of retaliation or disciplinary action. It is important to note that the existence and specifics of Safe Harbor provisions vary by state, with some states having well-established regulations, while others may have different mechanisms to address workload issues. Nurses should stay informed about the regulations in their specific state and facility to ensure compliance with professional standards and legal obligations.

### Whistleblowing

Advocacy can be frightening, particularly if a nurse recognizes a need to report larger-scale issues such as environmental safety or patient care issues and is afraid their employer will punish them as a result. If a nurse (or any employee) has followed the proper leadership structure to report legitimate concerns that have not been addressed, then other steps may need to be taken; it may be the only ethical way forward (Wiisak et al., 2022). The reporting of misconduct, such as fraud, abusive patient care, or unsafe conditions to outside authorities is known as **whistleblowing**. An individual making such a report is a **whistleblower**.

Whistleblowing should never be done in anger or trivial situations. It is an important ability that workers have to protect themselves, their patients, and even their agencies from problems caused by others. However, people intentionally engaged in inappropriate activities will not be happy to be questioned about their actions.

### LINK TO LEARNING

The ANA offers some [advice about whistleblowing \(https://openstax.org/r/77whistle\)](https://openstax.org/r/77whistle) that suggests a variety of things to consider when preparing to blow the whistle and when it should be done.

While it should not be done lightly, whistleblowing is an important protection for nurses and other healthcare professionals. Seeing unethical or illegal misconduct on the part of other employees or agencies can lead to moral distress and increased turnover among healthcare workers (Wiisak et al., 2022). Reporting unsafe and illegal practices can be a frightening thing to do; however, there are multiple federal and state laws in place to protect whistleblowers from retaliation by protecting their jobs (Kakacek, 2022). [Table 16.7](#) explores the federal laws and protections related to whistleblowing.

Law	Protections Provided
Whistleblower Protection Act (WPA)	This act protects federal workers if they make a disclosure about laws they believe are being violated within federal workplaces. It includes disclosure of broken laws, rules, and regulations; mismanagement of federal funds; abuses of authority; and compromising the health and/or safety of the public.
No FEAR Act	This act strengthened the protections of federal workers who file antidiscrimination or whistleblower claims. It establishes fines and damage claim procedures for federal employees whose rights are violated under the act.
Occupational Safety and Health Act	This act is administered by OSHA. It protects workers who make claims related to safe and healthy work environments.
Affordable Care Act	This act protects workers from whistleblowing related to insurance fraud.

**TABLE 16.7 Federal Whistleblower Laws** (Sources: Kakacek, 2022; NLRB, 2023; OSHA, n.d.)

## Importance of Nursing Advocacy

With over four million RNs in the United States, nursing advocacy has the potential to make changes, both large and small, throughout the healthcare landscape (Eaton, 2021). Nursing advocacy can take many forms. Individual nurses can work with their agencies, call their legislators, write letters, make phone calls, visit a legislator's office, volunteer, and even march for causes they find important. Individual nurses can also join coalitions or groups of like-minded individuals who are all advocating for the same initiatives (Association of Public Health Nurses, 2022). Organizations such as the Association of Public Health Nurses and the Alliance of Nurses for Healthy Environments offer a vehicle for many nurses to make their voices heard at one time. At a local level, nurses can work with their agencies to develop collaborative efforts to meet patient needs in conjunction with other agencies and public service sectors (Latham et al., 2020).

## LINK TO LEARNING

An advocacy toolkit that offers practical suggestions and advice for [public health advocacy \(https://openstax.org/r/77PHadvocacy\)](https://openstax.org/r/77PHadvocacy) is provided by the Association of Public Health Nurses, and it can also be used with all types of nursing advocacy.

## Improve Public Health

Nursing ethics, values, and even laws all offer a focus on equal access to health care, social justice, and nondiscrimination for all patients, leading naturally to nursing advocacy for public health (Williams et al., 2018). Nurses can advocate for policies that address public health by promoting justice, health equity, and the social determinants of health (SDOHs), such as education, financial stability, and housing. The SDOHs powerfully influence overall public health. For example, when life expectancy mapping was performed over an urban area in Virginia, differences in life expectancy (average age at death) of up to nineteen years were noted between different zip codes in the same city (Lathrop, 2020). Only by addressing the root causes of poor health can the entire public's health truly be improved (Lathrop, 2020; Williams et al., 2018). [Table 16.8](#) offers a few different ways in which nurses can engage in public health advocacy.

Area	Rationale	Evidence-Based Programs	Advocacy Opportunities
Early childhood education (ECE)	Lack of ECE is linked to poor academics in later years, depression, and attention deficits.	ECE programs Early childhood health visits Food assistance	Support universal access to ECE. Support public funding of programs for 3- to 5-year-olds.
Job security	Poor job security decreases the ability of families to make permanent choices in terms of housing and safety.	Family and Medical Leave Act Paid parental leave	Support policies that keep jobs available for those having children or experiencing major life events.
Safe working conditions	Lower paying jobs are frequently more dangerous.	Laws for workplace safety including OSHA and workers' compensation	Support labor laws that provide safety standards for work environments.
Social status	Social status is related to health outcomes.	Business training	Support development programs for women, children, and youth. Support job training programs.
Food security	Food insecurity leads to poor health outcomes, developmental impairments in children, malnutrition, and obesity.	School nutrition programs Federal nutrition programs (such as WIC and SNAP) Community gardens	Advocate for school subsidies. Support or start a local community garden.

**TABLE 16.8** Advocacy Opportunities in Public Health for Nurses (Source: Williams et al., 2018.)

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Recognize Cues: Identifying Social Determinants of Health

Identifying patients who are struggling with SDOHs can easily be achieved through screening tools that allow for integrating questions about health-related social needs (HRSNs) into patient assessments. This assessment can help the nurse identify patients who need assistance beyond their immediate health concerns. It can also help nurses find areas where their agencies may be able to aid individuals or communities in their own charitable endeavors.

Questions may include items such as the following:

- What is your living situation today?
- In the last twelve months, how often did you worry that your food would run out before you had money to buy more?
- In the last twelve months, how often did you miss or worry about missing medical appointments due to lack of transportation?
- How often does anyone, including family and friends, scream or curse at you?
- If, for any reason, you need help with day-to-day activities such as bathing, preparing meals, shopping, managing finances, and so on, do you get the help you need?

Knowing the answers to such questions may help nurses advocate both for the patient in front of them, as well as for the public health of the communities their patients live in.

The full [HRSN questionnaire \(https://openstax.org/r/77ahcmscreening\)](https://openstax.org/r/77ahcmscreening) developed by the Centers for Medicare and Medicaid Services provides additional information (CMS, n.d.; Latham et al., 2020).

### The Seven Domains of Health

One strategy to explore overall clinician health and well-being is by looking at the **seven domains of health**. This holistic framework of seven life dimensions that encompass various dimensions of well-being and health can be used by nurses to explore ways to advocate for themselves ([Figure 16.8](#)) (Kerley & Toney-Butler, 2023). Nurses can then explore ways to improve their own life and conditions within this framework.

<b>Physical functioning</b>	<ul style="list-style-type: none"> <li>Physical health</li> <li>Ability to physically perform job functions</li> </ul>
<b>Psychological well-being</b>	<ul style="list-style-type: none"> <li>Positive versus negative outlook and emotions</li> <li>Levels of depression, anxiety, and stress</li> </ul>
<b>Social functioning</b>	<ul style="list-style-type: none"> <li>Ability to perform social roles of advocacy</li> <li>Role of family and friends in support system</li> </ul>
<b>Pain</b>	<ul style="list-style-type: none"> <li>Pain, usually physical, but may be stress or emotional and its impact on daily living</li> </ul>
<b>Cognitive functioning</b>	<ul style="list-style-type: none"> <li>A clinician's memory, reasoning, and orientation and the clinician's perception of the same</li> </ul>
<b>Vitality</b>	<ul style="list-style-type: none"> <li>Fulfillment of basic needs, such as sleep, rest, nutrition</li> <li>Lack of basic needs can lead to poor concentration and performance</li> </ul>
<b>Overall well-being</b>	<ul style="list-style-type: none"> <li>Large scale of individual's satisfaction with their health and contentment, based on feelings of self-worth and purpose</li> </ul>

**FIGURE 16.8** The seven domains of health include physical functioning, psychological well-being, social functioning, pain, cognitive functioning, vitality, and overall well-being. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Optimizing the Workplace Environment

One area where nurses can lend their voices in advocacy is in improving their workplaces and improving working conditions. Issues such as safe staffing levels, high-quality training and orientation, physical and mental health support for staff, and technical education and support are all areas where nurses can advocate to improve workplace environments, patient care, and their own experiences. When advocating for change, always be solution focused. Rather than simply presenting problems that need to be addressed, present problems along with one or more possible ways to address them.

While direct care nurses are often best able to name opportunities for improvement, having an open line of communication with nursing leadership is important in workplace advocacy efforts (Cole et al., 2019). When leadership is not immediately responsive, work to determine whether others on your unit or in your facility are having similar issues or concerns. A group of nurses presenting a united front, advocating for their workplace environment, and presenting clearly thought-out suggestions for improvement can often succeed where an individual may fail (Wells & Delgado, 2023).

### Enhancing Healthcare Team Outcomes

Nurses are adept at enhancing healthcare team outcomes through their advocacy for patients. A large piece of advocacy in nursing is either helping patients find their voice or speaking for them when they are unable to. Because nurses spend more time with patients than any other healthcare team member, they frequently develop the

strongest therapeutic relationships and can facilitate enhanced team outcomes (Ganz, 2019). On teams, nurses can serve as mediators or liaisons between patients and their families and other healthcare professionals (Abbasinia et al., 2019; Ganz, 2019). Nurses can prepare other team members in advance of meeting a patient for cultural considerations, patient wishes, and expected healthcare literacy. They can help ensure that treatment decisions made by the team are fully understood and agreed to by the patient and that the patient is able to manage any treatments necessary on their part. Further, as the person to administer medications and perform written patient care orders, nurses can improve team outcomes by safeguarding their patients from incorrect interventions (Abbasinia et al., 2019). In primary care settings, nurses working as care coordinators develop relationships with their patients that enable them to advocate for patient needs with the team and improve their health-related outcomes (Karam et al., 2021).

## Barriers to Nursing Advocacy

Despite the importance of nursing advocacy, there are also many barriers to nurses being able to advocate appropriately for their patients. Barriers for nurses can be as simple as not having the time to appropriately advocate for their patients (Blackwood et al., 2019; Nikitara et al., 2019). Alternatively, patients may need advocacy in areas in which nurses are unfamiliar, such as substance use, advanced care planning, or diabetes care. Another barrier to advocacy can be the lack of resources in terms of equipment, educational materials, space, specialists to consult with, or available information technology (Nikitara et al., 2019). Other key barriers include lack of cooperation (among patients, among nurses, or among organizations), fear of negative outcomes, and patient-related factors.

### Lack of Cooperation

For nurses to engage in active and healthy advocacy, there must be some level of cooperation between people and entities. Despite the importance of advocacy to professional nursing, lack of cooperation in terms of environmental conditions and personal relationships or feelings may negatively impact nurses' ability to be effective advocates. For instance, in a high-stress clinical setting with inadequate resources, nurses may find it challenging to advocate for optimal patient care when faced with systemic barriers. Similarly, if there is a breakdown in communication or collaboration within the healthcare team, it may hinder the nurses' collective ability to advocate for the best interests of their patients. In such scenarios, the effectiveness of advocacy efforts becomes compromised, highlighting the need for a collaborative and supportive professional environment to fully realize the advocacy role in nursing.

### Among Patients

Patients who have had previously negative experiences with the healthcare setting and/or nurses may not trust nurses to advocate for them and may actively work against their nursing staff (Kwame & Petrucka, 2021). Other patients are simply angry, afraid, or unable to move out of their own concerns to cooperate with nurses in both patient care and advocacy efforts. Further, patients who are uncomfortable in healthcare settings are often less able to cooperate constructively with nursing staff. For example, a patient who is too hot or cold or overwhelmed by environmental noise may be unable to focus on other needs because of their immediate discomfort (Kwame & Petrucka, 2021).

### Among Healthcare Professionals

While nurses often act as patient care coordinators, are the healthcare professionals closest to the patient, and have the greatest ability to advocate for the patient, they are often left out of meetings between patients and providers. Being asked after the fact to explain issues and having to return to the provider with patient questions takes time and energy away from direct patient care. Consider the example of end-of-life care. Studies have shown that nurses are the healthcare staff most likely to identify **medical futility** (the point at which further interventions will not improve a patient's life expectancy) (Ganz, 2019). Further, they have been acting as the patient's advocate in the time leading up to end-of-life discussions, and they tend to be the healthcare professional most trusted by the patient. However, healthcare providers often do not include nurses in their end-of-life discussions with family members (Ganz, 2019). So clearly, even in environments where nurses have been able to advocate well for patients up to the final stages of their illness, they are often not invited to the table by other healthcare professionals.

### Among Healthcare Organizations

In many healthcare organizations, particularly those that lack a strong shared decision-making culture between

front-line staff and leadership, nurses may find it difficult to advocate effectively for themselves and for effective policies and procedures (Newans & Siddiqui, 2021). This type of barrier leads to leadership enacting policies that front-line staff are unable or unwilling to implement fully because leadership does not work in the given practice setting. Subsequently, nurses begin implementing work-arounds to provide more effective patient care, and these work-arounds may not take into account some of the goals of the leadership. As a result, when healthcare organizations place barriers to nurses' ability to advocate for themselves and their patients in the policy development process, patient care and organizational goals may be negatively affected.

Other barriers to effective advocacy are system-level barriers. Issues such as staffing shortages, inability to spend time with patients, and nursing burnout often impact nursing staff's ability to provide care, effective communication, and advocacy (Kwame & Petrucka, 2021). Further, when agencies have a strong focus on the completion of tasks associated with patient care, advocacy and communication with patients may be changed. Both completing patient care tasks and engaging with patients are important pieces of patient advocacy, but too often, different aspects are sacrificed based on policies and procedures at the institutional level (Kwame & Petrucka, 2021).

### Fear of Negative Outcomes

In healthcare environments in which nurses lack autonomy, they may be afraid to aggressively advocate for patients. Particularly in situations in which advocating for a patient's needs flows contrary to a facility's culture, nurses may be afraid of the impact their advocacy will have on their own careers (Nsiah et al., 2019). Some nurses even fear losing their jobs. Further, no nurse wants to do additional harm to a patient, and many will doubt themselves, letting their anxiety over making a mistake impact their willingness to speak up for their patients (Nsiah et al., 2019).

### Patient-Related Factors

Another barrier to patient advocacy can be factors intrinsic to patients and patient populations. For example, it may be difficult for nurses to effectively communicate with patients experiencing poor health literacy or who speak a language other than the nurse's language. Many nurses have reported difficulties in accessing interpreter services, and some studies have shown that even certified medical interpreters often rephrase questions and answers inappropriately and/or leave out information (Gerchow et al., 2021). Other patient-related factors such as gender nonconformity, religious differences, and culture may impact the nurse and create unintended biases in terms of advocacy and active engagement in advocacy.

## LIFE-STAGE CONTEXT

---

### Ageism in Critical Care Settings

While advocating for patients is intrinsically linked to nursing practice, there is good evidence that nurses are less aggressive advocates for older patients. As patients age and become sicker, they often use more healthcare resources and have greater needs. Some patients become "frequent fliers," moving in and out of the hospital multiple times, and their health conditions become progressively worse. In critical care settings, where there may be resource limitations in terms of equipment and time, some nurses may make conscious (or unconscious) decisions to provide higher levels of advocacy for younger patients who they feel have a better chance of returning to their baseline and high-level quality of life. Nurses must guard against expressing ageism (prejudice, discrimination, or stereotyping based on a person's age, particularly when directed toward individuals who are older or younger than the perceived societal norm) in their patient care, and advocate for all patients equally (Moniem et al., 2019).

---

## Summary

### 16.1 Value Considerations of Care

Values are the core convictions that underlie beliefs and behaviors. Values are at the center of both personal and professional lives. Values are learned from parents, religions, school, professional practice, education, and sociocultural environments. Professional nursing values include altruism, autonomy, integrity, social justice, and human dignity. These values are embedded in nursing practice, particularly in the nursing process itself.

### 16.2 Ethics in Nursing Practice

Ethics are essential to nursing practice; they are built into everything nurses do and the very fabric of nursing practice. Ethics play many roles in nursing practice from the underpinning that nursing values give to the profession to the Code of Ethics for Nurses with which nurses govern themselves. Ethical concepts such as a belief in autonomy, justice, and veracity should be threaded through all decisions nurses make and the care they offer their patients. Further, the Code of Ethics for Nurses supplies guidelines and guidance for nurses to follow throughout their careers and no matter what their job duties. Theories of ethics include principle- and care-based approaches to understanding ethics. Nursing ethical theories are grounded in classical theories such as deontology (actions are morally right or wrong) and utilitarianism (actions should do the most good for the greatest number and the least amount of harm for the rest). Yet, in recent years, nursing ethics has also embraced feminist ethics as it seeks to break down barriers related to institutionalized prejudices and social justice. Unfortunately, the most ethical decision is not always clear, which may cause moral distress. Nurses have many strategies available to them to assist with ethical decision-making on their own and in groups, including the MORAL model of ethical decision-making and the Four Topics Method.

### 16.3 Legal Dimensions of Care

Nursing is not simply about caring for patients. It is about caring for patients ethically and legally. Nurses must understand basic legal concepts, such as their state's NPAs and the related rules and regulations established by their SBONs. They must be aware of the legal regulations surrounding their educational institutions, certifications, and licenses. Nurses must also understand their exposure to various types of legal actions, both criminal and tort claims, and actively protect themselves from being found liable for providing inappropriate patient care or knowingly participating in harmful or fraudulent activities.

### 16.4 Advocacy in Nursing Practice

The role of nurses in advocacy for themselves, their patients, and even public health is a critical part of professional nursing practice. With over four million nurses in the United States and nurses having the most interaction with patients, nurses are uniquely placed to advocate for and impact health care on global and local levels, from Congress to a patient's room. However, there are several barriers to nursing advocacy, including lack of time, lack of cooperation from other people and agencies, fear of negative outcomes, and other patient-related factors.

## Key Terms

- abandonment** in the context of nursing, refers to the act of a nurse leaving a patient's care without making sure another qualified nurse is ready to take over and continue providing necessary medical attention and support
- administrative law** policies and procedures established by governments (federal, state, and local) that detail rules and procedures for statutory laws
- advocacy** publicly lending one's voice and/or support to a cause, person, or policy
- altruism** working for the well-being of others
- assault** intentionally putting another individual in fear of being hurt or touched in an offensive fashion
- autonomy** an individual's ability to make decisions and determine courses of actions based on being well informed, giving consent, and volunteering without coercion
- battery** intentionally causing harm or touching an individual offensively without their consent
- beneficence** ethical principle that underscores the obligation to do good and promote the well-being of patients
- care-based approach** ethics that combines the actions of providing care for others with the value of caring for the individual, while recognizing their frailty and vulnerability
- civil action** lawsuit in which one individual or group sues another for violating a social or legal contract or the

rights of others

**civil law** law dealing with people, things, and the relationships between them

**common law** unwritten law based on principles of justice, reason, and common sense

**confidentiality** maintaining patient privacy in terms of health and personal information

**conflict of interest** when an individual's personal interests could compromise their judgment, decisions, or actions at work

**conscience** inner feeling or voice inside an individual's head that tells them whether actions, thoughts, or behaviors are right or wrong

**conscientious objection** to preserve integrity, refusing to perform actions that violate values, as long as the refusal is not based on personal prejudice and/or convenience

**constitutional law** law written into the U.S. Constitution and its amendments

**credentialing** a process that agencies use to ensure that their clinical staff (all healthcare professionals) meet the necessary and legal criteria to practice

**crime** violating a criminal law

**criminal charge** legal action against an individual who has allegedly perpetrated a crime by acting against a specific statute or common law principle in a way that is harmful

**criminal law** law that defines crimes and the punishments for people perpetrating them

**defendant** the party against whom a legal action is brought

**deontology** a theoretical perspective that assumes that ethical decisions or actions are right or wrong because they meet a moral law or principle

**dilemma** a choice between two or more potentially correct answers

**ethical conduct** behaving in a manner aligned with the Code of Ethics for Nurses, nursing values and virtues, and nursing ethical principles

**ethical consideration** an issue that causes a nurse to stop to think through the ethics of a situation

**ethical dilemma** a choice between two or more actions that must be made, both of which are equally good, both of which are equally bad, or for which the benefits of both actions are unknown

**ethical principle** fundamental concept that guides individuals and professionals in determining what is right or wrong in a given situation

**ethics** a branch of philosophy and a set of moral principles, virtues, or ideals that guide behavior and help determine what is right and wrong

**ethics committee** a group that works together on a regular basis to address ethical issues within the organization

**expert witness** an individual whose job is to describe the applicable standards and their opinion of whether a nurse in each situation would have been reasonably expected to behave/perform in a particular way

**false imprisonment** restraining another person or causing them to be restricted to a specific area

**felony** more serious criminal act for which perpetrators are generally fined more than \$1,000 and/or jailed for more than one year

**fidelity** faithfulness and loyalty

**fraud** deceiving an individual or group for personal gain

**Good Samaritan law** law that protects healthcare professionals from civil liability in emergency situations as long as they are acting in a way that is expected, reasonable, and prudent from someone with the same background

**human dignity** every individual has worth on account of being human

**informed consent** a requirement that healthcare providers inform a patient or their surrogate of the potential benefits, risks, and alternative treatments for a procedure or treatment that is being offered

**injunction** prevents or requires defendants from particular actions or procedures in the future

**integrity** being honest and morally constant, supporting what is right even when not popular, and meeting commitments

**intentional tort** action that an individual knew or should have known was incorrect or inappropriate

**justice** treating all people equally and judging them on the same criteria

**laws** formal rules for conduct that governs behavior and is created and sanctioned by various agencies, such as Congress and states

**lay witness** individual with knowledge of a case who is called to court to speak to the facts of the case, what they saw and did not see

**level of evidence** an indication of how much proof is required to find a defendant liable for an event

- libel** negative, malicious, and/or false written remarks about another person to damage their reputation
- litigation** the process of resolving disputes or legal conflicts through the court system
- malpractice** professional negligence
- mandated reporter** individual required by law to report suspected or known abuse against children, older adults, people with disabilities, and between intimate partners
- medical futility** the point at which further interventions will not improve a patient's life expectancy
- misdemeanor** less egregious criminal act, for which perpetrators are generally fined less than \$1,000 and/or jailed for less than one year
- moral courage** the willingness to stand up for what is moral and ethical even when it may negatively impact the nurse
- moral distress** knowing the ethically correct action but being unable to perform it or being forced to act outside one's personal and professional values
- moral injury** when healthcare workers become psychologically harmed from being forced to act outside of their value system for an extended period of time
- motion to dismiss** request to dismiss a case
- negligence** results from an individual or organization who has a duty to act, breaches that duty, and causes damage; results from individuals not acting in a way that would be reasonably expected of someone in the same position
- nonmaleficence** ethical principle that emphasizes the obligation to do no harm intentionally
- Nurse Licensure Compact (NLC)** an agreement among certain U.S. states to recognize and accept a single nursing license that allows nurses to practice in multiple participating states
- nursing ethics** a moral base from which nurses work
- nursing practice act (NPA)** the statutory law guiding nursing practice for a state
- plaintiff** the person who files a lawsuit against someone
- presenteeism** coming to work but not being able to perform fully and competently due to illness or job stress
- principle-based approach (also, principlism)** draws from deontology and assumes that ethical principles can guide all actions and decisions for nurses
- risk management** strategies to prevent being named in a criminal or civil liability case
- self-advocacy** the act of speaking up for oneself and one's needs
- self-determination** the ways individuals control their lives and surroundings and express their autonomy
- settlement** an agreement between the parties to not go to trial but rather to have a payment to the plaintiff in exchange for no admission of guilt or liability for the defendant
- seven domains of health** a holistic framework that encompasses various dimensions of well-being and health
- slander** negative, malicious, and/or false oral remarks about another person to damage their reputation
- social justice** a belief that all people deserve equal treatment and access to health care
- standards** professionally developed criteria providing the minimal level of acceptable practice for all individuals within a profession
- Standards of Practice** standards designed by the ANA and based on the nursing process that provides a problem-solving-focused approach to nursing practice
- Standards of Professional Nursing Practice** statements of functions and conduct that all nurses, in every setting, are expected to execute capably
- Standards of Professional Performance** professional nursing behaviors and mindsets, including advocacy, respect, communication, collaboration, leadership, research, and environmental health
- statutory law** law established by legislative bodies, such as Congress, state legislatures, and local governments
- summons** formal notice issued by a court or other authorized entity, informing an individual (defendant) that a legal action has been initiated against them
- tort** a type of civil law focused on the rights and duties of individuals, in which an individual can sue another for damages after suffering harm because of wrongful actions on the part of the person being sued
- unintentional tort** causing harm to someone without intending to do so
- utilitarianism (also, consequentialism)** a theoretical perspective of ethics that focuses on doing the greatest good for the most people and the least amount of harm for others
- value** a central, guiding principle in an individual's life
- value system** the sum of an individual's or group's values, such as codes of conduct

**veracity** truthfulness

**verdict** legal decision

**virtue ethics** theory based on principle that people make decisions and perform actions based on their character

**whistleblower** an individual reporting misconduct

**whistleblowing** the reporting of misconduct, such as fraud, abusive patient care, or unsafe conditions to outside authorities

## Assessments

### Review Questions

- Where do most people encounter their first education on values?
  - elementary school
  - friends
  - church
  - parents
- Respecting an individual's decision not to participate in a research study is an example of what value?
  - autonomy
  - altruism
  - social Justice
  - integrity
- A nurse enters a patient's room and discovers their college nemesis, a person who made their life miserable while in school. Why might this be considered?
  - an opportunity to show integrity
  - a time to use a conscientious objection
  - a conflict of interest
  - an opportunity to be altruistic
- A nurse is determining a patient's needs regarding end-of-life care. At which stage of the nursing process is this most likely to happen?
  - assessment
  - diagnosis
  - implementation
  - evaluation
- The treatment team is discussing desirous outcomes and plans for a patient upon discharge. The team feels there is only one way to proceed with the plan. The nurse states the patient must be involved in their final decision. What value is the nurse representing?
  - altruism
  - autonomy
  - human dignity
  - integrity
- A nursing student is learning the nursing Standards of Professional Practice and is trying to understand the standard and competencies about advocacy. What set of nursing standards is the student focusing on?
  - Standards of Professional Practice
  - Standards of Professional Performance
  - Standards of Ethical Practice
  - Standards of Professional Ethics
- The provision two of the Code of Ethics for Nurses states "the nurse's primary commitment is to the patient, whether an individual, family, group, community, or population." What interpretive statement best reflects this provision?

- a. Respect human dignity and all human rights no matter the nature of the illness.
  - b. Protect the privacy and confidentiality of patients.
  - c. Nurses are responsible for caring for themselves as they care for patients.
  - d. Address conflicts of interest to preserve patient safety first, then professional integrity.
8. What is the ethical theoretical approach that carries an underlying assumption that human beings are mutually dependent on each other and need respect, protection, and concern?
- a. care-based approach
  - b. principlism
  - c. virtue ethics
  - d. feminist ethics
9. Lucy is working on a busy medical-surgical unit. One evening she cares for a very sick patient who needs to be transferred to the ICU; however, there are no beds available in the ICU. While the transfer center attempts to arrange for transfer to another facility with available ICU beds, Lucy must do her best to give the patient the care they need without having the resources available to do so. What condition might this situation cause Lucy?
- a. moral injury
  - b. moral distress
  - c. conscientious objection
  - d. ethical dilemma
10. What type of law is a nursing practice act?
- a. constitutional
  - b. statutory
  - c. administrative
  - d. common
11. A nurse witnesses a car wreck and knows that people are probably injured. As the only healthcare provider currently on the scene, the nurse attempts to give aid to the victims of the wreck. A hysterical parent is screaming for help with their child, and the nurse attempts to render aid. The child's body is very damaged, but the nurse tries to stabilize the child pending arrival of first responders. The nurse is confident that doing so is protected by which legal concept?
- a. Good Samaritan laws
  - b. their state's NPA
  - c. their nursing license
  - d. OSHA
12. What situation constitutes battery?
- a. threatening to withhold a patient's pain medication
  - b. using restraints to protect a patient from harming themselves or others
  - c. discussing a patient's name and diagnosis on an elevator with individuals who have no need to know
  - d. forcibly administering medication outside of an emergency situation
13. What does the newly graduated nurse accurately identify as a way nurses provide advocacy for patients?
- a. protecting and educating
  - b. medicating and championing
  - c. caring and talking
  - d. mediating and arguing
14. A group of nurses from several different units in a hospital have been meeting together to discuss the problems they have providing the level of patient care and advocacy they feel their patients deserve. What strategy might be most effective to advocate for change in their hospital?

- a. One nurse decides she needs to speak to the Director of Nursing and ask for longer working hours.
  - b. Individual nurses speak separately with their nurse managers about staffing issues on their respective units.
  - c. The group of nurses decides to speak to the Director of Nursing about short staffing issues and the impact it has on patient care and advocacy throughout the facility.
  - d. Two of the nurses decide to go to the Director of Nursing and say they will quit if more staff are not hired.
- 15.** In what kinds of environments are nurses most likely to be able to advocate for themselves and their patients?
- a. organizations that lack a culture of shared decision-making
  - b. environments in which nurses frequently have to use work-arounds to provide effective patient care
  - c. organizations with a strong culture of shared decision-making
  - d. environments with a strong focus on task completion
- 16.** A nurse is working with a patient, attempting to determine whether there are any needs beyond immediate healthcare needs with which the patient needs assistance. What question might illicit this information?
- a. How many children are currently living with you?
  - b. In the last twelve months, how often did you worry that your food would run out before you had money to buy more?
  - c. How often in the last twelve months have you and your family been able to engage in recreational activities?
  - d. When you are going grocery shopping or coming to doctor appointments, what kind of transportation do you use?
- 17.** What two laws protect whistleblowers?
- a. Whistleblower Protection Act; Healthcare Insurance Portability and Accountability Act
  - b. NPA; No FEAR Act
  - c. Occupational Safety and Health Act; Americans with Disabilities Act
  - d. No FEAR Act; Affordable Care Act

### Check Your Understanding Questions

1. Explain the difference between individual values and a values system. How are values systems often clarified?
2. Describe how you might identify a patient's values?
3. Discuss the concepts of deontology and utilitarianism and how they are used in nursing ethics.
4. Explain how statutes and administrative laws, such as nursing practice acts, impact nurses and other healthcare workers.
5. Explain the difference between intentional and unintentional torts in healthcare settings and provide examples of each type.
6. Explain the difference between criminal charges and intentional torts for healthcare professionals, such as nurses. Why can both be filed against the same individual for the same situation? How are the penalties different?
7. Discuss the importance of nursing advocacy in public health, and describe how nurses can advocate at different levels for public health outcomes.

### Reflection Questions

1. Consider everything you learned about the nursing process, and the discussion about nursing values. What additional values do you believe are important to the nursing profession that are not discussed here?

2. Consider the principles of nonmaleficence and beneficence. Describe the similarities and differences of these two principles, and discuss how it might be difficult to uphold them at the same time.
3. Consider the idea of being a mandated reporter. How do you feel about this? Can you imagine situations in which you may feel uncomfortable with having to report potential abuse? Why or why not?
4. Consider the various barriers to advocacy discussed and your own situation and personality. What types of barriers might you have the most difficulty overcoming and why? Can you think of any other barriers you might experience?

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #3: Part 2](#).  
What other ethical principles (besides autonomy) are relevant to the patient's current situation?

### What Should the Nurse Do?

An older patient has been brought into the emergency room early in the morning after being found unconscious in a park, presumably having been there all night. No identification is on the patient; they are now awake but confused. Their clothes are relatively clean and in good condition, but there are no clues as to the patient's identity. The patient had soiled themselves prior to admission. The emergency room staff have notified the police and social services that they have an unidentified older female, in case a missing person's report is filed.

1. Another patient asks the nurse if they think the patient was without housing. How should the nurse best respond to reflect the value of social justice?
2. A young nurse is assisting the nurse to care for this patient. She wrinkles her nose in front of the patient when they are helping the patient to undress, and the patient sees her, shrinking back from them in embarrassment. How might the nurse respond to preserve the patient's dignity?
3. Lab tests have come back showing a serious infection in the patient's system, which providers think may be contributing to her confusion. Providers want to start her on a round of antibiotics and request permission from the patient to do so. What should the nurse do to maintain her integrity and protect the patient?
4. Shara and Bob have been friends since nursing school. They work together on a medical-surgical unit. One evening, Bob was the charge nurse and Shara made a medication error that caused a patient to be transferred to the critical care unit. When completing the paperwork on the transfer, Bob realized the cause had been the medication error that Shara had not reported. When confronted, Shara asked Bob to keep that a secret between the two of them. What should Bob do, and what ethical considerations should he make?
5. A mother brings a young child into the emergency room with a broken arm saying the child fell off their bike. The mother is crying, and her tears are washing off eye makeup that appears to be covering bruises, and the nurse notices swelling on the mother's wrist as well. When looking at the patient's record, the nurse notes this is not the child's first broken bone. What should the nurse do?
6. Nurse Taylor works on a busy medical-surgical floor. Taylor has observed the unit is frequently understaffed during evening shifts, resulting in delayed responses to patient needs, longer medication administration times, and increased stress among the nursing staff. Despite attempts to communicate these concerns to the nursing manager, the issue persists, and Taylor is becoming increasingly worried about the impact on patient safety. What should the nurse do?

### Competency-Based Assessments

1. Consider a nurse who is working on a busy medical-surgical unit. One evening she cares for a very sick patient who needs to be transferred to the ICU; however, there are no beds available in the ICU. While the transfer center tries to arrange for transfer to another facility with available ICU beds, the nurse must do her best to give the patient the care they need without having the resources available to do so. Eventually, the transfer center finds a facility that can provide the patient with the required level of care, but the patient dies while the ambulance is on the way to pick them up from the nurse's hospital. The family is at the bedside, angry, in shock, and devastated. Put yourself in this nurse's shoes and use [this moral distress tool developed by the AACN](https://www.aacn.org/~media/aacn-website/clincial-resources/moral-distress/recognizing-addressing-moral-distress-quick-reference-guide.pdf) (<https://www.aacn.org/~media/aacn-website/clincial-resources/moral-distress/recognizing-addressing-moral-distress-quick-reference-guide.pdf>) to describe the experience in a brief one-page

statement.

2. Find and read your [state's nursing practice act \(https://ncsbn.org/policy/npa.page\)](https://ncsbn.org/policy/npa.page) using this website. Find five items in your state's NPA that surprise you or of which you were unaware. Identify each item and explain why you chose it.
3. Conduct some research and find out what the whistleblower protections are in your state. Are they primarily the federal ones, or does your state have additional protections? Describe the protections in your area in a brief paragraph.

# CHAPTER 17

## Patient and Family Education

**FIGURE 17.1** Nurses play a key role in patient and family education. (credit: modification of “Naval Hospital Jacksonville diabetes nurse educator 211026-N-QA097-111” by Navy Medicine/Flickr, Public Domain)

### CHAPTER OUTLINE

- 17.1 Informed Decision Making and Self-Care
- 17.2 Methods and Approaches to Learning and Teaching
- 17.3 The Nurse’s Role in Patient and Family Education
- 17.4 Evaluation of Teaching and Learning

**INTRODUCTION** As educators, nurses must be skilled at assessing patients’ learning readiness and needs. Often, the interaction between a patient and nurse takes place when a patient is at a distinct disadvantage: they may be physically compromised, or troubled by pain, worry, anxiety, or confusion. There are other times when patient care is routine rather than urgent or emergent, and the nurse’s focus can be placed on health promotion and disease prevention.

Health education not only addresses specific, existing symptoms or diagnoses but also focuses on proactive prevention of future health concerns. Barriers to education may be based on a patient’s health history, environmental or geographic factors, and lifestyles. Although patients may have interest in taking an active role in their health and well-being, they may not know where to begin. Nurses play a vital role in empowering patients to contribute to their own care and maintenance of health. Recognizing teaching moments or creating the best possible environment for health education and patient learning are important for nurses to have and are necessary to provide quality patient care and ensure patient satisfaction.

This chapter explores health education and its impact on different aspects of wellness, self-care, decision-making, and consent. Patient and family education in professional nursing practice is guided by the American Nurses Association (ANA) Scope and Standards of Practice. Evaluation of teaching and learning is an essential step of the

education process; it can determine how well the patient and family understand what was taught and guide goal achievement.

## 17.1 Informed Decision Making and Self-Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the purpose of health education and informed consent
- Recognize how to promote patient health through self-care

To begin exploring the education of patients and families, two major concepts are presented: health education and **health promotion** (i.e., improving health). As active participants in their health care, patients **consent** to (agree and permit) their care, which often begins by accessing the healthcare system through an appointment with a provider. Care may subsequently be directed, to include consultations, medications, diagnostic testing, treatments, and surgeries. Nurses play a critical role in the education of patients and families as they learn and contribute to their own place in health and wellness decision-making.

Purposes of health education, including maintaining health and wellness, and contributions of self-care to health promotion, guide the specific path of exploration. Health maintenance is supported by factors such as adherence and compliance, and education can be key for patients and their families to understand important pieces of their medical care, such as applicable diagnoses and components of their plans of care. As educators, nurses must consider various aspects of their patient's lives, which can have positive or negative impacts on their participation in their care. Considerations, such as the patient's level of medical knowledge, motivation, and coping skills, are significant issues relative to education.

### Purpose of Health Education

The purpose of patient education is to give patients the education and self-efficacy they need to maintain or improve health, and the ability to cope with new situations (Fereidouni et al., 2019). For patients who in a state of homeostasis, or physiologic normal balance, education may focus on health promotion and disease prevention.

Patients who are experiencing a current health challenge may be experience stress that affects their ability to learn (Cherry, 2022). Health problems may cause physical changes so dire that the body is merely trying to survive, or the physiological impact of stress itself may interfere with the ability to focus and understand new information (see [Chapter 34 Stress, Adaptation, and Homeostasis](#)). Although the purpose of education for this population shifts from promoting health and preventing disease to disease management, teaching remains critically important. For others, health education may need to center around coping with altered function due to a chronic condition. The possibilities of ongoing testing, therapies, and medications can be frightening and confusing, and there are typically numerous topics and approaches the nurse can use to educate under these circumstances.

Another component of patient education is empowering the patient to make informed decisions about their own care. In 1973, the American Hospital Association (AHA) adopted the Patient's Bill of Rights. The bill has since been updated, revised, and adapted for use throughout the world in all healthcare settings. There are different versions of the bill, but, in general, it safeguards a patient's right to accurate and complete information, fair treatment, and self-determination when making healthcare decisions. In 2018, the AHA created the Patient Care Partnership, which is an updated brochure of what a patient's rights and responsibilities are during a hospital stay.

### LINK TO LEARNING

Click here to view [The Patient Care Partnership \(https://openstax.org/r/77PtCarePartner\)](https://openstax.org/r/77PtCarePartner) document. This emphasizes the importance of a patient's right to make informed decisions about their care.

For almost all tests, procedures, and treatments, patients (or their designees) are required to provide consent before they can be completed. As the name implies, informed consent is a process that requires the education of the authorized decision-maker about the benefits, risks, and any alternatives of the procedure (Shah et al., 2023). Patients have legal and ethical rights to understand, guide, and approve of their own healthcare and treatment

decisions. This includes being given information about what a test, procedure, or treatment plan is, what it involves, how it is anticipated to aid in diagnosis and/or treatment, risks, benefits, and possible complications.

Healthcare providers such as physicians, nurse practitioners, and physician assistants are responsible for the thorough explanation of the procedure, including risks, benefits, alternatives, and any risks associated with the alternatives, and to ensure the patient or designee understands the whole process (Shah et al., 2023). Persuasion to comply with care through force, or **coercion**, is not acceptable, and the patient should have ample opportunity to clarify any information and ask questions as a participant in a collaboration of care (Strini et al., 2021).

Nurses tend to have the most interactions with patients and families, and often quickly establish relationships that foster opportunities for education. The registered nurse (RN) follows the scope, standards, and competencies of practice (ANA Scope and Standards of Practice, 2021). This includes being advocates for their patients. With regard to the informed consent process, this can involve collaborating with the prescriber and patient in various ways. This may include providing patients informational handouts and answering questions, arranging the time and space for the specific consent-related education between provider and patient, and contributing to the assessment of the patient's understanding of the circumstances (Strini et al., 2021). The nurse's role also includes witnessing the signatures of patient (or designee) and prescriber on the informed consent form. In circumstances where a patient has further questions after signing a consent form, or changes their decision, the provider is contacted by the nurse to inform them of the change in circumstance and facilitate another meeting between the parties.

## LINK TO LEARNING

You may find it helpful to refer to this short, but thorough [overview of patient education \(https://openstax.org/r/77PatientEduc\)](https://openstax.org/r/77PatientEduc) at various times throughout the chapter, as specific topics appear.

## Maintaining Health

Patient education plays an important role in establishing and meeting patient goals, decision-making, and creation of care plans (Saboktakin et al., 2021). Health maintenance involves helping patients identify their needs and participate in self-care as they learn to manage risk factors and prevent or control existing disease processes and diagnoses (Wang et al., 2022). Maintaining health also contributes to fewer complications from chronic illness or injury, shorter lengths of stay when hospitalized, and fewer readmissions after discharge (Bordonada et al., 2020).

Through patient teaching, nurses can help patients understand health and wellness as it pertains to their individual circumstances, how they can maximize participation in employment and social activities, and perform **activity of daily living (ADL)**, such as toileting, bathing, oral care, and ambulation. Another example of health and wellness maintenance is providing information about vaccinations. Although several immunizations are scheduled in early childhood, for prevention of disease, additional immunization boosters are required at various times throughout the life span for patients with certain chronic diseases. Education about various immunizations—how they work, recommended timing, the need for boosters, how they are administered, possible side and adverse effects—are all topics nurses can teach patients and families.

## LINK TO LEARNING

A Vaccine Information Statement (VIS) is a document produced by the Centers for Disease Control and Prevention that informs patients, family, and caregivers about the risks and benefits of a vaccine they are receiving. VISs are required by law to be given to the vaccine recipient or caregiver prior to a vaccination dose. Click here to view the [current VISs \(https://openstax.org/r/77VIS\)](https://openstax.org/r/77VIS) for multiple, routine, and nonroutine vaccinations.

Patient education is important in prevention of illness and injury, as well as in early identification of disease. Screenings, such as blood tests for diabetes mellitus (DM) and hyperlipidemia, and preventive diagnostic tests such as colonoscopy (a fiberoptic scope to visualize the colon) and **mammography** (radiographic examination of breasts) are important health maintenance activities that can provide early disease detection and prevention. Other preventive measures may include guidance for weight loss, smoking cessation, and mental health treatment.

Over the past decades, patients have become more interested and involved in maintaining their own health and well-being. Although some people take a more passive approach to their health and rely on their healthcare providers' advice, patients are increasingly understanding that the maintenance of their health requires active involvement. Nurses can help educate patients and family to promote health. Additionally, nurses can provide reputable resources to reinforce education and help alleviate concerns.

### Promoting Adherence and Compliance

Education, whether on maintaining existing health or managing risks and challenges to health, is necessary to help patients understand their circumstances, make informed decisions, and be compliant with treatment plans. Nurses can help patients discover their own role in the plan of care through education and the value of adhering to and complying with the plan developed for them. One way to promote adherence and compliance is for the patient to play an active role in the formation of their care plan.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Quality and Safety Education for Nurses (QSEN) Competency: Patient-Centered Care (PCC)

Disclaimer: Follow agency policies and procedures for patient education and documentation.

**Definition:** Recognize the patient as collaborator in provision of compassionate care.

**Knowledge:** The nurse will incorporate patient and family preferences in provision of care planning and education.

**Skill:** Integrate patient and family in interdisciplinary patient care. The nurse will:

- Inquire and establish patient and family education needs and preferences.
- Share the patient and family's values and preferences with interdisciplinary team members.
- Provide respectful patient care focused on the patient.

**Attitude:** The nurse will consider the patient's viewpoint and awareness of their own care, with respect for needs, values, and preferences.

---

Adherence and compliance are supported by patient understanding. Whether the education is about a diagnosis, planned procedure, or drug therapy, the more the patient comprehends about what is required of them, the better. This may include providing education on the disease process, pain expectations, and control after a surgery, or explaining how a new medication works in terms that are easy for the patient to understand. Nurses can promote adherence and compliance by ensuring their patient education includes the following (Wang et al., 2022):

- Barriers identified to education
- Participants in education
- Preference for teaching strategy for education
- Timing of education
- Topic of education

### Factors Affecting Adherence and Compliance

To adhere to and comply with healthcare plans, patients and caregivers must understand what is being asked of them. It is best if they are active participants in and agree with their plan of care. Consideration for potential hindrance to comprehension of care is important, as is recognizing positive influences. Some factors that can affect adherence and compliance include

- Cultural preferences (e.g., values and customs)
- Feelings and emotions (e.g., patients may be overwhelmed, apprehensive, worried, frightened, exhausted)
- Lack of comprehension of education (e.g., medical and nursing care plans can be complex and difficult to understand)
- Language needs (e.g., patients may speak and understand a language other than the one spoken by healthcare providers; delays for translation services)
- Patient care setting may be busy, even chaotic
- Physiological status (e.g., pain, discomfort)

- Unfamiliar terminology, medications, procedures, and laboratory studies

It is crucial for the nurse to be able to identify appropriate teaching moments, whether they be scheduled or spontaneous, and be responsive when a patient or family member asks a question. It is equally important to avoid potential barriers to adequate education in that moment and promote the effectiveness of the education given the challenges of the situation.

### Health Literacy

The ability to read and write is described by the word **literacy**; those who are unable to either read or write are referred to as **illiterate**. There are many who are literate, perhaps even very well educated, but for whom the language of medicine is foreign and unintelligible. Because of the specific nature of this language, it has been labeled **health literacy**, which is described as the ability of an individual to locate, comprehend, and make use of health-related material and make healthcare decisions (Healthy People 2030, n.d.).

In anticipation of educating patients and families, it is important to assess both the level of general literacy as well as health literacy to ensure communication is effective. This is also a good time to ask and otherwise assess the audience's (e.g., patient, family, friends) preference for style and technique of the teaching session. Recipients who have limited literacy of any sort are not likely to make use of, or benefit from, written materials, so establishing their choice(s) for style is important. Different styles of learning, and associated teaching methods to best serve learners, will be further explored later in this chapter.

## REAL RN STORIES

### Test Before a Test: Answering a Patient's Question

**Nurse:** Angela, BSN

**Clinical setting:** Oncology office

**Years in practice:** 8

**Facility location:** Suburb of large city in eastern Missouri

I took a call from Mrs. Wong, who had seen the oncologist the day before for a 6-month follow-up. She had a rather large melanoma skin cancer removed 6 months earlier and was to have CT [computed tomography] scans every 6 months. Mrs. Wong said she was confused because her cancer was of the skin, and the physician had given her a prescription to have bloodwork done before the CT. Since I didn't have her chart handy, I didn't want to just guess and give the patient wrong information, so I asked her what tests she was to have done. She told me, "BUN and CREAT."

I asked her what the physician had told her about the scan, and she gave a good explanation of it: showing if there are any spots of concern about the skin cancer spreading to other parts of her body. Then she told me she just didn't understand what a blood test was going to do about the skin cancer. It was so helpful for her to explain just how much she understood—which was a lot—and I was able to describe to her that when she goes for the CT scan, she'll have an intravenous [IV] line put in so a "contrast" drug could be injected, because that's how any spots would show up on the scan.

She told me that made sense, so I went on to tell her that BUN [blood urea nitrogen] and creatinine are tests of kidney function, because the contrast is hard on the kidneys. By having those tests done beforehand, the physician will know if a different type of scan may be needed or another drug should be prescribed to protect the kidneys, or if drinking plenty of water after the scan should be enough. Mrs. Wong laughed a little, and told me she just could *not* figure out what BUN and CREAT meant, and why any blood needed to be tested if the CT was going to tell if the cancer spread. She told me that it made sense now, and she sure didn't want her kidneys to be damaged.

Because health literacy also involves the ability of individuals to "use information and services" (Healthy People 2030, n.d.), health insurance or other means of accessing care is a part of the concept of health-specific literacy. Navigating through confusing documents and terminology specific to insurance can be daunting, and for those with no insurance, access to other sources like free or discounted care may not be easy to find. Nurses, social workers, case managers, and other navigators are valuable guides for patients as they try to steer their way through

confusing paths within health care. Health information can be confusing because it often involves unfamiliar, complicated terminology, and perhaps medical jargon. Plain language and numbers, and considerations for culture, can help improve patients' ability to locate, understand, and use health information to make health-related decisions.

Like Healthy People 2030, the Agency for Healthcare Research and Quality is a governmental resource that offers a multitude of information about health literacy under headings such as "Health Literacy Improvement Tools," "Professional Education and Training," "Patient Education and Training," and "Research Tools, Data, and Funding" (AHRQ, 2024). Under the patient education heading, there are materials for health literacy assessments, as well as how-to directions for making healthcare information easier to understand. Healthcare providers can complete training modules about informed consent, and there are toolkits for specific topics like universal precautions and engaging patients and families specific to catheter-associated urinary tract infection prevention. For patients, there are videos with recommendations for interactions with the healthcare team, as well as ways to increase participation in one's own health and self-care. There are also other resources for various patient interactions with the healthcare system.

---

### Motivation

Some people are driven by **intrinsic motivation**, or a drive toward achieving personal pleasure or fulfillment (Santos-Longhurst, 2019). Intrinsic motivation theory deals with basic psycho-physiologic necessities such as food, water, autonomy, and belonging as stimuli for health and wellness. Intrinsically motivated individuals are interested in their health and are open to learning about maintaining wellness and preventing illness. These are the easiest patients to teach because they are already enthusiastic and ready to learn. However, for many patients, health and wellness have not been a priority or interest, so finding ways to reach and motivate them can be challenging. These people may respond to **extrinsic motivation**, or a willingness to participate in self-care activities when offered a reward, rather than meeting a psycho-physiologic need (Santos-Longhurst, 2019).

Preventive healthcare visits are an opportune time to introduce health topics, which ideally will lead to questions from the patient and allow them to demonstrate interest. The more interested a person is in a subject, the more likely they are to be motivated to learn more about it. If intrinsically motivated, patients are inclined to take pleasure in such activities as finding ways to improve their diet by finding interesting new nutritious recipes, or to improve strength and balance by exercising regularly (Santos-Longhurst, 2019). For the extrinsically motivated, goals may be based on winning an athletic event like a tennis match, or in losing a clothing size and getting a new outfit as a reward.

A motivated patient is more apt to be receptive to teaching, which is a good time to discuss risks and prevention. It is during such visits that topics like diet and exercise can be introduced as ways to decrease risks or actual development of hyperlipidemia, hypertension, or DM.

## LINK TO LEARNING

---

The video [Motivational Interviewing \(MI\) \(https://openstax.org/r/77MotivInterview\)](https://openstax.org/r/77MotivInterview) can be helpful in motivating patients toward behavior change. This video provides details about MI and how nurses can incorporate this into practice.

---

Acute episodes of injury or illness add potential barriers to patient and family education. Although such acuity may provide its own element of motivation (by providing a specific topic of interest), barriers such as pain, anxiety, and a battery of diagnostic tests can pull away the patient and family's focus. They also may be overwhelmed and unable

to come up with questions. In such circumstances, nurses typically try to triage education, for example, focusing on physiological care priorities, explaining the most important items, and identifying the main concern of the patient and their loved ones.

Coaching is a motivational technique used frequently by employers, but it can apply to patient education as well. Like athletic coaches, nurses help patients identify a particular problem or issue, set goals, and assist them with creating solutions. The patient is an active participant and gets the support of the nurse as they take the necessary steps. The relationship between the patient and their nurse “coach” tends to build as the interactions are established and enhanced over time. Some recommendations for motivational coaching include (Practice, 2023):

- Establish accountability through progress checks, reassurance, and support if and when needed.
- Help patients honestly identify and prioritize their goals.
- Offer tools including specifics for activities (e.g., exercise, diet, nutrition), schedule for exercise, and a detailed plan for follow-up.
- Present new ideas, such as ways to implement positive techniques and habits.
- Set SMART (specific, measurable, attainable, relevant, and timely) goals so patients understand all aspects of the goal and how they can be reached.

## REAL RN STORIES

---

### SMART Help with Diabetes

**Nurse:** Karen, MS

**Clinical setting:** Nursing

**Years in practice:** 14

**Facility location:** Louisiana

I had been asked to work at the diabetes station at a health fair. A couple of other nurses and I were doing fingerstick glucose checks, and I had been asked to provide education for those who had more questions. I remember a particular patient who said he just wasn't able to control his weight or blood sugars. This gave me a chance to ask a few questions and find out more about him and why he decided to ask for more information that day. Poor fellow, he almost came to tears saying how he couldn't keep up like he used to, and he was afraid he wouldn't be able to see his grandkids grow up. With a few more questions, we were able to dig deeper into some things he was quite worried about, and what he hoped to accomplish. His biggest concerns were his weight and his blood sugar.

His wife joined us, and we spent a while on the laptop exploring the American Diabetes Association (ADA) website, looking at lifestyle recommendations like exercise, nutrition, and recipes. With his goal of weight loss in mind first (and thinking if he gets that down, his glucose may stabilize, too), I helped him with goal setting. We used the SMART format and, again using the ADA website, decided to start with their recommendation of a 7% weight loss goal. That was both specific and measurable, especially because he had just had his weight checked at the fair. To help with the goal being both achievable and realistic, we looked again at recipes and picked a few that he and his wife thought sounded good. We also explored exercise options in the small town, which included a public gym with a swimming pool and a fenced field and running track at the school. Baby steps: he didn't want to spend extra money on the gym at first, so he suggested he would walk at the track in the mornings before school started.

We came up with timing to give a chance for these measures to have some effect and suggested a clinic visit in 3 months to see if he's lost weight, and measure his hemoglobin A<sub>1C</sub> (a blood test that evaluates glucose control based on its relationship with hemoglobin) for long-term glucose control. Before starting the plan, because it involved implementing a new exercise program, he should make an appointment with a nurse practitioner at the clinic to have it approved or modified as needed. He took some printouts, and the notes we kept, and the phone number for the clinic to make his appointment Monday. His wife printed some recipes from the ADA website and was already planning to stop at the grocery store on the way home.

---

### Facilitating Coping

Nurses spend considerable time with patients, often in intimate circumstances. Patients learn to trust nurses and

come to respect their input. By recognizing distress in a patient or family, nurses can assess the cause and facilitate coping through teaching, shedding light by helping the patient and/or family understand more about the circumstance, and providing options or methods to help patients manage more effectively. In many facets of life, knowledge is associated with power; health care is no exception. As patients receive diagnoses, their abilities to manage and cope with challenges and possibly bad news can be threatened. Patient teaching facilitates coping by providing the necessary knowledge to help weather the storm of reactions such as worry, anxiety, and feelings of helplessness (Bordonada et al., 2020).

Patients can be empowered to redirect maladaptive coping mechanisms and focus instead on techniques that are more productive. Nurses can facilitate coping by, for example, helping a patient concentrate on health maintenance by adhering to a new drug regimen, rather than emphasizing possible long-term effects that may or may not happen. Nurses can provide education and information about such strategies, including distraction, focused deep breathing, and various complementary therapies such as aromatherapy, pet therapy, cognitive behavioral therapy, and music therapy. Replacing activities that are stress inducing with those that are stress reducing facilitates positive coping and reduces stress (Shostak et al., 2024).

## REAL RN STORIES

---

### Helping a Quitter

**Nurse:** Rick, BSN

**Clinical setting:** Step-down unit

**Years in practice:** 4

**Facility location:** Seattle, Washington

Jerry had open-heart surgery 5 days ago and was transferred from the ICU [intensive care unit] to my step-down unit the evening before I took care of him. Most of the postoperative open-heart patients I took care of were out of the ICU on post-op day 2 or maybe 3; Jerry though, he couldn't come off the ventilator for a while. He had been a heavy smoker, and although he was only 50 years old, his lungs struggled after that surgery. So, he was off the vent on day 3, and they kept him in the ICU for one more day; he made it here late on day 4. I was working nights, and Jerry was having trouble sleeping. It so happened he was my only patient, at least until I got a new admission, so we got to talking. He told me he'd been smoking since he was 17, and he smoked one or two packs a day. He said he'd tried quitting at least a dozen times, but he just couldn't beat the cravings.

Smoking cessation is such a big focus for our inpatients, and I knew there were a lot of resources for guys like Jerry. We went through some written materials we had on the unit. Jerry wasn't particularly interested in them. He said he didn't read much. He was really worried; he said he knew the surgery was like his final warning that he needed to quit. When he'd talk about quitting though, he'd get nervous, like he could feel the cravings again, even though he had a nicotine patch on. Then he'd feel his heart beat faster, which made him worry more. He said he couldn't afford the patch when he went home. I knew there was help for him through the state's quitline program. He had no idea! Seeing he could get help with patches or gum and other supports, just knowing such a program was available to him and wasn't going to cost him helped calm him down, and he started to think about being successful. Once he got excited about the quitline, and quitting, I couldn't slow him down! He called that night and set himself up with a coach and hoped his package would be at his apartment when he was sent home.

---

### Preparing for Positive Health Outcomes

Educating patients effectively contributes to improved participation of patients in their health care and tends to result in enhanced ability for self-care (Bagheri et al., 2022). Confusion is possible with unclear communication during a teaching session. Clear communication and effective education contribute to positive patient outcomes. Multimodal approaches like adding images, audio, and video to oral, lecture-type delivery and written supplements are generally well-received by learners (Stanford, 2019).

An approach to teaching and learning that incorporates factors such as language, culture, age, and **learning style** (i.e., one's preferred method of learning: auditory, visual, written, or kinesthetic), can improve patients' interest and their ability to comprehend and retain information provided ([Table 17.1](#)). Teaching children and adults shares some

principles, but there are differences, with considerations for attention span, vocabulary, and experience, as well as psychomotor abilities and skills.

Learning Style	Definition
Auditory	<ul style="list-style-type: none"> <li>Learn through listening and speaking, such as through discussions and lectures</li> <li>May use repetition or patterns (mnemonic devices) as a study technique</li> </ul>
Kinesthetic	<ul style="list-style-type: none"> <li>Hands-on learners; learn best through completing tasks independently</li> </ul>
Visual	<ul style="list-style-type: none"> <li>Learn through visual aids such as graphics, images, or maps to understand and retain information</li> </ul>
Written	<ul style="list-style-type: none"> <li>Learn through reading and writing; can understand abstract concepts and translate them into essays</li> <li>May be avid note takers or readers</li> </ul>

**TABLE 17.1** Learning Styles

When anticipating patient and family education, preparation is invaluable. Taking a moment to plan provides an opportunity to identify barriers to education. Positive outcomes are improved in some cases by educating not only the patient but family or friends, or a caregiver. This can be especially apparent with infants and very young children, and those who are cognitively impaired. Reinforcement from teaching multiple people can prove helpful in achieving positive outcomes.

It is sometimes necessary to educate patients and family members under conditions that are not optimal or conducive to teaching, and misunderstandings or inadequate education may influence a patient's adherence and compliance with the plan of care. Consider, for example, a patient who is pregnant and experiencing hyperemesis gravidarum (i.e., severe nausea and vomiting during pregnancy). As the nurse is attempting to teach the patient about dehydration and hypotension (low blood pressure), the patient's concentration is impaired by waves of nausea or interrupted by vomiting. If asked later about concepts presented, in an attempt to evaluate the teaching, it is likely the patient will not be able to recall information taught, and the education will need to be repeated.

## PATIENT CONVERSATIONS

### Problem-Solving: Worried for Mom

**Scenario:** A nurse in a primary care physician's office receives a phone call from a patient's daughter. She has several concerns about her mother.

**Nurse:** Please tell me a little more about why you're calling today.

**Patient's daughter:** I'm worried about my mom. She's living in her own apartment in a community for mostly older folks. Her dementia is getting worse, and she's been falling.

**Nurse:** Can you tell me more about the circumstances around her falls?

**Patient's daughter:** She hears voices sometimes. She says they're next door, or in the hall outside, or in her apartment. Last time she fell, she said she could swear someone was knocking on her door. She fell on her way to the door.

**Nurse:** Does your mom use a cane or walker?

**Patient's daughter:** Yes, a walker.

**Nurse:** When she went to answer the door, did she use her walker?

**Patient's daughter:** I don't think so.

**Nurse:** Does she sometimes think she can “make it” without the walker?

**Patient's daughter:** Yes. Or she is napping and rushes to get up, then forgets it.

**Nurse:** I see your mom takes metoprolol.

**Patient's daughter:** Yes. She has high blood pressure. And heart failure. She takes a water pill.

**Nurse:** Okay. Does she drink enough water?

**Patient's daughter:** I try to get her to drink more. She sips but doesn't usually finish a whole glass. She says she's worried because of her early kidney failure.

**Nurse:** For her blood pressure and heart failure, she needs less water, but with the water pill and metoprolol, she may become dehydrated—especially because she doesn't drink much. If she's dehydrated, there's a risk of her blood pressure dropping or not adjusting when she gets up suddenly. Keeping her fluids balanced, her blood pressure just right, and her heart and kidneys working is quite a balancing act. She needs enough water, but not too much. Often, we say 8 ounces an hour through the day, but let's check with the doctor as to how much *she* should have in a day with all that's going on. Then, we'll talk about some ways to get her to drink more water, how to get up gradually, and find ways to encourage her to use her walker.

**Patient's daughter:** Oh, that's a good idea. That information helps me to understand Mom's particular situation. And the doctor's specific recommendation as far as amounts to drink will be helpful. I can explain it better to Mom if I understand it better. I didn't realize how delicate the balancing act is between her heart, blood pressure, and water.

## Promoting Health Through Self-Care

One notable method of health promotion is helping patients realize the importance of self-care. A common misunderstanding about self-care is that it provides a rationale for overindulgences, offering justification for behaviors, such as overeating, substance use or abuse, or overspending (Bottaro, 2023). Self-care involves people placing their health and wellness as priorities, through such healthy choices as exercise, sleep, adequate fluid intake, and a balanced, nutritious diet based on whole foods (Bottaro, 2023).

Self-care and the inability to maintain such care for oneself in times of infirmity or illness are represented by Orem's self-care deficit nursing theory, originally presented more than half a century ago (Hartweg et al., 2021). Orem described self-care as individuals' activities toward health maintenance and wellness. The theory makes connections between patients and nurses, particularly when patients experience a deficit or inability to sustain self-care activities. During such times of disability, nurses collaborate with patients, and members of the multidisciplinary team, to provide care (Hartweg et al., 2021).

The International Self-Care Foundation (ISF) created a framework called the “Seven Pillars of Self-Care.” These pillars sort healthy (or positive) behaviors into natural groups that are similar to topics discussed in prior sections: health promotion, illness prevention, and health literacy. The ISF noticed synergistic relationships within these groups, whereby patients' positive responses to a healthy behavior may be associated with a similarly affirmative reaction to other self-care behaviors. [Table 17.2](#) describes the Seven Pillars (ISF, 2023).

	Pillar	Description (Example)
1	Knowledge and health literacy	Individuals' ability to find and understand health information and services for health-related decision-making
2	Mental well-being, self-awareness, and agency	Awareness of physiological status (e.g., body mass index, blood pressure, metabolic functions [via laboratory results], screenings [e.g., colonoscopy, mammography])

**TABLE 17.2** The Seven Pillars of Self-Care

	Pillar	Description (Example)
3	Physical activity	Regular participation of moderate physical activity (e.g., walking, bicycling)
4	Healthy eating	Diet containing balanced and nutritious components of appropriate calorie content
5	Risk avoidance or mitigation	Limitation or avoidance of negative behaviors (e.g., ultraviolet protection, smoking cessation, moderation of alcohol, vaccinations)
6	Good hygiene	Handwashing, oral care, safe and careful food preparation and storage
7	Rational and responsible use of products and services	Understanding health care: plans, drugs, diagnostics, potential side and adverse effects

**TABLE 17.2** The Seven Pillars of Self-Care

## LINK TO LEARNING

This video presents [information \(https://openstax.org/r/77selfcare\)](https://openstax.org/r/77selfcare) and examples of self-care, activities, and relative benefits. Watch the video and think about self-care activities you participate in, or how to incorporate self-care into your days.

### Illness Prevention

Health promotion is closely tied to illness prevention, because maintaining wellness naturally helps people avoid illness. The U.S. Department of Health and Human Services Office of the Assistant Secretary for Health established measurable health objectives for public health, with the first Healthy People initiative appearing in 1980 as Healthy People 1990 (health.gov). Since that time, Healthy People has been updated each decade, with goals identified for the upcoming 10 years. Healthy People recognizes public health issues and prioritizes them in an effort to improve health. With Healthy People 2030, there are 10 objectives identified, with associated volumes of data, and a number of tools available.

One goal of Healthy People 2030 is to “help people get recommended preventive health care services” (OASH, n.d.). This goal recognizes how critical education is to ensuring comprehension of the relevance of preventive care for patients and family members. It includes several objectives reflecting screenings, organizations that offer services focused on illness prevention, medication adherence, and access to care. When possible, it is ideal to prevent occurrence of disease.

Education can influence a patient’s overall compliance with the plan of care and encourage illness prevention (Bagheri et al., 2022). For example, a patient newly diagnosed with hypertension may be educated on the importance of a heart-healthy diet, medication adherence, and the importance of exercise. These practices will help control hypertension and prevent heart disease.

### Factors Affecting Self-Care

As patients are informed about self-care and its influence on their health, wellness, and prevention of illness and injury, there are factors that nurses planning educational interventions must consider. Common factors affecting self-care include the knowledge, skills, and attitudes of the patient, readiness to learn, ability to learn, and learning environment.

### Knowledge, Skills, and Attitudes

A deficit in knowledge, lack of skills, or unhealthy attitude can all have a negative effect on self-care and compromise the patient’s ability to care for themselves effectively. These can have multiple causes, but most commonly occur because of:

- conflicting information from multiple sources
- cultural or spiritual beliefs
- lack of ability to perform tasks
- lack of engagement or motivation
- lack of time
- severe anxiety or stress

It is important to assess a patient's current knowledge, attitude, and ability to perform skills in order to address barriers and develop a successful self-care plan. This may include treatment modifications to comply with cultural beliefs, ADL aids to assist with self-care, creation of schedules to allow for adequate time, and positive reinforcement.

### Learning Readiness

Optimal learning takes place when the recipient is ready to learn. This can include openness to new ideas and information and good physical condition without pain, anxiety, or worry. If a patient is not ready to learn, they won't be able to absorb any of the self-care information being taught.

Ideally, nurses can identify teaching moments when patients express an eagerness, or at least interest, in learning. This may be apparent by questions from the patient or family member. If such a moment does not present itself, communication with the audience during the planning stage may help. Patients tend to respond well when they know what is happening, so letting them know an approximate time assists with readiness to learn. Also, if pain management is ongoing, analgesia administration before teaching promotes learning.

## PATIENT CONVERSATIONS

---

### Preparing a Patient to Go Home

**Scenario:** Mr. Reggie Washington had abdominal surgery and is scheduled for discharge to home the following day. There are several self-care items the nurse will teach him about before discharge. To prevent overwhelming him, the nurse decides to teach one subject at a time and plans to educate him about changing the abdominal dressing with its next scheduled change.

**Nurse:** Mr. Washington, the surgeon is expecting you to go home tomorrow.

**Patient:** I can't wait! I don't get good sleep here.

**Nurse:** I'd like to start teaching you and your wife about changing the bandage on your surgical wound, so you'll have a couple times to get used to it before you leave the hospital.

**Patient:** My wife will be here in about an hour.

**Nurse:** Let me get you your next dose of pain medicine now. That way, you can take it and have a little nap before she gets here. When she arrives, I'll get things together and we'll go through the first dressing change. The pain medicine will still be in your system at that time, which will help you tolerate the dressing change.

**Patient:** That sounds like a plan.

**Nurse:** I'll show you where you can watch a video about bandage changes, too. You and your wife can watch it as many times as you want, and I'll show you how you can even look at it from home if you need a refresher.

---

### Ability to Learn

Literacy or cognitive function deficits can influence a person's ability to perform self-care, and they create a challenge when trying to educate the patient about the importance of self-care. For example, a patient may not be able to learn healthy relaxation techniques to reduce stress, if they are unable to comprehend the information being given to them. Additionally, patients with cognitive function deficits may lack the problem-solving capacity to recognize their own signs and symptoms of agitation or stress and perform appropriate self-care interventions.

Physical deficits can also have a negative effect on a patient's ability to learn. Patients with visual, auditory, movement, or mobility deficits may benefit from the incorporation of assistive devices when learning self-care skills.

Neurological function, including gross and fine motor movements, are especially important if the education involves intricate skill acquisition and demonstration, such as for wound dressing changes.

### Learning Environment

It is difficult to learn in an environment filled with distractions. There are times when such a setting is unavoidable, but whenever possible, arranging for patient and family education to be held in a comfortable environment fosters learning. Patient education frequently happens in a patient's room, with the patient in bed or a chair. If there is time for planning and there are different options for locations, considerations for ideal teaching and learning should include the following (Kuipers et al., 2021; Timme, 2022):

- Appropriate resources (e.g., audio-visual equipment)
- Comfortable seating
- Comfortable temperature and ventilation
- Minimal distractions (e.g., noise, activity)
- Privacy
- Sufficient lighting
- Visibility of the educator and any visual or task aids

Nurses, patients, and family create relationships and a collaborative environment for care, including teaching and learning. Positive relationships and interactions cultivate constructive discussion within the teaching session (Kuipers et al., 2021). This includes bidirectional active listening: the audience pays attention to the educator during presentation of information or demonstration of actions, and there is the opportunity for patients and their family members to ask questions, with the nurse actively listening and then answering the questions or clarifying any confusion.

### UNFOLDING CASE STUDY

#### Unfolding Case Study 3: Part 3

Refer to [Chapter 16 Legal and Ethical Considerations](#) for Unfolding Case Study Parts 1–2 to review the patient data. The nurse is caring for a 58-year-old female with metastatic lung cancer who is a patient on the oncology unit of the hospital. The patient's health has been deteriorating for the past few months and she has expressed an interest in discussing palliative care options. Initially, the patient requested her family not be notified about her interest in palliative care; however, she has since changed her mind and her three children are present at the bedside waiting for the palliative care team to make their rounds to discuss her options.

Past Medical History	<p>Patient has been receiving chemotherapy intermittently over the past 2 years. She reports one brief period of remission 6 months ago; however, the cancer returned shortly after.</p> <p><b>Medical history:</b> COPD [chronic obstructive pulmonary disease], 1 pack/day smoker for more than 30 years, GERD [gastroesophageal reflux disease].</p> <p><b>Social history:</b> Three adult children, no known medical conditions. Husband of 35 years passed away 5 years ago in a car accident.</p> <p><b>Family history:</b> Both parents deceased from natural causes.</p> <p><b>No current medications and no known allergies. Last chemotherapy round ended 2 months ago.</b></p>
Nursing Notes	<p><b>1400: Assessment</b></p> <p>Palliative care team arrived at 1230 to discuss options with patient and family. Patient's two daughters were visibly distraught during the conversation and made several comments indicating they would prefer their mother to undergo more chemotherapy in place of palliative care. Patient's son was agreeable to palliative care and stated his support for his mother to make her own healthcare decisions. Patient visibly upset about the situation and stated, "See, this is exactly why I didn't want to get my kids involved!" Patient has requested time to talk with her children and that the palliative care team come by again tomorrow for more discussion.</p>
<ol style="list-style-type: none"> <li>1. Recognize cues: What cues indicate the patient and her family have inadequate learning readiness regarding palliative care options?</li> <li>2. Analyze cues: Is there anything the nurse could consider doing to make the environment more conducive to learning when the palliative team comes back the next day?</li> </ol>	

## 17.2 Methods and Approaches to Learning and Teaching

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the different methods of learning
- Understand the different approaches to teaching
- Recall the methods used for effective teaching

Teaching and learning are dynamic processes of interaction between the educator and learner(s). Three methods or domains of learning have been identified: cognitive, affective, and psychomotor. Although each method is unique, they do not function in isolation; they work in concert with one another. Teaching is approached by focusing on one person at a time or a group of people together. Education also has multiple methodologies, with delivery of content through different means. In nursing, this includes lecture, demonstration, handouts, and simulation. Like the methods of learning, teaching techniques frequently overlap and combine for multimodal delivery and to maximize delivery and retention of content and concepts. This section will move from the “whys” of patient and family education and the “hows” of health promotion through self-care, to methods and approaches to teaching and learning.

### Learning Objectives

There are multiple objectives of learning recognized by psychologists, educators, and nurses, and each focuses on a different component (or domain) of learning. In the process of learning and moving from little or no experience to levels of more understanding, awareness or ability is the expectation of progress and achievement in the academic setting. The three components of learning are: cognitive, affective, and psychomotor.

As a clinical, practice-oriented profession, it is important to understand and use these three domains of learning when developing patient education. is also affected, and as higher levels of cognition (the process of knowing, thinking, perceiving, or understanding) are reached, different feelings and emotions are recognized.

## Cognitive Learning

The process of knowing, thinking, perceiving, or understanding is called **cognition**. Learning based on the process of understanding, or cognition, is called **cognitive learning**. Understanding includes, but is not only, basic knowledge; it encompasses remembering through analysis and evaluation and, ultimately, generation or creation of new information (data, ideas, groupings, and evidence of learning) (Iowa State University Center for Teaching and Learning [hereafter, Iowa State University], n.d.). Within education, the widely accepted categorization of levels of cognitive learning is Bloom's Taxonomy, which was revised in 2001 (Figure 17.2) (Armstrong, 2023). Notably, the original taxonomy included the term "synthesize" in the familiar pyramid diagram as one step higher in cognition than "analyze." The revised version retains the original concepts but changed "synthesis" to "create," and moved it to the pinnacle of the pyramid.

**FIGURE 17.2** Bloom's Taxonomy (original and revised) is commonly illustrated as a pyramid, with levels of thought moving from basic remembering or recall, through creation of new ways of thinking or new conceptual insights. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

At the lower levels of Bloom's Revised Taxonomy, learners recognize and remember vocabulary and concepts, then move to understanding those concepts and then having an ability to make connections (Iowa State University, n.d.). At the next levels of application and analysis, the learner is first able to perform or employ a new task or idea, then to scrutinize it in more detail, with potential to reorganize findings in new ways and with novel considerations. The highest levels of Bloom's Revised Taxonomy involve evaluation and creation, whereby learners are first able to assess and critique thoughts and, ultimately, to develop hypotheses, propose new ideas, and present their own knowledge. These high levels are sometimes referred to as **metacognition**, which is colloquially known as, "thinking about thinking." A more comprehensive definition is that metacognition is an elevated level of thinking that allows comprehension, examination, and command of thoughts and the thinking process.

Cognitive learning is certainly a common focus on which patient education is based, with teaching presented through verbal instruction, essentially using a lecture format. Nurses explain parts of the care plan at various times while providing patient care. This may include describing how a medication works, possible side effects, and concerning adverse effects to be aware of, prior to administering the drug. Or they may include step-by-step

instructions delivered verbally about a dressing change before demonstrating it by changing the dressing. These can be supported by written and visual aids. The supplemental written or visual tools give patients something to refer to after the teaching session, to recall what was taught, and reinforce what is remembered. Educating patients and families may also incorporate the use of affective and psychomotor learning methods as an accompaniment to cognitive learning. More information on these items and concepts appears later in this section, and evaluation of teaching and learning is discussed later in the chapter.

### Affective Learning

Centered on feelings, including attitudes, interests, and values, **affective learning** fosters the ability to recognize and address a person’s own emotions and morals, and one’s aptitude and comfort when facing ethical dilemmas and necessary decisions (Iowa State University, n.d.). Affective learning is associated with feelings typically internalized and not necessarily shared externally. The affective learning domain includes the following subdomains (Peak Performance Center, 2024):

- Receiving: passive awareness of ideas or incidents; open to situations
- Responding: active involvement in learning; aware of and responsive to stimulus
- Valuing: seeing value in something and being able to express its worth; motivation and commitment
- Organizing: an ability to sort and accumulate ideas, values, and materials; makes associations with existing beliefs; invests in prioritized beliefs and values
- Characterizing: actions represent the established, internalized values; able to analyze and describe behaviors and values

These subdomains can be visualized similarly to Bloom’s Revised Taxonomy using a pyramid, representing the process of increasing complexity as a person’s affect internalizes and influences behavior—from the general awareness of receiving, through the total devotion and internal motivation of characterizing ([Figure 17.3](#)) (Peak Performance Center, 2024).

**FIGURE 17.3** The affective domain of learning, as represented in a hierarchical pyramid, with higher levels of affective learning processes as the pinnacle is reached. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

In nursing, affective traits tend to be visible through caring practices seen in interpersonal interactions, particularly with patients and families. Helping patients and families identify and cope with new feelings about changes in health status, limitations to mobility, and pain, are examples of teaching and learning within the affective method of learning. Some techniques used to heighten patients’ affective learning and identify changing, growing affective elements within themselves include journaling, simulation, group discussions, and participation in role-play activities (Iowa State University, n.d.).

### Psychomotor Learning

The development of organized patterns of muscular activities guided by signals from the environment is called

**psychomotor learning.** Coordination is a combination of neurological control and musculoskeletal movement, with development over time, and through learning and doing. In patient education, some tasks are taught through all three learning methods, and psychomotor learning may be the best example of combining them for success (Alqahtani, 2022).

Often, patients are introduced to a diagnosis first through cognitive learning, at which time affective learning is also influenced because something new (perhaps involving an emotional reaction) is confronted. Adjustments to the patient's prior norm can result in new tasks, techniques, and skills for the patient and/or family members.

An example is a patient newly diagnosed with type I DM who must now learn how to use a glucometer, analyze its results, and self-inject insulin. Or, if the patient is a young child, family will need to learn how to perform the tasks. There is important information to be delivered by the nurse through cognitive teaching and learning methods to build an adequate level of understanding of the pathophysiology, current physiological status, and medications. Through psychomotor learning methods, the appropriate people will be taught and demonstrate acquisition of the following skills: glucometer use, read and respond to the appropriate insulin order, and inject the appropriate dose. Details on specific psychomotor teaching methods and evaluation of learning are discussed later in this section and chapter.

## PATIENT CONVERSATIONS

---

### Teaching about Insulin Administration

**Scenario:** The provider has prescribed regular insulin before meals for the patient, Mrs. Lovato, and has provided verbal and written directions about when and when not to inject insulin and how much insulin to inject. The provider has now asked the nurse to teach Mrs. Lovato how to check her glucose and use an insulin pen.

**Nurse:** Mrs. Lovato, I'm Melinda. I've been asked to teach you about checking your blood sugars and how to inject insulin.

**Patient:** Nice to meet you, Melinda. Yes, I need to learn. The doctor was telling me about how I just became diabetic after that infection I had. It's scary how that happened. But now I need to learn how to take care of myself.

**Nurse:** What a great attitude you have. I see you already have your glucometer, or glucose machine.

**Patient:** Yes, I do. I read the manual and think I know how to do this, but I'm glad you'll show me.

**Nurse:** First, I'm going to explain the steps. First, wash your hands, then put one of the strips from the little bottle into the glucometer. Then, take one of the devices with the sharp lancet and prick the tip of your finger. Touch the drop of blood to the test strip so it takes the blood and starts analyzing it. As you wait for the result, you can hold a cotton ball or tissue on your fingertip to stop any bleeding. When the meter finishes its analysis, it will show you your blood glucose level. Now you can take the used test strip out and throw it away. The lancet should go in a container for sharps, like for used needles. With the number from the glucometer, you can look at the directions the doctor gave you about insulin, and determine how much to give yourself. Don't worry, I have this all in a pamphlet for you, so you don't have to memorize the steps.

**Patient:** Oh good. I was so glad the doctor gave me the list of what to do when.

**Nurse:** Let's check your glucose now. This time, I will tell you the steps, and you can concentrate on trying to do them. I'll be right here to help if you need some help at any point.

**Scenario follow-up:** The patient successfully completes the process of checking her glucose, with just a little help getting the lancet to open. Her blood glucose is 172 mg/dL. The nurse now teaches her about her insulin pen.

**Nurse:** Your insulin pen is loaded with the type of insulin the doctor wants you to take. This is a pretty easy device to use: you look at the amount of insulin you need from the note. For 172 mg/dL, you need 3 units, so you dial that in with this, then you take the pen, hold it to the spot you are going to inject, and push this button. These are subcutaneous injections, and you should rotate the sites: you can use your upper arms, thighs, buttocks, and abdomen. Don't use the same place every time; rotate the spots to avoid lumps or deposits of fat.

**Patient:** It sounds easy enough. Let's try this.

**Nurse:** Absolutely!

**Scenario follow-up:** Like the glucometer, the patient demonstrates understanding of the insulin pen by injecting a dose of 3 units as prescribed.

## Approaches to Teaching

Patient-centered care and patient engagement are important inclusions of patient and family teaching. Nurses need to incorporate topics of education that are important to the healthcare team, as well as the patient's (and caregiver's) interests, preferences, and priorities for information, by collaboration and mutual goal setting (Kuipers et al., 2021). Although some teaching moments are captured spontaneously by questions being asked, many times nurses can plan education sessions.

Assessing the audience's capability for learning, learning style, and health literacy is a valuable step for preparation of a teaching session. The patient's physiological condition and availability of family or other members of their support team are also important considerations. Once the nurse knows who will compose the audience—one or more people and who those people are, the nurse is able to better consider other details about approaches to teaching.

## Individual Teaching

One-to-one teaching sessions may be preferred by either the patient or nurse for a variety of reasons (Figure 17.4). When the topic of education is particularly sensitive, for example, teaching only the affected person is often favored. Another example is urgency, when the patient is alone and something must be taught without delay. Sometimes, there is discord between family members and the patient, and patients may request to be the sole recipient of education.

**FIGURE 17.4** Education can take place in many settings, and nurses use different resources to support the content being taught. (credit: modification of "U.S. Army Photo" by Jason W. Edwards/Health.mil, Public Domain)

Additionally, people are likely to have different goals, even when the same diagnosis or procedure is the topic of teaching and learning. Consider multiple patients anticipating knee replacement: different postoperative pain-control drugs and delivery devices may be ordered, so use and understanding of them will vary. Expectations for pain control are similarly variable, and personalized teaching for reasonable goal setting is ideal. One patient may expect, and desire, return to normal function at home, promptly; another anticipates transfer to a rehabilitation

facility to improve strength prior to discharge home.

Teaching one individual allows the nurse to take advantage of the relationship established with the patient. When there is a positive foundation in place, the patient is typically more receptive to education. This is particularly valuable if difficult content, or undesired behavioral change, must be discussed. Individual teaching is probably preferred, for example, for a patient diagnosed with breast cancer. Because the patient is to be taught about caring for an incision and multiple drains as part of the upcoming surgical plan, both the nurse and the patient are apt to prefer a private discussion and the ability to very specifically address concerns of one, rather than several, patients. Personalized instruction also supports ongoing relationships as the patient is more able to participate in the conversation, including freedom to ask questions, and be part of individualized goal setting. There are times when teaching, of necessity or by design, must be implemented in a group setting.

## LINK TO LEARNING

---

The nurse in this video [provides a patient with teaching \(https://openstax.org/r/77PainEducation\)](https://openstax.org/r/77PainEducation) about pain. Watch how the nurse is able to gather information and provide education.

---

### Group Teaching

In certain situations, such as a patient who is unable to make their own healthcare decisions, teaching should include the family or caregivers. Nurses will have to rely on family and/or friends to assist with reinforcing and reminding the patient of new behaviors or forgotten instructions. It is necessary to include these people in teaching whenever possible. Even for people who are independent in decision-making, having another person present for education can be helpful. Individuals understand things differently and may have questions to ask and concepts that need clarification.

## LINK TO LEARNING

---

Watch this video and notice [how the nurse provides care and education after the patient has ambulated \(https://openstax.org/r/77AmbulatnCare\)](https://openstax.org/r/77AmbulatnCare) and the responses of the patient and her husband.

---

Establishing relationships with patients was mentioned as a positive aspect of individual teaching, but connections can also be created between nurses and groups, and the group itself may enhance the dynamic of the education environment. Group teaching may involve a patient and spouse or significant other, or it may be several people with the same diagnosis. Some groups are formal support or interest groups, like members of Alcoholics Anonymous (AA), or a particular cancer survivors' support group. Nurses may need to be more intentional in creating smaller groups within a larger population, but if desired, more intimate groups can be fostered for patients and/or their family members.

Depending on the goals of teaching and learning, group settings may be favored. Cognitive learning, for example, fits well with either individual or group environments, but the final selection may be based on whether several questions are anticipated or there is a psychomotor aspect to be demonstrated and exemplified. Such activities can require extra time, and the physical setting requires visibility of the action to be taught.

Affective learning can be nurtured through group interactions because some of the techniques used to establish and foster emotions, attitudes, and interests include storytelling, role-playing and simulation, and shared discussions. Sharing with others, receiving feedback, and inspiring discussion often results in patients learning and realizing more about their own feelings, and, essentially, how they feel about those emotions and responses. Group therapy relies on the nature of this dynamic for the beneficial outcomes of sharing, interacting, and supporting.

Psychomotor learning lends itself to either setting, depending on the complexity and sensitivity of the skills. Ostomy care, for example, is probably not ideal for a group setting, unless it is being taught initially on manikins. However, patients in a preoperative hip replacement surgery class could be taught as a group about postoperative positioning and use of walkers and other assistive devices. The facilitator's time could be well spent in such a setting, with

demonstration and return demonstration being evaluated during one session.

## Methods of Teaching

Instruction methods can be distinguished as direct or indirect. Both methods are considered effective strategies in education (Lakha, 2023; Renard, 2023). Learning that involves active engagement of the educator and learners is called **direct instruction** (Austin Peay State University, n.d.). The teacher leads the teaching and learning through examples such as lecture, discussions about assigned readings, a question-answer session, or sharing a video. On the other hand, indirect instruction involves learners using learned tools to fulfill an assignment, with limited involvement from the educator (Austin Peay State University, n.d.). Examples of assignments within indirect instruction include reading an assigned article or chapter, submitting an assignment (e.g., presentation or paper), or viewing a recorded lecture.

Educating patients may involve using a combination of indirect and direct instruction, and may make use of multiple learning methods. Patient and family education can be delivered in different ways, including lecture, demonstration, handouts, or simulation. Understanding a patient's learning preferences enables the nurse to have the right delivery method prepared. Preparation provides the best potential for achieving patient care goals.

## Lecture

Lecture is a familiar teaching method and is often seen as an ideal way to deliver high volumes of information. Teachers and learners tend to be familiar with the lecture format, and it brings an inherent feeling of comfort (Baylor University Academy for Teaching and Learning [hereafter, Baylor University], n.d.). Although it is efficient at delivery, it is less efficient at the receiving end, because much of the information is unlikely to be retained (Baylor University, n.d.; Berkeley Center for Teaching and Learning [hereafter, Berkeley], n.d.; Bosnich & Lee, 2022). Verbal instructions may also be misunderstood or quickly forgotten.

One recommendation to make the content more easily understood and retained is to make the lecture more interactive (Baylor University, n.d.; Berkeley, n.d.). Strategies for supplementing a lecture include ensuring the presenter has expertise in the topic being presented, is well prepared for the lecture, and is using an active method of delivery (Figure 17.5). Lectures may also be supported by other teaching methods (Stanford et al., 2019), including diagrams, handouts, videos, moments for discussion and/or question-answer periods, demonstration, or time to work through a case study.

**FIGURE 17.5** When lecturing to a small audience, interact closely with learners, accompanying the verbal lecture with nonverbal gestures and visuals when appropriate. (credit: “U.S. Navy Lt. Cmdr. Suzanne Maldarelli, right, a medical officer, conducts a subject matter expert exchange on advanced cardiac life support with Lissette Recinos, a public health nurse, at a hospital in Toledo 140627-N-XQ474-030” by MC3 Andrew Schneider/Wikimedia Commons, Public Domain)

When nurses are educating patients, there are added components that may influence the retention of information that is presented. Both literacy and health literacy are concerns, because patients may have deficits in reading and general writing abilities. Additionally, those with high levels of literacy may not understand health-specific information. Ensuring that medical terms and concepts are fully defined in plain language prior to delivery of a large amount of information is an important step. Continuing with a simple-to-complex format can be helpful because it allows the nurse to continue to provide a foundation before moving on with more intricate details. In the healthcare setting, enhancing the lecture format with other methods, such as activities and practical applications, can be even more valuable for maintaining patient interest and comprehension.

### Demonstration

Teaching of patients and families often is focused on psychomotor learning. The teacher typically begins by explaining the topic of education (the lecture [cognitive learning] component). At that time, the nurse may supplement with written information (e.g., handouts [cognitive learning]), and demonstration provides a complete illustration of the procedure. Imagine a nurse working with a patient who has a new ostomy and needs to learn how to assess the surgical stoma, as well as perform ongoing care like emptying the bag and replacing appliances, as needed. The nurse first explains the stoma, normal and abnormal findings, appliances, and what is involved in each step of care. At that time, the nurse demonstrates the assessment and procedures, offers a chance for questions if they were not asked during the demonstration, and provides the learner(s) with written and/or video information for review and ongoing reference (Figure 17.6). The patient and/or family member is expected not only to demonstrate the task back to the nurse but reiterate steps and entertain questions while performing the skill.

**FIGURE 17.6** There are multiple steps to ostomy care. This image can be used to aid in teaching a patient how to change the ostomy wafer and bag. (credit: modification of work “Figure 10.17 Application of ostomy appliance” by Pressbooks/<https://pressbooks.bccampus.ca/>, CC BY 4.0)

Either at a scheduled time or when assessment indicates it is time to repeat the procedure, the nurse again welcomes questions and asks the patient (or the individual who will be completing the actions) to provide a return demonstration by explaining and performing the process. Upon completion by the learner, the nurse may ask for clarification and understanding of any part of the return demonstration or critique the process. Questions and reflection by the patient and family at this stage may offer insight into their emotional state (affective learning) and adjustments being made internally relative to feelings and attitudes about the tasks, and their implications. The nurse may need to repeat part or all of the demonstration. As with any new technique, the level of skill should improve with repeated attempts.

### Handouts

Informational handouts are useful for patient and family education (Bosnich & Lee, 2022; Kostie, 2019). Some benefits to handouts are that they can be referred to after the educational session ends and reviewed for clarification. Often, the amount of information being taught quickly is overwhelming to the learner. Even if defined clearly, medical and technical terminology can be confusing. Additionally, printed handouts may include illustrations and diagrams that help support verbal explanations from the lecture style of teaching (Figure 17.7). Visual learners find these features especially helpful. Handouts can also include links for electronic resources, websites for further information, and audio links to hear unusual sounds, informational podcasts, and videos for animations, narrative information, and context.

**FIGURE 17.7** The plate is a nutrition and dietary tool to assist patients with healthy portion size and dietary choices. This tool can be provided to patients as a resource to use when creating balanced meals. (credit: "Start Simple with MyPlate" by U.S. Department of Agriculture, Public Domain)

Written information is not well received by all, especially patients whose reading abilities are extremely limited (Stanford et al., 2019). Therefore, including multiple, complementary ways of teaching for patient and family education is more effective than using one method exclusively (Bosnich & Lee, 2022).

## LINK TO LEARNING

The nurse in this video [instructs a patient and family \(https://openstax.org/r/77WalkerUse\)](https://openstax.org/r/77WalkerUse) on use of a walker. Notice how the nurse incorporates lecture, demonstration, and handouts.

### Interactive Simulation

Simulation can be a valuable teaching method or method to enhance information provided either verbally through lecture or on written handouts. Simulation can be very simple, such as working through a straightforward case study or having a group role-play activity. Case studies can also increase in complexity. In specific laboratory settings for simulation, it may also involve technically advanced, high-fidelity manikins, hospital-like sets, scripts, and/or standardized actors in particular roles and scenarios. No matter the level of fidelity, the educator is involved in facilitating the scenario and ensuring important concepts are identified and resolved or explained.

## LINK TO LEARNING

This [simulation \(https://openstax.org/r/77DMEducation\)](https://openstax.org/r/77DMEducation) demonstrates a nurse educating a patient and his mother about DM. Watch for the nurse's teaching style, what is included in the education, how it is presented, and the inclusion of psychomotor skills, as well as cognitive, informative teaching and learning.

Simulation can incorporate lecture-type verbal teaching with demonstration, through the addition of a realistic scenario that includes the desired educational objectives for the patient and/or family. This allows the learner(s) to see information presented through a varied teaching methodology and practice or demonstrate competence by actions.

### UNFOLDING CASE STUDY

#### Unfolding Case Study 3: Part 4

Refer to [Unfolding Case Study 3: Part 3](#) for a review on the patient data.

Nursing Notes	<p><b>1000: Assessment</b></p> <p>Patient reports her children are agreeable to her decision to pursue palliative care. She expresses interest in receiving care in her own home and that her daughters would like to learn how they can help care for her as well. These requests were passed on to palliative care team who will be back to speak to the patient and family members later this afternoon.</p>
---------------	---

3. Prioritize hypotheses: Which type of learning (cognitive, affective, or psychomotor) do you think is going to be most important during the conversation with the palliative care team and why?
4. Generate solutions: What teaching strategies might the palliative care team use to teach the patient's daughters how to care for their mother at home?

## 17.3 The Nurse's Role in Patient and Family Education

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine how providing patient education meets nursing standards
- Determine the different roles of the nurse for providing patient education
- Recognize essential skills needed to provide effective teaching

Health care is an interdisciplinary effort, with members of the team representing a variety of professions. Each member, from physicians to nurses, varied therapists, counselors, and spiritual representatives, contributes their specific and specialty care. Registered nurses, as care planners and those who spend a great deal of their time in directly caring for patients, are in a natural position to educate patients and their families. It is more than the interaction that places nurses in a position for patient teaching; the nursing standards of practice (ANA, 2021) specify the RN's roles and competencies relative to health teaching, promotion, and prevention of illness.

Patients and families encounter nurses in a multitude of settings, with nurses taking different positions and roles. Each role may involve nurses providing education on different topics, in different ways, and with different goals. Nurses must be able to evaluate teaching and learning to determine its effectiveness and assess a patient's goal achievement.

Nurses need a variety of skills to be effective educators. Behaviors such as approachability, dependability, and flexibility are necessary to establish trust and develop quality relationships with patients and families. Knowledge of the topic to be taught is also essential, enabling the nurse to present information and manage discussion and questions, which may not be possible to anticipate. Perhaps the most important skill for patient and family education is communication. Proficiency in the other teaching skills may be manifested through excellence and clarity in communication.

In this section, how nursing standards are met by patient education will be detailed. Some of the roles played by nurses in the provision of patient education will also be discussed. Finally, the required skills for effective teaching will be explained.

### ANA Scope and Standards of Practice

The ANA Scope and Standards of Practice offers decision-making and practice guidance for professional RN practice. The nursing profession involves a practice scope for RNs, which is expressed as “the who, what, where, when, and why” of nursing roles and professional practice (ANA, 2021, p. 3). Additionally, RNs practicing in any nursing role are expected to adhere to authoritative standards of practice. The standards are broken down into “Standards of Practice,” and “Standards of Professional Performance” (ANA, 2021, p. 4). The distinction is that practice standards relate to competency in nursing practice, whereas professional performance standards reflect professional role competency.

Competence is a key feature of professional nursing practice, and the ANA document defines competencies for each standard. Competencies are listed for RNs, as well as nurses with advanced practice licensure. Professional performance competence is displayed through involvement in leadership activities at the level of the nurse’s education, role, and expertise.

The ANA (2021) recognizes that professional nursing practice is anything but static and, therefore, is subject to change. Clinical and environmental circumstances may also influence how nursing standards apply to a particular situation. Although each standard offers several exemplars, the ANA also recognizes that additional competencies may be realized in certain situations. Health teaching and promotion are specifically addressed in Standard 5B as “the registered nurse employs strategies to teach and promote health and wellness” (ANA, 2021, p. 85).

### Health Teaching and Health Promotion

A holistic, individualized approach to patient and family education is within the RN’s scope of practice and is expected to include health promotion and disease prevention strategies.

Educating patients and their families about their medical and healthcare concerns is both a natural and developed expectation of nursing practice. Health teaching and promotion, Standard 5B, include seven competencies for the RN, as listed in the ANA Scope and Standards of Practice (2021, pp. 85–86): In the areas of coping, adaptability, and resiliency, the RN

- Engages consumer alliance and advocacy groups in health teaching and health promotion activities for health-care consumers.

In the area of healthy lifestyles, the RN

- Provides anticipatory guidance to healthcare consumers to promote health and prevent or reduce risk.
- Provides healthcare consumers with information and education about intended effects and potential adverse effects of the plan of care.
- Provides opportunities for the healthcare consumer to identify needed health promotion, disease prevention, and self-management topics such as self-care and risk management.
- Uses feedback from the healthcare consumer and other assessments to determine the effectiveness of the strategies uses.
- Uses health promotion and health teaching methods in collaboration with the healthcare consumer’s values, beliefs, health practices, developmental level, learning needs, readiness and ability to learn, language preference, spirituality, culture, and socioeconomic status.
- Uses technologies to communicate health promotion and disease prevention information to the healthcare consumer.

These competencies are clear in that health promotion and disease prevention are both critical topics of health education, and various aspects of patients’ lives may be relevant and incorporated into the teaching. As discussed previously regarding health literacy, nurses as educators also assist patients and families to access and comprehend information to make their own healthcare decisions (Healthy People 2030, n.d.).

### Advocacy

In professional nursing practice, advocacy is a process involving support and recommendations for a cause or action

plan (ANA Scope and Standards of Practice, 2021). Standard 8 of the ANA Scope and Standards of Practice (2021) is dedicated to advocacy and states, “the registered nurse demonstrates advocacy in all roles and settings” (p. 91). Following the standard statement, there are 15 advocacy-related competencies, with more listed for graduate-prepared and advance practice nurses. Some examples of these competencies are in the following list (ANA Scope and Standards of Practice, 2021, pp. 91–92):

- Addresses the urgent need for a diverse and inclusive workforce as a strategy to improve outcomes related to the social determinants of health and inequities in the healthcare system.
- Champions the voice of the healthcare consumer.
- Considers societal, political, economic, and cultural factors to address social determinants of health.
- Develops policies that improve care delivery and access for underserved and at-risk populations.
- Embraces diversity, equity, inclusivity, health promotion, and health care for individuals of diverse geographic, cultural, racial, gender, and spiritual backgrounds across the life span.
- Empowers all members of the healthcare team to include the healthcare consumer in care decisions, including limitation of treatment and end of life.
- Promotes self-care, safe work environments, and sufficient resources.
- Recommends appropriate levels of care, timely and appropriate transitions, and allocation of resources to optimize outcomes.

Elements of advocacy apply to professional nursing in provision of patient care in a variety of ways, including

- Assistance with access to care
- Community programs
- Direct patient care and skills
- Ethics committees
- Patient and family education
- Policymaking

Professional nursing education programs include elements of advocacy in courses such as those focused on leadership, management, professional role development, policy, and global perspectives (Regis University, 2023-2024; University of Phoenix, 2023). Exposure to elements of advocacy while in nursing school, at a minimum, introduces these elements and more, so students are at least familiar with the concept of advocacy. Ideally, students begin to make connections during classroom and clinical experiences, realizing some of the places where advocacy is apparent or perhaps where it is lacking. For some, exposure to the concept of advocacy, and realizing at least some of the ways it can be used by nurses, is merely the first taste. Such students are intrigued by and become active participants in advocacy through the National Student Nurses Association and other organizations. This active appreciation for advocacy may continue through a nurse’s professional career.

The healthcare system is often confusing for patients and their families. Education is an important way to assist healthcare consumers as they navigate this large and complicated system. As with diagnoses and direct care, patients and their families tend to function better when they understand their circumstances. Teaching patients about the resources available for any aspect of the system represents advocacy and could include, for example, a Medicaid application or information on how to find safe housing. Referring a family member to appropriate people, departments, or agencies while their loved one is physically incapacitated is another example. As advocates of healthcare consumers, nurses may bring status changes and patient questions to the attention of the physician or advanced practitioner. Or the advocacy role can be reversed, when the nurse advocates to the patient through education, acting as an intermediary between the interdisciplinary team and the patient. Health promotion and disease-prevention-education ideas, plans, and programs can also be considered advocacy, because patients are assisted toward better health and wellness.

### Roles of the Nurse

Nursing is a multifaceted profession, with varied roles in different practice areas and specialties. Regardless of the setting, the importance of education cannot be understated. Nurses, as the healthcare members who spend significant amounts of time with patients, play key roles not only as direct care provider but as teacher, counselor, and evaluator. These three roles are elaborated upon in the next sections.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Prioritize Hypotheses: Discharge Teaching and Pain Control

Mr. Isaacson is being discharged to home after outpatient laparoscopic cholecystectomy. Until this surgery, Mr. Isaacson had no hospitalizations or surgeries, and his medical history includes only hypertension, which controlled with hydrochlorothiazide. Mr. Isaacson has required four 50- $\mu$ g doses of fentanyl since surgery to maintain pain at  $\leq 3$  on a 1–10 scale. Mr. Isaacson is concerned he will become addicted to pain medicine, so he is hesitant to have his wife fill his prescription for home.

The nurse considers Mr. Isaacson's needs for discharge education and prioritizes pain control as top priority, because surgical pain is usually most severe in the first day or two. Because Mr. Isaacson is concerned about the potential for addiction, the nurse first addresses that concern. Then, the patient and his wife are taught about pain, how the pain medicine he has a prescription for works to control pain, and proper use of the medication.

### Nurse as a Teacher

The role of teacher is often a natural one for nurses, and its value cannot be overstated. Patients who are educated about their health, well-being, and illness or injury prevention express increased satisfaction in their healthcare interactions (Bordonada et al., 2020). These patients also tend to participate more in self-care, health promotion, and illness or injury prevention activities.

As providers of direct care and members of the healthcare team who spend much time with patients, nurses can establish relationships with patients and have many opportunities for interaction throughout a shift. Teaching moments present themselves during different activities nurses do with patients. For example, the opportunity may arise while a dressing is being changed and a patient asks questions, or the nurse simply teaches as the task is accomplished by describing the steps and explaining normal versus abnormal findings. Another example would be when the nurse and aide have a patient dangle their legs from a sitting position in bed in anticipation of standing and walking. This is the perfect opportunity to explain why these careful steps must be taken for the patient's well-being. The nurse can then teach the safety features of a gait belt, while putting it on for transfer or ambulation.

Patients and family members tend to be more comfortable when providers clearly communicate with them, and when they understand roles they have in the plan of care. Comprehension of the diagnosis, diagnostic tests, procedures, and recovery all help reduce worry, facilitate adequate pain control, and prevent complications. A patient who is concerned about an upcoming surgery will benefit when nurses can offer repeated preoperative teaching. This can be especially valuable when a patient is in hospital and day and night shift staff nurses can both reiterate teaching topics and ensure the patient and family have all their questions answered.

## REAL RN STORIES

### Successful Coaching

**Nurse:** Margaret, BSN, RN

**Clinical setting:** ICU

**Years in practice:** 5

**Facility location:** Aurora, CO

A colleague (Sara) and I found ourselves working together for our shifts: she worked on days and I worked on nights. In report, she told me our mutual patient, Mr. Hernandez (Mr. H), was scheduled for coronary artery bypass graft surgery the next morning. He was anxious about the surgery and had shared he had a history of general anxiety. Sara began his preoperative (preop) education that day and suggested we “tag team” him with frequent teaching sessions so he would understand as much as possible about the surgery, what to expect postoperatively (postop), and how best to proceed through all the steps involved. We reassured Mr. H that we would be taking care of him for at least the 24 hours after his surgery, so he would have familiar faces and voices when he woke up.

I spent a lot of time in his room, doing his preop preparation, but more importantly just being there, which gave him

the opportunity to ask questions and talk. He wanted to do everything required to do well post-op. Sara and I agreed it was important for him to realize he would remain intubated on the ventilator and his wrists would be restrained throughout the night, which was expected to be somewhat uncomfortable and maybe a little frightening. On the plus side, however, as long as he was hemodynamically stable, the ventilator would allow better pain control.

Through the shifts, we reviewed with Mr. H that the more cooperative he could be, the more quickly things were likely to progress, with extubation anticipated about 6 a.m. When I returned for my second shift, his surgery had gone well: he was back in his room, sedated on propofol, and receiving morphine for pain. Sara reported that when his sedation was lightened for neurologic assessments, he awakened “a bit rough.” With both of us at the bedside before she went home, we woke him up. “Mr. H, you’re in the ICU. Surgery’s over, you’re doing great. Sara and I are both here now.” His eyes popped open, and bounced around, his arms reached up, pulling at the restraints. We could tell when he saw us, though, and remembered what he had been taught. His eyes focused and held, he let his arms drop. He nodded, and as we coaxed him to slow his breaths, he did, and his mouth relaxed around the tube. This was the pattern whenever I wakened him through the night. It was so awesome to see him recall the coaching and will himself to overcome the anxiety. His recovery proceeded exactly as we all hoped: he was extubated by the time Sara returned and up in the chair in time for an ice-chip breakfast.

---

### Nurse as a Counselor

Although nursing degrees do not license RNs specifically as counselors, an element of counseling is often associated with the role of a nurse. Patients facing new limitations, diagnoses, and treatment recommendations are coping with challenges and the need for emotional and physical support, as well as education ([Figure 17.8](#)).

**FIGURE 17.8** Nursing care is a combination of art and science that places nurses in a position to provide counseling and education that address the needs of patients and families with compassion and nursing knowledge. (credit: “Nurse administers chemotherapy” by Rhoda Baer/Wikimedia Commons, Public Domain)

Nurses play an important role in counseling patients and families in primary care with chronic health diagnoses. By addressing concerns such as health literacy, knowledge deficits, acute and chronic illness, and emotional and educational needs, nurses counsel patients in multiple ways. Nurses assess, and assessments of learning needs and preferences, literacy and health literacy, and physical limitations are all well within nursing practice. The relationships established between nurses and their patients and families provides a natural venue for this aspect of nursing care. Counseling, including coaching, advising, and teaching, as well as guiding patients toward techniques for self-care, follows intuitively within professional nursing practice.

### Nurse as an Evaluator

The nursing process includes assessment, analysis or diagnosis, planning, implementation, and evaluation. When presented in this way, the process looks linear, with the evaluation step as the final place on the line. Evaluating the process at completion is based on the assessment findings that led to the diagnosis, the creation of the care plan (e.g., goal setting, planning interventions), and implementation of the interventions. Evaluation is used to determine if goals were met or an identified problem resolved.

However, the nursing process is not linear. It is often represented more accurately as a cycle in which evaluation leads to a continuation of the process, and assessment, once again, starts a new iteration of priorities and actions (Figure 17.9).

**FIGURE 17.9** The nursing process includes the five steps of assessment, diagnosis, planning, implementation, and evaluation in this image in an ongoing cyclical manner. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

In spring 2019, a newsletter from the National Council for State Boards of Nursing (NCSBN) introduced the Clinical Judgment Measurement Model (CJMM). This model provides a more comprehensive approach to the clinical judgment of nursing. Within the model, the evaluation process occurs in the second and third layers and includes both action-taking and outcome evaluation steps (see [Nursing Process](#) and [43.1 Clinical Judgment Measure Model](#)). Whichever model is used, evaluation plays an integral role in determining the accomplishment of goals and outcomes, and guides a return to either assessment or recognition of cues from the component of hypothesis-formation component of the CJMM.

### LINK TO LEARNING

For [more of the NCSBN's description \(https://openstax.org/r/77CJMMDescr\)](https://openstax.org/r/77CJMMDescr) of the CJMM, read the first three pages of the spring 2019 newsletter, followed by the action model.

### Skills Needed for Effective Teaching

As previously introduced, the purposes of patient education include promoting health, preventing disease, restoring function, and facilitating coping and adjustment to the new normal when necessary. To accomplish goals related to patient education, the nurse should understand teaching theories and use them suitably to maximize the effectiveness of the teaching for an individual patient and/or family.

In addition to teaching and learning theories, styles, and strategies, there are skills based on behaviors and the ability for human interactions. These include the ability to effectively communicate and be approachable, knowledgeable, flexible, and dependable. These skills can be found throughout the history of nursing, nursing practice, and nursing education. Florence Nightingale, for example, was knowledgeable, as evidenced by her hands-on approach to nursing care, nursing (and pharmacy) education, and statistical prowess (Lewis, 2020). Watson's

Caring Science and Theory of Human Caring, and implications noted by Gandhi and Mukherji (2023) can also be found within skills for effective teaching. The following sections explore these skills in more depth.

### Effective Communication

The ability to communicate effectively has been a recurring theme in this chapter. Assessment of patients' and families' needs and goals, literacy and health literacy, cultural background, learning preferences, surroundings, comfort, tools needed for the session, and physical status are all considerations for the nurse when planning and implementing education. Preparation for teaching fosters the nurse's ability to effectively communicate by allowing them the time to review any lapse in knowledge, which they can use to optimize the delivery of information. This also permits time for skill review, if the nurse has not recently performed a particular task.

## CULTURAL CONTEXT

---

### Cultural Considerations

Culture influences many facets of a patient's life, including spiritual and religious behaviors and practices, diet and nutrition, communication and displays of respect, and ADLs. If and when time allows, it can be helpful for the nurse to become familiar with cultural practices that are important to each patient and family. Generalizations may cause unnecessary expenditure of time, effort, and education, with teaching focused on a practice not followed by a particular patient. An example is the nurse making an assumption about a patient who belongs to a group noted for having many members who are vegetarians. The nurse plans potential goals and dietary education based on a meatless diet, only to discover that the patient eats fish and chicken.

Even when nurses are familiar with a particular culture, they need to be wary of inherent assumptions based on broad conceptual strokes, which can lead to misunderstandings. When setting educational goals and priorities with patients and their families, perhaps the best method for clarifying cultural practices and preferences is to ask straightforward questions. There may be surprises, and the inquiry can become a pathway to building a positive relationship. The act of asking illustrates an interest and respect for the individual, and actively listening to the replies indicates the specific interests, practices, preferences, and behaviors are important to the nurse.

Another element of effective communication is the ability to discuss necessary information, including medical terminology, procedures, and medications, in lay terms. This can be time-consuming and is similar to translating between different languages. But if patients and families do not have the necessary vocabulary, understanding more complicated concepts will be difficult or impossible, and will ultimately take longer time. Effective communication avoids confusion and establishes and fosters trust between nurses and their patients (Wright, 2021).

Communication should be clear, the volume of speech or audio-visual materials should be adequate, visual enhancement (e.g., closed captioning) should be provided for any audience member with hearing impairment, and communication should be at a level of understanding for the patient and family. Visual impairment should also be considered and accommodated with assistive resources. For example, large print can be used on teaching material. Information should be delivered through varied methods, such as written or video formats. Multiple methods support behavioral, linguistic, and community preferences. All materials should be culturally appropriate. Post-session evaluation of teaching effectiveness should be incorporated through opportunities including questions and answers, teach-back, and demonstration.

### Approachability

Being easy to talk to or interact with is known as **approachability**. Some consider friendliness as akin to approachability. There is a common tendency among those who choose nursing as their career to be caring and compassionate individuals who have a desire to help people and alleviate suffering. These traits commonly associated with nurses and nursing practice have led to nurses being considered approachable by patients even—and perhaps especially—at the most difficult times (Petronio-Coia & Schwartz-Barcott, 2020; Thakur & Sharma, 2021).

Research has explored the influence of smiling on the patients' healing process and revealed that patients felt nurses who smiled were more approachable and caring, which tends to support the synonymous nature of the term friendliness with approachability (Thakur & Sharma, 2021). These welcoming traits help nurses cultivate

relationships and settings that foster effective teaching. This can include teaching moments, spontaneous and scheduled, as well as a safe and comfortable environment for learners to ask questions, make mistakes and learn from them, establish competence with new skills, and demonstrate acquisition of new knowledge and abilities.

## LINK TO LEARNING

---

Explore [Dr. Watson's 10 Caritas Processes \(https://openstax.org/r/7710Caritas\)](https://openstax.org/r/7710Caritas) and consider the characteristics and behaviors of effective teaching and the roles of the nurse. Compare the processes. Where do you think caring intersects with nursing?

---

### Knowledgeable

Nursing relies on conceptual and procedural knowledge. Courses in nursing curricula include focus on both aspects. However, because nursing is a practice discipline, theoretical and didactic classes are not the only approach. Clinical courses are required, offering experiential teaching and learning. Clinicals set in outpatient clinics, mental health and community facilities, and acute care facilities offer students experiences with direct patient care. This provides interactions with patients and their families and friends, opportunities for therapeutic communication, skills practice, and an introduction to patient teaching.

Patients and their families rely upon and trust nurses for personification and practice of both the art and science of nursing. To teach effectively, nurses should have knowledge not only of the specific patient situation, diagnosis, pathophysiology, treatment plan, medications, and procedures, but also some understanding of teaching and learning theories and principles. The patient learning-needs assessment, in addition to frank discussion with the patient and family about literacy, health literacy, and how much they already know and understand, all provide guidance for the nurse on the patient's needs.

To best meet those needs and achieve goals, knowing at least some basics of the different learning theories, including how learning is received and processed, techniques, and implications for the learner(s), allows for individualizing educational interventions. There are five major learning theories: behaviorism, cognitivism, constructivism, connectivism, and humanism, with implications for applying learning theories to both the traditional classroom-and-student scenario and patients ([Table 17.3](#)) (Ghandi & Mukherji, 2023).

Learning Theory	Description	Teacher Implications	Learner Implications
Behaviorism	<ul style="list-style-type: none"> <li>• Stimulus + response = learning</li> <li>• Reward and punishment reinforce knowledge.</li> <li>• Behavior modification from reinforcement of positive behaviors</li> </ul>	<ul style="list-style-type: none"> <li>• Teacher centered</li> <li>• Possess adequate knowledge and provide environment necessary for accurate learner reaction(s)</li> <li>• Provide reinforcement to learner responses.</li> </ul>	<ul style="list-style-type: none"> <li>• Evaluation: measurement of outcome(s) by demonstration of new behavior</li> <li>• Fits with clinical tasks</li> <li>• Feedback and practice develop correct actions and step-by-step skills.</li> </ul>
Cognitivism	<ul style="list-style-type: none"> <li>• Internal information processing</li> <li>• Information reframed with existing knowledge</li> </ul>	<ul style="list-style-type: none"> <li>• Provide organized focus of content.</li> <li>• Experiential reflection</li> <li>• Metacognition</li> </ul>	<ul style="list-style-type: none"> <li>• Learner centered</li> <li>• Fits with didactic course(s)</li> <li>• Acquire and cognitively reorganize new material into one's own knowledge</li> </ul>
Constructivism	<ul style="list-style-type: none"> <li>• Existing knowledge and experiences provide foundation.</li> <li>• New information and ideas + prior experience(s) = learning.</li> </ul>	<ul style="list-style-type: none"> <li>• Facilitate learning.</li> <li>• Provide guidance.</li> </ul>	<ul style="list-style-type: none"> <li>• Learner centered</li> <li>• Fits with didactic and clinical combination course(s)</li> <li>• New learning viewed through prior experiences</li> <li>• Subjective ideas, associations, and conclusions</li> </ul>

**TABLE 17.3** Major Learning Theories and their Implications

Learning Theory	Description	Teacher Implications	Learner Implications
Connectivism	<ul style="list-style-type: none"> <li>• Connections between life (roles, interests, activities) + cognitivism principles + constructivism = network of learning.</li> <li>• Knowledge from individual and locating/reorganization of external information</li> </ul>	<ul style="list-style-type: none"> <li>• Use life experience(s) and networks to identify materials.</li> <li>• Provide guidance to external foci of learning and knowledge for individual incorporation.</li> </ul>	<ul style="list-style-type: none"> <li>• Learner centered</li> <li>• Learning combines internal and external application aspects of a group.</li> <li>• Fits with didactic and clinical combination course(s) and digital learning</li> </ul>
Humanism	<ul style="list-style-type: none"> <li>• Similar to constructivism and theory of adult learning</li> <li>• Freedom and autonomy</li> <li>• Self-actualization as objective</li> </ul>	<ul style="list-style-type: none"> <li>• Little structure</li> <li>• Guide and inspire toward autonomy</li> </ul>	<ul style="list-style-type: none"> <li>• Learner centered</li> <li>• Innate desire for learning</li> <li>• Survival/physical fulfillment of needs results in self-actualization.</li> </ul>

**TABLE 17.3** Major Learning Theories and their Implications

### Flexibility

The nature of nursing requires flexibility: the ability to modify (or change) or be modified. Patient care is very dynamic; physical status can change unexpectedly and quickly, and nurses must act promptly in response. Anticipation of potential alterations to plans and proactive maneuvers are often even more effective than reactive responses. Even when a patient is stable and remains so, other patients can influence the nurse's priorities. Wait times may lengthen, surgery or other procedures may be rescheduled, and personnel may be called to other care areas when more urgent or emergent situations arise.

From the onset of nursing school, students learn to become flexible. Some situational examples that would require the nurse's flexibility are:

- COVID-19 resulted in canceled in-person classes and clinicals.
- Patient assignments can change as patients are transferred to other areas or discharged.
- Patient death
- Patient isolation requirements may prohibit students from direct interaction (e.g. tuberculosis).
- Student or faculty illness and absence

Upon licensing, nursing responsibilities increase from those of students. The ability to leave work on a regular schedule at the end of every shift can change because nurses are considered essential personnel. Nurses have obligations to be relieved by another nurse, and one may have to wait for relief to arrive. Natural disasters and weather conditions may require flexibility; for example, a blizzard may halt traffic in an affected area, and essential personnel may be expected to stay within a designated region for availability.

Other situations requiring flexibility include equipment malfunctions and availability of certain rooms or supplies. As part of a larger multidisciplinary team, nurses and other partners do not always have complementary schedules, so waiting is sometimes necessary for treatments, therapies, or tasks to be completed. Education may be one of the items postponed or rescheduled, or it may need to be modified such that it can be delivered under different circumstances than those originally planned. Discharge teaching, for example, may be delayed while something else of higher priority must be handled first, or it may be provided by another nurse.

If a patient's status has deteriorated and immediate transfer to higher level of care is needed, the focus of teaching changes from detailed to limited, and the importance of follow-up should be highlighted. An example is telling a family member, "Your wife is being transferred to intensive care. I need to call report to the nurse there and get her moved. One of my colleagues will show you to the ICU waiting room, and I'll come talk to you after she's settled into the room there." By providing at least that explanation, family members do not feel forgotten and have some idea of what to expect next.

### Dependability

Being reliable, or trusted, describes **dependability**. Through clear and effective communication, an approachable attitude, a strong knowledge base, reliability, flexibility, and consistency, nurses demonstrate and personify dependability. Effective teaching is strengthened by nurses who are dependable, follow through with expectations, and establish themselves through the combination of actions and words. Patients, families, and interdisciplinary team members rely on dependable nurses, as do other partners in health care. Trust in nurses as dependable professionals fosters strong relationships among healthcare providers, with open communication and collaboration contributing to enhanced patient outcomes.

## 17.4 Evaluation of Teaching and Learning

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe different evaluation methods for teaching and learning
- Understand the importance of analyzing and interpreting evaluation methods

The evaluation step of the nursing process allows nurses to determine whether goals were met using the interventions created. Similar to the nursing process, the education of patients and families must also be evaluated for its efficacy. Without this essential step, there is no way to determine that the teaching session was successful.

It is also important for the nurse to analyze results and interpret how they influence the next steps for the patient. If goals have been achieved, the education on a topic or topics may be concluded. If goals are unmet, however, the process continues with reassessment. Subsequent findings from the patient's updated needs assessment will indicate the need for further education, typically with revisions to the goals, the teaching methods, or both.

### Evaluation Methods

Teaching may take place separate from learning; an educator can present information and concepts, yet learning may not be effective and established goals may not be achieved. Patients and family members may respond to teaching with head nods or smiles, but those reactions could be attempts at being polite rather than a demonstration of actual understanding. Nonverbal responses like nodding or shaking the head may contribute to the evaluation of learning, but specific and objective measures, such as direct observation of actions, demonstration of an acquired skill, verbalization of comprehension, and use of a checklist, offer more reliable corroboration of learning.

#### Direct Observation of Actions

Observing the learner in normal setting for actions and behaviors illustrating learning acquisition is referred to as **direct observation of actions**. There are similarities of this evaluation method with return demonstration and verbalization of understanding, because the nurse is engaged in visual and/or auditory observation of a skill or body of information. Direct observation is different from the other listed methods because the observation is done surreptitiously, or not in such an overt manner as the other evaluation methods.

### REAL RN STORIES

#### Deep Breathe and Cough

**Nurse:** Brian

**Clinical setting:** Neurological-trauma unit

**Years in practice:** 3

**Facility location:** Baltimore, MD

I'd been taking care of a 77-year-old who had fallen down the stairs outside her home; she had a couple of rib fractures and fractures to the right clavicle and wrist. She was pretty bruised up, and she didn't want to take deep breaths because it hurt. We talked about using her incentive spirometer (IS) hourly and how important it was for preventing pneumonia, but she really didn't want to use it. At about 1:30 in the afternoon, her grandson came to visit; he was about 5 years old. I went in the room to take out her lunch tray, and the boy was playing with the IS in his lap. I stood for a minute outside the door and heard him ask her what it was. "Oh that," she said, "it's to keep me from getting sicker. They don't want me to get pneumonia." The boy asked how that would help her not get sick. I listened to her as she described that pneumonia might happen if she didn't take nice, deep breaths, so she was supposed to use the little machine to take deep breaths, 10 times an hour if she was awake. He asked something I couldn't hear, but her answer was that the deep breaths would probably make her cough, and both those things together would keep her lungs working right. Funny: for all her resistance, she really had been listening, and she actually gave her grandson a good explanation of pneumonia and the IS. And she showed him just how deep a breath she was able to take, then she coughed. Her grandson cheered her on for nine repetitions. I dropped off her tray and sat down to document evaluation of her IS teaching by direct observation.

---

Direct observation is frequently combined with checklists as a way to minimize subjectivity and maximize objectivity in observational evaluation (Nayyeri et al., 2021). Checklists provide clear descriptions of criteria for the actions under evaluation. Some direct observations are formalized through a process called **direct observation of procedural skills**, which are particularly helpful for evaluation of step-by-step psychomotor tasks. For patient education, this could be exemplified by a nurse watching a family member changing the patient's wound dressing and listening to the description of the appearance of the wound, incision, and how much drainage is noted in the dressing during the procedure.

It can be helpful to observe that patients are following suggestions they were taught, even when they don't realize they're being watched (Fix et al., 2022). Examples of direct observation include surveying a patient's actions while they are eating a meal and drinking a beverage. This often does not include a formal tool like a checklist, but it is during such activities that the nurse can monitor whether a patient who has been taught careful mastication and swallowing techniques is using those techniques for safety and aspiration prevention. Another example of informal evaluation is watching a patient ambulating with a family member, observing for correct application and use of a gait belt or assistive device such as a cane or walker.

Direct observation of actions may be a valuable method for evaluating literacy or health literacy skills. An example might be a nurse who hears a patient describe their medical diagnosis and related testing that is scheduled, or a parent explaining to a child why there is no breakfast tray on the morning of their surgery. In the next section, return demonstration of skills is explored, which has some overlap with direct observation.

### Return Demonstration of Skills

A patient or family member's ability to demonstrate a psychomotor skill (or multiple skills) after having it presented by the nurse is referred to as a **return demonstration**, which has the patient showcase the ability to complete the task by performing it back to the educator. This evaluation method involves the nurse educating the patient and/or family with a combination of verbal explanation and showing the process of a particular skill. The description and task may be exemplified separately, or the nurse may illustrate the steps of the procedure and simultaneously narrates. After the primary demonstration, the learner is offered an opportunity to ask questions and practice before evaluation of return demonstration.

Mastery varies depending on the complexity of the skill, abilities of the learners, and expectations as to how many teaching and learning sessions required. It is also expected that learners approach a new skill in a linear, stepwise fashion. At different stages, acquisition of a skill may take longer. While putting the pieces together, most learners are not able to multitask by speaking while doing. Asking for a description of the procedure before requesting a demonstration is a common way to approach a task that involves multiple, coordinated actions.

When a patient or family member can demonstrate a newly acquired skill with precision, this is known as **skill acquisition**. The learner can not only correctly perform the skill but do so more rapidly while maintaining accuracy. At this stage, proficiency is being developed. The ability of the learner to not only accomplish the skill properly but do so promptly and to converse at the same time, illustrates full understanding of the task. All three of the learning methods discussed earlier are incorporated into this demonstration. The patient shows an understanding of both

the cognitive and psychomotor processes, the fluency involved in multitasking, and comfort in holding a conversation at the same time—all of which supports the affective component of learning.

### Verbalization of Understanding

Another method for evaluation of teaching and learning is for the learner to verbalize understanding. Asking open-ended questions that require more than one-word answers can illustrate acquisition of learning. Giving patients and family members an opportunity to describe what they comprehend at various intervals provides the nurse with insight about how much they know and understand. Allowing time for questions offers the nurse a chance to determine understanding or confusion about topics that have been taught. Verbalization of understanding may be used as an independent evaluation method or in combination with another method, such as discussion with a patient after a return demonstration.

## PATIENT CONVERSATIONS

---

### Education: A Lot to Swallow

**Nurse:** Mr. Alvarez, I saw you eat breakfast while I was setting things up for your shower. I noticed that since the speech therapist gave you some tips, your swallowing has improved. I didn't see you hesitate between chewing and swallowing, as was happening before. How do you feel about eating and swallowing today?

**Patient:** So much was going on in my brain! Remembering what the therapist said and trying to chew more than I used to. And not to swallow too soon! I was really nervous!

**Nurse:** I know it can be a lot. You have many therapies to think about since your stroke, but you're working very hard to recover! I want you to know, you felt nervous, but you did all the steps the speech therapist told you, and I didn't notice you were nervous.

**Patient:** Thank you. I'm going to try just as hard with walking when I see the physical therapist later.

**Nurse:** Excellent, Mr. Alvarez. I'll plan to watch you walk later and see how you do.

---

The teach-back method is a commonly used technique in health care whereby the patient or family member is asked to repeat, in their own words, the information they received through education. As mentioned earlier, when patients are first presented with new information, they may understand and retain only a portion of it. By asking the patient to recall information and explain it in their own words, the nurse can get a better understanding of what information was retained and what information needs to be retaught or clarified.

## LINK TO LEARNING

---

The teach-back method is an evidence-based intervention used to improve patient–healthcare provider communication and health outcomes. Explore the [Teach-back Toolkit \(https://openstax.org/r/77teachback\)](https://openstax.org/r/77teachback) and how you can incorporate it any time important information is being shared.

---

The use of teach-back in discharge education reduced rates of hospital readmissions and improved patient satisfaction (Yen & Leasure, 2019). Patients also have a higher ability for self-care, greater understanding of their diagnosis, and compliance with their medication and treatment regimen (Yen & Leasure, 2019). Teach-back may also be used in conjunction with return demonstration after the teaching of a psychomotor skill.

## UNFOLDING CASE STUDY

### Unfolding Case Study 3: Part 5

Refer to [Unfolding Case Study 3: Part 4](#) for a review on the patient data.

Nursing Notes	<p><b>1630: Assessment</b></p> <p>The palliative care team has met with the patient and family and addressed all concerns. They all agreed for the patient to be discharged immediately and receive care at home. The patient's daughters were taught how to safely reposition their mother in bed and how to administer her medications.</p>
------------------	---

5. Take action: What evaluation methods might the nurse use to determine whether the teaching provided to the patient's daughters was successful?
6. Evaluate outcomes: What findings would indicate the teaching provided to the patient's daughters was adequate?

### Checklist

Checklists can serve as an independent evaluation or provide documentation of evaluation, such as direct observation of actions, return demonstration of skills, and verbalization of understanding. Checklists can be simple or complex, depending on what is being evaluated. More complicated psychomotor skills, such as those that require multiple steps, a combination of evaluation methods, or illustration of acquisition of a skill in more than one learning domain, require a checklist that reflects the patient's various achievements.

A checklist also helps objectify the evaluation process, which can be valuable for complex skills or processes, which have different levels of achievement and acquisition. Checklists permit the educator-evaluator to make notations for listed skills, as well as levels of performance. Spaces can also be included for initials and/or signatures of both the teacher(s) and learner(s). Space may be allotted for comments, which is helpful when there is the possibility of a note being vague or inconclusive without explanation ([Figure 17.10](#)).

### Analyzing and Interpreting Teaching and Learning

Evaluation also involves analyzing the teaching and learning process to determine whether the teaching was effective and successful. Teaching efficacy is reflected by whether the patient learned what was taught and if the learner's goals were achieved. If evaluation of the data indicates one or more goals set prior to the educational intervention were not met, the care plan may be modified to meet the goals for the patient. This involves reassessing the patient's educational needs, revising patient goals, and revising teaching methods.

### Reassessment of Patient's Educational Needs

Reassessment is key to identifying changing learning interests and priorities, as well as causes for why teaching was successful or unsuccessful. If the educational session was successful, the patient acquired the correct knowledge or skill, and the goals were achieved. When an education session is unsuccessful, reassessment of the patient's educational needs can determine what interventions need to be adjusted to meet education goals. For example, a patient who is unable to complete a return demonstration on how to inject insulin may need another interactive demonstration by the nurse. They may also have a fine motor function deficit that makes it difficult for them to draw insulin into a syringe and so be a better candidate for an insulin pen instead. During reassessment, a nurse can discover unmet needs and adjust the education being given to meet those needs.

### Revision of Patient Goals

There are many reasons why patients' healthcare goals change. Considering the patient's physical and emotional status, the nurse assesses, intervenes, and evaluates continuously while providing patient care. Awareness of changes allows the nurse to understand factors that influence learning. For example, if a patient is anxious or in pain or physiologically compromised, then their mental state is not optimal for taking in new information.

Patient goals can also change based on external factors, such as ambient temperature or environmental distractions. Creating an environment free of distraction to facilitate learning can help set the patient and family up for success with learning. It is important for the nurse to recognize and accommodate changes in the patient's goals and work with the patient to produce goals that meet the needs of the patient, family, and care team. Learning goals and techniques may be affected by a teaching technique that was expected to be successful but was ultimately ineffective for the patient.

### Revision of Teaching Methods

If the patient's goals have not changed but a teaching session was determined to be unsuccessful, it may be worth exploring a revision of the teaching method. Perhaps during assessment of the patient's needs, the patient shared a preference for verbal delivery of information "because I learn best by listening." However, in asking the patient for verbalization of understanding after an explanation of a new medication, it was discovered that much of the information was misunderstood, including the drug's classification, the dose prescribed, and what time of day it should be taken. Through further reassessment, and with additional input from the patient's adult child, the nurse may determine that a combination of verbal information with written information would be more effective. The nurse may revise the teaching method and use a whiteboard and markers, writing the name of the drug, what type of drug it is, the dose, and a drawing of a clock face with the time to take it to offer the patient multiple ways to learn the information.

## Summary

### 17.1 Informed Decision Making and Self-Care

Informed decision-making and self-care have been the focus of this section exploring aspects of patient and family education. The four purposes of health education were identified as health promotion, disease prevention, function restoration, and facilitation of coping and adjustments to health challenges and changes (the “new normal”). Health maintenance and promotion include considerations for an overall more actively involved population of healthcare consumers who have more interest in health promotion and illness prevention. Nurses play a role in promoting adherence to and compliance with health promotion and illness prevention even for patients who are not as invested in their healthcare decisions and actions.

Factors such as health literacy, feelings, and anxiety, and physical influences like pain or limitations influence patients’ adherence to and compliance with treatment and nursing care plans. For those patients whose lives are chronically, drastically, or permanently altered due to illness, injury, or health changes, education by nurses focuses on fostering the best possible outcomes and supporting patients and their families as they learn to cope with changes. Another consideration is motivation, which affects participation in healthcare decisions and potentially all aspects of health care and self-care, including commitment and enthusiasm for learning.

Preventing injuries and illness is another aspect of self-care and health maintenance, and can be influenced by knowledge, skills, and attitudes, as well as other factors, including readiness for learning, learning capabilities, and the environment for learning. These issues all take on a different tone in the specific and often overwhelming world of health care. Nurses engaged in patient teaching should consider these factors and plan teaching accordingly, based on relevance to individual learners.

### 17.2 Methods and Approaches to Learning and Teaching

Methods of learning and teaching are critical considerations when planning and implementing patient and family education. There are three learning methods: (1) cognitive, or learning associated with thinking and understanding; (2) affective learning, or that which is associated with feelings and emotions; and (3) psychomotor learning, which involves the neuromuscular coordination of skills and tasks.

Educators are most effective when different methods of learning and other factors are included. Some of these additional factors include dynamics of the teaching session, such as whether the audience is an individual or a group of learners. It is also helpful for the teacher to be aware, in advance, of setting, materials, and resources like audio-visual equipment. The nurse can be better prepared by knowing as much as possible in advance. Such preparation also allows the educator to individualize the teaching method for the particular audience.

Nurses use a variety of teaching methods, depending on factors like volume and type of information to be delivered, whether the topic includes skill practice and acquisition, setting, and patient preferences. Lecture remains a good method for sharing a lot of information but is more effective when combined with handouts for reference. Demonstration and simulation tend to be better remembered after practice, because they incorporate multiple learning methods.

### 17.3 The Nurse’s Role in Patient and Family Education

Education of patients, families, and communities has a natural role within nursing and is based on the relationships nurses establish with patients and others involved in their care. The relationship between the provision of education and nursing standards is exemplified by Standard 5B, Health Teaching and Health Promotion. Additionally, nurses play an integral role in advocacy, which has been explored in this chapter.

Nurses are trusted professionals, and they fulfill many roles in addition to that of caregiver. Nursing’s Scope and Standards of Practice (ANA, 2021) describes all aspects of nursing practice (“who, what, where, when, and how”), as well as Standards of Professional Practice, which is focused on competency in the practice of the professional nurse. Such practice includes that of the RN and advance practice roles. Additionally, the Standards of Professional Performance center on competency in professional roles, particularly leadership.

Nurses take on the roles of teachers, counselors, and evaluators. How nurses fulfill the obligations of the varied roles of the profession has been explored and exemplified. A variety of skills enables nurses to effectively educate

patients and their families in a multitude of settings. Such skills include being approachable, knowledgeable, flexible, dependable, and effective communicators.

## 17.4 Evaluation of Teaching and Learning

Evaluation, analysis, and interpretation of educational interactions are necessary steps after a teaching session. These processes allow the educator to determine whether learning has occurred, whether the educational interventions were successful, and whether goals have been met.

Evaluation methods, including direct observation, return demonstration, verbalization of understanding, and the checklist, have been described in this final section of the chapter. These methods allow for the objective, structured evaluation of teaching and learning, as well as ways to document the accomplishment or lapse.

Following the evaluation process, analysis and interpretation of the evaluation data are indicated. The findings may prompt reassessment of the patient's educational needs. Depending on assessment findings, revising either the patient's goals or the method used for teaching may be indicated. It can also be possible that both the patient's goals and teaching method need revising. These varied processes and possibilities have been explored and examples provided throughout this chapter.

## Key Terms

**activities of daily living (ADLs)** skills required to perform essential and routine tasks independently for oneself (e.g., bathing, toileting) without assistance

**affective learning** the learning process centered on feelings, including attitudes, interests, and values

**approachability** easy to talk to or interact with

**coercion** persuasion through intimidation

**cognition** the process of knowing, perceiving, thinking, or understanding

**cognitive learning** learning based on the process of understanding

**consent** to agree to and permit (something)

**dependability** reliable or trusted

**direct instruction** active engagement of the educator and learners

**direct observation of actions** evaluation method of observing the learner in the normal setting for actions and behaviors illustrating learning acquisition

**direct observation of procedural skills** evaluation of step-by-step psychomotor tasks

**extrinsic motivation** a willingness to participate in self-care activities when offered a reward

**health literacy** the ability of an individual to locate, comprehend, and use health-related material and make healthcare decisions

**health promotion** improving health

**illiterate** an inability to either read or write

**intrinsic motivation** a drive toward achieving personal pleasure or fulfillment

**learning style** preferred method of learning: auditory, visual, written, or kinesthetic

**literacy** the ability to read and write

**mammography** radiographic examination of breasts

**metacognition** an elevated level of thinking that allows comprehension and examination; higher-order thinking that enables understanding, analysis, and command of thoughts and the thinking process

**psychomotor learning** the development of organized patterns of muscular activities guided by signals from the environment

**return demonstration** evaluation method whereby the patient showcases the ability to complete the task by performing it back to the evaluator

**skill acquisition** acquiring a new skill with precision

## Assessments

### Review Questions

1. A patient is scheduled for surgery, and informed consent is to be obtained. The student nurse is aware of what action as a potential responsibility of the RN?

- a. Describe the procedure in detail.
  - b. Review the risks of the procedure.
  - c. Witness the patient's signature.
  - d. Explain alternatives to the surgery.
2. The concept of health literacy is represented by what description?
- a. find, understand, and use medical information
  - b. an ability to understand a teaching pamphlet
  - c. superior skill accessing internet websites
  - d. advanced university education and degrees
3. What is not associated with a patient's readiness to learn?
- a. post-therapy fatigue
  - b. education level
  - c. extreme pain
  - d. increasing anxiety
4. A patient is scheduled for surgery to start in 30 minutes. After the surgeon met with the patient, obtained informed consent, and left for the operating room, the patient tells the nurse, "I don't think I want to have this surgery. It's so risky, and I still have many questions." How should the nurse respond?
- a. "It's too late now, you've signed the consent form."
  - b. "It will be fine; the doctor has done many of these."
  - c. "Let me call the doctor to address your concerns."
  - d. "I'll call the operating room to cancel the surgery."
5. A patient has scheduled to talk to the nurse practitioner about increasing inability to plan and prepare meals. The nurse distinguishes this as a component of which of the Seven Pillars of Self-Care?
- a. physical activity
  - b. good hygiene
  - c. healthy eating
  - d. risk avoidance or mitigation
6. In anticipation of teaching a large group of learners, a nurse prepares by analyzing journal articles about higher stages of thoughts and thinking. What term distinguishes this concept?
- a. cognitive
  - b. affective
  - c. metacognitive
  - d. psychomotor
7. A nurse has taught a patient's family how to perform tracheostomy suction and daily care. After several practice sessions, the nurse provides a critique. What level of Bloom's Revised Taxonomy does this represent?
- a. creation
  - b. analysis
  - c. evaluation
  - d. application
8. A patient who has had heart failure for a year tells the nurse he tires quickly, and he asks for ways to improve his heart function so he can do more. The nurse establishes what behavior as representing which affective subdomain?
- a. receiving
  - b. responding
  - c. valuing

- d. characterizing
9. A nurse is teaching a patient who rides a motorcycle about the benefits of wearing a helmet when riding. Such education represents which directive of professional nursing practice?
- a. ANA's Social Policy Statement
  - b. NCSBN's NCLEX-RN exam
  - c. ANA's Scope and Standards of Practice
  - d. the state's Nurse Practice Act
10. A nurse is guiding a patient's spouse to assistance available for access to food. This illustrates what nursing role?
- a. counselor
  - b. teacher
  - c. evaluator
  - d. observer
11. A nurse who smiles during interactions with patients and families demonstrates what skill that aids effective teaching?
- a. knowledgeable
  - b. dependable
  - c. flexible
  - d. approachable
12. A nurse notifies the hospitalist about a patient's treatment wishes. What ANA Standard of Professional Practice does this exemplify?
- a. Standard 1: Assessment
  - b. Standard 5B: Health Teaching and Health Promotion
  - c. Standard 8: Advocacy
  - d. Standard 9: Respectful and Equitable Practice
13. A patient has been taught how to use an automated blood pressure cuff and to keep a daily diary. Later in the day, the nurse observes the patient showing a grandchild how to use the device. This is an example of what evaluation method?
- a. verbalization of understanding
  - b. return demonstration of skill
  - c. direct observation of action
  - d. completion of checklist
14. A patient has been taught about the pathophysiology related to a new diagnosis. What method will be most effective to determine effectiveness of the teaching?
- a. checklist
  - b. direct observation
  - c. verbalization
  - d. return demonstration
15. A nurse determines a patient does not understand the use of a glucometer after teaching. To determine next steps, what action should the nurse take?
- a. Reevaluate the patient's glucometer use.
  - b. Ask the patient to describe the use of the glucometer.
  - c. Make changes to the checklist so it is shorter.
  - d. Reassess the patient's learning needs.
16. After teaching a patient how to use an insulin pen, the nurse asks the patient to show the steps and describe

what is being done. What evaluation method is the nurse using?

- a. verbalization of understanding
  - b. direct observation of actions
  - c. return demonstration of skills
  - d. checklist
- 17.** The nurse determines that a patient did not understand teaching about a new medication. What action should the nurse take?
- a. Work with the patient to define new goals.
  - b. Consider a different teaching method.
  - c. Ask if the patient has questions about the medication.
  - d. Document that education was provided.
- 18.** Evaluation of education provides the nurse educator with what piece of important information?
- a. whether the identified problem has been resolved
  - b. information about the patient's learning preference
  - c. critical planning information based on diagnosis
  - d. necessary background about teaching methodology

### Check Your Understanding Questions

1. Describe three ways self-care can affect health promotion and/or illness prevention.
2. Explain at least two benefits of teaching a group of learners.
3. Describe the difference between direct and indirect teaching methods. Include at least two examples of each.
4. Describe the relationship between patient and family education and professional nursing practice.
5. Explain how a checklist can be used as an independent evaluation method.

### Reflection Questions

1. Think about a patient who is struggling with a newly prescribed low-fat, low-salt diet. How can you present the information using different learning styles to improve adherence and compliance?
2. Reflect on affective development you have undergone as you have prepared for and begun nursing school. List at least three methods you plan to use to inspire affective growth and learning in your patients.
3. Reflect on topics and concepts you have learned about during prenursing courses and current courses. Compare with methods of evaluation in this chapter. Which methods have been used to evaluate your learning?
4. Reflect on and compare the evaluation process in providing patient care and in patient and family education.

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study 3: Part 3](#).  
What factors may affect the patient's compliance with and adherence to the treatment plan at home?
2. Refer to [Unfolding Case Study 3: Part 4](#).  
Do you think group teaching is appropriate for this family? Why or why not?
3. Refer to [Unfolding Case Study 3: Part 5](#).  
How could the nurse use a checklist to help the daughters learn to care for their mother?

### What Should the Nurse Do?

A patient's type 2 DM has advanced to require insulin injections.

1. What teaching method should the nurse use to meet the patient's initial cognitive learning needs?
2. The patient has never held a syringe. What cognitive domain should the nurse address to teach the patient to

give an injection?

3. The nurse brings the patient lunch, and the patient asks, “Why do I need to have my blood sugar checked again? My sugars were improving.” What should the nurse do to foster effective learning?

### Competency-Based Assessments

1. A nurse with the Indian Health Service has noticed several community members who were diagnosed with hypertension have not been making or keeping follow-up appointments. The nurse decides to reach out to this patient population with a series of educational videos. Use of which method in the videos is likely to improve self-care and treatment compliance?
  - a. Use standard hypertension handouts written at 10th grade level.
  - b. Include popular celebrity actors in the video.
  - c. Integrate local tribal language(s) into the video’s narration.
  - d. Introduce medical jargon as colloquialisms in the video.
  
2. The nurse preceptor notices the new graduate does not make eye contact and mumbles while explaining drug side effects to a patient. The nurse will discuss a lapse in which effective teaching skill with the new graduate?
  - a. dependability
  - b. knowledgeability
  - c. approachability
  - d. communication
  
3. A patient has had toenail removed in an outpatient surgery setting. There was local anesthetic, and the gauze dressing is clean, dry, and intact. Choose items from the following checklist to include in a teaching plan for the patient.
  - sedation
  - when to make routine appointment
  - incision care
  - go to the emergency department for:
  - type of surgical procedure
  - pain control
  - type of anesthesia used
  - upcoming procedures
  - reasons to call the surgeon
  - new prescriptions
  - length of inpatient stay

## CHAPTER 18

# Leadership and Management in Nursing

**FIGURE 18.1** Nurse leaders and managers play an influential role in achieving positive patient care outcomes. (credit: “Army Reserve surgical nurse answers call to assist in Philadelphia” by Spc. Joshua Cowden/Army Reserve, Public Domain)

### CHAPTER OUTLINE

- 18.1 Concepts of Leadership in Nursing
- 18.2 Concepts of Management in Nursing
- 18.3 Implementing Leadership and Management into Nursing Practice
- 18.4 Certifications for Nurse Leaders and Managers

**INTRODUCTION** Imagine stepping into a role where decisions impact not only patient outcomes but also the growth and morale of your team. Leadership and management in nursing go beyond clinical expertise; they encompass inspiring your team through challenges, innovating care practices, and navigating the complexities of modern health care. This chapter delves into the essence of nursing leadership and management, preparing you to lead with confidence and compassion.

Nurse leaders and managers play a pivotal role in shaping healthcare environments that thrive on teamwork, diversity, and effective communication. It is important to discover strategies to foster a culture of collaboration, in which every team member feels valued and empowered to contribute their best. Through this journey, we aim to equip you with the knowledge and skills needed to transform healthcare settings, enhance patient care, and lead with purpose and integrity.

## 18.1 Concepts of Leadership in Nursing

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the attributes of effective leadership in nursing
- Recognize different leadership styles in nursing
- Describe the goals of nurse leaders

Leadership is a concept that transcends a simple definition, as it embodies a range of behaviors, styles, and qualities that vary greatly across different contexts. At its core, **leadership** involves guiding, influencing, and motivating followers, whether individuals or groups, toward achieving a common goal. It is not merely about holding a position of authority or power; rather, it is about the ability to inspire and drive positive change. Leadership is characterized by vision, decision-making, empathy, and the capacity to foster an environment of growth and innovation. Importantly, effective leadership is not about commanding or controlling but rather empowering and enabling others. Good leadership is vital in any field as it sets the tone and direction of the organization or team, shapes organizational culture and values, and facilitates the achievement of overarching objectives (American Association of Colleges of Nursing, 2024).

In health care, and nursing in particular, leadership takes on a nuanced and critical role. In this setting, leadership is not only about managing resources and coordinating tasks; it is deeply intertwined with the welfare and outcomes of patients. Leadership in health care is about advocating for patient safety, quality care, and ethical practices. It involves navigating the complexities of healthcare systems, policies, and technologies while ensuring that compassionate and competent care remains at the forefront. In nursing, leadership extends beyond the administrative roles to include clinical leadership at the bedside. Nurse leaders play a crucial role in mentoring and supporting other nurses, contributing to professional development, and leading by example in delivering patient-centered care. The impact of leadership in nursing is profound, as it directly influences patient experiences, team dynamics, and the overall effectiveness of healthcare services. Nurse leaders are therefore tasked with a significant responsibility: to uphold the standards of their profession and to continuously strive for excellence in all facets of patient care and team management.

### Leadership Attributes

The American Nursing Association (ANA) identifies eighteen standards of nursing practice; leadership is standard 12 (ANA, 2021). Nurse leaders embody a wide range of attributes and utilize many different competencies to guide, influence, and inspire. The ANA organizes these competencies into three distinct abilities: leading oneself, leading others, and leading the organization ([Table 18.1](#)) (ANA, 2018).

Leading Oneself	Leading Others	Leading the Organization
Adaptability	Communication	Business acumen
Image	Conflict	Change
Initiative	Diversity	Decision-making
Integrity	Employee development	Influence
Learning capacity	Relationships	Problem-solving
Self-awareness	Trust	Systems thinking
Responsibility	Respect	Vision and strategy
Accountability	Mentorship	Project management

**TABLE 18.1** Competencies for Nurse Leaders

## LINK TO LEARNING

---

More about the [ANA's competency model for leadership \(https://openstax.org/r/77ANACcomp\)](https://openstax.org/r/77ANACcomp) is presented at the ANA website.

---

### Commitment to Excellence

In nursing, a commitment to excellence is the relentless pursuit of the highest standards in patient care and professional practice. Nurse leaders with this attribute are unafraid of change and embrace it to improve the quality of care, seeking to implement best practices and refusing to be satisfied with the status quo. They lead by example, demonstrating a strong work ethic and a dedication to continuous learning and improvement, and they inspire the same dedication in their colleagues. A nurse leader might initiate and lead quality improvement projects, advocate for evidence-based practices, or mentor others to enhance their skills and knowledge. This commitment is crucial not just in direct patient care where it translates into better patient outcomes but also in organizational contexts where it fosters a culture of excellence among colleagues and sets high standards for the entire healthcare team.

### Commitment to Profession

Commitment to the profession in nursing goes beyond performing the duties of the job; it is about a deep-rooted dedication to the nursing field and its advancement. Nurse leaders with a strong commitment to their profession are actively involved in professional organizations, stay abreast of current trends and research in health care, and advocate for the rights and interests of nurses and patients. Leaders think systemically, which means thinking not only about how decisions may affect their own career or their own patients' health, but also the well-being of their organization or even the broader healthcare industry. Leaders may be involved in policy-making, participate in professional conferences, or contribute to nursing education. Their influence often extends to community outreach and public health initiatives, where they represent the nursing profession's values and contribute to broader health and wellness objectives.

### Problem-Solving Skills

Effective problem-solving skills are vital for nurse leaders, as they often face complex challenges that require innovative and practical solutions. This involves critical thinking and the ability to analyze situations from multiple perspectives and make informed decisions. A nurse leader with strong problem-solving skills can more efficiently address staffing challenges, resolve conflicts among team members, or develop strategies to improve patient care processes. For example, in response to high patient readmission rates, a nurse leader might analyze the contributing factors and implement targeted interventions to address these issues, demonstrating a proactive and solution-oriented approach.

## REAL RN STORIES

---

### Overcoming Staffing Challenges: A Nurse Leader's Approach

**Nurse:** Aisha, RN, Charge Nurse

**Clinical setting:** Emergency department

**Years in practice:** 12

**Facility location:** Atlanta, Georgia

One evening in our busy emergency department, we faced an unexpected staffing shortage. Two nurses had called in sick, significantly reducing our capacity to manage the usual patient influx. As the nurse manager on duty, I knew immediate problem-solving was essential to maintain patient care standards.

First, I assessed our current resources and patient load. I reassigned roles based on skill set and urgency, ensuring that critical areas were adequately staffed. I also facilitated a quick team meeting, communicating the situation and encouraging a team-based approach to manage the shift effectively.

Realizing the importance of maintaining morale and efficiency, I stepped into a more hands-on role to assist where needed most, setting an example and keeping the team motivated. I also coordinated with other departments to

manage patient flow, facilitating smooth transitions for patients who needed to be admitted.

Despite the initial challenges, our team managed to provide quality care throughout the shift. This experience reinforced the importance of quick thinking, flexibility, and effective communication in managing unexpected situations. It was a testament to the team's resilience and commitment, and it underscored the critical role of nurse leaders in navigating the complexities of healthcare environments.

---

### Trustworthiness and Integrity

Trustworthiness and integrity are foundational attributes for nurse leaders. These qualities mean adhering to ethical principles, being honest, and maintaining a strong moral compass. Nurse leaders with these attributes earn the respect and trust of their colleagues, patients, and the broader community. They set a standard for ethical practice and create a culture of honesty within their teams. For example, a nurse leader might face a situation where an error has occurred in patient care. Demonstrating integrity, they would ensure the mistake is acknowledged, reported, and addressed transparently, prioritizing patient safety and learning from the incident. This approach not only fosters trust among team members but also strengthens patient trust in the healthcare system.

### Accessibility

Accessibility refers to nurse leaders who are approachable and available to colleagues, patients, and other stakeholders. Accessible leaders create environments in which team members feel comfortable seeking guidance, sharing ideas, or voicing concerns. This quality is crucial for collaborative teamwork and effective communication. For instance, a nurse leader could establish regular open-door hours for staff to discuss professional challenges or patient care issues. By making themselves accessible, nurse leaders can better support their teams, facilitate problem-solving, resolve conflicts, and ensure that patient care needs are met efficiently and compassionately.

### Creativity

Creativity in nursing leadership involves the ability to think outside the box and develop innovative solutions to complex healthcare challenges. Nurse leaders who exhibit creativity are adept at adapting to changing circumstances, finding new ways to improve patient care, and leading their teams through uncertain or difficult situations. For example, in response to resource limitations, a creative nurse leader might develop a novel approach to patient care that maximizes existing resources while maintaining high care standards. Similarly, they might lead the implementation of new technologies or approaches to care that enhance patient outcomes and operational efficiency. By fostering a culture of innovation, nurse leaders encourage continuous learning and improvement within their teams while supporting shared governance.

## Leadership Styles

Leadership styles in nursing play a crucial role in shaping the dynamics of healthcare teams and the quality of patient care. Each style comes with its unique approach to decision-making, team interaction, and problem-solving. The choice of a leadership style can significantly affect the work environment, staff morale, and overall effectiveness of care delivery. While some leaders may naturally gravitate toward a particular style, effective nurse leaders often adapt their approach based on the situation, team needs, and specific goals. Understanding and utilizing various leadership styles allows nurse leaders to effectively guide their teams through the diverse and complex situations encountered in healthcare settings ([Table 18.2](#)) (ANA, 2024).

Style	Pros	Cons	Effectiveness
Autocratic	<ul style="list-style-type: none"> <li>• Quick decision-making</li> <li>• Clear chain of command</li> <li>• Clear direction</li> </ul>	<ul style="list-style-type: none"> <li>• Can stifle creativity and innovation</li> <li>• Can negatively affect morale</li> <li>• Promotes dependency on leader</li> </ul>	<ul style="list-style-type: none"> <li>• Can be efficient and effective in a crisis or when needs are urgent</li> <li>• Less effective for collaborative, creative projects</li> </ul>
Democratic	<ul style="list-style-type: none"> <li>• Staff engagement</li> <li>• Encourages diverse input</li> </ul>	<ul style="list-style-type: none"> <li>• Time consuming</li> <li>• Conflicts and disagreement can arise</li> </ul>	<ul style="list-style-type: none"> <li>• Works well when consensus is the goal</li> <li>• Can be used for projects that would benefit from multiple perspectives</li> <li>• Less likely to be effective or practical in emergencies or with inexperienced teams</li> </ul>
Laissez-faire	<ul style="list-style-type: none"> <li>• Autonomy for highly skilled and self-motivated teams</li> </ul>	<ul style="list-style-type: none"> <li>• Can lack a sense of direction</li> <li>• Can lack accountability</li> </ul>	<ul style="list-style-type: none"> <li>• Can work well in creative environments with minimal supervision needs</li> <li>• Less likely to work in teams that need oversight or guidance</li> </ul>
Transformational	<ul style="list-style-type: none"> <li>• Inspiring</li> <li>• Promotes teamwork</li> <li>• Builds a sense of shared vision</li> </ul>	<ul style="list-style-type: none"> <li>• Can be too optimistic</li> <li>• Goals can be “too big” or unrealistic/unachievable</li> </ul>	<ul style="list-style-type: none"> <li>• Can be helpful for organizations ready for change</li> <li>• Less likely to benefit crisis situations or inexperienced teams</li> </ul>
Transactional	<ul style="list-style-type: none"> <li>• Clear rewards and consequences</li> <li>• Efficient</li> </ul>	<ul style="list-style-type: none"> <li>• Can dampen initiative</li> <li>• Does not encourage long-term growth</li> </ul>	<ul style="list-style-type: none"> <li>• Can work well for short-term needs with clear goals or strict compliance requirements</li> <li>• Less likely to help when creativity, innovation, and problem-solving are required</li> </ul>

**TABLE 18.2** Leadership Styles

Style	Pros	Cons	Effectiveness
Servant	<ul style="list-style-type: none"> <li>• Fostering a culture of care, empathy, and community</li> <li>• Can lead to high levels of team satisfaction and patient trust</li> </ul>	<ul style="list-style-type: none"> <li>• It requires a strong sense of selflessness and a commitment to others from the leader</li> </ul>	<ul style="list-style-type: none"> <li>• Can work well for less-structured environments where teams innovate together</li> <li>• Less likely to work well where strict protocols, timeliness, and accuracy are required</li> </ul>
Quantum	<ul style="list-style-type: none"> <li>• Focused more on the individual and value-based decisions</li> <li>• Fosters growth and adaptability</li> </ul>	<ul style="list-style-type: none"> <li>• Can be too theoretical</li> <li>• Hard to measure effectiveness</li> </ul>	<ul style="list-style-type: none"> <li>• Can help when change needs to be made and there is a lot of uncertainty, especially when ethical standards are high</li> <li>• Less likely to work in situations that need a clear structure or process</li> </ul>

**TABLE 18.2** Leadership Styles

### Autocratic Leadership

Also known as authoritarian leadership, **autocratic leadership** is characterized by individual control over decisions with little input from team members. In nursing, this style can be effective in critical situations where quick and decisive action is needed, such as during a medical emergency in an intensive care unit. For example, an autocratic nurse leader might make rapid decisions about patient care during a code blue situation, directing team members clearly and authoritatively to ensure immediate and coordinated action. However, this leadership style can be less effective in noncrisis situations, as it may limit team input and reduce morale. It is important for nurse leaders employing this style to be aware of these limitations and balance authority with team engagement in everyday situations.

### Democratic Leadership

In contrast to authoritative leadership, **democratic leadership** (or participative leadership), involves a more collaborative approach. This style values the input of team members and stakeholders in the decision-making process. In a nursing context, a democratic leader might facilitate team meetings to discuss patient care plans, encouraging input from all members of the healthcare team, including nurses, doctors, and support staff. For instance, when implementing a new patient care protocol on a unit, a democratic nurse leader might gather feedback from the nursing staff, discuss potential challenges, and collaboratively develop an implementation strategy. This approach can lead to higher job satisfaction and a sense of ownership among team members, but it may also require more time to reach decisions compared to more directive styles.

### Laissez-Faire Leadership

Often referred to as a “hands-off” style, **laissez-faire leadership** is characterized by a high level of autonomy granted to team members. In this approach, the leader provides minimal direction and allows staff to make decisions, solve problems, and manage their work independently. (The French phrase *laissez-faire* translates to “allow to do.”) In a nursing context, a laissez-faire leader might empower experienced nurses to lead their own patient care initiatives or research projects within the healthcare setting. For example, in a situation where a nursing team is tasked with developing a new patient education program, a laissez-faire nurse leader might provide the initial goal and necessary resources but leave the planning, design, and implementation to the team. This leadership style can be highly effective in fostering innovation and professional growth, particularly with experienced and self-

motivated team members. However, it may lead to a lack of direction or oversight in less-experienced teams, potentially impacting patient care and team cohesion.

### Servant Leadership

In nursing, **servant leadership** is an approach where the leader prioritizes the needs and wishes of team members above their own. This style focuses on empowering and uplifting others, fostering a culture of care, empathy, and community. A servant leader in nursing actively works to identify and meet the needs of their team members, supporting them in delivering the best possible patient care. For instance, a nurse leader practicing servant leadership might focus on staff development by providing opportunities for further education, mentorship, and career advancement. They likely also advocate for patient rights, ensuring that patient needs and preferences are at the forefront of care decisions. An example of servant leadership could be a nurse manager who collaborates with the staff to redesign shift schedules to better balance workload and reduce burnout, thereby enhancing team well-being and patient care. Servant leadership can lead to high levels of team satisfaction and patient trust, but it requires a strong sense of selflessness and a commitment to the growth and well-being of others.

### Quantum Leadership

A contemporary approach, **quantum leadership** views organizations and their environments as interconnected and constantly evolving. This style is characterized by adaptability, flexibility, and a focus on fostering innovation in response to rapidly changing healthcare landscapes. Quantum leaders in nursing are known for their ability to anticipate changes in health care, such as technological advancements or shifts in patient care models, and adapt their strategies accordingly. For example, a quantum nurse leader might lead the integration of telehealth technologies into traditional care practices, embracing new methods to enhance patient access to healthcare services. This leadership style requires a high degree of vision and the ability to thrive in uncertain or complex situations. It is particularly effective in environments where change is constant, and innovation is necessary for progress (Harrington, 2023). However, since it is a more adaptable process that can change, it may not be helpful in situations that would benefit from a clear, consistent structure or process.

### Transactional Leadership

In nursing, **transactional leadership** is based on a system of rewards and penalties and is focused on maintaining the routine flow of operations. This leadership style is characterized by clear structures and rules, where performance is closely monitored, and feedback is provided in the form of rewards for meeting objectives or corrective actions for failing to meet them. For instance, a transactional nurse leader might implement a reward system for staff who consistently adhere to hand hygiene protocols, thereby promoting patient safety standards. While this approach can be effective in achieving specific short-term goals or in maintaining established protocols, it may not be as effective in environments that require ongoing innovation or high levels of staff motivation and morale; more-experienced staff may chafe and interpret the strictures as a lack of trust in their abilities.

### Transformational Leadership

A style that inspires and motivates team members to exceed their own expectations and capabilities is known as **transformational leadership** and often leads to profound changes in both individual performance and organizational outcomes. In nursing, transformational leaders empower their teams, encourage professional development, and foster a shared vision for exceptional patient care. For example, a transformational nurse leader might inspire the team to adopt a more patient-centric approach to care, leading to improved patient satisfaction and outcomes. They achieve this by modeling the desired behaviors, challenging traditional approaches, and encouraging creative thinking. If successfully implemented, this leadership style is effective in driving significant changes, fostering team development, and creating a strong sense of purpose and commitment within the team. This leadership style places significant reliance on the leader, increasing the risk of burnout, especially if there is a strong resistance toward change from staff members.

### Goals of Nurse Leaders

The overarching goals of nurse leaders extend beyond the management of day-to-day operations. They involve shaping the future of nursing practice and healthcare delivery through strategic planning, team development, and quality improvement. Nurse leaders aim to create a positive impact on patient outcomes, staff well-being, and organizational efficiency. Their objectives are multifaceted and include fostering a supportive work culture, ensuring high standards of patient care, and leading initiatives that adapt to the evolving healthcare landscape. Often, the

nurse leader must be a role model, exemplifying the behavior they want to normalize. These goals require a blend of strategic vision and empathy and a commitment to excellence in both clinical and administrative aspects of nursing (Morganelli, 2021).

### Culture Development

One of the primary goals of nurse leaders is the development of a positive and productive workplace culture. Culture in a healthcare setting encompasses the values, beliefs, and behaviors that characterize how work is done and how staff members interact with each other and with patients. A positive culture is crucial for effective teamwork, staff retention, and high-quality patient care. Nurse leaders play a key role in shaping this culture through their actions, communication, and policies. For example, they might promote a culture of open communication, where staff members feel comfortable sharing ideas and concerns, or they might emphasize a patient-centered approach in all aspects of care. By actively working to create and maintain a healthy workplace culture, nurse leaders can improve job satisfaction, reduce burnout, and enhance the overall performance of their teams.

### Employee Satisfaction

Developing a positive workplace culture directly supports the overall goal of achieving and maintaining high levels of employee satisfaction. Satisfied employees are more engaged, motivated, and committed to providing quality patient care (Goula et al., 2022). Nurse leaders contribute to employee satisfaction by recognizing and addressing the needs and concerns of their staff. This can include offering opportunities for professional development, ensuring fair and adequate staffing levels, and providing support for work-life balance. For example, a nurse leader might implement regular staff meetings or employee satisfaction surveys to address concerns and gather feedback, or they might advocate for resources that support staff well-being, such as access to mental health services. By prioritizing employee satisfaction, nurse leaders not only enhance the morale and retention of their staff but also indirectly impact the quality of care provided to patients.

### Create and Develop New Leaders

A critical goal for nurse leaders is to identify and nurture potential leadership within their teams. The development of new leaders ensures the sustainability and growth of nursing as a profession and fosters a culture of continuous improvement and innovation in healthcare settings. Nurse leaders can achieve this by mentoring and coaching staff, providing opportunities for professional growth, and encouraging the pursuit of advanced education and leadership roles. For instance, a nurse leader might establish a mentorship program within their department, pairing experienced nurses with those showing leadership potential, providing guidance on career development, and offering support in skill enhancement. By investing in the development of new leaders, nurse leaders contribute not only to the individual growth of their staff but also to the advancement and resilience of the nursing profession as a whole.

## REAL RN STORIES

---

### Mentoring Tomorrow's Leaders Today

**Nurse:** Sandra, MSN, RN

**Clinical setting:** Acute care hospital

**Years in practice:** 15

**Facility location:** Portland, Oregon

Throughout my career, I've been passionate about nurturing the growth of future nurse leaders. I believe that part of being a successful nurse leader is the ability to recognize and cultivate leadership potential in others. One of my most rewarding experiences was with a young nurse, Emilio, who joined our team as a new graduate.

Emilio demonstrated a natural inclination for leadership early on. He was proactive, keen to learn, and always willing to go the extra mile for patients and colleagues. Recognizing his potential, I took him under my wing, offering mentorship and opportunities for professional development. We worked on enhancing his communication skills, understanding the nuances of team management, and developing strategies for effective problem-solving.

I encouraged Emilio to lead a project aimed at improving patient education on medication management, a task that involved coordinating with different departments and presenting the project outcomes to hospital leadership.

Through this experience, he honed his leadership skills, gaining confidence and visibility within the organization.

Today, Emilio is a charge nurse and a rising leader in our hospital. He's actively involved in various committees and is a mentor to other young nurses. Seeing his growth and the positive impact he has on the team reaffirms my belief in the power of mentorship and the importance of investing in future leaders. As nurse leaders, we have the privilege and responsibility to guide the next generation, ensuring the continued excellence and evolution of our profession.

---

### Align Behaviors with Facility Values

Aligning staff behaviors with the values of the healthcare facility is another key goal of nurse leaders. This alignment ensures that the team's actions and decisions are consistent with the broader mission and ethical standards of the organization. Nurse leaders can foster this alignment through clearly communicating expectations, role modeling the desired behaviors, and implementing policies and practices that reflect these values. For example, if a facility prioritizes patient-centered care, a nurse leader might implement training sessions that focus on empathy and effective communication skills, ensuring that all team members are equipped to engage with patients in a manner that aligns with this core value. Aligning behaviors with facility values not only enhances team cohesion and efficiency but also contributes to a consistent and high-quality patient experience.

### Communication Liaison

A critical goal for nurse leaders is to serve as an effective communication liaison between various stakeholders in the healthcare environment. This role involves facilitating clear and consistent communication among the healthcare team, patients, and their families, as well as between the nursing staff and higher-level administration. As communication liaisons, nurse leaders ensure that information is accurately conveyed and understood by all parties, which is crucial for coordinated care and decision-making.

For instance, in situations where new policies or procedures are introduced in a healthcare facility, nurse leaders play a key role in explaining these changes to the nursing staff and ensuring their understanding and compliance. They also gather feedback and concerns from the staff and communicate these effectively to the administration, advocating on behalf of both the nursing team and the patients. Nurse leaders also act as intermediaries for patients, ensuring that members of the care team answer the patient's and family's questions, address their concerns, and keep them informed of care plans and progress. This communication is vital for patient satisfaction and for building trust between the patient and the healthcare team.

## 18.2 Concepts of Management in Nursing

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the attributes needed for nursing management
- Describe different management structures
- Identify how to implement and manage change as a nurse manager
- Explain management functions in nursing

In nursing, the concepts of leadership and management are both pivotal yet distinct elements that drive the success and efficiency of healthcare delivery. Leadership, as explored in the previous module, is the practice of guiding, influencing, and motivating individuals or groups toward achieving a common goal. It is about setting a vision, inspiring nurses to strive for excellence, and fostering an environment where each team member can thrive and contribute to patient care and organizational objectives. Leadership focuses on the “why” and “what” of work, emphasizing direction, inspiration, and the broader picture of healthcare outcomes.

Contrastingly, **management** in nursing takes a more structured approach to achieving healthcare goals. It involves the practice of determining what tasks need to be completed to accomplish a particular goal and ensuring all team members complete those tasks effectively and efficiently. Management is concerned with the “how” of work, focusing on planning, organizing, coordinating, directing, and controlling (Greenhalgh, 2023). It ensures that the resources are appropriately allocated, the nursing staff is adequately supported, and the operational aspects of patient care are conducted within established guidelines and standards. While leadership seeks to motivate and engage—often in the service of transformational change—management aims to establish order and consistency through predictable processes and systems (Gavin, 2019).

Understanding the distinction between leadership and management is crucial for nursing professionals. While a nurse leader might inspire their team to adopt new patient care innovations, a nurse manager ensures that the day-to-day operations support these innovations. Both roles are essential in a healthcare setting and require a keen understanding of how to get the best out of a team. Often, effective nurse managers embody qualities of both leaders and managers, blending inspiration with organization to meet the complex demands of modern health care.

### Management Attributes

In nursing management, certain attributes stand out as essential for ensuring that a healthcare team operates smoothly and effectively (Table 18.3). These attributes not only facilitate the accomplishment of tasks and goals but also contribute to a positive and productive work environment. Effective nurse managers possess a blend of skills that enable them to address the multifaceted challenges of healthcare management. Among these, conflict resolution and employee engagement skills are particularly vital, impacting everything from team cohesion to patient care quality.

Skill	Key Points
Conflict resolution skills	<ul style="list-style-type: none"> <li>Identifying root causes of conflict</li> <li>Facilitating open communication</li> <li>Negotiating mutually agreeable solutions</li> <li>Mediating a dispute over patient care priorities</li> </ul>
Employee engagement skills	<ul style="list-style-type: none"> <li>Providing clear communication</li> <li>Recognizing and valuing contributions</li> <li>Offering professional development opportunities</li> <li>Creating an inclusive environment</li> <li>Implementing feedback sessions, celebrating team wins, involving staff in decision-making</li> </ul>
Mentoring skills	<ul style="list-style-type: none"> <li>Guiding and supporting less-experienced nurses</li> <li>Identifying strengths and growth areas</li> <li>Offering personalized advice and feedback</li> <li>Facilitating shadowing, workshops, and coaching</li> </ul>
Decision-making skills	<ul style="list-style-type: none"> <li>Analyzing information</li> <li>Weighing risks and benefits</li> <li>Making choices in support of patient care, staff, and the organization</li> <li>Reallocating staff or resources during a patient influx</li> </ul>
Technical skills	<ul style="list-style-type: none"> <li>Proving proficiency with healthcare technology (electronic health records, medical devices)</li> <li>Demonstrating clinical assessment skills</li> <li>Possessing time management, organizational, and communication skills</li> <li>Troubleshooting technology, guiding staff in new procedures, managing schedules, and facilitating clear communication</li> </ul>

**TABLE 18.3** Nursing Management Attributes

#### Conflict Resolution Skills

Conflict resolution skills are crucial in nursing management due to the high-stress, fast-paced nature of healthcare settings. Conflicts may arise from a variety of sources, including interpersonal disagreements, workload disparities, or differing opinions on patient care. Effective conflict resolution involves identifying the root cause of a dispute, facilitating open communication between the parties involved, and negotiating a solution that is acceptable to all.

For example, if two nurses disagree over patient care priorities, a nurse manager with strong conflict resolution skills might arrange a meeting to discuss each nurse's perspective and mediate a consensus that aligns with the patient's best interest and team capabilities. This not only resolves the immediate issue but also models constructive communication and problem-solving techniques for the team, fostering a culture of collaboration and mutual respect.

## REAL RN STORIES

---

### Harmony in Diversity: A Story of Conflict Resolution

**Nurse:** Priya, BSN, RN, Nurse Manager

**Clinical setting:** Multicultural community health center

**Years in practice:** 8

**Facility location:** Minneapolis, Minnesota

Working in a multicultural clinic in Minneapolis has taught me the invaluable lesson of navigating differences in approach with grace and understanding. A memorable instance of this was when two of my team members, Amina and Lekan, found themselves at odds over patient education methods. Amina, with her straightforward communication style, clashed with Lekan, who preferred using storytelling as a tool for educating patients. This difference in approach led to a palpable tension within the team, affecting their collaboration and, ultimately, patient care.

As the nurse manager, I knew it was crucial to address this conflict promptly. I decided to bring Amina and Lekan together for a discussion. I started by acknowledging the problem but framing it in a positive way: "I understand that both of you are passionate about patient education, but we need to find a way to combine your strengths."

During our meeting, I encouraged both nurses to express their viewpoints and listened carefully to understand the reasons and assumptions underlying each approach. It became clear that both methods had merit, and the challenge was to find a way to integrate them effectively.

Leveraging my conflict resolution skills, I proposed a solution where Amina and Lekan could lead a patient education session together, combining direct advice with storytelling. This approach not only resolved the conflict but also enhanced our patient education sessions, making them more engaging and effective.

Reflecting on this experience, I realized the power of empathy, listening, and creativity in overcoming misunderstandings. It reinforced my belief in the importance of fostering an inclusive environment where diverse perspectives are seen as an asset rather than a problem. This incident was a pivotal moment in my career as a nurse manager, teaching me that leadership is as much about resolving conflicts as it is about guiding and mentoring.

---

### Employee Engagement Skills

Employee engagement skills are equally critical for nurse managers, as engaged employees are more likely to be committed, motivated, and satisfied with their work. Engagement in nursing can influence job satisfaction, retention rates, and ultimately the quality of patient care (Wei et al., 2023). Nurse managers can foster engagement by providing clear communication, recognizing and valuing employees' contributions, offering professional development opportunities, and creating an inclusive work environment that respects diversity and individuality. For instance, a nurse manager might implement regular feedback sessions to understand and address nurses' concerns, celebrate team achievements, and involve staff in decision-making processes related to patient care protocols or department policies. By engaging employees, nurse managers not only enhance team morale but also drive improvements in care delivery and operational efficiency.

### Mentoring Skills

Mentoring skills in nursing management involve guiding and supporting less-experienced nurses to develop their professional competencies, confidence, and career paths. Effective mentorship is crucial for fostering a learning culture within the healthcare environment, enhancing staff retention, and ensuring high-quality patient care. A nurse manager with strong mentoring skills can identify individual strengths and areas for growth among their team members, offering personalized advice, setting achievable goals, and providing constructive feedback. For example,

a nurse manager might pair a newly graduated nurse with a more-experienced nurse for shadowing opportunities, facilitating hands-on learning and professional development. Additionally, by organizing regular career development workshops and one-on-one coaching sessions, nurse managers can inspire their staff to pursue further education and specialty certifications, thereby strengthening the overall skill set of the nursing team.

### Decision-Making Skills

Decision-making skills are indispensable for nurse managers, allowing them to navigate the complexities of healthcare delivery and administrative responsibilities effectively. This involves analyzing information, weighing the benefits and risks of different courses of action, and making choices that best support patient care, staff well-being, and organizational goals. In the context of nursing, decision-making can range from clinical judgments about patient care to operational decisions regarding staff scheduling or resource allocation. For instance, a nurse manager faced with a sudden influx of patients must quickly decide how to redistribute tasks and resources to maintain patient care standards without overburdening the staff. This might involve reallocating nurses from less critical areas or approving overtime work. Effective decision-making ensures that nurse managers can respond swiftly and appropriately to changing conditions, optimizing both patient outcomes and team performance.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Safety: Patient Acuity Change

**Definition:** Reduce the risk of harm to patients through effective, efficient, and competent performance.

**Knowledge:** The nurse manager will create a culture of safety with the nursing staff, allowing them to recognize elevated acuity and care limitations of the unit.

**Skill:** Demonstrate effective communication to the healthcare team to deliver adequate patient care. The nurse manager will do the following:

- Assist nursing staff in notifying the provider for a change in patient acuity.
- Monitor the patient along with nursing staff until the provider arrives.
- Advocate for patient safety with the provider, to facilitate transfer to an upgraded level of care.
- Explain to the patient and family/caregivers what is happening and allow the patient to express any concerns. Provide reassurance to the patient.
- Facilitate transfer to an appropriate unit.
- Assist with the patient transfer, if necessary, or monitor the nurse's other patients while they travel with the patient.

**Attitude:** The nurse manager will value the vigilance and prompt communication of the nursing staff in recognizing a change in patient acuity and advocating for safe and appropriate patient care.

---

### Technical Skills

Technical skills in nursing management encompass both hard skills (technical, measurable abilities acquired through education, training, or job experience) related to healthcare technologies and clinical assessment and soft skills such as time management, organization, and communication. In today's healthcare environment, nurse managers must be proficient in using electronic health record systems, understand the latest medical devices, and stay informed about advancements in patient care techniques. For example, a nurse manager should be able to troubleshoot a malfunctioning patient monitoring system or guide staff in implementing a new telehealth service. Equally important are soft skills (interpersonal and behavioral traits that facilitate effective interactions, collaboration, and adaptability at work), which enable nurse managers to efficiently plan schedules, manage patient information, and facilitate clear and effective communication among staff and with patients. For example, a nurse manager might use project management software to organize team assignments or implement communication protocols to ensure that critical information is shared promptly and accurately. Together, these technical skills are vital for managing the operational aspects of nursing care, leading to innovations in patient services, and enhancing team collaboration.

## Management Structures

Management structure in an organization delineates how decision-making authority is distributed across various levels. In the realm of nursing and health care, understanding the nuances of different management structures is crucial for effective administration and leadership. Two primary management structures are centralized and decentralized (Figure 18.2). Each of these structures has its implications on how decisions are made, how information flows within the organization, and how responsive the organization can be to changes in the healthcare environment. While **centralized management** features a top-down approach, where higher-ranking managers hold the decision-making authority, **decentralized management** adopts a more diffuse approach, spreading authority across various individuals and teams, regardless of their rank within the organization (Mishra, 2021).

**FIGURE 18.2** In a centralized structure, authority moves from higher-ranking to lower-ranking employees. In a decentralized structure, authority is spread across diverse individuals and teams. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Centralized Management

In centralized management structures, decision-making authority is concentrated at the top levels of the organization. This structure is characterized by a clear hierarchy where directives flow from higher-ranking managers down to the frontline staff. In the context of nursing, a nurse manager operating within a centralized structure might receive specific protocols and policies from the hospital administrators regarding patient care standards, staffing ratios, or budget allocations. For example, the implementation of a new electronic health record system would be decided by senior management, with nurse managers then responsible for ensuring their teams are trained and compliant with this system. While centralized management can ensure uniformity and consistency across a large healthcare organization, it may limit the flexibility of nurse managers to make swift decisions based on immediate patient care needs or to innovate based on frontline experiences.

### Decentralized Management

Decentralized management structures distribute authority more evenly across different levels of the organization, empowering a wider range of individuals and teams to make decisions. In nursing, this means that nurse managers and even frontline nursing staff may have more autonomy to develop and implement practices that best meet the needs of their patients and work environment. For instance, in a decentralized management structure, a nurse manager may have the authority to adjust staffing levels or to pilot a new patient care initiative without needing approval from higher up the hierarchy. This approach can lead to increased responsiveness to patient needs, greater job satisfaction among nursing staff due to a sense of empowerment, and more innovative problem-solving. However, it also requires strong communication and coordination to ensure that decentralized decisions align with the organization's overall goals and standards. Furthermore, decentralized structures still require leaders to set the organization's core values and direction and hold teams accountable for their decisions. Table 18.4 lists advantages and disadvantages of each type of structure.

Management Structure	Advantages	Disadvantages	Best Suited for . . .
Centralized	<ul style="list-style-type: none"> <li>Ensures consistency and uniformity across the organization</li> <li>Simplifies decision-making</li> <li>Streamlines policy implementation</li> </ul>	<ul style="list-style-type: none"> <li>Can slow down decision-making due to hierarchical bottlenecks</li> <li>May limit innovation and flexibility at lower levels</li> </ul>	Large healthcare organizations where uniform standards and policies are critical for cohesive operation
Decentralized	<ul style="list-style-type: none"> <li>Empowers frontline staff</li> <li>Increases job satisfaction</li> <li>Encourages innovation and flexibility</li> <li>Enhances responsiveness to patient needs</li> </ul>	<ul style="list-style-type: none"> <li>Can lead to inconsistencies in care and policy implementation</li> <li>Requires strong communication and coordination to align with overall goals</li> </ul>	Smaller clinics or units within a hospital where rapid adaptation and innovation are necessary

**TABLE 18.4** Advantages and Disadvantages of Management Structures

## Implementing and Managing Change

In the dynamic field of health care, change is both inevitable and essential. For nurse managers, being prepared to implement and manage change is not just a skill but a necessity. The healthcare environment is continually evolving due to advancements in medical technology, changes in patient care standards, regulatory updates, and shifts in patient demographics. Each of these changes has the potential to significantly impact nursing teams, requiring adjustments in workflows, roles, practices, and even in the organizational culture itself.

Effective management of change is crucial for maintaining high standards of patient care while ensuring that the nursing team remains resilient, motivated, and cohesive. Nurse managers play a pivotal role in guiding their teams through periods of transition, whether it is adopting new electronic health record systems, shifting to patient-centered care models, or implementing new health policies. Their leadership can make the difference between a team that struggles with change and one that thrives, adapting successfully to new challenges.

### Change Theory

There are numerous theories and models regarding change management that can help nurse managers navigate these transitions (Forbes Councils, 2022). These theories offer insights into the processes of change, strategies for effective implementation, and methods for overcoming resistance. By understanding and applying these theories, nurse managers can respond more effectively to change and also leverage it to improve team performance, enhance patient outcomes, and drive innovation within their organizations. Embracing change as an opportunity rather than a hurdle allows nurse managers to lead their teams with confidence and vision, positioning themselves and their staff for success in a rapidly changing healthcare landscape.

One of the foundational theories is **Lewin's model for change management**, developed by the psychologist Kurt Lewin in the early 1950s (Figure 18.3). Lewin posited that effective change occurs through three intentional steps: unfreezing, changing, and refreezing (Barrow et al., 2022).

1. The unfreezing step involves preparing the organization for change, which may include recognizing the need for change and reducing resistance from team members by communicating the limitations of current practices and the benefits of the intended change.
2. Unfreezing sets the stage for moving, when the actual transition occurs. During this step, change occurs as new processes, behaviors, and attitudes are introduced and adopted by the team.

- The final step, refreezing, involves solidifying the new state as the standard practice. This ensures that the changes are integrated into the organization's culture and operations, thereby preventing a regression to old habits.

**FIGURE 18.3** Lewin's model for change management consists of three stages: unfreezing, changing, and refreezing. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Whereas Lewin's theory focuses on the process of solving a problem, a more recent theory, **appreciative inquiry**, builds from a foundation of what is already working within an organization (Naca-Abell, 2020). Appreciative inquiry engages team members to envision what their organization could be, based on its successes and peak experiences, rather than dwell on what is lacking. This process is structured around four stages: discover, dream, design, and destiny.

- In the discover phase, nurse managers and their teams identify the best of what is currently happening within the organization.
- During dream, the team envisions what the organization might become.
- During design, the team plans and prioritizes actions for turning their dreams into reality.
- Finally, in the destiny phase, the team implements the proposed design, with an eye toward sustaining the changes and celebrating the successes.

### Planned Change

Both Lewin's model and appreciative inquiry are examples of **planned change**, a deliberate, systematic process for introducing transformation into an organization or system. In essence, planned change includes any theory that approaches change proactively, in an intentional, systematic way, rather than reactively. As you have seen, there are many different approaches to planned change, from problem-focused theories such as Lewin's to success-oriented theories such as appreciative inquiry. However, most approaches include the following basic steps:

- First, the organization must recognize the need for change.
- Next, someone must be appointed to lead the change effort, and a team must be assembled.
- Working together, the team must then make several decisions that will drive the change process:
  - What are the goals?
  - What is the current climate within the organization, and how receptive will people likely be to these goals?
  - What approach will likely be most effective at achieving these goals in light of this climate?
- Once these questions are answered, the team is ready to develop and implement a plan for change.
- Finally, the team should evaluate the results of the plan to determine whether the goals were met, whether the reception to change has been positive, and how best to proceed based on these results.

### Resistance to Change

Resistance to change is a natural human response, particularly in high-stress environments like health care, where routines and established practices provide a sense of security and predictability. In nursing, resistance might manifest when introducing new technology, shifting staffing models, or altering patient care protocols. For instance, a nurse manager implementing an electronic health records system might encounter resistance from staff who are accustomed to paper records and wary of the learning curve associated with new software. Such resistance can stem from fear of the unknown, perceived threats to job security, or concerns about increased workload. Understanding the root causes of resistance is crucial for nurse managers to address concerns empathetically and effectively, ensuring a smoother transition to new practices.

### Overcoming Resistance to Change

Overcoming resistance to change involves a combination of communication, education, and support. Clear,

transparent communication about the reasons for the change, its benefits, and its impact on staff can help alleviate fears and build trust. For example, in the case of transitioning to electronic health records, a nurse manager might organize demonstrations to showcase the system's efficiency benefits and patient safety improvements. Education and training are also vital, providing staff with the skills and confidence needed to adapt to new systems or procedures. Furthermore, creating a supportive environment where staff can express concerns, ask questions, and provide feedback on the change process encourages participation and ownership of the change. To foster a positive attitude toward change, nurse managers can recognize and celebrate milestones and successes, reinforcing the value of new practices. By employing these strategies, nurse managers can transform resistance into engagement, leading their teams through change with resilience and optimism.

## Goals of Nurse Managers

Nurse managers play a critical role in healthcare settings, bridging the gap between the administrative and clinical sides of nursing. Their goals encompass a wide range of responsibilities aimed at ensuring the delivery of high-quality patient care, fostering a positive work environment, and maintaining operational efficiency. To achieve these objectives, nurse managers engage in planning, staffing, organizing, directing, and regulating. These foundational management activities enable nurse managers to effectively lead their teams, optimize resources, and navigate the complexities of the healthcare landscape. By setting clear goals in these areas, nurse managers contribute to the overall success and sustainability of healthcare organizations, ensuring high-quality patient care.

### Planning

Planning is the first critical step in achieving the goals of nurse managers. It involves setting objectives for the nursing team and developing strategies to reach these goals within the constraints of available resources. Effective planning requires a deep understanding of the healthcare facility's needs, patient care standards, and capabilities of the nursing staff. For example, a nurse manager might plan to implement a new patient triage system in the emergency department to reduce wait times and improve patient outcomes. This would involve assessing current processes, forecasting future patient flow, and determining the staffing and training needs to support the new system. By carefully planning, nurse managers ensure that initiatives are well-designed, achievable, and aligned with broader organizational goals.

## REAL RN STORIES

---

### The Keystone of Management: My Journey in Mastering Planning

**Nurse:** Aarav, MSN, RN, Nurse Manager

**Clinical setting:** General medical unit

**Years in practice:** 10

**Facility location:** Houston, Texas

As a new nurse manager in a bustling general medical unit, I quickly learned that effective planning is the foundation on which all other management goals rest. Coming into the role, I was eager to make improvements and enhance our unit's patient care quality. However, I soon realized that without a solid plan, even the best intentions could lead to confusion and missed opportunities.

One of my first initiatives involved redesigning the patient discharge process to reduce wait times and enhance patient satisfaction. Initially, the process was haphazard, often causing delays in patient discharge and, consequently, in admitting new patients. Recognizing the need for a systematic approach, I began by mapping out the current discharge process, identifying bottlenecks and areas for improvement. Engaging the team in brainstorming sessions, we developed a streamlined discharge checklist that included predischARGE education, medication reconciliation, and follow-up appointment scheduling to be initiated on admission rather than at discharge.

Implementing this plan required detailed organization, from training staff on the new procedures to coordinating with the pharmacy and outpatient services. The results were significant—not only did our patient satisfaction scores improve, but we also saw a decrease in readmission rates, a testament to the effectiveness of thorough discharge planning.

This experience taught me the undeniable value of planning in achieving management goals. It showed me that by taking the time to plan carefully, we could anticipate challenges, allocate resources efficiently, and ultimately provide better care for our patients. Planning has become my keystone for management, guiding my approach to subsequent projects and initiatives within the unit.

---

### Staffing

Appropriate staffing is another essential goal for nurse managers, who must ensure their team includes the right number of staff with the appropriate skills to meet patient care needs at all times. Effective staffing involves not only recruiting and hiring but also scheduling, developing, and retaining nursing staff. For instance, a nurse manager in a pediatric unit might identify a need for more nurses trained in pediatric oncology due to an increase in patient admissions. Addressing this need could involve hiring new staff with specialized skills or providing existing staff with targeted training opportunities. Additionally, the nurse manager would need to consider the optimal scheduling patterns to cover all shifts adequately while allowing for rest, thereby reducing the risk of burnout. Proper staffing ensures that the nursing team can provide high-quality, continuous care to all patients, reflecting the nurse manager's commitment to excellence in patient care and staff well-being.

### Organizing

For nurse managers, organizing involves the arrangement of resources, staff, and processes to ensure efficient operation and high-quality patient care. Effective organization requires a clear understanding of the department's goals, the roles and responsibilities of each team member, and the resources available. In the context of nursing, organizing might include developing a streamlined process for patient admissions and discharges to minimize delays and improve patient flow. For example, a nurse manager might reorganize the shift patterns to ensure that staff with specific skills are available when most needed, such as having more experienced trauma nurses during peak emergency room hours. Additionally, organizing can involve setting up interdisciplinary teams for complex patient care, ensuring that all necessary specialists are coordinated to provide comprehensive treatment plans. By effectively organizing, nurse managers create a structured and supportive environment that enables staff to focus on delivering the best possible care to patients.

### Directing

Directing involves leading and motivating staff to achieve the healthcare facility's goals. This goal is crucial for nurse managers, as it encompasses guiding the nursing team through daily tasks, addressing challenges, and ensuring that everyone remains focused on providing exceptional patient care. Effective directing requires strong leadership, clear communication, and the ability to inspire and engage team members. For instance, a nurse manager might direct the team through a significant change, such as the adoption of a new policy or procedure, by clearly explaining the benefits, providing training, and offering support throughout the transition. Another aspect of directing is offering regular feedback and recognition, which are key to motivating staff and promoting a positive work culture. Through directing, nurse managers ensure that the nursing team is aligned with the organization's vision and values and that all team members are working cohesively toward common objectives.

### Regulating

Regulating encompasses establishing and enforcing standards and policies to ensure the nursing team's activities align with clinical quality, financial accountability, and regulatory compliance. This goal is vital for maintaining the integrity of healthcare services and ensuring patient safety. Nurse managers play a crucial role in regulating by implementing evaluation systems that monitor performance in areas such as patient care, staff efficiency, and resource utilization. For example, a nurse manager might introduce a quality improvement program that regularly assesses patient outcomes and identifies areas for enhancement, such as reducing hospital-acquired infection rates. Additionally, regulating involves ensuring financial accountability by managing budgets effectively, optimizing resource use, and justifying the need for additional resources or staff when necessary. Through careful regulation, nurse managers ensure that their departments not only meet but exceed the standards set by healthcare authorities and accreditation bodies, thereby upholding the organization's reputation and commitment to excellence in patient care.

## 18.3 Implementing Leadership and Management into Nursing Practice

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine the nurse manager's and leader's role in patient care coordination
- Recognize how nurse leaders and managers delegate patient care
- Identify how nurse managers and leaders can provide support for professional development

In the multifaceted world of health care, the roles of nurse managers and leaders extend far beyond administrative duties, deeply influencing patient care and the professional growth of their teams. This module delves into several critical areas where nurse managers and leaders make a tangible impact: the coordination and delegation of patient care and the support of nursing staff as they pursue professional development. Understanding these areas is essential for ensuring that patient care is seamless, holistic, and of the highest quality.

### Patient Care Coordination

Organizing a patient's healthcare needs across providers, settings, and time is called **patient care coordination** and is a cornerstone of effective healthcare delivery. Care coordination ensures that patients receive comprehensive and cohesive care tailored to their individual needs. For nurse managers and leaders, this involves a proactive approach to organizing and overseeing all aspects of a patient's care journey, from admission to discharge and beyond. It includes the strategic use of interdisciplinary referrals and the meticulous management of cases, especially for patients with complex health conditions. Effective care coordination leads to improved patient outcomes, enhanced patient satisfaction, and a reduction in unnecessary hospital readmissions (NEJM Catalyst, 2018). It demands clear communication, collaboration among healthcare professionals, and a deep understanding of each patient's unique healthcare needs.

### LIFE-STAGE CONTEXT

---

#### Care Coordination: Older Adults

While care coordination is important for patients of all ages, it's particularly important for older adults. It's not uncommon for older patients to have multiple chronic health conditions, be prescribed one or more medications, and have more than one provider managing their care.

When acute medical needs are added to their chronic needs, such as in the case of an injurious fall or serious infection, the coordination of care can have a significant effect on outcomes. In some cases, it may even be a matter of life or death.

Older adults may also have physical and cognitive limitations that must be factored into their care planning, such as the need for transportation or caregiver assistance. For these patients, coordination of care is not just among providers but also includes allied healthcare professionals, community resources, and family members. Recent research suggests that older adults who experience better care coordination were also more satisfied with the healthcare services that they receive (Eastman et al., 2022).

---

#### Interdisciplinary Referrals

A critical component of patient care coordination, **interdisciplinary referrals** allow for a holistic approach to health care. When a primary care provider identifies a need beyond their expertise or resources, best practice is to refer the patient to a specialist to address specific health issues (Morris et al., 2021). For nurse managers and leaders, facilitating an interdisciplinary referral involves ensuring that it is appropriate, that the specialist has all the necessary information to provide targeted care, and that there is a seamless communication loop between all parties involved, including the patient. For example, a patient with heart failure may require a referral to a cardiologist at an advanced heart failure center. Many healthcare facilities utilize an electronic medical record (EMR) system, enabling practitioners to electronically submit interdisciplinary referrals. The nurse manager plays a role in facilitating this process for the primary care provider. This involves ensuring that the patient's EMR is transmitted to the cardiologist, scheduling appointments as necessary, and educating the patient about the significance of the appointment with the specialist.

### Case Management Duties

The role of a **case manager**, often fulfilled by a nurse, is integral to patient care coordination, particularly for patients with chronic illnesses or long-term conditions. Case managers assess patients' needs, develop personalized care plans, and coordinate the various services and resources required to implement these plans. They act as advocates for the patient, navigating the healthcare system to ensure timely access to necessary treatments and interventions. Moreover, they monitor the patient's progress and adjust care plans as needed, in consultation with other healthcare professionals and the patient themselves (Western Governors University, n.d.). For instance, a case manager working with a patient with congestive heart failure would coordinate care among cardiologists, dietitians, physical therapists, and home health services, ensuring that all aspects of the patient's care are addressed in a cohesive and integrated manner. Nurse managers and leaders support case managers by providing the necessary resources, guidance, and leadership to ensure that comprehensive, patient-centered care is delivered efficiently and effectively.

### Delegating Patient Care

As discussed in [15.4 Nursing Standards of Delegation](#), **delegation** is the act of requesting staff members to perform tasks or procedures that are outside of their normal job but within the limits of their job description (ANA, 2013). Per the National Guidelines for Nursing Delegation, staff members who can accept delegated tasks are unlicensed assistive personnel (UAP), which includes nursing assistants, patient care technicians, and other assistive personnel. Depending on the nurse's role and position, they may also delegate or transfer patient care to other RNs (ANA-NCSBN, 2019). The delegating nurse always retains accountability, or responsibility, for the delegated task and therefore is functionally a manager of the delegatee, regardless of their actual title. So it is especially important for nurse managers and leaders to know exactly how delegation does and does not work.

### Knowledge of Scope of Practice

Recall the five "rights" of delegation ([Table 18.5](#)), which were also discussed in [15.4 Nursing Standards of Delegation](#). To ensure all these rights are upheld, nurse leaders and managers must know the scope of practice of all potential delegates and ensure all staff also understand the scope of practice of their coworkers. As discussed in [1.3 Nursing as a Profession](#), **scope of practice** refers to the defined limits and parameters within which a professional within a particular field is authorized to work, make decisions, and provide services (ANA, 2021). Nurse leaders and managers also have the task of promoting teamwork and building a supportive environment where nurses are empowered and confident in delegating appropriate tasks, and UAP are receptive to receiving tasks (Campbell et al., 2020).

Right	What the Right Entails
Right task	The task must be appropriate for delegation.
Right circumstance	The circumstances must be appropriate for delegation.
Right person	The individual must be able to perform the task.
Right communication	The instructions regarding the task must be clear.
Right supervision	The individual performing the task must be properly supervised.

**TABLE 18.5** Rights of Nursing Delegation

### Determination of Clinical Ability

The determination of clinical ability is a critical aspect of delegating patient care, requiring nurse managers to assess the skills and competencies of their team members accurately. This involves not just a general understanding of each team member's qualifications and experience but also an ongoing evaluation of their performance and professional development. When determining clinical ability, nurse managers must consider the following:

- The complexity of the care needs of the patient and whether the staff member has demonstrated proficiency in similar tasks.

- The staff member's current workload and the potential impact of additional responsibilities on their ability to deliver safe, quality care.
- The need for, and availability of, additional training or support to equip the staff member with the skills needed to perform the delegated task successfully.

For example, before delegating a task such as wound care for a patient with diabetes, a nurse manager would need to assess whether the UAP has the requisite knowledge of diabetes management and wound care principles and the ability to recognize and report signs of infection or other complications. This might involve reviewing the assistant's training records, observing their performance in related tasks, or arranging for a more-experienced nurse to provide mentorship and oversight initially. By carefully assessing clinical competency, nurse managers ensure that delegation enhances patient care without compromising safety or quality.

## Supporting Professional Development

Supporting professional development is a key responsibility of nurse managers and leaders, essential for nurturing the growth of nursing staff and ensuring high standards of patient care. Through professional development, nurses can enhance their knowledge, skills, and competencies, adapting to the evolving demands of health care. Effective strategies for supporting professional development include mentorship, preceptorship, engagement with professional organizations, and continuing education (CE). By investing in the professional growth of their team, nurse managers not only improve individual nurse performance but also contribute to the advancement of the nursing profession as a whole.

## LIFE-STAGE CONTEXT

### Age-Related Considerations for Nurse Leadership

Age-related considerations are important in nursing leadership and management, as “generation gaps” can influence how leaders at different life stages interact with their teams, address the needs of patients across different age groups, and navigate generational differences in the workplace. Here are some key age-related considerations for nursing leadership and management, both for nurses and staff as well as patients:

- **Generational diversity:** Nursing leaders and managers should recognize and appreciate generational diversity within their teams. They should understand the characteristics, values, and communication styles of different generations, such as baby boomers, Generation X, millennials, and Generation Z, and be flexible in their leadership approaches.
- **Mentorship and succession planning:** Nursing leaders play a crucial role in mentoring and developing the next generation of nurse leaders. They should provide opportunities for younger nurses to gain leadership experience and offer guidance and support as they progress in their careers. Additionally, nursing leaders should engage in succession planning to ensure continuity of leadership and knowledge transfer as experienced nurses retire or transition out of leadership roles.
- **Age-friendly care:** Nursing leaders should promote age-friendly care practices that address the unique needs and preferences of patients across the life span. They should ensure that staff are trained in age-specific care protocols, such as pediatric care, adult care, and geriatric care, and that care environments are designed to accommodate the physical, cognitive, and psychosocial needs of patients of all ages.
- **Work-life balance:** Nursing leaders should be mindful of the work-life balance needs of nurses at different stages of their careers and life. They should facilitate flexible scheduling options, support policies for parental leave and caregiver responsibilities, and promote wellness initiatives that address the physical and emotional well-being of staff members across different age groups.
- **Technology adoption and digital literacy:** Nursing leaders should recognize variations in willingness to adopt technology and overall digital literacy among nurses of different ages. They should provide training and support to help older nurses adapt to new technologies and digital healthcare platforms, while also leveraging the technological skills of younger nurses to enhance workflow efficiency and patient care delivery.
- **Continuing education and professional development:** Nursing leaders should support lifelong learning and professional development opportunities for nurses of all ages. They should encourage staff to pursue continuing education, certification programs, and advanced degrees to stay abreast of current practices and

advance their careers.

- Retirement planning and transition support: Nursing leaders should provide resources and support to nurses nearing retirement age to help them plan for the transition out of the workforce. This may include access to financial planning services, retirement seminars, and opportunities for phased retirement or mentorship roles.

By considering these age-related factors, nursing leaders and managers can create inclusive, supportive work environments that foster collaboration, innovation, and high-quality patient care across all age groups.

---

### Mentorship

Mentorship plays a vital role in the professional development of nurses, offering guidance, support, and knowledge-sharing that can significantly impact a nurse's career trajectory. A **mentor** is an experienced practitioner who serves as a role model, adviser, and advocate for a student or less-experienced colleague, facilitating their professional and personal growth. This relationship can help the mentee navigate the complexities of the healthcare environment, develop critical thinking and decision-making skills, and set and achieve career goals. For instance, a mentor might help a new nurse develop confidence in patient interactions, provide feedback on clinical skills, or offer advice on balancing work and continuing education. Effective mentorship creates a supportive learning environment that encourages curiosity, innovation, and excellence, enhancing the overall quality of care provided to patients (ANA, n.d.-b).

### Preceptorship

Preceptorship is another key component of professional development, focusing on the practical application of nursing skills and knowledge in clinical settings. A **preceptor** is a licensed professional who coaches and supervises students or new nurses during their clinical rotations, providing hands-on learning opportunities, real-time feedback, and evaluation. This one-on-one relationship allows the preceptee to gain valuable clinical experience under the guidance of an experienced nurse, bridging the gap between theoretical knowledge and practice. For example, a preceptor working in a critical care unit might guide a nursing student through the process of monitoring a patient's vital signs, interpreting data from medical equipment, and responding to emergent situations. Through preceptorship, novice nurses learn to apply their knowledge confidently and competently, preparing them for independent practice and contributing to their professional competence and growth (Baylor University, n.d.).

In nursing, preceptors differ from other guidance roles such as mentors, coaches, and supervisors. A mentor is a trusted individual who provides long-term guidance on the nurse's career and professional development. Coaches help nurses work on specific performance improvements by asking questions that promote reflection and problem-solving. Supervisors oversee the nurse's day-to-day work activities by ensuring adherence to policies, evaluating performance, and encouraging staff accountability.

### Professional Organizations

As discussed in [1.2 Nursing Education Programs](#), professional nursing organizations are collective bodies formed by nurses to represent and advocate for the interests of the nursing profession. These organizations play a crucial role in supporting the development of nurse leaders and managers and provide numerous resources and opportunities for professional growth and networking.

Professional nursing organizations offer educational programs, conferences, and workshops designed for nurse leaders and managers. These events typically cover topics such as leadership development, healthcare administration, policy and advocacy, as well as the latest trends and best practices in nursing management. Nurse leaders and managers can enhance their knowledge, skills, and competencies by attending these events, particularly if they want to learn how to more effectively lead and manage their teams, drive innovation, and navigate the challenges of the healthcare industry. Examples of the benefits of being part of and active in a professional nursing network include the following:

- Networking opportunities: Nurse leaders and managers gain access to a broad network of peers and mentors through professional associations. Networking events (virtual and in person) facilitate the exchange of ideas, sharing of best practices, and collaborations between professionals that can influence policy and practice on a much larger scale.
- Continuing education and professional development: Many nursing organizations offer workshops, seminars, and conferences throughout the year that are designed to enhance nursing leadership skills. These

educational opportunities help nurses stay current regarding the latest trends, innovations, and regulations in health care, and give them the knowledge they need to remain competent and competitive in their field. Many professional nursing organizations also provide specialized certifications and credentialing programs for nurse leaders and managers. Examples of these certifications are discussed in previous sections (e.g., NE-BC, NEA-BC, CNML, CENP).

- **Advocacy and influence:** Nurse leaders who are part of professional organizations are well positioned to become advocates for changes in healthcare policy, nursing practice, and patient care standards. Professional bodies often have the resources and political influence necessary to successfully lobby for legislative changes that can significantly affect the nursing profession and healthcare delivery systems.
- **Research and resources:** Access to cutting-edge research and a wealth of academic resources, including case studies, white papers, and evidence-based practice guidelines, supports nurse managers with learning about and implementing effective patient care strategies and operational improvements within their organizations.
- **Leadership and volunteer opportunities:** Participating in committees or holding office within these organizations gives nurse leaders the chance to develop critical management and decision-making skills. These roles provide them practical experience in leading diverse teams and projects, significantly enhancing their leadership capabilities and helping them feel more confident and at ease in leadership roles.
- **Recognition and awards:** Professional organizations often recognize outstanding contributions to the nursing field by giving awards and acknowledgments. This type of public recognition not only bolsters an individual's career but also highlights the critical role that nurse leaders play in advancing health care.

Nurse leaders and managers may also choose to take on various roles within these professional organizations, such as serving on boards or committees, presenting at conferences, or contributing to research and publications.

Examples of these roles may include the following:

- **Committee membership:** Serve on committees that focus on ethics, practice standards, education, and policy, providing strategic direction and making pivotal decisions that shape the profession.
- **Mentorship programs:** Lead mentorship initiatives to prepare less-experienced nurses for future leadership roles, enhancing the profession's overall strength and sustainability.
- **Policy development:** Engage in policy development efforts that directly influence clinical practices and healthcare outcomes.
- **Educational speaker:** Serve as speakers or panelists at professional conferences, sharing knowledge and innovations that can educate and inspire other nursing professionals.

By actively participating in these organizations, nurse leaders can enhance their professional development and contribute to the advancement of the nursing profession as a whole. [Table 18.6](#) lists some of the major national and international nurse leadership organizations and their respective missions, highlighting the diverse resources and opportunities available to nurse leaders and managers.

Organization	Mission
American Academy of Nursing	"The American Academy of Nursing's mission is to improve health and achieve health equity by impacting policy through nursing leadership, innovation, and science." (AAN, n.d.)
American Association of Colleges of Nursing	"As the collective voice for academic nursing, AACN serves as the catalyst for excellence and innovation in nursing education, research, and practice." (AACN, 2024)

**TABLE 18.6** Professional Nursing Organizations for Nurse Leaders and Managers

Organization	Mission
American Nurses Association	<p>“ANA exists to advance the nursing profession by:</p> <ul style="list-style-type: none"> <li>• Fostering high standards of nursing practice;</li> <li>• Promoting a safe and ethical work environment;</li> <li>• Bolstering the health and wellness of nurses; and</li> <li>• Advocating on healthcare issues that affect nurses and the public.” (ANA, n.d.-a)</li> </ul>
American Organization for Nursing Leadership	<p>“Transform health care through expert and influential nursing leadership.” (American Organization for Nursing Leadership, 2024)</p>
Association for Leadership Science in Nursing	<p>“ALSN is an international nursing organization celebrating its members unique contributions to nursing leadership science.” (ALSN, n.d.)</p>
International Council of Nurses	<p>“ICN’s mission is to represent nursing worldwide, advance the nursing profession, promote the wellbeing of nurses, and advocate for health in all policies.” (ICN, n.d.)</p>

**TABLE 18.6** Professional Nursing Organizations for Nurse Leaders and Managers

Additionally, each nursing specialty has its own professional organization, such as the Academy of Medical-Surgical Nurses, the Emergency Nurses Association, and Society of Pediatric Nurses. Most states also have multiple professional organizations, in addition to a **board of nursing (BON)**, which oversees the practice of nursing within that state.

### Continuing Education

A cornerstone of nursing practice is **continuing education (CE)**. By participating in ongoing educational activities, nurses remain at the forefront of medical knowledge, technological advancements, and best practices in patient care. Continuing education is essential for personal and professional growth. These activities can range from workshops, seminars, and conferences to online courses and academic programs, all designed to keep nursing professionals informed and competent in their practice.

For nurse leaders and managers, supporting and encouraging CE is crucial for fostering a culture of lifelong learning within their teams. This support can manifest in various ways, such as providing time off for staff to attend CE events, offering reimbursement for educational courses, or organizing in-house training sessions on emerging healthcare trends. For example, a nurse manager might coordinate a series of workshops on the latest evidence-based practices in wound care, enabling the nursing staff to update their skills and apply new techniques to improve patient outcomes.

Moreover, CE is not only about enhancing clinical skills but also about developing leadership, communication, and critical thinking abilities that are vital for effective nursing practice. It prepares nurses to adapt to changes in healthcare delivery, meet the challenges of modern nursing, and take on advanced roles within the healthcare system. By prioritizing CE, nurse managers and leaders ensure that their teams are not only competent but also confident and innovative, contributing to the overall excellence in healthcare services.

## CULTURAL CONTEXT

### Cultural Considerations for Nurse Leadership

Cultural considerations are crucial in nursing leadership and management, as they influence how health care is delivered, how teams function, and how patients experience care. Here are some key cultural considerations related to nursing leadership and management:

- Diversity, equity, and inclusion: Effective nursing leaders recognize and value diversity among their staff and patient populations. They promote a culture of inclusivity where all individuals feel respected, supported, and empowered to contribute their unique perspectives and talents.
- Cultural competence: Nursing leaders and managers should possess cultural competence—the ability to understand, communicate with, and effectively interact with people from diverse cultural backgrounds. They should be knowledgeable about diverse cultural beliefs, practices, and healthcare preferences, which will help them provide culturally sensitive care and support their staff in delivering culturally competent care.
- Language and communication: In multicultural healthcare settings, language barriers can impede effective communication between healthcare providers and patients. Nursing leaders should ensure that patients have access to interpretation services and language assistance to facilitate clear communication and understanding. They should also promote the use of plain language and nonverbal communication techniques to bridge cultural, linguistic, and health literacy divides.
- Cultural sensitivity in care delivery: Nursing leaders and managers should promote cultural sensitivity in care delivery by encouraging their staff to recognize and respect patients’ cultural beliefs, values, and preferences. This may involve adapting care practices, treatment plans, and communication styles to align with patients’ cultural norms and expectations.
- Health disparities and equity: Nursing leaders have a responsibility to address health disparities and promote health equity among diverse patient populations. They should advocate for policies and practices that reduce barriers to healthcare access and improve health outcomes for marginalized or underserved communities.
- Cross-cultural team dynamics: In multicultural healthcare teams, nursing leaders play a vital role in fostering collaboration, mutual respect, and understanding among team members from different cultural backgrounds. They should promote cultural humility—the recognition of one’s own cultural biases and the willingness to learn from others’ cultural perspectives.
- Conflict resolution and cultural sensitivity: Nursing leaders should be adept at resolving conflicts that arise due to cultural differences or misunderstandings. They should facilitate open dialogue, promote empathy and understanding, and seek mutually acceptable resolutions that respect the cultural values and dignity of all involved parties.
- Cultural competence training and education: Nursing leaders should provide ongoing training and education to their staff on cultural competence, diversity, and inclusion. This may include workshops, seminars, or online courses to enhance staff awareness, knowledge, and skills in working effectively with diverse patient populations.

By integrating these cultural considerations into nursing leadership and management practices, healthcare organizations can create a culturally responsive environment that promotes high-quality, patient-centered care and enhances the well-being of both patients and healthcare providers.

---

## 18.4 Certifications for Nurse Leaders and Managers

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Compare types of certifications in nursing
- Recall leadership and management organization-specific certifications
- Describe nursing degrees for leadership and management

In the evolving landscape of health care, the need for skilled nurse leaders and managers is more critical than ever. These professionals not only ensure the delivery of high-quality patient care but also guide nursing teams through the complexities of modern healthcare environments. To prepare for these vital roles, many nurses choose to obtain specific certifications or pursue advanced degrees that provide the necessary knowledge, skills, and recognition. This module explores the various pathways available for nurses seeking to advance their careers into leadership and management positions, detailing the types of certifications, organization-specific certifications, and degrees that support this professional growth.

### Certifications in Nursing

As discussed in [1.2 Nursing Education Programs](#), obtaining a license and pursuing certification are two distinct steps

in a nurse's professional development. Licensure is mandatory for all nurses and is granted by state boards of nursing, authorizing individuals to practice nursing within a specific state. This legal requirement ensures that all practicing nurses meet a minimum standard of knowledge and competency essential for patient care. On the other hand, certification is a voluntary process that goes beyond licensure, allowing nurses to gain recognition in a specialty area of practice. While licensure demonstrates a broad competency in nursing, certification highlights a nurse's expertise and commitment to a specific field or specialty within nursing. It is a testament to a nurse's dedication to professional development, expertise in a particular area, and commitment to providing the highest quality of care (Bradley University, n.d.).

### Board and Specialty Certification

The process of certification allows nurses to showcase their specialized knowledge and skills in various nursing specialties, ranging from pediatrics and gerontology to critical care and oncology. Two types of certification in nursing include specialty certification and board certification. To obtain **specialty certification**, nurses typically must meet specific eligibility criteria, which can include a certain number of hours of clinical experience in the specialty area, completion of a minimum number of contact hours of nursing CE in the specialty, and successful completion of testing. This certification is also typically offered by smaller nursing organizations. Considered an advanced nursing specialty certification, board certification has more eligibility requirements, such as a higher number of clinical experience hours, more education hours required, and more advanced testing. Board certification is offered by large nursing organizations, such as the American Nurses Credentialing Center.

Certification is recognized as a significant achievement in a nurse's career, signaling to employers, colleagues, and patients a nurse's advanced proficiency and expertise in a particular area of nursing. It not only enhances a nurse's professional credibility but also often leads to better job prospects, higher salaries, and opportunities for advancement (American Association of Critical-Care Nurses, n.d.). Additionally, maintaining certification typically requires ongoing education and professional development, ensuring that nurses stay current with the latest best practices, technologies, and research in their specialties. Through this continuous learning, certified nurses contribute to the improvement of patient care standards and outcomes across healthcare settings.

### Leadership and Management Organization-Specific Certifications

For nurses aspiring to elevate their careers into leadership and management roles, specific certifications are designed to recognize their expertise and qualifications. These certifications serve as benchmarks of professional achievement and leadership competence, signaling a nurse's readiness to take on executive roles within healthcare organizations. Unlike board certifications that focus on clinical specialties, leadership and management certifications assess a nurse's ability to lead teams, manage resources, and improve healthcare delivery systems. They highlight a commitment to excellence in nursing leadership and a dedication to advancing the profession.

#### Certified Nurse Manager and Leader

The **Certified Nurse Manager and Leader (CNML)** is a specialty certification designed for nurse leaders in managerial positions who are responsible for the daily operations of a unit or service within a healthcare facility. Offered by the American Organization for Nursing Leadership (AONL), this certification focuses on validating the essential skills needed for effective nursing leadership, including financial management, human resources, performance improvement, and strategic management and technology. Candidates for the CNML certification must meet specific educational and experience requirements and pass a comprehensive examination (AONL, 2024a).

#### Nurse Executive Certification

The **Nurse Executive Certification (NE-BC)** is a board certification aimed at nurse leaders who hold key administrative roles and are involved in shaping policies, procedures, and strategies that impact the delivery of care within a unit or team. This certification is offered by the American Nurses Credentialing Center (ANCC) and examines a nurse's ability to contribute to the strategic vision of their organization, lead change initiatives, and ensure the delivery of quality, patient-centered care. The NE-BC credential recognizes nurse executives who have demonstrated advanced knowledge and leadership skills in nursing administration (ANCC, n.d.-a).

#### Nurse Executive, Advanced Certification

**Nurse Executive, Advanced Certification (NEA-BC)** is a board certification for experienced nurse leaders who have moved beyond the management of single units or teams to influence the operations of entire systems or

organizations. This advanced certification, also offered by the ANCC, assesses a leader's ability to effect organizational change, manage complex environments, and lead innovations in healthcare practice. Eligibility for the NEA-BC includes holding a master's or higher degree, having a current RN license, and demonstrating specific leadership experience at the executive level (ANCC, n.d.-b).

### Certified in Executive Nursing Practice

The **Certified in Executive Nursing Practice (CENP)** specialty certification is specifically designed for nurse leaders who are at the executive level, overseeing the strategic, operational, and financial outcomes in healthcare organizations. This prestigious certification, offered by the AONL, is tailored for those who have a broad base of professional leadership experience and education. The CENP certification focuses on core areas such as leadership, communication, business skills, professionalism, health and public policy, and knowledge management. To be eligible for the CENP, candidates must demonstrate a high level of experience in executive nursing leadership roles and complete a rigorous examination that assesses their competency in these critical areas.

Obtaining the CENP credential signifies a nurse leader's commitment to excellence in executive nursing practice. It acknowledges their depth of knowledge in the field and their capability to drive the vision and strategic direction of healthcare delivery. The CENP is recognized across the healthcare industry as a mark of distinction for nurse executives, highlighting their leadership in improving patient care, fostering professional development among their teams, and contributing to the overall success of their organizations (AONL, 2024b).

### Renewal Process for Certifications

The renewal process for leadership and management certifications in nursing is designed to ensure that nurse leaders continue to meet the high standards of professional development and stay abreast of the latest practices in healthcare leadership and management. Typically, these certifications require renewal every three to five years, although the specific time frame varies by certifying body.

To renew these certifications, nurse leaders are usually required to demonstrate continued professional development and leadership growth. This may involve accumulating a certain number of continuing education (CE) units in topics relevant to nursing leadership and management, participating in professional activities such as serving on boards or committees, presenting at professional conferences, or contributing to the development of leadership policies or standards. Additionally, some certifications may require candidates to retell their leadership experiences, showcasing how they have applied their skills to improve healthcare delivery and patient outcomes in their organizations. The renewal process not only validates the ongoing commitment of nurse leaders to their professional excellence but also ensures that they remain at the forefront of leadership and management practices, ready to tackle the challenges of the ever-evolving healthcare landscape.

## Degrees for Leadership and Management

Nurses interested in taking on leadership or management roles within healthcare organizations should consider pursuing graduate-level education. Advanced degrees, such as a Master of Science in Nursing (MSN) or a Doctor of Nursing Practice (DNP), provide nurses with the knowledge, skills, and credentials needed to succeed in leadership positions. These programs often cover topics such as healthcare administration, organizational behavior, finance, and leadership strategies, which provide the nurse with the competencies required to lead teams, manage healthcare resources, and advocate for organizational change.

A graduate degree also elevates the nurse's credibility and demonstrates their commitment to professional growth and development. It can open doors to new career opportunities, such as nursing administration, nursing education, and executive leadership.

As discussed in [1.2 Nursing Education Programs](#), higher education can be a crucial component of professional development. The four certifications discussed in the previous subsection all require at least a baccalaureate degree in nursing. The Nurse Executive, Advanced Certification (NEA-BC) also requires a graduate degree (ANCC, n.d.-b), and CENP candidates with a graduate degree require half as many hours of professional experience as candidates with only a baccalaureate (AONL, 2024b). Graduate degrees include master's degrees and doctorates.

### Master of Science in Nursing

A **Master of Science in Nursing (MSN)** degree is a graduate-level program that equips nurses with advanced

practice knowledge, leadership, and management skills necessary for high-level roles in healthcare settings. For aspiring nurse managers and leaders, an MSN offers specialized tracks such as nursing administration, health policy, education, nurse leadership, population health, and informatics. This degree not only deepens clinical expertise but also focuses on critical areas like organizational management, financial acumen, strategic planning, and healthcare policy, which are essential for effective leadership in nursing.

Nurses with an MSN degree are prepared to take on roles such as nurse manager, clinical nurse leader, nurse administrator, or even executive positions within healthcare organizations. The curriculum typically includes courses on advanced healthcare systems, quality improvement, patient safety, and evidence-based practice, all aimed at enhancing the delivery of patient care through effective management and leadership. Additionally, many MSN programs offer opportunities for practical leadership experience through internships or capstone projects, allowing students to apply their learning in real-world settings. The MSN degree is an excellent option for nurses aiming to impact health care at the organizational or system level, providing the tools they need to lead effectively and drive positive change.

### Doctorate Degree in Nursing

Doctorate degrees in nursing include the **Doctor of Nursing Practice (DNP)**, the **Doctor of Philosophy (PhD) in Nursing**, and the **Doctor of Education (EdD) in Nursing Education**. These degrees represent the pinnacle of educational achievement in the nursing profession. While all three degrees prepare nurses for leadership roles, they cater to different career paths within the field. The DNP is practice oriented, focusing on applying research to improve healthcare outcomes, policy, and patient care delivery systems. The DNP-prepared nurses are equipped for executive roles in clinical settings, healthcare administration, policy-making, and advocacy, emphasizing the translation of research into practice to enhance patient care and health systems.

On the other hand, a PhD in Nursing is research focused, preparing nurses to contribute to the profession through original research that advances nursing science and practice. The PhD-prepared nurses often pursue careers in academia, research, and leadership positions where they can influence nursing education, policy, and practice through their research findings. Both doctoral degrees elevate a nurse's capacity to lead, innovate, and advocate for advancements in health care, whether through direct patient care improvements, policy reform, or the generation of new nursing knowledge. Pursuing a doctorate in nursing opens doors to opportunities for significant impact on the future of health care, shaping the direction of nursing practice and improving health outcomes on a broad scale.

For nurses interested in pursuing leadership roles in nursing education, the Doctor of Education (EdD) in Nursing Education is a specialized degree program that prepares them for careers as nurse educators, academic administrators, and leaders in educational institutions. The EdD in Nursing Education degree focuses on developing advanced competencies in teaching and learning, curriculum development, and educational leadership. The EdD nurses are equipped to shape nursing education programs, implement innovative teaching strategies, and conduct educational research. Their work supports the training and development of future nurses, ensuring educational standards and practices meet the evolving demands of health care. This degree helps nurses excel as educators in academic or healthcare settings, and they may pursue careers at colleges or universities, as nurse preceptors in clinical settings, or as leaders in educational program development for nurses.

## Summary

### 18.1 Concepts of Leadership in Nursing

Leadership is the practice of guiding, influencing, and motivating individuals or groups toward achieving a common goal. Effective leadership in nursing is a multifaceted concept that includes a range of attributes, diverse leadership styles, and specific goals that are essential for guiding healthcare teams and improving patient care. Key attributes of successful nurse leaders include a strong commitment to excellence and professionalism, exceptional problem-solving skills, trustworthiness, integrity, accessibility, and creativity. These qualities enable nurse leaders to inspire their teams, encourage high standards of care, and adapt to the dynamic challenges of the healthcare environment.

Various leadership styles, each with distinct characteristics and applications, play a crucial role in nursing. Autocratic leadership is decisive and directive, suitable for emergency situations where quick action is required. Democratic leadership, in contrast, emphasizes collaboration and team input, fostering a participative and inclusive environment. Laissez-faire leadership offers autonomy and independence, ideal for experienced teams, while servant leadership focuses on empowering and uplifting team members. Quantum leadership adapts to rapid changes in health care, emphasizing innovation, whereas transactional leadership relies on established routines and rewards for performance. Transformational leadership inspires and motivates teams to exceed their potential, driving significant improvements in practice and care.

The goals of nurse leaders are comprehensive, extending beyond immediate patient care. They aim to develop a positive workplace culture that promotes employee satisfaction, mentorship, and professional growth. Nurse leaders also strive to align staff behaviors with the values of their healthcare facility, ensuring that care delivery is ethically and morally sound. Additionally, they serve as vital communication links, effectively bridging gaps between various stakeholders, including healthcare teams, patients, and administrative bodies.

### 18.2 Concepts of Management in Nursing

Whereas leadership focuses on the “why” and “what” of work, management focuses on the “how”: that is, how can team members complete their tasks effectively and consistently each day? Effective nursing management is underpinned by a set of critical attributes that enable nurse managers to lead their teams successfully through the complexities of health care. These attributes include conflict resolution, employee engagement, mentoring, decision-making, and technical skills, which encompass both the hard skills of healthcare technology and the soft skills of communication and organization. Mastery of these attributes equips nurse managers to create a positive work environment and lead their teams effectively.

Understanding different management structures—centralized and decentralized—is crucial for nurse managers. Centralized management consolidates decision-making at the upper echelons of an organization, ensuring uniformity and streamlined processes. In contrast, decentralized management distributes decision-making authority more broadly, fostering innovation and flexibility. Each structure has its benefits and challenges, and choosing the appropriate model can significantly impact the efficiency and adaptability of nursing teams.

The ability to implement and manage change is another cornerstone of nursing management. Change theories, including Lewin’s model and appreciative inquiry, offer strategies for guiding teams through transitions. Effective change management involves understanding the dynamics of change, planning and executing interventions thoughtfully, and addressing resistance through communication and support. This ensures that changes lead to improvements in patient care and team functioning.

Finally, the goals of nurse managers—planning, staffing, organizing, directing, and regulating—are integral to their role. Planning sets the direction for future actions, staffing ensures that the team has the right mix of skills, organizing arranges resources for efficiency, directing guides and motivates staff toward objectives, and regulating maintains standards and compliance. These goals are interconnected, each contributing to the overarching aim of delivering high-quality patient care while fostering a supportive and productive work environment.

### 18.3 Implementing Leadership and Management into Nursing Practice

Nurse managers and leaders play a pivotal role in ensuring that patient care is delivered efficiently, effectively, and compassionately. Their involvement in patient care coordination is fundamental, requiring them to orchestrate

various healthcare services and professionals to meet the comprehensive needs of patients. By facilitating interdisciplinary referrals and overseeing case management duties, they ensure that care is seamless across different specialties, enhancing patient outcomes and satisfaction.

Delegating patient care is another critical responsibility for nurse managers and leaders, allowing for the optimal use of the nursing team's skills and time. Understanding the scope of practice and determining the clinical ability of each team member are essential to delegate tasks appropriately. This ensures that patient care is provided safely and that each staff member works within their competencies, promoting a high standard of care and fostering a supportive work environment.

Supporting professional development within the nursing team is key to maintaining high levels of clinical competence and adapting to the rapidly changing healthcare landscape. Through mentorship and preceptorship programs, nurse managers and leaders play a direct role in the growth and development of their staff, offering guidance and learning opportunities that build on individual strengths and interests. Furthermore, promoting engagement with professional organizations and encouraging CE are vital for keeping the nursing team informed of the latest evidence-based practices and innovations in patient care.

Overall, the integration of effective patient care coordination, skilled delegation, and robust support for professional development underlines the multifaceted role of nurse managers and leaders in advancing healthcare quality and fostering an environment of continuous learning and improvement within nursing teams.

## 18.4 Certifications for Nurse Leaders and Managers

Certifications and advanced degrees in nursing serve as key components for nurses aiming to transition into leadership and management roles within healthcare settings. Differentiating between licensure, which is a requirement for practice, and certification, this module underscores the importance of voluntary certifications in demonstrating specialized competence and commitment to excellence in nursing. Board certification offers nurses the opportunity to validate their expertise in various clinical specialties, while leadership and management organization-specific certifications, such as CNML, Nurse Executive Certification (NE-BC), Nurse Executive, Advanced Certification (NEA-BC), and CENP, are tailored to underscore proficiency in navigating the complexities of healthcare leadership and administration.

Furthermore, the pursuit of higher education through master's and doctoral degrees in nursing equips nurses with the theoretical knowledge and practical skills necessary for high-level management and leadership positions. These degrees focus on advanced practice knowledge, strategic planning, financial management, policy development, and the application of evidence-based practice in leadership roles. Master's programs provide a foundation in nursing leadership, whereas doctoral degrees, including the Doctor of Nursing Practice (DNP) and Doctor of Philosophy (PhD) in Nursing, offer paths to practice-based leadership or research-focused roles, respectively. Collectively, these certifications and degrees form a comprehensive framework for professional development, preparing nurses to lead effectively in the ever-evolving healthcare landscape.

## Key Terms

**appreciative inquiry** a theory that builds from what is already working within an organization through four stages of change management: discovery, dream, design, destiny

**autocratic leadership** a leadership style characterized by individual control over decisions with little input from team members

**board certification** considered an advanced nursing specialty certification where there are more eligibility requirements, such as a higher number of clinical experience hours, more education hours required, and more advanced testing

**board of nursing (BON)** a regulatory body tasked with overseeing the practice of nursing within its jurisdiction, typically a state or territory

**case manager** a nurse responsible for developing and coordinating care plans for patients with chronic illnesses or other long-term conditions

**centralized management** a top-down organizational structure in which higher-ranking managers have authority over lower-ranking managers

**Certified in Executive Nursing Practice (CENP)** a specialty certification designed for nurse leaders who are at the

- executive level, overseeing the strategic, operational, and financial outcomes in healthcare organizations
- Certified Nurse Manager and Leader (CNML)** a specialty certification designed for nurse leaders in managerial positions who are responsible for the daily operations of a unit or service within a healthcare facility
- continuing education (CE)** ongoing educational activities
- decentralized management** a diffuse organizational structure in which authority is distributed among a variety of individuals and teams, regardless of rank
- delegation** the act of requesting staff members to perform tasks or procedures that are outside of their normal job but within the limits of their job description
- democratic leadership** a leadership style that values the input of team members and stakeholders in the decision-making process
- Doctor of Education (EdD) in Nursing Education** a specialized degree program that prepares nurses for careers as nurse educators, academic administrators, and leaders in educational institutions
- Doctor of Nursing Practice (DNP)** a practice-focused doctoral degree that emphasizes advanced clinical practice, leadership in healthcare systems, and evidence-based decision-making
- Doctor of Philosophy (PhD) in Nursing** a research-focused doctoral degree that emphasizes the generation of new nursing knowledge through rigorous scientific inquiry
- interdisciplinary referral** a request by a primary care provider to transfer a patient to a specialist
- laissez-faire leadership** a leadership style in which team members receive a high level of autonomy to make decisions, solve problems, and manage their work independently
- leadership** the practice of guiding, influencing, and motivating individuals or groups toward achieving a common goal
- Lewin's model for change management** a theory that effective change happens in three intentional steps: unfreezing, moving, refreezing
- management** the practice of determining what tasks need to be completed to accomplish a particular goal and ensuring all team members complete those tasks
- Master of Science in Nursing (MSN)** an advanced graduate degree that provides nurses with a higher level of education and specialization in various areas of nursing practice
- mentor** an experienced practitioner who serves as a role model or guide for a student or less-experienced colleague
- Nurse Executive Certification (NE-BC)** a board certification designed for nurse leaders who hold key administrative roles and are involved in shaping policies, procedures, and strategies that impact the delivery of care within a unit or team
- Nurse Executive, Advanced Certification (NEA-BC)** a board certification designed for experienced nurse leaders who have moved beyond the management of single units or teams to influence the operations of entire systems or organizations
- patient care coordination** organizing a patient's healthcare needs across providers, settings, and time
- planned change** in Lewin's theory, a deliberate, systematic process for introducing transformation into an organization or system
- preceptor** a licensed professional who coaches and supervises students during their clinical rotations
- quantum leadership** a leadership style is characterized by adaptability, flexibility, and a focus on fostering innovation in response to rapidly changing healthcare landscapes
- scope of practice** defined limits and parameters within which a professional is authorized to work, make decisions, and provide services
- servant leadership** a leadership style that prioritizes the needs of team members and fosters a culture of care, empathy, and community
- specialty certification** official recognition of a nurse's expertise in a particular area of nursing
- transactional leadership** a leadership style characterized by clear structures and rules, where performance is closely monitored and feedback consists of rewards for meeting objectives or corrective actions for failing to meet them
- transformational leadership** a leadership style aimed at inspiring and motivating team members to exceed their own expectations and capabilities

## Assessments

### Review Questions

1. What is an essential attribute for effective leadership in nursing?
  - a. an advanced degree
  - b. flexibility in approach
  - c. excellent clinical skills
  - d. the ability to work in isolation
2. In a situation where rapid decision-making is required to save a patient's life, what leadership style is most appropriate?
  - a. autocratic
  - b. democratic
  - c. laissez-faire
  - d. servant
3. A nurse leader actively encourages her team to participate in decision-making, provides mentorship opportunities, and regularly organizes professional development workshops. What goal is this nurse leader primarily pursuing?
  - a. role modeling desired behaviors
  - b. serving as a communication liaison
  - c. creating and developing new leaders
  - d. promoting a culture of patient-centered care
4. What is an example of a nurse manager demonstrating effective mentoring skills?
  - a. organizing a meeting to resolve a conflict between two team members
  - b. analyzing staff shift patterns to optimize coverage and reduce overtime
  - c. setting up a weekly review session with a new nurse to provide feedback
  - d. implementing a new software system to streamline patient documentation
5. What management structure encourages nurse managers to distribute decision-making authority across various levels of the nursing team?
  - a. autocratic
  - b. centralized
  - c. decentralized
  - d. transactional
6. According to Lewin's model, what is the first step in effectively implementing change within a nursing team?
  - a. appreciating
  - b. moving
  - c. refreezing
  - d. unfreezing
7. What is an example of a nurse manager focusing on the goal of regulating?
  - a. conducting a monthly audit of the team's budget
  - b. mapping out their annual objectives for personal growth
  - c. developing a comprehensive onboarding program for new hires
  - d. creating a flexible staffing model to accommodate fluctuations in admissions
8. What is the main role of a case manager in patient care?
  - a. supervising the care of all patients within a healthcare setting or facility
  - b. conducting research to implement evidence-based practices in patient care
  - c. teaching patient care techniques to nursing students during clinical rotations

- d. coordinating individualized care plans for patients with long-term conditions
9. What must nurse managers consider when delegating patient care?
    - a. the scope of practice of the delegatee
    - b. the individual preferences of the delegatee
    - c. the length of time that the delegatee has been working
    - d. the place of the delegate within the organizational structure
  10. What is an example of continuing education for a nurse manager?
    - a. supervising nursing students during a clinical rotation
    - b. participating in a workshop to develop leadership skills
    - c. mentoring a colleague who was recently transferred to the team
    - d. advocating for subordinates who want more professional development
  11. What is a key difference between licensure and specialty certification for nurses?
    - a. Licensure focuses on clinical skills, whereas specialty certifications assess leadership abilities.
    - b. Licensure is mandatory for all nursing positions, whereas specialty certifications are voluntary.
    - c. Licensure is the first level of higher education, whereas specialty certifications are the highest level.
    - d. Licensure is regulated by national nursing organizations, whereas specialty certifications are offered by state nursing boards.
  12. What type of certification is most appropriate for nurses who are responsible for the daily operations of a unit within a hospital?
    - a. Certified in Executive Nursing Practice (CENP)
    - b. Nurse Executive Certification (NE-BC)
    - c. Certified Nurse Manager and Leader (CNML)
    - d. Nurse Executive, Advanced Certification (NEA-BC)
  13. What advanced degree is focused on applying research to improve healthcare outcomes, policy, and patient care delivery systems?
    - a. Bachelor of Science in Nursing (BSN)
    - b. Master of Science in Nursing (MSN)
    - c. Doctor of Nursing Practice (DNP)
    - d. Doctor of Philosophy (PhD) in Nursing

### Check Your Understanding Questions

1. How does a commitment to professionalism manifest in a nurse leader's daily activities? Provide an example.
2. Describe a scenario in which a servant leadership style would be particularly effective in nursing. Explain your thinking.
3. Why is promoting a culture of patient-centered care an important goal for nurse leaders?
4. List two essential attributes needed for effective nursing management.
5. What is the difference between centralized and decentralized management?
6. Briefly explain the four stages of appreciative inquiry.
7. List two functions of effective nurse managers, and briefly explain why each goal is important.
8. Describe the role of interdisciplinary referrals in patient care coordination.
9. Identify two of the five "rights" of delegation and explain why it is important for nurse managers to uphold them.
10. Identify a professional nursing organization and explain why a nurse manager would likely belong to it.

11. What is the purpose of specialty certification for nurses?
12. Name two certifications specifically designed for nurse leaders, and briefly describe the focus of each.
13. Describe the primary goal of pursuing a Doctor of Nursing Practice (DNP) degree for a nurse interested in leadership.

### Reflection Questions

1. Consider a time when you observed a nurse leader demonstrating creativity in problem-solving. How did this impact the team and patient care?
2. In a busy hospital unit, there has been an unexpected surge in patient admissions. The existing staff is feeling overwhelmed, and there is a need to quickly adapt to the increased workload while maintaining high standards of patient care. Choose two leadership styles. Describe how each style would likely respond to this scenario, and then decide which style is better suited for the scenario and why.
3. Reflect on the importance of nurse leaders serving as communication liaisons. How does this role impact team performance and patient outcomes?
4. Describe how a nurse manager's effective decision-making skills can impact patient care in a high-pressure situation. Provide a specific example.
5. How might a nurse manager operating in a decentralized management structure approach the implementation of a new patient care protocol differently than in a centralized structure?
6. Identify a strategy a nurse manager might use to overcome resistance to change among their team when introducing a new healthcare technology.
7. How might a nurse manager implement the function of regulating in their daily operations?
8. Reflect on a time when effective patient care coordination made a significant difference in a patient's outcome. What role did the nurse manager or leader play in this situation?
9. Think about a scenario where delegation of patient care was mishandled. What were the consequences, and how could applying the "rights" of delegation have prevented the issues?
10. How can nurse managers and leaders support their staff's participation in continuing education and professional development?
11. Reflect on how obtaining a certification in a nursing specialty could influence your career path and professional development.
12. Considering the leadership and management certifications available, how do you envision these certifications fitting into your career goals?
13. Reflect on the value of pursuing advanced degrees, such as an MSN or DNP, in achieving your leadership and management goals in nursing.

### What Should the Nurse Do?

At a regional rehabilitation center, the nursing staff has been experiencing low morale. One key issue identified through an anonymous survey is poor communication within the team. Many nurses feel that their feedback and concerns about patient care and workplace challenges are not being heard or addressed effectively. Additionally, there is a sense of stagnation among the staff, as there seem to be limited opportunities for professional growth and career advancement within the center. The newly appointed head nurse, Alex, is tasked with addressing these issues to improve the work environment and staff satisfaction.

1. How can Alex utilize effective leadership attributes to improve communication and address the concerns of the nursing staff?
2. Which leadership style might be most effective for Alex to encourage professional growth and career advancement among the nursing staff and why?
3. As a nurse leader, what goals should Alex set to enhance employee satisfaction and overall team

performance in this scenario?

Maya is a nurse manager at a community health clinic that serves a diverse population. The clinic has recently decided to focus on improving patient education regarding chronic disease management, aiming to enhance patient outcomes and reduce hospital readmissions. As part of this initiative, Maya is tasked with leading her team through the necessary changes, which include developing new patient education materials, training staff on the latest best practices in chronic disease management, and reorganizing the clinic layout to accommodate a new patient education area.

4. Given the scenario, how should Maya utilize her conflict resolution and communication skills to address any concerns or resistance from her team regarding the new focus on patient education?
5. How might the choice between a centralized and decentralized management structure affect the implementation of the new patient education initiative in Maya's clinic?
6. According to Lewin's model of change management, what strategies should Maya employ to implement and manage the change involved in focusing on patient education?
7. Considering the goals of nurse managers, how can Maya effectively plan and organize the resources at the clinic to support the new focus on patient education for chronic disease management?
8. Jordan is a nurse manager in a large urban hospital's emergency department (ED). Recently, the hospital initiated a project to improve patient outcomes and efficiency in the ED. Jordan is tasked with leading this project, which involves integrating advanced nursing certifications, leveraging leadership skills, and enhancing educational opportunities for the nursing staff. The project's goals include reducing wait times, improving patient satisfaction scores, and increasing staff engagement and retention. Jordan plans to encourage staff to pursue certifications relevant to emergency nursing, implement leadership development workshops, and facilitate access to continuing education programs. Given the project goals, how could Jordan encourage her team to pursue board certification in emergency nursing, and what impact might this have on the project outcomes?

### Competency-Based Assessments

1. Recall what you read about the pros and cons of each leadership style. Create a list comparing each style and note nursing situations where each style would be most effective.
2. Reach out to a nurse leader in your community and ask them what leadership style they use most often and why.
3. Choose a style of nursing leadership that resonates with you and describe its influence on your work.
4. Research the reasons for resistance to change in health care. Discuss its potential consequences for patients and strategies that nurse leaders can use to address the problem.
5. Reach out to a nurse leader in your community and discuss a change, the process used, and the outcome.
6. Make a table comparing the different management structures.

## CHAPTER 19

# Oxygenation and Perfusion

**FIGURE 19.1** The respiratory system and cardiovascular system together form the cardiopulmonary system. Nurses support patients' respiratory needs in many ways, including by providing them with oxygen, as this critical care nurse is doing for a patient with COVID-19. (credit: "Navy Medical Team Supports Louisiana Hospital" by Mass Communication Specialist 2nd Class Michael H. Lehman/Flickr, Public Domain)

### CHAPTER OUTLINE

- 19.1 Respiratory System
- 19.2 Cardiovascular System
- 19.3 Factors Affecting Cardiopulmonary Function
- 19.4 Management of Impaired Cardiopulmonary Functioning

**INTRODUCTION** Basic life support training uses the first three letters of the alphabet to quickly refer to the most crucial lifesaving actions for a patient who experiences an arrest situation: assessment of the patient's airway, breathing, and circulation. Until a few years ago, these were referred to as they appear alphabetically—A-B-C. The 2010 American Heart Association (AHA) guidelines changed the order to reflect circulation as the first response, followed by airway and breathing, so it is now C-A-B (AHA, 2020).

In either order, the respiratory system is associated with two-thirds of the immediate and emergent lifesaving response recommended for cardiac and/or respiratory arrests, which suggests its importance. The cardiovascular system is also critical because it is the adequacy of the heart's pumping action and vascular circulation that delivers oxygen (O<sub>2</sub>) and other nutrients. Without adequate perfusion, all body systems and components are at risk for significant compromise and ultimately cell death. Consequently, the first three letters of the alphabet are certainly appropriate as quick and recognizable identifiers of the most necessary immediate lifesaving measures to take in

hopes of patient survival.

## 19.1 Respiratory System

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the structures and functions of the respiratory system
- Recognize the physiology of the respiratory system
- Describe the regulation of the respiratory system

The primary purpose of the respiratory (or pulmonary) system is gas exchange, which is necessary to support human life. The **gas exchange** happens where the capillaries and alveoli meet, with a very thin membrane between them—the capillary-alveolar bed (or membrane). The process of breathing—inspiration (inhaling) and expiration (exhaling)— provides O<sub>2</sub> and removes CO<sub>2</sub> waste. The cardiovascular system provides the means of transport for O<sub>2</sub> and other nutrients and the removal of waste products. The blood vessels provide the medium for the exchange of gases by the pulmonary circulation through interaction with respiratory alveoli. The joining of these systems as the **cardiopulmonary system** combines the actions of cardiac **perfusion** (vascular circulation powered by the pumping heart, which delivers O<sub>2</sub> and other nutrients to the body) with **respiratory ventilation** to provide the essential processes of oxygenation and perfusion. Prior to considering the complexity of the combined cardiopulmonary system, each system is explored individually, and these concepts are investigated more deeply later in this section.

This chapter also considers dysfunctions of the cardiovascular and pulmonary systems, diagnostics for recognition and assistance in planning care, and management of patients, particularly nursing actions and skills. The following section explores the structure and function, physiology, and regulation of the respiratory system.

### Structures and Functions of the Airway

What is considered the airway consists of structures from the head and face through the pulmonary cavity in the chest ([Figure 19.2](#)). The study of the structure (anatomy) of the airway tends to be considered as two components: upper and lower airways. The upper airway extends from the sinuses and nose through the **trachea** to the **carina**, where the airway bifurcates into left and right bronchi and continues into the lungs. This helps to focus on the different locations of the sections of the airway, as well as the normal function of each, and the variation of pathophysiology when things go awry. Disturbed function may arise from a variety of issues, including microbial invasions, exposure to noxious or toxic gases, and injuries. This section explores the structures of the upper and lower airways and their function, physiology of the respiratory system, and respiratory system regulation.

**FIGURE 19.2** Air enters the respiratory system through the nasal cavity and pharynx and then passes through the trachea and into the bronchi, which brings air into the lungs. (credit: modification of work from *Biology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Upper Airway

The upper airway includes the trachea as its lowest part and structures above including the sinuses, nose, **pharynx**, **epiglottis**, **glottis**, and **larynx**. Behind the nose is a space that includes the **nasal turbinates** or conchae, which are composed of folded mucosal tissues. The nasal turbinates protect the airway from inhaled particles and increase the surface area in the nasal cavity, helping to warm and humidify inhaled air. The **sinuses** are bilateral cavities named based on the bones where they are located, including frontal (above each eye, maxillary), posterior to the maxillae bilaterally, sphenoid (near the pituitary gland and optic nerves and the sphenoid bone of the eye sockets), and the ethmoid (several small air-filled cells comprising front, middle, and rear groups, each with independent openings to the nasal cavity). The mucus lining the sinuses helps to humidify the air we breathe, and cilia lining the sinuses (hairlike fibers) help to trap and remove excess secretions and foreign objects from the upper airway.

Three regions comprise the pharynx:

- the **nasopharynx**—behind the turbinates at the posterior of the nasal cavity
- the **oropharynx**—located at the posterior of the oral cavity
- the **laryngopharynx**—below the oropharynx, extending to the larynx, familiarly referred to as the voice box

The epiglottis is a cartilaginous structure, which rests its loose end on the glottis, thereby protecting the trachea. When a person swallows, the epiglottis closes the opening from the **esophagus** (part of the gastrointestinal tract, which sits posterior to the trachea), thereby preventing food or fluid from flowing into the trachea. Located within the glottis are false and **true vocal cords**. The **false vocal cords** are also known as vestibular folds and are composed of mucus membrane tissue. True vocal cords have muscular attachments to the thyroid and to laryngeal cartilage; the movement of the inner aspects of the vocal cords provides the mechanism for sound production.

The trachea, commonly referred to as the windpipe, provides the pathway from the upper to lower airways. The esophagus carries fluids and chewed foods from the oral cavity to the stomach. A combination of cartilage and connective tissue gives the trachea its shape and maintains it open for the passage of air. Cilia line the trachea, continuing the process of trapping foreign objects and allowing for their removal, in the same fashion as in the higher structures of the upper airway. Where the trachea bifurcates into the left and right mainstem bronchi is the location of the carina. The carina is the border of the upper and lower airways.

## REAL RN STORIES

---

### Endotracheal Suctioning

**Nurse:** Danisha, RN

**Clinical setting:** Intensive care unit (ICU)

**Years in practice:** Less than one year at the time

**Facility location:** Dallas, Texas

As a student, I took an elective course between junior and senior years of nursing school—it was a course modeled after senior capstone and included 400 clinical hours with a preceptor. My placement was night shift in the ICU. My first night's patient was an older adult Asian female who was intubated and on mechanical ventilation; she was on pressors to maintain her blood pressure adequately. I remember coming in with lofty goals in mind, and when I saw this patient with all the tubes and wires and the monitor and ventilator, I was overwhelmed. One of the first tasks necessitated by the patient's status was to suction her through an inline suction catheter that passed through the endotracheal tube. She was coughing, and my nurse preceptor showed me how to advance the suction catheter through the tube; she demonstrated the suction control, and while withdrawing the catheter, she suctioned the patient of moderate secretions.

As the patient recovered between passes, she asked how I would know if the catheter had advanced to touch the carina. At that point in my nursing education, I had no idea. "She'll cough," she told me, "The carina is sensitive, so when it's touched, the patient will cough, and you've gone too far. Ideally, you want to pay attention to how far that is, so you don't go that far again." Through over ten years in the ICU, I never forgot that recommendation and tried not to stimulate the discomfort of hitting the carina when suctioning.

---

### Lower Airway

The lower airway consists of structures below the carina. The bronchi are the major structures of the lower airway and begin with the bifurcation of the right and left mainstem bronchi, which enter into the right and left lung, respectively. Subsequently, the mainstem bronchi continue paths through the lungs as the primary, secondary, and tertiary bronchi, becoming smaller, and branching further throughout the lungs. Bronchi continue to be lined with cilia and goblet cells for mucus production and have cartilaginous rings like the trachea, to provide support and prevent airway collapse.

From the tertiary bronchi, the branching of the airway becomes even smaller, as they are identified as bronchioles. These continue to their smallest form as terminal bronchioles; at this point, the airway is no longer supported by cartilage, and the muscles comprising the walls can dilate and constrict to control the flow of air. The tiny terminal (or respiratory) bronchioles reach alveolar ducts, which are also a combination of smooth muscle and connective tissues, where alveoli (the minuscule, round sacs of air involved in gas exchange) cluster together. These clusters of alveoli are where the most common type I alveolar cells and the smallest capillaries of the bloodstream exchange gases (primarily O<sub>2</sub> and CO<sub>2</sub>) through a very thin alveolar-capillary membrane (Ball et al., 2023). Another alveolar cell type (type II) is responsible for the production of surfactant. A phospholipid substance that prevents the collapse of alveoli by reducing surface tension is called **surfactant**. The third type of alveolar cells, alveolar macrophages, remove foreign substances and waste products from this delicate and essential region.

### Lungs

The lungs are responsible for respiration and house the smaller structures involved in the process of ventilation. The right and left lungs are slightly different in structure: the left lung is shaped to include the cardiac notch, which provides space for the heart. The left lung has two lobes: upper and lower; the right lung contains three lobes:

upper, middle, and lower. Normal, healthy lungs are supple and yield in size and shape to the demands of respiration, including **compliance**, the ability to accommodate deep and shallow breaths, and elastic recoil, or the ability to bounce back to normal size and shape after the expansion of inhaling, during exhalation. Lungs are designed to be air-filled. When taxed by disease, fluid accumulation, or exposure to toxic or noxious gases, the lungs can lose effectiveness, and the respiratory processes may become compromised.

Within the lungs are the structures of the lower airway, including the right and left bronchi, primary, secondary, and tertiary, bronchioles, alveoli, and the alveolar-capillary bed, where the cardiopulmonary system interacts, and gases are exchanged. Deoxygenated blood undergoes removal of CO<sub>2</sub>, and O<sub>2</sub> is brought into the system. These processes are studied in more detail in the next section, through exploration of the physiology of the respiratory system.

### Physiology of the Respiratory System

The exchange of gases, primarily O<sub>2</sub> and CO<sub>2</sub>, is the purpose of the respiratory system. The removal of CO<sub>2</sub> during expiration also helps to regulate the body's acid-base balance. Acid-base balance is measured by pH level. The body is sensitive to alterations in pH, and there is a narrow range of normal for pH: 7.35 to 7.45. In circumstances when the body's pH has fallen out of range, the respiratory system is able to adjust quickly in an effort to normalize it (Daniels, 2020). By increasing the rate and depth of respirations, excess CO<sub>2</sub> is released through exhalation, and an acidic pH (less than 7.35) may be improved. An alkalotic pH (over 7.45) may be corrected by shallow, slow breaths, allowing the accumulation of CO<sub>2</sub> to bring pH closer to normal.

Cilia and mucus throughout the respiratory system provide mechanisms for isolating and removing foreign substances, such as inhaled gases and microbiota. Cilia move pathogens and other inhaled particles that become trapped in mucus out of the lungs and into the bronchi, where expectoration is assisted through coughing.

The lungs also play a role in the conversion of angiotensin I to angiotensin II, in conjunction with the renin-angiotensin-aldosterone system (RAAS) ([Figure 19.3](#)) (Fountain et al., 2023). Angiotensin II is recognized for its powerful vasoconstriction properties and therefore increases blood pressure. Angiotensin I is produced by a combination of the enzyme renin from the renal system and angiotensinogen. Angiotensin I is not a potent vasoconstrictor, but when combined with angiotensin-converting enzyme (ACE), it is transformed into angiotensin II and increases blood pressure by its properties of vasoconstriction. Capillaries within the lungs are a major location for ACE production.

**FIGURE 19.3** The renin-angiotensin-aldosterone system regulates fluid output and blood pressure. (credit: modification of work from *Anatomy and Physiology*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Oxygenation involves interactions between the respiratory and cardiovascular systems, including air movement through the lungs, where  $\text{O}_2$  and  $\text{CO}_2$  are exchanged through the alveoli and capillaries as the respiratory and circulatory systems connect and interact at the alveolar-capillary bed. Physiological processes involved include **ventilation** (the movement of air in and out of the lungs) and perfusion. This combination of respiratory ventilation and cardiovascular perfusion provides  $\text{O}_2$  (and other nutrients) to the body's tissues and removes waste products including  $\text{CO}_2$  from the tissues.

The part of the respiratory cycle whereby the diaphragm and intercostal muscles contract, which enlarges the space within the thorax, is called **inspiration**. This enlargement lowers the pressure within the alveoli, and air flows into the lungs. During **expiration**, the muscles that expanded the thoracic cavity now relax, and elastic recoil reduces the pressures in the lungs and surrounding thorax. The pressure within the intrapulmonary system is momentarily higher than atmospheric pressure, and air is passively exhaled from the lungs. Lungs that are compliant and retain the properties of elastic recoil are able to increase and decrease in size and shape with each respiratory cycle ([Figure 19.4](#)).

**FIGURE 19.4** (a) Inhalation (breathing in) and (b) expiration (breathing out). The orange arrows indicate chest and diaphragm movement as air is inhaled and exhaled. (credit: modification of work from *Biology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Potential problems of the respiratory system include any changes to the normal structure and/or function of any part of the system. This may include injuries, such as rib fracture(s) or burns to any part of the airway.

Pathophysiological changes from diseases such as asthma or chronic obstructive pulmonary disease can alter the structure of the airways and the processes and effectiveness involved in gas exchange.

#### Gas Exchange in Alveoli

Alveoli are found in groups clustered around alveolar ducts, and when inflated, they resemble a cluster of grapes. There are three types of alveolar cells: type I, type II, and alveolar macrophages (Naeem et al., 2022). Type I cells cover approximately 90 percent, or 70 square meters, of surface area within the lungs. These cells are responsible for gas exchange ([Figure 19.5](#)). After inspiration,  $O_2$  travels across the capillary-alveolar bed and attaches to hemoglobin, where it is transported throughout the bloodstream and to the body tissues. At the tissues,  $O_2$  is released from the hemoglobin and taken up by the tissues as needed. It is also here that the waste product,  $CO_2$ , returns from the body by diffusion (a transport process that involves molecular movement driven by a concentration gradient) into the bloodstream and subsequently the lungs, where it is ultimately removed from the body by exhalation. The respiratory membrane is extremely thin, only about half of a micrometer, which enables gases to easily move to and from the bloodstream and air space within the lungs.

**FIGURE 19.5** In the structures at the alveolar-capillary bed are where gas exchange occurs. (credit: modification of work from *Biology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

For alveoli to easily reinflate, or to maximize inflation, surfactant is synthesized and released from type II alveolar cells. These cells are located among the type I cells and are made up of proteins and phospholipids. By coating the exterior of the alveoli, the cells reduce the surface tension, which prevents collapse (Naeem et al., 2022). Surfactant is produced by deep breaths, such as sighs, yawns, sobs, and gasps. Deep breaths often inspire coughing, and coughing causes deep breaths, which fosters continued production and release of surfactant and prevention of **atelectasis** (alveolar collapse). For this reason, patients are encouraged to cough and deep breathe when inspiration is limited. Nurses and respiratory therapists (RTs) instruct patients on the use of the incentive spirometer, which involves slow, deep breaths, often subsequent coughing, and tends to improve pulmonary function.

The third type of alveolar cell, the macrophages, like phagocytic cells elsewhere in the body, provide the immune system function of phagocytosis (Naeem et al., 2022). Alveolar macrophages are able to travel within the alveolar areas and isolate, consume, and remove foreign particles that have invaded the alveolar region. These cells are not involved directly in the gas exchange process.

### LIFE-STAGE CONTEXT

#### Incentive Spirometer Patient Education

With advanced age, some people experience hearing deficit or even total hearing loss (deafness). Older adults may

also experience one of the cognitive impairments related to dementia. These sensory or cognitive deficits can influence a patient's comprehension of a nurse's teaching because the patient is unable to hear or understand the instructions.

Use of the incentive spirometer can be confusing to patients and requires education by the nurse and/or respiratory therapist to properly describe its use. In addition to telling the patient how to use the device, it is recommended the nurse evaluate the patient's use of the incentive spirometer by demonstration. Often, patients assume that since the mouthpiece is attached to a strawlike hose, they should blow into it instead of the correct action of inhaling deeply through the mouthpiece. The device includes numbers representing volumes, and there is an indicator (piston) that moves with the patient's inhalation ([Figure 19.6](#)). Nurses often write a line with a marker to indicate a goal volume for a particular patient.

Patients with hearing impairment or cognitive deficit may require a more active explanation of the use of the incentive spirometer, including a demonstration by the nurse (using an incentive spirometer dedicated to such patient education), which may also include gestures and dramatic movements to illustrate deep intake of breath through the mouthpiece instead of a blowing action. Again, the patient should provide a return demonstration so the nurse is able to assess proper understanding and use of the incentive spirometer. These patients may also respond well to having a goal indicated by a line on the device, and written reminders as to how often and how many inhalations should be done may be helpful, depending on the type and extent of impairment.

**FIGURE 19.6** Explaining the incentive spirometer's components and demonstrating its correct use can help patients understand the device's importance. (credit: modification of work "Kendall Respiflo VS 5000, Atemtrainer, Incentive Spirometer" by Stefan Bellini/Wikimedia Commons, Public Domain)

---

## Respiration

The term **respiration** is a rather general term, often synonymous with the word *breathing*. It also may be used interchangeably with the term *ventilation*, as it involves inhalation and exhalation. Respiration is associated with the process of gas exchange, the primary purpose of the respiratory system.

Respiration is a basic function, generated by the neurological system, with control centers within the medulla oblongata and pons. Regulation by these systems, including actions stimulating the length and depth of each breath, is controlled by opposing actions of the apneustic and pneumotaxic centers, in efforts to maintain homeostasis, or stability, throughout the body.

Respiration is a critical function and is included as one of the vital signs, which most commonly include respiratory rate, heart rate, temperature, and blood pressure. In addition to the respiratory rate, nursing assessment of the respiratory system also includes auscultation of breath sounds and observation of depth and regularity of breathing, symmetry, whether the patient relies on the use of accessory muscles to breathe, their desired position, and how they breathe (e.g., pursed lips, gasping, apneic pauses), as well as apparent anxiety. A noninvasive device called a pulse oximeter measures saturation of hemoglobin with O<sub>2</sub> and can be a valuable respiratory assessment tool. Arterial blood gas (ABG) testing offers important data in some circumstances of respiratory compromise and potential failure, but ABGs are invasive and typically considered painful. Additional diagnostics may include chest radiographs (x-rays), computed tomography or magnetic resonance imaging, ventilation-perfusion (V/Q) scan, and a variety of pulmonary function tests, depending on the diagnosis being explored.

### Diffusion

Diffusion is a transport process that involves molecular movement driven by a concentration gradient. Molecules move from areas of high concentration to those with low concentration. In the case of respiratory gas exchange, diffusion is the primary process for the transport of gas molecules, moving the gas that is in high concentration to a low concentration area. Concentration gradients and the diffusion process are responsible for the exchange of gas between blood, with a high concentration of CO<sub>2</sub> and low O<sub>2</sub> concentration from the body, and the air in the lungs, which is high in O<sub>2</sub> concentration and has low CO<sub>2</sub> levels. The diffusion process is often very dynamic, as is the case in the respiratory system, as the molecules are not static. The concentration of gases changes with each breath and as tissues take up O<sub>2</sub> and release wastes.

### Perfusion

Perfusion, as previously defined, is associated with the circulatory system and is evidenced by the cardiovascular system's delivery of O<sub>2</sub> and nutrients to body tissues. Adequate perfusion indicates there is enough pumping action of the heart, which is referred to as **contractility**, and enough volume in the body's vascular system, as shown by a normal blood pressure. Under conditions of adequate perfusion, patient assessment includes vital signs within normal ranges, normal or baseline mentation, pulses typified as 2+ (normal), no dependent edema noted, breath sounds that are clear without adventitious sounds, and skin that is warm, dry, and of normal color for race.

Inadequate perfusion tends to involve a variety of signs and symptoms. Examples of poor perfusion include deterioration of vital signs, which may include **tachycardia** (heart rate over 100 beats per minute), hypotension (low blood pressure, e.g., under 90 systolic), abnormal body temperature, **tachypnea** (respiratory rate over 20 breaths per minute), mental status or level of consciousness changes that may range from slight confusion to lethargy to unconsciousness, peripheral edema, potentially adventitious breath sounds like crackles, and skin that feels cool, clammy, and is notably changed in appearance from normal to demonstrating pallor.

Respiratory changes due to lack of perfusion are particularly important, as the respiratory system is often the first to display signs and symptoms indicative of this negative status change. The signs emanating from the respiratory system may be obvious, such as tachypnea or crackles, or may be reflected in a neurological change, such as a change in mental status.

### Regulation of the Respiratory System

The respiratory system is controlled by the neurological system. As a basic function of life, respiration is an involuntary effort. Control of several involuntary respiratory and cardiovascular functions, and some movement of the muscular system, originates within the brainstem and cerebellum.

The medulla oblongata, the primary respiratory center in the brainstem, is responsible for signaling to respiratory muscles that allow the process of ventilation. The two sets of respiratory muscles are the ventral and the dorsal respiratory groups, and they cause muscle movement for expiration and inspiration, respectively. Some reflex responses like sneezing, vomiting, and coughing are also under the control of the medulla.

The respiratory rate is controlled by the pons. There are two centers within the pons that are involved in this

process. First is the apneustic center, which is involved in signals for length and depth of breaths, or **tidal volume**. The intensity of respirations is limited by stretch receptors of the muscles involved in breathing and by further signaling from the pneumotaxic center. Inhibitory signals from the pneumotaxic center also provide fine-tuning of respiratory rate control by limiting the action of the phrenic nerve. The actions of the pneumotaxic center lead to diminished tidal volume.

Watch the video “[Neural Control of Breathing: Respiratory System](https://openstax.org/r/77NeurConBreath)” (<https://openstax.org/r/77NeurConBreath>) and make note of the importance of C-5 as the narrator says, “C-5 Keeps You Alive.” Also, notice the impact of thoracic nerves on breathing.

### Dyspnea

The medical term for the subjective feeling of shortness of breath or difficulty breathing is dyspnea. Patients can be asked to rate their dyspnea on a scale of zero to ten, similar to using a pain rating scale. The feeling of dyspnea can be very disabling for patients. Nurses can objectively assess the response to the experience by noting a climbing respiratory rate, shallow breaths, the use of accessory muscles, and whether the patient is able to speak only one word between breaths. Certain pathological changes to normal physiology, like asthma, heart failure (HF), chronic obstructive pulmonary disease (COPD), **hypercapnia** (elevated CO<sub>2</sub>), and anxiety, may contribute to dyspneic episodes. Interestingly, anxiety can both cause and result from dyspnea, as struggling to breathe is one of the most helpless, frightening experiences most people can have.

Episodes of dyspnea may or may not require intervention from the healthcare team. Sometimes, the symptoms are mild and transitory, resolving as quickly as they began. However, if the patient’s respiratory status is compromised, prompt action may be necessary. Observations and assessments of respiratory deterioration may include a falling O<sub>2</sub> saturation as seen on pulse oximeter, exhaustion from sustained tachypnea and use of accessory muscles, intolerance of lying flat, and decreased breath sounds.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Recognize Cues: Patient with Dyspnea

Mr. Wu is a 73-year-old Asian immigrant who moved to California when he was 27 years old. Mr. Wu has been smoking two packs of cigarettes a day since he was 15 years old and was diagnosed with emphysema ten years ago. He presents to the emergency department stating he cannot breathe. Mr. Wu is sitting upright on the gurney and leaning forward onto the bedside table.

The nurse asks about his health history, and Mr. Wu is only able to say one word before he has to pause to try to catch his breath. The nurse auscultates Mr. Wu’s breath sounds and can barely hear inspiratory and expiratory sounds from either front or back.

Mr. Wu’s vital signs are as follows:

- HR 118 beats per minute
- BP 162/94
- RR 26 breaths per minute
- T 99.3°F
- SaO<sub>2</sub> 75 percent

The nurse considers this patient’s subjective and objective presentation and determines the following: Important information includes medical history and vital signs (HR, BP, RR, SaO<sub>2</sub>). Priority information includes SaO<sub>2</sub> and severely diminished breath sounds. Ventilation and oxygenation are the nurse’s immediate concern.

### Hypoxia

A reduced level of tissue oxygenation is the definition of **hypoxia**. Hypoxia has many causes, ranging from

respiratory and cardiac conditions to anemia. A specific type of hypoxia is **hypoxemia**, defined as decreased partial pressure of oxygen in the blood ( $\text{PaO}_2$ ) indicated in an ABG result.

Early signs of hypoxia are anxiety, confusion, and restlessness. As hypoxia worsens, the patient's level of consciousness and vital signs will worsen with an increased respiratory rate and heart rate and decreased pulse oximetry readings. Late signs of hypoxia include bluish discoloration of the skin and mucous membranes called **cyanosis**.

### Hyperventilation

Rapid, deep breathing is referred to as **hyperventilation**. A faster respiratory rate and depth cause low levels of  $\text{CO}_2$  in the blood. Hyperventilation can occur due to anxiety, panic attacks, pain, fear, head injuries, or mechanical ventilation. Acute asthma exacerbations, pulmonary embolisms, or other respiratory disorders can initially cause respiratory alkalosis as the lungs breathe faster in an attempt to increase oxygenation, which decreases the  $\text{PaCO}_2$ . After a while, however, these hypoxic disorders cause respiratory acidosis as respiratory muscles tire, breathing slows, and  $\text{CO}_2$  builds up in the blood ([Table 19.1](#)).

Physiological Challenge	Respiratory Pattern	Subsequent Acid-Base Imbalance	Resultant Compensatory Change	Ideal Result
Anxiety, pain, fear, asthma exacerbation, pulmonary embolus	Hyperventilation	Respiratory alkalosis (pH >7.45; $\text{PaCO}_2$ <35 mm Hg)	Hypoventilation in response to alkalosis	Normal pH (acid-base balance) with return to normal respiratory rate and depth
Decreased level of consciousness, obesity, weak respiratory muscles	Hypoventilation	Respiratory acidosis (pH < 7.35; $\text{PaCO}_2$ >45 mm Hg)	Hyperventilation in response to acidosis	Normal pH with return to normal respiratory rate and depth

**TABLE 19.1** Hyperventilation and Hypoventilation

## 19.2 Cardiovascular System

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the structures and functions of the cardiovascular system
- Understand the physiology of the cardiovascular system
- Recall regulation mechanisms of the cardiovascular system

In this section, the cardiovascular system is at the center of discussion. Without the cardiovascular system, gas exchange would not be useful, as perfusion is necessary for  $\text{O}_2$  and other nutrients to be distributed throughout the body and reach the tissues.

The contribution of this critical body system to the essential process of oxygenation is its pump and tank, which circulate and deliver vital elements to cells and tissues. This section explores the structure, function, and regulation of the cardiovascular system and its indispensable role in oxygenation.

### Structures and Functions of the Cardiovascular System

The heart is the central feature of the cardiovascular system; it is the pump that provides power. Considering the heart as the pump, the volume of circulating fluid is stored in the body's fuel tank and dispersed throughout the body by the blood vessels, or the vascular system. There has to be an adequate amount of fuel within the tank to be pumped around the body and perfuse the cells, tissues, and organs.

#### Heart

The human heart is located within the thoracic cavity, medially between the lungs in the space known as the **mediastinum**. The great veins, the superior and inferior venae cavae, and the great arteries, the aorta and

pulmonary trunk, are attached to the superior surface of the heart, called the base. The base of the heart is located at the level of the third costal cartilage. The inferior tip of the heart, the apex, lies just to the left of the sternum between the junction of the fourth and fifth ribs. It is important to remember the position of the heart when placing a stethoscope on the chest of a patient and listening for heart sounds.

The heart consists of four chambers: two atria and two ventricles. The right atrium receives deoxygenated blood from systemic circulation, and the left atrium receives oxygenated blood from the lungs. The atria contract to push blood into the lower chambers, the right ventricle, and the left ventricle. The right ventricle contracts to push blood into the lungs, and the left ventricle is the primary pump that propels blood to the rest of the body.

The heart tends to be considered as the muscle it is, but its structure actually includes three layers of slightly different cellular makeup. The outer layer is composed of fat and connective tissue and is an extension of the serous pericardium, one of three layers of protective pericardial tissue that surrounds the heart. Endothelial cells make up the heart's inner layer and envelop the valves; this tissue is the same as that of the inner layer of the nearby larger blood vessels. It is the midlayer of the heart that consists of muscle cells specific to the heart. The coronary arteries are the source of perfusion specifically to the heart muscle cells, or **cardiomyocytes**.

Cardiac cells are unique in a few ways. First, they are able to initiate spontaneous action potential, also called **automaticity**. Another distinctive property is the heart's own circulation: coronary arteries perfuse the cardiac muscle itself, and this blood flow is primarily supplied during diastole. Cardiac perfusion is enhanced by vasodilation of coronary arteries in response to catecholamines, hormones that function as neurotransmitters.

### Blood Vessels

After blood is pumped out of the ventricles, it is carried through the body via blood vessels. An **artery** is a blood vessel that carries blood away from the heart, where it branches into ever-smaller vessels and eventually into tiny capillaries where nutrients and wastes are exchanged at the cellular level ([Figure 19.7](#)). Capillaries combine with other small blood vessels that carry blood to a **vein**, a larger blood vessel that returns blood to the heart. Compared to arteries, veins are thin-walled, low-pressure vessels. Larger veins are also equipped with a **valve** that promote the unidirectional flow of blood toward the heart and prevent backflow caused by the inherent low blood pressure in veins as well as the pull of gravity ([Figure 19.8](#)).

**FIGURE 19.7** The arteries in the circulatory system carry oxygenated blood from the heart throughout the body. (credit: "Arterial System" by "LadyofHats"/Mariana Ruiz Villarreal/Wikimedia Commons, Public Domain)

A. = artery  
V. = vein

**FIGURE 19.8** The veins in the body carry blood to the heart to be oxygenated. (credit: "Venous System" by "LadyofHats"/Mariana Ruiz Villarreal/Wikimedia Commons, Public Domain)

In addition to their primary function of returning blood to the heart, veins may be considered blood reservoirs because systemic veins contain approximately 64 percent of the blood volume at any given time. Approximately 21 percent of the venous blood is located in venous networks within the liver, bone marrow, and integument. This volume of blood is referred to as **venous reserve**. Through venoconstriction, this reserve volume of blood can get back to the heart more quickly for redistribution to other parts of the circulation.

The amount of fluid within the blood vessels, or **intravascular volume**, contributes to blood pressure as measured by pressure within the arteries. Other organs may contribute waste products from metabolic functions into the bloodstream to be transported for further metabolism, and ultimately for some waste excretion from the body. An example is water entering the body through oral intake, absorption through the gastrointestinal tract, delivery to cells in need of fluid, and excess being delivered to the renal system for processing and urinary excretion.

## Physiology of the Cardiovascular System

From the first heartbeat to the last, the cardiovascular system is responsible for a constant blood supply to all body systems, including its own. Blood flow provides nutrients of all types to body tissues, and its allotment to specific areas changes as physiological demands change. Activity and rest alter the needs for O<sub>2</sub>, and nutrients such as carbohydrates, proteins, and fats, as well as dispersing hormones and other chemicals at the correct times to meet the body's requirements. All systems require constant blood flow, though most have periods of high versus low demand. Even the cardiopulmonary requirements are reduced during low activity but increase during stress, exercise, and any other stimulation of the sympathetic nervous system. The brain is an exception, as its need for circulation is continual and essential to the normal function of many bodily processes.

Blood pressure (BP) and heart rate (HR) vary in response to the demands of activity and rest, and they also vary as needed as the body reacts to fluid changes, autonomic nervous system input, and other systemic influences. Another concept is that of cardiac output (CO), which is the amount of blood pumped by the left ventricle in one minute. Cardiac output is considered one of the advanced hemodynamics (beyond basic vital signs) that can be monitored in certain critical care settings with specialized equipment. Refer to [Table 19.2](#) for more details about the information provided, the formulas involved (Bonsall, 2016; Bruss & Raja, 2022), and examples.

Terms	<p><b>Cardiac Output (CO):</b> amount of blood pumped by the heart in one minute Normal range 4 to 8 liters/minute (L/min)</p> <hr/> <p><b>Cardiac Index (CI):</b> CO with consideration for body surface area (BSA) Normal range 2.5 to 4 L/min/m<sup>2</sup></p> <hr/> <p><b>End-systolic volume (ESV):</b> amount of blood remaining in the heart at the end of systole*</p> <hr/> <p><b>End-diastolic volume (EDV):</b> amount of blood remaining in the heart at the end of diastole*</p> <hr/> <p><b>Heart Rate (HR):</b> number of heartbeats per minute Normal range 60 to 100 bpm</p> <hr/> <p><b>Stroke Volume (SV):</b> left ventricular volume pumped with each beat of the heart Normal is approximately 1 mL/kg of body weight; obtained by echocardiogram, Doppler ultrasound*</p>
Calculations	<p>CO = HR × SV CI = CO/BSA SV = EDV – ESV</p> <p><b>Note:</b> These are not typically calculated by bedside ICU nurses but are monitored by them for trends and hemodynamic changes.</p>
Examples	<ul style="list-style-type: none"> <li>• A patient with a slow HR (bradycardia). This HR leads to a lower CO, but the SV may compensate by ejecting more volume with each beat. This allows for the continuation of normal CO, at least temporarily.</li> <li>• A patient with a fast HR (tachycardia). This increase in HR can compensate, at least temporarily. However, if the HR becomes too fast, SV suffers because there is not enough time for ample ventricular filling.</li> </ul>

\*ESV, EDV, and SV are obtained by specialized testing. Information is entered into the CO monitor, and it obtains actual and/or estimated information that is converted into numbers displayed for continuous monitoring.

**TABLE 19.2** Advanced Hemodynamics

### Circulation

There are two distinct but linked circuits in human circulation called the pulmonary and systemic circuits ([Figure](#)

19.9). The pulmonary circuit transports blood to and from the lungs, where it picks up oxygen and delivers carbon dioxide for exhalation. The systemic circuit transports oxygenated blood to virtually all of the tissues of the body and returns deoxygenated blood and carbon dioxide to the heart to be sent back to the pulmonary circulation.

**FIGURE 19.9** Blood flows through the cardiopulmonary circuit and the heart. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

There are potential physiological interruptions that lead to a body not being in a state of homeostasis. An example is **arteriosclerosis**, or stiffening of the arterial walls, and a subcategory, **atherosclerosis**, or buildup of plaque deposits within the artery walls. Arteriosclerosis lessens the elastic properties of blood vessels and, therefore, the ability for vasodilation, which increases the intravascular pressure. Atherosclerosis narrows the internal space of blood vessels, which also increases the pressure within the intravascular space. These two pathophysiological properties often occur together, and either can cause hypertension when renal arteries are impacted. While hypertension is a possible result, uncontrolled hypertension is also a risk factor for the development of arteriosclerosis (AHA, 2023;

Poznyak et al., 2022). Other risk factors include dyslipidemia, diabetes mellitus (DM), and cigarette smoking. Hypertension contributes to the development of arteriosclerosis by thickening the walls of blood vessels, plaque development, and the potential for rupture of the blood vessel walls. It is not uncommon for patients with these diagnoses to also be hypervolemic, from either cardiac or renal (or a combination) dysfunction. In these cases, multiple pathologies are contributing to excessive vascular volume and pressure. Temporary increases in fluid and BP can be helpful compensatory mechanisms for the improvement of perfusion; however, with these diagnoses, there is little relief from the elevated pressures, little rest for the body system, and ultimately, a reduction in perfusion.

Another example of a lack of stable perfusion is hypovolemia or a lack of fluid in the vascular space. This can be from different issues, like blood loss from surgery or traumatic injury, or fluid loss from exertion or hot weather. The loss of volume means less fluid volume in the circulatory system, which is typified by a low BP, manifested by signs and symptoms of low perfusion, such as mental status changes ranging from slight confusion to, potentially, seizure, cool and clammy skin, low urine output, climbing creatinine, and other laboratory results illustrating a concentrated sample.

## CULTURAL CONTEXT

---

### Buerger Disease

Buerger disease (BD) affects small blood vessels and causes a lack of perfusion often leading to gangrene and subsequent amputation. The major risk factor for BD is cigarette smoking, and it occurs more frequently in men than women (Baran et al., 2019; Bucci et al., 2013; Kurata et al., 2003). In spite of the risks associated with smoking, many patients who have suspected or confirmed BD are addicted to nicotine and/or the habitual behaviors associated with smoking and find it impossible to quit.

In the United States, a patient example from the early 2000s illustrates the grip smoking often has on people: the patient was a female about 55 years old, who had spent many years as a nurse. She was also a cigarette smoker of at least a pack per day for forty years. At the time of the nursing encounter, the patient was hospitalized in anticipation of her fourth limb amputation secondary to BD. Her three other limbs had been amputated above the joints (knees and elbow), and the remaining arm was scheduled for amputation. The patient had continued to smoke up to just prior to admission.

Some recent studies about smoking and smoking cessation have brought some insight into the cultural component of smoking and the difficulty of “kicking the habit.” Smoking has long been associated with masculinity (Khanal et al., 2023). It can be difficult to overcome long-standing traditions, in spite of the potential contribution to disease processes like BD.

Another study focused on socioeconomic factors and noticed that higher rates of smokers were found within lower socioeconomic positions (Manns et al., 2023). One of the reasons given for difficulty in cessation of smoking is a lack of support for, and more barriers to, quitting. Also noted, the sociocultural circle within the lower socioeconomic positions tends to include more smokers, and therefore, a culture of continued cigarette smoking.

In a study exploring the reduction of the smoking habit, there is hope for the role of family support offering a positive impact on cessation (Cho et al., 2023). Smokers eating alone were found to smoke more than those who ate meals with their families. Cultural input can be influential to behaviors, whether in supporting smoking or its cessation. The value of a strong social circle, offering group interest and support to quitting smoking brings hope to those attempting to quit a highly addictive habit like smoking.

---

### Stroke Volume

The amount of blood expelled from the left ventricle during a single systolic contraction is known as **stroke volume (SV)**. Three primary factors that affect SV are **preload**, or the stretch on the ventricles prior to contraction; contractility, or the force or strength of the contraction itself; and **afterload**, the force the ventricles must generate to pump blood against the resistance in the vessels. The calculation for SV is  $EDV - ESV$ .

The **ejection fraction (EF)** is the percentage of blood within the ventricle that is expelled during a single systolic

contraction. A low EF means that the heart is not creating an efficient contraction, and this is a sign of HF. HF can occur with intact EF, or it can be reduced. Normal EF is approximately 50 to 70 percent; it is therefore considered preserved if it is over 50 percent (Bruss & Raja, 2022). Reduced EF is indicated when there are clinical manifestations of HF and the EF is at or under 40 percent. The formula for EF is  $SV/EDV$ . Cardiologists use information about EF to explore cardiac-related diagnoses like hypertrophy and HF, as well as to confirm adequate perfusion and function.

## Regulation of the Cardiovascular System

Cardiovascular regulation is an autonomic body function that is controlled from within the brainstem, specifically the cardiovascular center of the medulla oblongata. Recall that the autonomic nervous system (ANS) has two systems: the sympathetic nervous system (SNS), nicknamed the “fight or flight,” and the parasympathetic system (PSNS), with the nickname “rest and digest.” The SNS, when stimulated, is involved in the release of powerful neurotransmitters like epinephrine and norepinephrine, to initiate physiological responses like bronchodilation, pupillary dilation, glucose release, increased HR and BP, which may assist the person to escape a life-threatening circumstance.

As the term “fight or flight” indicates, this may allow for a burst of energy and strength to battle or flee from an aggressor. In the case of illness, such physical responses may provide at least temporary improvement of vital signs to preserve adequate perfusion until medical assistance can be provided. The PSNS is associated with responses opposite those of the SNS, including slow HR, lower BP, constricted pupils, and bronchoconstriction. With proper function, the two systems work in concert to maintain homeostasis.

There are three functional centers within the cardiovascular center, responsible for different responses and actions. First, the cardioaccelerator center is involved with the stimulation of the SNS and the cardiac accelerator nerve. The result, as the name and association with the SNS indicate, are signs and symptoms of SNS responses, some of which were previously listed. The second center is the cardioinhibitory center, which works with the PSNS and the vagus nerve. When stimulated, it results in the PSNS reactions including those listed earlier. Finally, the vasomotor center is involved with the contraction of smooth muscles and vascular tone, which is necessary for the constriction of blood vessels and, therefore, regulation of BP.

The nervous system plays a critical role in the regulation of vascular homeostasis based on baroreceptors and chemoreceptors. Baroreceptors are specialized stretch receptors located in the aorta and carotid arteries that respond to the degree of stretch caused by the presence of blood and then send impulses to the cardiovascular center to regulate BP. In addition to the baroreceptors, chemoreceptors monitor levels of oxygen, carbon dioxide, and pH. When the cardiovascular center in the brain receives this input, it triggers a reflex that maintains homeostasis.

## REAL RN STORIES

### Balancing Cardiopulmonary Nursing Care

**Nurse:** Amanda, RN

**Clinical setting:** Cardiovascular ICU

**Years in practice:** Less than one year at the time of the event

**Facility location:** Delta, Colorado

I started my career as a new graduate nurse in a Cardiovascular ICU working nights. On one particular shift, I was assigned to take a report from the emergency department (ED) on a Black male patient who had presented about an hour earlier with chest pain, dyspnea, and hypertension. A twelve-lead electrocardiogram (ECG) in the ED did not show any signs of ST elevation, and oral nitroglycerin, morphine, and 2 L of O<sub>2</sub> via nasal cannulas subsided his

symptoms. The emergency room had placed him on a nitroglycerin drip and was sending him to my unit to be on observation overnight. This was a standard chest pain observation patient, and the cardiologist had a standing order set that allowed me to titrate the nitroglycerin to chest pain and to keep the systolic BP above 90 mm Hg.

I distinctly remember this patient, as he could not move without his chest pain increasing and becoming short of breath. Just admitting him to his room I had to increase the nitroglycerin drip to keep his pain under control and help his oxygenation. Soon after he settled, however, a fifteen-minute BP check showed his pressure had plummeted to 87/45, just with a minor adjustment of the drip. I decreased the drops (gtt). In about fifteen to twenty minutes after this decrease, he began to rate his chest pain at a four out of ten and complained of not being able to catch his breath. However, his pressure only increased a bit, hovering around 90 systolic, so I knew increasing the drip would only cause that pressure to plummet. I increased his O<sub>2</sub> to 4 L, called the physician, and received PRN orders for morphine every four hours as needed. This did help his breathing and pain. What ensued for the next five hours of my shift was a delicate balance of titration of nitroglycerin, morphine (when able), O<sub>2</sub>, keeping the patient still, and a lesson for me in the significant relationship of the vascular system and respiratory system. When his chest pain increased, I knew his BP would be stable, however, his breathing would not be. The amount of nitroglycerin needed to keep his pain gone and his breathing stable was not stable for his BP, and it had to be supplemented with morphine and, at times, increasing his O<sub>2</sub>. After about five hours of this and a few phone calls from me, the cardiologist took him to the Cath lab around 2 a.m. A stent was placed for a 50 percent occluded artery. I never was able to completely keep his pain gone for long without making him unstable in some other area; however, by morning I had learned the importance of my role as his cardiovascular RN. If I (or any nurse) had not been there to consistently check his status, he could have had a major cardiovascular event and may have needed more than just a stent.

---

The next section offers a discussion about the electrical system of the heart, including the specific pathway through the heart. The electrical system responds, as mentioned earlier, to the body's changes and responses to the ANS, and in accordance causes reactions from the mechanical system, in actions like cardiac pumping and vascular circulation.

### Electrical Impulses

The human body includes an electrical system, which directly and indirectly affects all systems. Cardiac electrical impulses ([Figure 19.10](#)) lead to the mechanical (muscle) movement of the myocardium, which pumps and circulates blood through both systemic and pulmonary circuits, thereby (in normal circumstances) perfusing the entire system.

**FIGURE 19.10** Normal electrical conduction through the heart travels from the sinoatrial node, to the internodal pathways, the atrioventricular node, the bundle of His, to the bundle branches (right and left), and to the Purkinje fibers. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Sinoatrial Node

Known as the pacemaker of the heart, the sinoatrial (SA) node has the highest rate of depolarization. It initiates the sinus rhythm or normal electrical pattern followed by contraction of the heart. Criteria for normal sinus rhythm include that the impulse begins at the SA node, travels from the SA node to the atrioventricular (AV) node in 0.12 seconds or less, and has a rate between 60 and 100 beats per minute. The firing of the SA node can be visualized by an **electrocardiogram** (ECG or EKG), which is a noninvasive test that involves attaching leads to a patient's chest and limbs: the machine then obtains a visual interpretation of the electrical impulses involved in the cardiac cycle ([Figure 19.11](#)).

**FIGURE 19.11** (a) Cardiac conduction from the SA node of the right atrium through the Purkinje fibers of the ventricles. (b) The associated rhythm as seen on an ECG is shown in the image. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Atrioventricular Node

Normal cardiac electrical signals originate in the SA node and travel next to the AV node, which is found in the right atrial wall close to the coronary sinus, and then the septum between the atria. The electrical impulse next travels to the bundle of His, which leads to bilateral ventricular contraction. The normal conduction rate at the AV junction is 40 to 60 beats per minute. In the event the SA node does not fire, the AV node is able to initiate an impulse. While

the slower rate is likely to be noticed symptomatically by the patient because of lower CO from both reduced HR and SV, it is often able to maintain an adequate HR and BP until a definitive intervention can be done.

### Bundle of His

The bundle of His may also be referred to as the atrioventricular bundle, which helps identify its location and where it is in the cardiac electrical pathway. The bundle of His is composed of atrioventricular tissue, and it carries the electrical impulse from the AV node down the interventricular septum to the right and left bundle branches, which lead to the Purkinje fibers of the respective right and left ventricles. As the electrical impulse makes its way down the bundle branches and to the Purkinje fibers, it initiates the muscular action of ventricular contraction.

### Dysrhythmia

The word **dysrhythmia** refers to a rhythm abnormality; the term arrhythmia indicates a lack or absence of rhythm but is often used synonymously with dysrhythmia to mean an abnormal rhythm. Dysrhythmias can be minor or extreme and life threatening, depending on where the anomaly originates, what it causes, and how extensive it is. One of the indicators of the severity of dysrhythmia is the patient's symptoms. Depending on a patient's medical history, level of well-being, mental state, and potentially other factors including the specific abnormal rhythm, there may be compensatory changes supporting little or no symptoms, or the patient may feel any combination of symptoms, including dizziness, weakness, syncope, palpitations, chest pain, or cardiac arrest.

Dysrhythmias have a variety of causes. A few examples are provided in the following paragraphs. Sometimes, irritable spots (foci) develop in the cardiac muscle where the property of automaticity may become a hindrance. This can lead to electrical misfires, as the irritable focus generates an impulse that may cause the normal electrical system to be interrupted, or the pathway altered.

Injuries to the heart or to a particular group of cells may also cause the normal electrical pathway to be disrupted, and slight changes or delays can develop, which are visible on ECGs when waves, intervals, and complexes are assessed and measured. An example is a first-degree heart block, where there is a delay in the period of time the impulse travels from the SA node to the AV node. On an ECG, this is seen as a prolonged PR interval.

Certain infectious diseases like bacterial endocarditis can lead to damage to the heart, including vegetations on valves causing valvular malformation, or an inability to open and close properly. This can produce disturbances in normal forward blood flow, which may be heard by auscultation with a stethoscope as a murmur.

Atrial fibrillation (A-fib) is a common dysrhythmia that sometimes is intermittent, may resolve on its own, or may respond well to treatment with medications or cardioversion. Sometimes, when interventions have not been successful in converting the patient out of A-fib, the goal becomes to minimize complications from inefficient atrial movement and subsequent increased risk for blood clot development. Medications like anticoagulants are used in this situation to prevent clot formation.

### LINK TO LEARNING

More information on [dysrhythmias, defibrillation versus cardioversion, and potential complications](https://openstax.org/r/77DysDefvsCard) (<https://openstax.org/r/77DysDefvsCard>) is presented in this video.

Ventricular dysrhythmias are generally considered more dangerous than those originating in the atria, as the ventricles are integral in oxygenation and perfusion. These abnormal rhythms can be the result of a variety of influences, including illicit drugs like cocaine or methamphetamine, a traumatic injury such as being hit directly in the chest by a baseball, or as a consequence of a myocardial infarction (MI), where both electrical and mechanical tissue can be damaged.

Nurses are trained to respond to respiratory and cardiac emergencies, some of which are the result of dysrhythmias. This may include basic life support (BLS) training incorporating the combination of rescue breathing and chest compressions of **cardiopulmonary resuscitation (CPR)**. BLS instruction also includes the use of an **automated external defibrillator (AED)**, which is an easy-to-use portable device available in many settings that can analyze a cardiac rhythm and defibrillate, if appropriate, in order to reestablish an effective cardiac rhythm. It is noteworthy that AEDs identify heart rhythm but do not provide an option for the operator to view it; they are more designed for

bystander CPR response.

On patient care units within acute care hospitals, manual defibrillators are more common and offer portable monitoring on a small screen where medical providers can view and assess the patient's rhythm, as well as other features. Defibrillators provide shocks of the intensity to treat ventricular tachycardia or fibrillation but can also be set to deliver lower joules to attempt synchronized cardioversion for such dysrhythmias as A-fib. Additionally, the option to externally pace a patient is available on these devices. Newer manual defibrillators have an automatic AED option ([Figure 19.12](#)).

(a)

(b)

**FIGURE 19.12** (a) A manual defibrillator provides various options for monitoring, recording, and interventions, and (b) an AED is used for automated responses. (credit a: modification of work “Manual external defibrillator monitor” by “Aededitor”/Wikimedia Commons, CC BY 3.0; credit b: modification of work “AED & Fire Extinguishers, both necessary” by “David Bruce Jr.”/Flickr, CC BY 2.0)

In **advanced cardiac life support (ACLS)**, extra training is involved, often for medical providers in prehospital and hospital settings, and this includes the addition of resuscitation and support cardiac medications. Commonly, these include drugs in the antidysrhythmic classification as well as those like catecholamines that increase BP—both of these classes of medicines are used in arrest circumstances to attempt to convert abnormal rhythms to normal, and/or enhance perfusion through other means.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety: Defibrillation

A hospitalized patient who experiences a ventricular fibrillation (VF) arrest is treated by a system of assessments, actions, and interventions, coordinating members of an interdisciplinary healthcare team, with QSEN Competencies in mind (QSEN, 2022). Associated competencies for the intervention defibrillation include patient-centered care, teamwork and collaboration (T&C), and safety (S). Considering the interdisciplinary nature of treatment of cardiac arrest, let us explore the knowledge, skills, and attitudes within the T&C competency through an unfolding example (QSEN, 2022):

1. **Knowledge:** “Describe scopes of practice and roles of healthcare team members” (p. 3).

*Example:* VF arrest – code called by bedside RN, who immediately begins CPR while awaiting arrival of code team and equipment. Upon arrival of the team, there are predetermined roles based on scope of practice for the different professions. Team leader is typically a physician or advanced practitioner. BLS-certified personnel can alternate chest compressions every one to two minutes.

**Skills:** “Function independently within own scope of practice as a member of the healthcare team” (p. 3).

*Example:* The bedside nurse identified the arrest situation, called the code, and began CPR—all within the RN scope of practice. Others function within their professional scope as personnel converge on the patient setting, for example, RT begins bagging the patient during chest compressions by other personnel, team leader clearly states orders for interventions based on VF/cardiac arrest algorithm, education, and other skills, pharmacist provides ordered medications from the code cart as ordered, for the RN-assigned medication

administration.

**Attitudes:** “Value the perspectives and experiences of all health team members” (p. 3).

*Example:* The team members realize, understand, and practice their specific roles during an arrest situation. Collaboration between all members of the patient care/code team is respectful and values all members equally.

2. **Knowledge:** “Describe strategies for identifying and managing overlaps in team member roles and accountabilities” (p. 3).

*Example:* Hospital personnel, through BLS and ACLS certification/recertification, are practiced at the roles and responsibilities during emergencies. RNs assume roles including the primary nurse (whose patient is involved in the emergency), medication RN, recording RN—once the particular role is assumed, each of these nurses tends to continue that particular role throughout the event. RT provides bagging with the Ambu bag, followed by assisting with intubation, CO<sub>2</sub> confirmation, and placement of the patient on a ventilator. Various team members serve as compressors, providing chest compressions for one to two minutes at a time in relay format.

**Skills:** “Clarify roles and accountabilities under conditions of potential overlap in team member functioning” (p. 3).

*Example:* The primary RN role is changeable, based on nurse-patient assignments; an experienced team may have predesignated selections based on preference and experience/skill level, so the recorder may be the nursing supervisor, and the charge RN may administer medications. The team leader is usually a physician—intensivist or ED physician is common. As various members of the team provide chest compressions for short periods, transition from one compressor to another should be anticipated and verbally planned and executed for minimal disruption.

**Attitudes:** “Respect the unique attributes that members bring to a team, including variations in professional orientations and accountabilities” (p. 3).

*Example:* Team leaders tend to be those with advance practice background and prescriptive authority. The primary RN is considered to have the best familiarity with the patient—history, status trends, medications, and so on, and therefore can provide a quick overview. Various team members may be able to serve in more than one capacity, and clear communication is critical throughout an emergency, and in any transitions.

3. **Knowledge:** “Describe examples of the impact of team functioning on safety and quality of care” (p. 4).

*Example:* Treatment of a VF arrest includes early defibrillation. The prompt arrival of the code team, and the code cart with the defibrillator/monitor to confirm the rhythm, and subsequently treat it, are necessary. Placement of pads on the patient, activation of the machine, and its readiness for defibrillation when charged all must be clearly communicated throughout the event.

**Skills:** “Assert own position/perspective in discussions about patient care” (p. 4).

*Example:* Each team member’s role is a critical part of the total situation, and the contribution is important and should be shared at appropriate times. A nurse may be responsible for pulse checks when chest compressions are briefly halted, and that nurse’s input is vital at that time. Whether the patient has bilateral breath sounds after intubation is also key, and the RN or RT who auscultates the chest should distinctly state these findings.

**Attitudes:** “Appreciate the risks associated with handoffs among providers and across transitions of care” (p. 4).

*Example:* During an emergency circumstance like a cardiac arrest and code response, all members of the healthcare team should realize the importance of clear, concise communication among personnel. Whether this is to have a second physician join the team, or RT and an RN help with intubation and securing the endotracheal tube (ETT), or to change compressors after a minute or two of exhausting work, transitions should always maintain the central focus on the patient and clearly move from one situation or care provision to another.

---

### Ischemia

A lack of O<sub>2</sub> delivery to a part of the body, especially the cardiac tissue, is termed **ischemia**. Angina pectoris is a rather common ischemic event whereby O<sub>2</sub> supply does not meet demand. Angina can be chronic and stable, in which case it is predictable, and patients are often able to treat it by discontinuing activity, resting, and administering sublingual nitroglycerin. If angina becomes unpredictable, it is described as unstable angina and is

associated with acute coronary syndrome (ACS), which involves worsening coronary disease. Ischemia is reversible if adequate perfusion is reestablished promptly. Coronary artery disease (CAD) can progress along a continuum, beginning with a healthy coronary system, to a diagnosis of stable angina pectoris, and to unstable angina. If it worsens and perfusion is inadequate for too long, it can advance to a MI. Once the tissue is damaged, terminology changes to infarction. Infarcted tissue does not recover and leads to permanent repercussions; a common adverse outcome of CAD is HF.

### Heart Failure

Inefficiency of the heart's contractility characterizes HF. Ineffective contractility may arise from chronic hypertension, often associated with hypervolemia (fluid volume excess). According to Starling's law, the heart is capable of stretching muscle fibers, which initially improves the strength of muscle contraction and is a desired effect, as it increases SV. However, if this is a chronic situation, there can be a limit to this ability to stretch, and if exceeded, the cardiac muscle can become either hypertrophied (excessively enlarged) or unable to rebound from being overstretched, in which case the muscular walls become weak and floppy. Either circumstance reduces cardiac contractility, which is seen as HF symptoms, as seen in [Figure 19.13](#).

## UNFOLDING CASE STUDY

### Unfolding Case Study #4: Part 1

Mrs. Jenson, a 72-year-old female, presents to the emergency room with worsening shortness of breath, fatigue, and swelling in her lower extremities over the last week. She reports increasing difficulty performing activities of daily living due to weakness and increased dyspnea.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, heart failure (class III), osteoarthritis</p> <p><b>Family history:</b> No significant family history reported.</p> <p><b>Social history:</b> Widowed ten years ago, currently living in an assisted care facility. No children.</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Lisinopril 20 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Metoprolol 50 mg PO once daily</li> <li>• Aspirin 81 mg PO once daily</li> <li>• Furosemide 40 mg PO once daily</li> <li>• Losartan 25 mg PO once daily</li> <li>• Ibuprofen 400 mg PO Q6 hours PRN mild arthritic pain</li> </ul>
Nursing Notes	<p><b>1100: Assessment</b></p> <p><b>Neurological:</b> Alert and oriented x4, follows commands appropriately</p> <p><b>Respiratory:</b> Labored and shallow breathing pattern, bilateral crackles in bases</p> <p><b>Cardiovascular:</b> Bilateral lower extremity edema, tachycardia</p> <p><b>Abdominal:</b> Bowel sounds present in all four quadrants, no pain or tenderness noted</p> <p><b>Musculoskeletal:</b> Limited range of motion in bilateral shoulder joints, patient reports pain in wrist joints related to osteoarthritis</p> <p><b>Integumentary:</b> Generalized pallor</p>
Flow Chart	<p><b>1100: Assessment</b></p> <p>Blood pressure: 158/89 mm Hg</p> <p>Heart rate: 111 beats/minute</p> <p>Respiratory rate: 27 breaths/minute</p> <p>Temperature: 98.9°F (37.2°C)</p> <p>Oxygen saturation: 88 percent on room air</p> <p>Pain: 6/10 (joint pain)</p>
<ol style="list-style-type: none"> <li>1. Recognize cues: Based on the assessment findings, what are the most important cues for the nurse to recognize?</li> <li>2. Analyze cues: What is the relationship between the recognized cues and the patient's past medical history?</li> <li>3. Prioritize hypotheses: Based on the patient's symptoms, which type of heart failure (left or right) is the patient most likely experiencing?</li> </ol>	

## 19.3 Factors Affecting Cardiopulmonary Function

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine physiological considerations for impaired cardiopulmonary function
- Recognize lifestyle and behavioral pattern considerations for impaired cardiopulmonary function
- Remember diagnostic testing used to monitor cardiopulmonary functioning

In the upcoming section, pathophysiology is considered, as impaired cardiopulmonary function is examined. Nonmodifiable and modifiable influences can have significant impacts on cardiopulmonary function and are thus considered risk factors. Age and genetics are examples of nonmodifiable risk factors, as the alterations or changes to the cardiopulmonary system are unavoidable. Risk factors that are modifiable include behaviors and lifestyle choices, so whether a person is active and follows a diet that helps prevent negative cardiopulmonary changes is considered modifiable. Sometimes such positive behaviors are successful at halting or slowing processes like the

development of hypertension, obesity, or hyperlipidemia.

In health care, it is often considered more beneficial to take a proactive approach and focus on the prevention of medical diseases and diagnoses, rather than waiting for a reactive response. Patients who have an understanding of their own health status and play an active role in their care are more inclined to seek preventive care and screenings, thereby avoiding preventable illness, or obtaining care early. Some such patients are able to minimize dysfunction of the cardiopulmonary system.

A variety of diagnostic tests assist healthcare providers in the identification of abnormalities, whether through preventive screenings or prompt recognition. Depending on the test, providers can monitor the progress of the disease or the effectiveness of treatment, whether medical, surgical, or pharmacological. Care plans can therefore be evaluated and redesigned based on individual patient status and goals of the patient and healthcare team.

### Physiological Considerations for Impaired Cardiopulmonary Function

Homeostasis is a delicate balance, and minute changes can lead to slight or major changes physiologically. In the case of cardiopulmonary function, such alterations may affect either of the interrelated systems. Nonmodifiable risk factors for impaired cardiopulmonary function include advancing age, genetics, race, family history, and health status. Modifiable risk factors include physical inactivity, smoking, diet, and obesity.

Nurses need to anticipate such alterations and be prepared to act on changes. In many situations, proactive actions can make a huge difference, sometimes even more than reactive responses to an already symptomatic problem (Agency for Healthcare Research and Quality [AHRQ] PSNet, 2019). This section explores several factors that are likely to have effects on the cardiopulmonary system, followed by diagnostic testing that is used to monitor the function of this inescapably intertwined set of systems.

#### Age

Some cardiovascular changes within the heart, vessels, and blood occur naturally with age. Within the heart structure, the sinoatrial (SA) node can lose cells, and fat deposits and fibrous tissues can develop causing the SA node to fire at a slightly lower HR. In some people, enlargement of the left ventricle can occur with age, causing the chamber to hold less blood. Arrhythmias can develop, such as A-fib, caused by types of heart disease. Deposits of lipofuscin, degeneration of heart cells, and thickened heart valves can cause a heart murmur from turbulent blood flow within the heart.

In the blood vessels, baroreceptors can become less sensitive with aging, causing dizziness or orthostatic hypotension. Capillary walls may thicken, slowing the rate of exchange of nutrients and oxygen for waste and carbon dioxide. The aorta can thicken and stiffen, creating an increase in BP and cardiac hypertrophy.

A reduction in body water increases the viscosity of blood, causing a decrease in blood volume. Red blood cells are produced at a slower rate, delaying the body's response to anemia or blood loss. A decrease in neutrophils reduces the body's immune response to infection.

Aging also affects the pulmonary system. Aging lungs lose elastic recoil, causing small airway collapse and decreased alveolar surface area, decreasing lung compliance. Spirometry changes include a decrease in total lung capacity, an increase in residual volume, and a decrease in the vital capacity of the lungs. In the chest wall cavity, conditions such as osteoporosis, arthritis, calcification of the thoracic spine, and changes to intercostal muscles can increase chest wall rigidity. The chest wall can become barrel shaped to compensate for a loss of lung elasticity, causing the diaphragm to flatten and become less efficient.

#### Genetics

There are genetic disorders that affect the pulmonary and/or cardiovascular systems. Research has identified several such inherited cardiovascular diagnoses and described them as vascular, cardiomyopathies, or involving arrhythmias (Musunuru et al., 2020). For example, elevated lipids can be difficult to treat for some individuals; familial hypercholesterolemia may be the genetic source of this dyslipidemia.

A rather common example of a vascular genetic disorder is Marfan syndrome, which is often associated with excessive height and other long bones like those of the hands and feet. However, Marfan syndrome also frequently impacts blood vessels, including the aorta. The risk of aortic aneurysm and possible dissection is a major concern with this genetic diagnosis (Musunuru et al., 2020). Another genetic disorder, Loeys-Dietz syndrome, is similar to

Marfan syndrome, as it impacts connective tissues and can cause aortic aneurysm and potential dissection.

Long QT syndrome and bradycardia syndrome are arrhythmias associated with genetics, although there are other possible causes, including certain medications (Musunuru et al., 2020). Genetic cardiomyopathies include several of the muscular dystrophies, including Duchenne, limb-girdle, and Emery-Dreifuss. Dilated and hypertrophic cardiomyopathies can also be rooted in genetics.

More than sixty genes have been identified as involved in at least a dozen pulmonary syndromes (Brigham and Women's Hospital, 2023). One of the most common breathing disorders is asthma, and for some people, the cause is genetic. Many of the pulmonary syndromes are rather rare. Pulmonary syndromes are distinguished by those associated with cysts (causing the formation of abnormal cysts), **fibrosis** (causing abnormal, scar-like tissue), or **bronchiectasis** (causing dilated airways).

While rare and involving organs other than the lungs, cystic fibrosis (CF) is perhaps best recognized as a lung disorder; it is considered a bronchiectatic syndrome (Brigham and Women's Hospital, 2023). CF causes mucus to become thick and sticky, with respiratory secretions among those affected; this can cause airway limitations and difficulty breathing. Pulmonary fibrosis and pulmonary hypertension are both fibrotic genetic disorders. Alpha-1 antitrypsin deficiency is a genetic cystic pulmonary disorder that affects the lungs and potentially the liver. Alpha-1 antitrypsin deficiency involves symptoms similar to those of emphysema, and indeed patients may progress to an emphysema diagnosis (Brigham and Women's Hospital, 2023).

### Health Status

The status of one's health at baseline can be critical for outcomes when faced with any sort of alteration of normal physiological function. Those people who are generally healthy when there is a challenging event, whether illness, injury, or emotional stress, have a far better chance of confronting the event with little physiological decline or residual effect. Conversely, someone whose baseline is poor health, as reflected by multiple **comorbidities** (multiple medical diagnoses), is at a disadvantage as far as withstanding the challenging event.

The **metabolic syndrome** is an example of a cluster of diseases (including hypertension, high blood sugar levels, a large waistline or apple shape, high triglycerides, and low HDL cholesterol) that occur together, increasing the likelihood of developing heart disease. Some patients are not identified as having the syndrome, as they experience only one or two of the diagnoses. There are certain disorders that commonly cluster together like those of metabolic syndrome, with the possibility of additive effects from the multiple disorders identified. Several comorbidities have been identified with frequent prevalence in patients with cardiopulmonary disorders. The four cardiopulmonary diagnoses isolated in this research were HF, peripheral arterial disease (PAD), coronary heart disease (CHD), and stroke. DM, COPD, and low vision were identified as the comorbidities with the most statistically significant impact on the development of the disorders.

The interaction of comorbidities and their contribution to the diagnoses can be exemplified (Buddeke et al., 2019):

- DM is also associated with the development of microvascular damage, which can play a part in vision problems, as well as hypertension and PAD.
- Hyperlipidemia is a frequent contributor to intravascular plaque development, hypertension, and ultimately significant heart disease that may lead to MI and/or stroke. MI is a common cause of HF.
- COPD is often associated with cigarette smoking; impaired gas exchange is one of the common results. The cardiovascular system is also likely to be impacted, resulting in MI and/or stroke.

### Medications

Medications are prescribed for any number of reasons, and they are not without potential for problems. Drugs have desired effects and side effects. Sometimes, side effects are negative or even dangerous, referred to as adverse effects. Following are some examples of medications that have the potential to negatively affect the cardiovascular or pulmonary systems, or both.

Often, medications to treat one problem can lead to another. An example is the antidysrhythmic class of drugs. Most of these drugs are accompanied by a warning they may cause other dysrhythmias. Amiodarone is one such drug, as there is a risk for cardiac rhythm changes. Amiodarone may also affect the pulmonary system, with pulmonary fibrosis (Penn Medicine, 2023) and acute respiratory distress syndrome possible.

Chemotherapeutic agents, typically for the treatment of cancers, are associated with many side and adverse effects, some of which can be very uncomfortable or toxic to body systems. Cyclophosphamide, an alkylating antineoplastic is one such drug, with the potential to cause pulmonary fibrosis and cardiotoxicity. While cyclophosphamide's impact on the cardiac system is considered reversible, another cardiotoxic chemotherapy drug, daunorubicin, has a cumulative effect with dosing, and therefore a maximum dose. To avoid cardiac problems such as HF, daunorubicin is carefully considered with regard to the type of cancer, type of previous treatment, and total dose administered in the past.

## Lifestyle and Behavior Patterns

Lifestyle and behavior patterns include decisions people make about dietary choices, habits they acquire, activities they involve themselves in, and the level of activity in which they participate. Such behaviors have a significant influence on health and wellness in a general and holistic way, and certainly, there are important considerations when one looks particularly at the cardiopulmonary system. As mentioned previously with discussion of overall health status, there are a variety of pathophysiological changes and medical diagnoses that are more likely to occur when certain lifestyles are lived and behaviors are selected, especially when these are habitual and/or frequent.

Smoking contributes to a number of diseases of the lungs, heart, and vessels. Constant exposure to chemicals in the lungs, mouth, and larynx can cause abnormal cells to divide and cause cancer. Smoking causes a disruption of the mucociliary elevator in the lungs, which can lead to increased colonization of bacteria in the lower respiratory tract and frequent infections. It also causes atherosclerosis, increasing a person's chances for CHD, hypertension, stroke, peripheral artery disease, and abdominal aortic aneurysm (CDC, 2020).

## PATIENT CONVERSATIONS

---

### Teen Vaping

**Scenario:** Patient is a 15-year-old named Richard, who has been vaping for the past year. The patient has been to see the primary care provider on a monthly basis for “a cold” that doesn't improve, over the past four months.

**Patient:** I suppose you're going to lecture me.

**Nurse:** I doubt lecturing will be helpful. Unless you think it would be.

**Patient:** My parents gripe at me all the time about it. Doesn't do anything. Just makes me more pissed off.

**Nurse:** Exactly.

**Patient:** Yeah. Won't do anything.

**Nurse:** What I would like to do is tell you a bit about the cold you've had so long, that won't go away.

**Patient:** Yeah. Why won't the doctor give me something to fix it?

**Nurse:** That's the problem. What you've got going on is not a cold, but what your body's doing from the vaping. It looks like your lungs aren't happy about this, and what seems like a cold is your lungs trying to recover after each time you use your vape pen.

**Patient:** But my friends don't have any problems with it.

**Nurse:** Maybe they don't yet. Or maybe some of them never will. But the problem is, you're here today and have been before because *your* lungs aren't taking it well. And what the doctor can do is help you cut down and stop if you'll give it a chance. If today's not the day, I'd like to ask you to come in again to see me in a week. That way, you can think about it, read this pamphlet, and if you have questions, write them down. I'll answer them next week.

**Patient:** It probably won't help, but I'll take the paper and see you in a week.

---

Choices about one's diet are also major contributors to pathophysiological changes, and this can be from deficits or excesses. Some people make decisions about avoiding certain foods and end up with disorders related to certain nutritional deficits. Electrolytes are a good example of nutrients that, like acid-base balance, must be maintained

within the established window of normal ranges for proper metabolic function. Sodium is an electrolyte often first considered for its concerns when levels are high or low. Either abnormality may present with neurological changes, perhaps some mild confusion, but can be far more extreme, and/or long lasting. Sodium retention is associated with water retention, so elevated plasma sodium tends to cause hypervolemia and hypertension. Potassium can cause devastating problems if it is not kept in range: if elevated or decreased, minor symptoms may be apparent, or ultimately dysrhythmias are possible, and may be deadly. Phosphate is another electrolyte and is often overlooked for its importance in metabolic function. Recall that cellular energy involves ATP, and the P is phosphate. Therefore, without adequate levels of phosphate, ATP production is reduced. With functions as critical as those of the respiratory and cardiac systems, a constant supply of energy is necessary.

Perhaps more often considered as a nutritional abnormality is overconsumption, especially when the proper combination of necessary nutrients is not part of the diet. Rather, consumption is not only excessive but may involve improper dietary intake, such as sweetened beverages and snacks, high-sodium meals and snacks, and a lack of balance of essential dietary sources. This results in not only higher weight but also malnutrition. Overeating and subsequent higher weight may involve hyperlipidemia or be associated with hypertension or type 2 DM. Or it may be related to excessive sodium intake, and associated fluid retention and hypertension.

### Physical Activity Level

One of the behaviors with an impact on cardiopulmonary function is physical activity. At least 150 minutes of moderate aerobic exercise activity weekly is recommended by the AHA (2023) to maintain and possibly improve health status and avoid complications. The success of the AHA recommendations appears to lie in patients making exercise habitual and incorporating other healthy living activities into these new lifestyle choices.

Improved circulation is one of the major benefits of increased activity, as it maximizes oxygenation and perfusion, and all body systems reap the benefits, from improved neurological function to enhanced elasticity of blood vessels and improved BP, to normalizing lipid levels and reducing atherosclerotic plaque formation and CAD.

### LINK TO LEARNING

The AHA provides [various resources about healthy living \(https://openstax.org/r/77hearthealthy\)](https://openstax.org/r/77hearthealthy) that can be used in patient education.

### Cultural Influences

Whether conscious of it or not, cultural influence is within the very fabric of people's lives. From birth, it surrounds people, and throughout the life span, it influences and guides relationships and decisions in so many ways. With regard to the cardiopulmonary system, culture may have effects on acceptance of medical advice and the healthcare system, dietary choices and traditions, how and what activities are accepted and utilized, emotional and societal support systems, and stress levels (Acare Pro, 2023).

Culture determines dietary habits. Many people in the United States, for example, continue the practice of consuming meals with meat as the primary component, potatoes or another starchy carbohydrate as a major side dish, and a small helping of vegetables. This high-calorie diet, combined with a sedentary lifestyle, increases the likelihood of weight gain; higher weight is a risk factor for cardiovascular disorders.

Adding spices for flavor is another example of cultural influence, with some adding hot and savory spices, while others minimize additive flavors. Salt is an extremely common and popular spice, and processed foods like lunch meats and canned soups tend to have high sodium content, which is contraindicated for some, particularly with cardiac conditions like hypertension and HF.

Some cultures embrace complementary alternative medicine practices, while others do not. Herbal remedies, and the notion of whether a food or beverage should be consumed at a certain temperature, are important in certain cultural settings (Acare Pro, 2023). Some drugs may be recommended to be taken on an empty stomach, or with food, and cultural influences may interfere with either medical instruction. Communication is impactful herein, as misunderstandings are possible and lead to a lack of treatment and worsening of the health condition.

While the likelihood that the exploration of influences of culture upon health status, and cardiopulmonary health in

particular, could continue with many more exemplars, the final example here is that of medical care. Cultural perspectives prompt a variety of attitudes about health care (Acare Pro, 2023): is it embraced openly and fully, or approached with extreme caution? This may be demonstrated by whom patients choose for their health care. Do they require their provider to be a well-educated physician, a naturopathic practitioner, or a neighborhood healer whose training was obtained informally but is well accepted in the area? The preference and selection as to which expertise is sought may be from cultural mores over years or perhaps even decades or longer. If patients are distrustful of medical practitioners, they are again less likely to follow recommended treatment plans.

### Environmental Influences

Environmental stressors can have a negative impact on cardiopulmonary health. Living in the city can intensify these stressors. Examples of environmental stressors include air pollution, noise and light pollution, wildfires, and climate change (Münzel et al., 2021). The cardiovascular and pulmonary systems are both susceptible to these environmental influences.

Noise, especially that related to traffic, can possibly increase the risk of hypertension, MI, and stroke (Münzel et al., 2021). The premise is related to the stress response, with increased release of cortisol and catecholamines causing the signs and symptoms associated with stress. This includes SNS stimulation and often results in elevated HR and BP. If sustained, such stress-associated manifestations have the potential to lead to MI and stroke. Climate change is also implicated in contributing to stress-related changes, such as cardiac strain and sleep disturbances, as well as inflammatory responses to airborne pollutants such as dust and wildfire smoke (Münzel et al., 2021).

Air pollution is identified as a contributor to cardiovascular disease itself, as sources such as automobile exhaust or burning of fossil fuels release chemicals into the air (Münzel et al., 2021). Such chemicals can cause mild irritation or an allergic response or may be toxic and lead to inflammatory and immune responses, and infections. With long-standing exposure, CAD can develop, with the risk of ACS including MI and ultimately HF or death. Dysrhythmias and stroke are also potential results from exposure to air pollutants.

Environmental influences on the pulmonary system focus on a variety of means of damaging lungs through accelerated aging and reducing cellular healing abilities (Eckhardt & Wu, 2021). Means of pulmonary damage include inflammation, oxidation, damage to DNA, and cellular dysfunction, including impaired healing. Environmental exposures may also cause allergic responses, which can vary from mild to severe.

Environmental exposures to such substances toxic to the respiratory system include tobacco smoke, combustion of fossil fuels, and automobile exhaust. Tobacco smoke contains numerous chemicals, which can cause mild results like inflammation or may be carcinogenic. Burning of fossil fuels releases sulfur and nitrogen dioxide (among other chemicals), which contribute to pulmonary damage (Eckhardt & Wu, 2021). Employment-related exposure may also include populations who mine granite or sandstone and are therefore exposed to silica dust, and coal miners, who are exposed to coal dust and at risk for pneumoconiosis (“black lung”). Mesothelioma is another possible lung disorder related to environmental exposure to asbestos.

### Diagnostic Testing Used to Monitor Cardiopulmonary Functioning

As varied as the potential dysfunctions of the cardiopulmonary system may be, so too are the diagnostic tests used to determine what is happening with a patient, and the extent of the dysfunction(s). Such testing may be invasive or noninvasive, may concentrate on the cardiovascular system or the respiratory system, and may provide information about general function (or lack thereof), infection, or injury.

### Cultures

Cultures are obtained to identify whether an infection of some sort is present by growing particular microbes in the laboratory. Varied sources can be cultured, including samples of blood, sputum, urine, or swabs from a wound or throat (MedlinePlus, 2023). Not only can cultures verify the presence of bacteria in general, but identification of which bacteria are present is typically provided. Other microbes may also be cultured, including mycobacterium (the specific type of bacteria that causes tuberculosis), viruses, and fungi.

Cultures are routinely allowed to grow for forty-eight to seventy-two hours; particularly virulent microbes often grow quickly and are clearly identified within forty-eight hours. To ensure accuracy in results, some cultures are grown for longer periods. Examples include bacteria cultures incubated for up to five days, fungal cultures for up to four weeks, and mycobacterial cultures for three to eight weeks (Van Leeuwen & Bladh, 2023).

In addition to culture, for treatment purposes, sensitivity is often ordered. This offers identification of a particular bacteria and exposes the microbes to various antibacterial drugs to distinguish the drugs that are effective, most effective, or ineffective in reducing or eliminating the microorganism(s). For what is anticipated to be a simple infection, the healthcare provider may order merely a culture, but sensitivity results can be extremely helpful in narrowing broad-spectrum antibacterials to effective but narrower-spectrum drugs. Hospitalized patients frequently have complicated infections, and bacterial resistance is a reality, so it is common for healthcare providers to order the culture and sensitivity (C&S) at the time of the original order.

### Blood

Blood cultures are ordered when sepsis is suspected. In many facilities, laboratory personnel draw blood samples for blood cultures to avoid contamination of the sample. With some infections, pathogens are only found in the blood intermittently, so a series of three or more blood cultures, as well as blood draws from different veins, may be performed to increase the chance of finding the infection.

Blood cultures ([Figure 19.14](#)) are incubated for several days before being reported as negative. Some types of bacteria and fungi grow more slowly than others and/or may take longer to detect if initially present in low numbers.

**FIGURE 19.14** Blood collection bottles can be used for aerobic and anaerobic cultures. (credit: modification of work “Blood Culture Bottles” by “Moose G.”/Flickr, CC BY 2.0)

A positive result indicates bacteria have been found in the blood (bacteremia). Other types of pathogens, such as a fungus or a virus, may also be found in a blood culture. When a blood culture is positive, the specific microbe causing the infection is identified, and susceptibility testing is performed to inform the healthcare provider which antibiotics or other medications are most likely to be effective for treatment.

### Sputum

A sputum culture is a diagnostic test that evaluates the type and number of bacteria present in sputum. The patient is asked to cough deeply and spit any mucus that comes up into a sterile specimen container. The sample is sent to a laboratory where it is placed in a special dish ([Figure 19.15](#)) and is watched for two to three days or longer to see if bacteria or other disease-causing germs grow. Acid-fast bacillus testing, along with C&S testing, is used to diagnose tuberculosis (TB). When testing for TB, at least three consecutive samples are collected, with at least one being an early morning sample.

**FIGURE 19.15** An image of a sputum culture, which can be used to diagnose diseases like TB. (credit: modification of work by National Library of Medicine; CC BY 3.0)

### Blood Gases

Blood gases are done to acquire information as to a patient's oxygenation and acid-base balance. This includes pH, partial pressure of CO<sub>2</sub> (PaCO<sub>2</sub>), partial pressure of O<sub>2</sub> (PaO<sub>2</sub>), O<sub>2</sub> saturation (SaO<sub>2</sub>), bicarbonate (HCO<sub>3</sub>), and base excess (the amount of base present in the blood).

Blood gas samples are drawn with a specific heparinized syringe that only needs a small sample of blood. In years past, the syringe had to be placed on ice and sent to the laboratory for testing. Now it is more common to use a point-of-care device called an iSTAT. From the syringe, blood is placed into the receiving area of an iSTAT cartridge, which is then placed into the analyzer. Within approximately two minutes, the results are available.

### Arterial

Arterial blood gases (ABG) are measured by collecting blood from an artery, rather than a vein, and are most commonly collected via the radial artery. Acquiring an ABG requires training and is often painful for the patient. Therefore, this test is not done on a routine basis and is not typical for a stable patient. In severe illness, however, with a patient whose O<sub>2</sub> status is questionable or at risk, the information from an ABG can provide the necessary results for guiding immediate care and planning ongoing interventions.

While some components of blood gas testing are closely correlated between an arterial and venous sample, those indicative of oxygenation (PaCO<sub>2</sub>, PaO<sub>2</sub>) are most reliable if the source is arterial (Lentz et al., 2019). Acid-base information: pH, HCO<sub>3</sub>, and base excess (or deficit) demonstrate a reasonable correlation between arterial and venous samples. For accuracy in the results of bicarbonate, a plasma sample for specific chemistry should be obtained, as it is not a measured value as part of a blood gas (Lentz et al., 2019).

## PATIENT CONVERSATIONS

### ABG

**Scenario:** The patient is Gloria, who is 74 years old; her history includes emphysema and frequent urinary tract infections. She was brought to the hospital by her son, who found her sitting in her recliner, very confused. She is now in the ICU, and the nurse is preparing to draw an ABG. Her son, Reggie, is in the room with her.

**Nurse:** Gloria, I need to get a blood sample from your wrist.

**Patient:** MmmHm. Oh, what? Who?

**Nurse:** I'm going to put a needle in your wrist for a blood sample. Reggie, would you sit on that side of her and hold her hand?

**Patient's son** She already has an IV in her arm. Won't that work?

**Nurse:** This is different, this sample has to come from her artery. I want to use the one on the inside, where we often feel for a pulse, the radial artery. This will tell us more about why she was so quiet and confused when you found her, and why she's still like that. And if her emphysema is worse now.

**Patient's son** Oh, okay. I think she had that last time. She was on a respirator, you know, about three months ago. Her breathing got real bad.

**Nurse:** Yes, I'll bet you're right. She probably had this done then, too. So, I'm going to draw from her right side, and if you can just hold her left hand and let her know you're here. Try to keep her still, so she doesn't jump or pull away when she feels the stick. The results only take a couple of minutes, so we'll have a better idea of things when I call the doctor with the results. Thanks for your help.

---

## Venous

Venous blood gas (VBG) acquisition is considered less painful than an arterial sample; veins tend to be more superficially located and are often visible and/or palpable. Arteries are deeper and the puncture for an ABG is done blindly, based on palpation. Occasionally, while attempting an ABG, a venous sample is accidentally obtained, or a mixture of arterial and venous blood. In such a circumstance, the results may provide inadequate information. Because a VBG is less painful to draw, if the physician is attempting to determine acuity versus chronicity, hypercarbia, or whether the problem has a respiratory or metabolic cause (Lentz et al., 2019), a VBG may be ordered.

## Cardiac Biomarkers

There are three major cardiac biomarkers: creatine kinase (CK), troponin I, and creatine kinase myocardial band (CK-MB). CK-MB and troponin I are the two tests commonly ordered when a MI is suspected, or an exacerbation of HF. CK-MB is elevated within four to six hours after an MI, peaks within twenty-four hours, and normalizes within seventy-two hours (Van Leeuwen et al., 2023). Troponin I levels rise between two and six hours post-MI, followed by two peaks—the first between fifteen and twenty-four hours postinjury, and again at sixty to eighty hours after injury.

Another cardiac biomarker that is used to diagnose HF is the brain natriuretic peptide (BNP). BNP is used not only for initial diagnostic purposes but also to manage ongoing treatment, assess progression of HF, and evaluate patients during exacerbations (Van Leeuwen & Bladh, 2023). BNP rises when a stretch of the heart occurs from hypervolemia, and so as the congestive nature of HF increases, so does this peptide.

## Capnography

Two methods are used to monitor ventilation and oxygenation: **capnography** (the amount of CO<sub>2</sub> at the end of exhalation) and pulse oximeter, respectively. Since capnography measures exhaled CO<sub>2</sub>, it is also referred to as end-tidal CO<sub>2</sub> (ETCO<sub>2</sub>); the normal range is 35 to 45 mm Hg (Sullivan, 2020). Commonly, patients whose medical condition indicates the necessity for ETCO<sub>2</sub> monitoring are critically ill. Patients in low perfusion states (e.g., shock, hypovolemia) may be candidates for capnography, as healthcare providers are seeking specific information about ventilatory status and the ability of the tissues to access circulating O<sub>2</sub>. It can also be a helpful tool for monitoring interventions and modifying treatment promptly (Sullivan, 2020).

Capnography can be done with a special type of nasal cannula, which can deliver O<sub>2</sub> and obtain ETCO<sub>2</sub> results. Or the nasal prongs can be in place while a patient is receiving O<sub>2</sub> by mask (simple, continuous positive airway pressure [CPAP], or nonrebreather). There is also an attachment that can be used in conjunction with the ventilator for mechanically ventilated patients to be continuously monitored. There are specific monitors for ETCO<sub>2</sub>, whether static or portable, and specific settings, as capnography is done by anesthesia providers during surgery, and in ICUs it is monitored by nurses in addition to continuous monitoring of other vital functions, like pulse oximetry, RR, HR, and BP. The waveform depicts the respiratory cycle and indicates the amount of CO<sub>2</sub> at each phase (Sullivan, 2020). Waveform variations ([Figure 19.16](#)) from the rather square shape of normal indicate likely pathophysiological changes, like pulmonary embolism, pneumothorax, or airway obstruction (Duckworth, 2017).

**FIGURE 19.16** Normal ETCO<sub>2</sub> waveform and respiratory phases and variations to the waveform in different pathophysiological conditions. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Pulse Oximetry

To understand pulse oximetry, it is important to recall the hemoglobin molecule and its relationship to O<sub>2</sub>. Hemoglobin is a molecule within red blood cells, and each of these molecules can carry four molecules of O<sub>2</sub>. A pulse oximeter is a noninvasive device (Figure 19.17) placed on the finger that is able to read this saturation of hemoglobin using light. It is portable in many settings, including available for home use, or attached for continuous monitoring in settings like emergency departments, ICUs, or operating rooms.

**FIGURE 19.17** A portable pulse oximetry device that goes on a patient's finger. (credit: Untitled by "MIKI Yoshihito"/Flickr, CC BY 2.0)

A normal saturation at sea level is 94 to 98 percent. At elevation, it may be acceptable for patients' pulse oximetry to be lower, yet still be considered normal. Also, certain pathophysiological changes affect pulse oximetry or have effects on what percentage is desired for a particular patient. In patients with COPD or emphysema, a normal oxygen level is 88 to 90 percent, because lung disease causes a lower  $O_2$  and higher  $PaCO_2$  balance. A patient who has experienced blood loss after a surgery or traumatic injury or is anemic because of a disorder like iron deficiency may have a lack of  $O_2$  being circulated because there is a lack of carriers.

A demonstration of [teaching a patient how to use a peak expiratory flow rate \(PEFR\) for monitoring asthma](https://openstax.org/r/77PEFRTeachPat) (<https://openstax.org/r/77PEFRTeachPat>) is presented in this video.

### Pulmonary Function Studies

To help diagnose respiratory dysfunction and determine whether a problem is restrictive or obstructive, pulmonary function tests (PFTs) may be performed ([Figure 19.18](#) and [Table 19.3](#)). A restrictive disorder is when air has difficulty flowing out of the lungs, and an obstructive disorder is when the movement of airflow is restricted by the inability of lung tissue and/or chest wall to expand. The results of PFTs are dependent on the effort of the patient, and results should be considered with the patient's history when reaching a diagnosis (Ponce et al., 2022).

### Electrocardiogram

ECGs use a special type of paper, which looks rather like fine graph paper: the horizontal lines indicate the passage of time, with each small box representing 0.04 seconds and each larger box, which contains five small boxes, indicating 0.2 seconds. The vertical lines indicate electrical voltage. When an ECG tracing is viewed, there is a line established that indicates a straight passage of time: measurements of components of the cardiac cycle are made based on deflection and return from and to this line. This is referred to as the **isoelectric line** or baseline. Most commonly, nurses note whether the inflection rises from the isoelectric line or has a downward path, or a combination of both. The voltage is not necessarily routinely measured ([Figure 19.19](#)).

**FIGURE 19.19** Electrocardiogram tracing including waves, complexes, segments, and intervals. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nursing education programs provide introductions to cardiac rhythms—the depth of information depends on the type of program and other specific requirements. In settings like the ED, ICU, telemetry, and postanesthesia care unit (PACU), nurses are educated to recognize normal and abnormal traits of the cardiac cycle and, depending on facility policy, to provide a **rhythm strip** (six-second tracing of one or two leads from a continuous monitor), with measurements to indicate any noted abnormalities in conduction.

The electrical impulses in the heart produce electrical currents that flow through the body and can be measured on the skin using electrodes. This information can be observed as an electrocardiogram (ECG), a recording of the electrical impulses of the cardiac muscle ([Figure 19.20](#)). ECGs are extremely valuable for diagnosis and guiding treatment of patients with cardiac symptoms.

**FIGURE 19.20** The beating of the heart is regulated by an electrical impulse that causes the characteristic reading of an ECG. The signal is initiated at the sinoatrial valve. The signal then (a) spreads to the atria, causing them to contract. The signal is (b) delayed at the atrioventricular node before it is passed on to the (c) heart apex. The delay allows the atria to relax before the (d) ventricles contract. The final part of the ECG cycle prepares the heart for the next beat. (credit: modification of work from *Biology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

An ECG is often combined with cardiac biomarker testing when acute symptoms indicative of MI or other cardiac emergencies are present. ECG can also be performed to monitor conditions and treatments or used for routine screening for cardiomyopathy. An ECG machine conventionally has twelve leads, which are labeled with their respective placement on the body ([Figure 19.21](#)).

**FIGURE 19.21** ECG electrode placement. (credit: modification of work by Jacqueline Christianson/Nurses International, CC BY 4.0)

Small graph paper ([Figure 19.22](#)) is used to record and measure an ECG. The vertical axis shows the electrical signal strength, and the horizontal axis shows the passage of time. Measurements are taken based on the boxes. Each large box is outlined in a darker shade and contains five smaller boxes, both horizontally and vertically. Horizontally, each small box shows the passage of 0.04 seconds, so each large box (four small boxes) indicates 0.2 seconds.

**FIGURE 19.22** This example shows typical ECG graph paper. (credit: modification of work by Jacqueline Christianson/Nurses International, CC BY 4.0)

On the ECG paper, the firing of the SA node and the electrical signal to the AV node, with atrial contraction, is known as the P wave. Next the AV node receives and holds the signal after the atria contract, while the ventricles fill, called the PR segment. The PR interval is the time from the beginning of the P wave to the start of the Q wave. The QRS complex is the flow of electricity from the AV node through the bundle of His and to the Purkinje fibers—this leads to ventricular contraction. Last is the T wave, when the ventricles repolarize. The QT interval measurement is taken from the beginning of the Q through the end of the T wave. Finally, the ST segment measurement is from the end of the S to the start of the T wave (Figure 19.23) (Christensen et al., 2023).

**FIGURE 19.23** This diagram correlates an ECG tracing with the electrical and mechanical events of a heart contraction. Each segment of an ECG tracing corresponds to one event in the cardiac cycle. Provider's Orders	<p><b>1145: New orders</b></p> <ul style="list-style-type: none"> <li>• Admit to telemetry unit.</li> <li>• Perform 12-lead ECG.</li> <li>• Administer oxygen therapy to maintain oxygen saturation &gt; 92 percent.</li> <li>• 20 mg furosemide IV STAT.</li> </ul>
Nursing Notes	<p><b>1200:</b> 12-lead ECG completed; results show sinus tachycardia. 2 L oxygen via nasal cannula applied, patient reports slight improvement in dyspnea. IV placed in right AC, 20 mg furosemide IV administered. Patient instructed to call before getting up to use bathroom. Patient has not voided since admission. Patient admitted to room on cardiac unit and handoff given to telemetry nurse.</p>
Flow Chart	<p><b>1230: Assessment</b> Blood pressure: 150/82 mm Hg Heart rate: 108 beats/minute Respiratory rate: 22 breaths/minute Temperature: 98.9°F (37.2°C) Oxygen saturation: 93 percent on 2 L nasal cannula Pain: 6/10 (joint pain)</p>

4. Generate solutions: What is the rationale for each of the provider's orders?
5. Take action: What additional actions should the nurse take at this time?
6. Evaluate outcomes: What signs indicate that the patient's condition is improving? Does anything indicate that the patient's condition is not improving?

## 19.4 Management of Impaired Cardiopulmonary Functioning

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe nursing actions for management of impaired cardiopulmonary functioning
- Understand interdisciplinary collaboration for management of impaired cardiopulmonary functioning
- Describe emergency interventions for impaired cardiopulmonary functioning

Nurses are involved in the management of cardiopulmonary care throughout the care plan, from assessment and planning through evaluation and reassessment. Nursing actions while caring for patients with impaired cardiopulmonary function are varied, from routine to emergent care. Patients with cardiovascular and/or pulmonary dysfunctions may be stable or experiencing an emergency event, such as a deadly cardiac rhythm or a respiratory or cardiac arrest. Depending on the care setting, nurses have to be able to respond and act to patients' changes in status, with interventions, patient education, and guidance regarding self-monitoring, through drug therapy (routine and emergent), defibrillation, and CPR. Nurses are also part of a healthcare team and as such work with other members from different disciplines. Interdisciplinary care provides a holistic approach to patients and their care and brings about positive outcomes.

### Nursing Actions

Nurses are directly involved in patient care. From assessment to evaluation, nurses are creating, implementing, and

evaluating their care plans based on the current status of their patients. Nursing actions relative to the cardiopulmonary system reflect particular actions designed for the respiratory system and those for the cardiovascular system. Some interventions, like O<sub>2</sub> therapy and behavioral modifications, are apt to benefit both components of the cardiopulmonary system. Even drug therapy in one category is prone to assist with symptoms or deficits in the other, as an improvement in ventilation, oxygenation, or perfusion can be expected to improve the others. In this section, specifics as to assessment, a variety of tools and techniques, medications, and topics for patient education are discussed. Additionally, interdisciplinary collaborative examples are explored as are emergency interventions specific to the respiratory and cardiovascular systems.

### Respiratory Assessment

The evaluation of the respiratory system includes collecting subjective and objective data through a detailed interview and physical examination of the thorax and lungs. This examination can offer significant clues related to issues associated with the body's ability to obtain adequate oxygen to perform daily functions. Inadequacy in respiratory function can have significant implications for the overall health of the patient.

Collect subjective data using interview questions, paying particular attention to what the patient is reporting. The interview should include questions regarding any current and past history of respiratory health conditions or illnesses, medications, and reported symptoms. Consider the patient's age, gender, family history, race, culture, environmental factors, and current health practices when gathering subjective data.

A focused respiratory objective assessment includes interpretation of vital signs; inspection of the patient's breathing pattern, skin color, and respiratory status; palpation to identify abnormalities; and auscultation of lung sounds (Figure 19.24) using a stethoscope. The nurse must have an understanding of what is expected given a patient's age, gender, development, race, culture, environmental factors, and current health condition to determine the meaning of the data that are being collected.

**FIGURE 19.24** There is a systematic approach to auscultation of the chest for breath sounds, (a) anterior and (b) posterior. (credit a: modification of work “Anterior Respiratory Auscultation Pattern.png” by Meredith Pomietlo, CC BY 4.0; credit b: modification of work “Posterior Respiratory Auscultation Pattern.png” by Meredith Pomietlo, CC BY 4.0)

### LINK TO LEARNING

Visit [Lung Sounds Made Easy \(https://openstax.org/r/77Lungsounds\)](https://openstax.org/r/77Lungsounds) to learn more about abnormal lung sounds.

When certain findings indicate further exploration, palpation and percussion may be performed. An example is if on inspection the nurse finds apparent edema around one or both collarbones, especially if the patient was recently intubated with an ETT. Palpation can be used in such a situation to assess for **subcutaneous emphysema** (air in the subcutaneous tissue), as the tiny air pockets feel crispy (**crepitus**) to the fingertips. Percussion is helpful for the nurse to determine underlying structures in the pulmonary cavity, whether a region that should be air filled instead

contains fluid or a solid mass. Refer to [Table 19.4](#) for expected and unexpected assessment results.

Assessment	Expected Findings	Unexpected Findings (Document and Notify Provider if a New Finding*)
Inspection	<ul style="list-style-type: none"> <li>• Effortless work of breathing</li> <li>• Regular breathing pattern</li> <li>• Respiratory rate within normal range for age</li> <li>• Symmetrical chest expansion</li> <li>• Absence of cyanosis or pallor</li> <li>• Absence of use of accessory muscles, retractions, and/or nasal flaring</li> <li>• Anteroposterior: transverse diameter ratio 1:2</li> </ul>	<ul style="list-style-type: none"> <li>• Labored breathing</li> <li>• Irregular rhythm</li> <li>• Increased or decreased respiratory rate</li> <li>• Accessory muscle use, pursed-lip breathing, nasal flaring (infants), and/or retractions</li> <li>• Presence of cyanosis or pallor</li> <li>• Asymmetrical chest expansion</li> <li>• Clubbing of fingernails</li> </ul>
Palpation	<ul style="list-style-type: none"> <li>• No pain or tenderness with palpation</li> <li>• Skin warm and dry</li> <li>• No crepitus or masses</li> </ul>	<ul style="list-style-type: none"> <li>• Pain or tenderness with palpation</li> <li>• Cool, clammy, or moist skin</li> <li>• Crepitus, palpable masses, or lumps</li> </ul>
Percussion	<ul style="list-style-type: none"> <li>• Clear, low-pitched, hollow sound in normal lung tissue</li> </ul>	<ul style="list-style-type: none"> <li>• Dull sounds heard with high-density areas, such as pneumonia or atelectasis</li> </ul>
Auscultation	<ul style="list-style-type: none"> <li>• Bronchovesicular and vesicular sounds heard over appropriate areas</li> <li>• Absence of adventitious lung sounds</li> </ul>	<ul style="list-style-type: none"> <li>• Diminished lung sounds</li> <li>• Adventitious lung sounds, such as crackles, rales, wheezes, stridor, or pleural rub</li> </ul>
*CRITICAL CONDITIONS to report immediately		<ul style="list-style-type: none"> <li>• Decreased oxygen saturation (&lt;92 percent or as prescribed)</li> <li>• Pain</li> <li>• Worsening dyspnea</li> <li>• Decreased level of consciousness, restlessness, anxiousness, and/or irritability</li> </ul>

**TABLE 19.4** Expected versus Unexpected Respiratory Assessment Findings

### Cardiovascular Assessment

The evaluation of the cardiovascular system includes a thorough medical history and a detailed examination of the heart and peripheral vascular system. Nurses must incorporate subjective statements and objective findings to elicit clues of potential signs of dysfunction. Symptoms like fatigue, indigestion, and leg swelling may be benign or may indicate something more ominous. As a result, nurses must be vigilant when collecting comprehensive information to utilize their best clinical judgment when providing care for the patient.

The subjective assessment of the cardiovascular and peripheral vascular system is vital for uncovering signs of potential dysfunction. To complete the subjective cardiovascular assessment, the nurse begins with a focused interview. The focused interview explores past medical and family history, medications, cardiac risk factors, and reported symptoms. Symptoms related to the cardiovascular system include chest pain, peripheral edema, unexplained sudden weight gain, shortness of breath (dyspnea), irregular pulse rate or rhythm, dizziness, or poor peripheral circulation. Any new or worsening symptoms should be documented and reported to the healthcare

provider.

The physical examination of the cardiovascular system involves the interpretation of vital signs, inspection, palpation, and auscultation of heart sounds. Jugular venous distension may be visible, especially as patients are repositioned. As the nurse is examining the patient, palpation may accompany, as clothing is moved or removed and the patient is touched. Further signs of perfusion can be assessed, like the temperature and moisture of the skin (e.g., warm and dry versus cool and clammy). To complete palpation, capillary refill and peripheral pulses should be assessed. After completing a cardiovascular assessment, it is important for the nurse to use critical thinking to determine whether any findings require follow-up ([Table 19.5](#)).

Assessment	Expected Findings	Unexpected Findings (Document and Notify Provider if a New Finding*)
Inspection	Apical impulse may or may not be visible	<ul style="list-style-type: none"> <li>• Scars not previously documented that could indicate prior cardiac surgery</li> <li>• Heave or lift observed in the precordium</li> <li>• Chest anatomy malformation</li> </ul>
Palpation	Apical pulse felt over midclavicular fifth intercostal space	<ul style="list-style-type: none"> <li>• Apical pulse felt to the left of the midclavicular fifth intercostal space</li> <li>• Additional movements over precordium such as a heave, lift, or thrill</li> </ul>
Auscultation	S1 and S2 heart sounds in regular rhythm	<ul style="list-style-type: none"> <li>• Irregular heart rhythm</li> <li>• Extra heart sounds such as a murmur, S3, or S4</li> </ul>
*CRITICAL CONDITIONS to report immediately		<ul style="list-style-type: none"> <li>• Symptomatic tachycardia at rest (HR &gt;100 bpm)</li> <li>• Symptomatic bradycardia (HR &lt;60 bpm)</li> <li>• Hypotension (systolic BP &lt;100 mm Hg)</li> <li>• Orthostatic BP changes</li> <li>• New abnormal cardiac rhythm</li> <li>• New extra heart sounds such as a murmur, S3, or S4</li> <li>• Reported chest pain, calf pain, or worsening shortness of breath</li> </ul>

**TABLE 19.5** Expected versus Unexpected Cardiac Assessment Findings

Auscultation is routinely performed over five specific areas of the heart to listen for corresponding valvular sounds. These auscultation sites are often referred to by the mnemonic “APE To Man,” referring to aortic, pulmonic, Erb point, tricuspid, and mitral areas ([Figure 19.25](#)).

**FIGURE 19.25** Locations for heart auscultation. (credit: modification of work “*Cardiac Auscultation Areas*” by Meredith Pomietlo, CC BY 4.0)

Auscultation usually begins at the aortic area (upper right sternal edge). Use the diaphragm of the stethoscope to carefully identify the S1 and S2 sounds. They will make a “lub-dub” sound. Note that when listening over the area of the aortic and pulmonic valves, the “dub” (S2) will sound louder than the “lub” (S1). Move the stethoscope sequentially to the pulmonic area, Erb point, and tricuspid area. Repeat this process with the bell of the stethoscope. The apical pulse should be counted over a sixty-second period. For an adult, the HR should be between 60 and 100 with a regular rhythm to be considered within normal range.

## LINK TO LEARNING

A [review of blood flow and the heart’s sounds \(https://openstax.org/r/77BloFlowHeaSou\)](https://openstax.org/r/77BloFlowHeaSou) is provided in this video. Listen for normal and abnormal sounds and what they mean.

The first heart sound (S1) identifies the onset of systole, and the second heart sound (S2) identifies the end of systole and the onset of diastole; when the semilunar valves close, the AV valves open, and the ventricles fill with blood. When auscultating, it is important to identify the S1 (“lub”) and S2 (“dub”) sounds, evaluate the rate and rhythm of the heart, and listen for any extra heart sounds.

### Encourage Breathing Techniques

There are several techniques a nurse can teach a patient to use to enhance their breathing and coughing. These techniques include diaphragmatic breathing, pursed-lip breathing, incentive spirometry, and coughing and deep breathing.

### Diaphragmatic Breathing

Diaphragmatic breathing is a technique that is helpful for patients who are tachypneic, whether from a physiological source or anxiety. The technique helps focus attention on breathing and consciously learn to control it. The nurse teaches the patient to intentionally realize whether the chest or the abdomen is the source of breaths. It is often

recommended to advise the patient to place a hand on the chest and one on the abdomen and self-assess the source. This begins the slowing and relaxing process. Once the patient realizes the source of breath is the chest, teaching is aimed at the patient redirecting attention toward breathing from the abdomen (diaphragm). With concentration on the technique, the tachypnea should begin to resolve, and with it, an improvement as the physical response to pH changes from hyperventilation normalizes and/or a sense of relaxation and anxiety reduction takes place. Sometimes the anxiety involved with severe dyspnea, or from a mental health situation, may respond well to anxiolytic drug therapy in addition to diaphragmatic breathing.

### **Pursed-Lip Breathing**

Pursed-lip breathing is a technique that allows people to control their oxygenation and ventilation. The technique requires a person to inspire through the nose and exhale through the mouth at a slow, controlled flow. This type of exhalation gives the person a puckered or pursed appearance. By prolonging the expiratory phase of respiration, a small amount of positive end-expiratory pressure is created in the airways that helps to keep them open so that more air can be exhaled, thus reducing air trapping that occurs in some conditions such as COPD. Pursed-lip breathing often relieves the feeling of shortness of breath, decreases the work of breathing, and improves gas exchange. People also regain a sense of control over their breathing while simultaneously increasing their relaxation.

### **Incentive Spirometry**

An incentive spirometer is a medical device often prescribed after surgery to prevent and treat atelectasis ([Figure 19.6](#)). Atelectasis occurs when alveoli become deflated or filled with fluid, and this can lead to pneumonia. While sitting upright, the patient should breathe in slowly and deeply through the tubing with the goal of raising the piston to a specified level. The patient should attempt to hold their breath for five seconds, or as long as tolerated, and then rest for a few seconds. This technique should be repeated by the patient ten times every hour while awake. The nurse may delegate this intervention to unlicensed assistive personnel, but the frequency at which it is completed and the volume achieved should be documented and monitored by the nurse.

### **Coughing and Deep Breathing**

Teaching the coughing and deep breathing technique is similar to incentive spirometry, but no device is required. The patient is encouraged to take deep, slow breaths and then exhale slowly. After each set of breaths, the patient should cough. This technique is repeated three to five times every hour.

## **REAL RN STORIES**

---

### **Preventive Pulmonary Toilet**

**Nurse:** Aarti, RN

**Clinical setting:** ICU

**Years in practice:** 2

**Facility location:** San Jose, California

My patient assignment for the night was a male (Mr. Leonard, or Mr. L) who had undergone coronary artery bypass grafting (CABG) earlier in the day. His surgery had gone well, with no major events during or in the first few hours of recovery in the ICU. As we did shift report, and bedside check, hemodynamics were stable, and Mr. L's major issue was pain. I brought a syringe of morphine with me when I did his initial assessment and gave him his first divided dose. By the time I was done with a head-to-toe at 7:30 p.m., he was gently snoring.

The standard for ICU patients was for them to be turned at least every two hours; post-op CABG patients hourly, to keep pulmonary secretions mobile, and the chest tubes draining. The IS orders were for “ten times while awake,” but Mr. L had refused the previous hour with the day shift nurse, and now he was asleep. I let him rest at 7:30 p.m., and since he was still sleeping at 8 p.m., didn't wake him. His VS continued to be fine, and while I turned him at 9 p.m., I didn't insist he do his ten reps of the IS. When I checked his VS at 10 p.m., all was stable except his temperature of 100.6°F (38°C); I medicated his 8-of-10 pain and went to the nurses' station to review the flowchart and chart—his temperature had been 97.8°F (36.6°C) at 7:30 p.m. One of my colleagues asked how Mr. L was doing, and I told her about the low-grade fever. Her first question was, “How has he been doing on his IS?” Surprised, I

admitted that I hadn't had him do it, as I was focused on his pain control and rest. But her question clicked that subject open in my mind, and I began consistent pulmonary toilet—while he was not happy to be kept awake, he did the breathing exercises as I requested. An hour later, I medicated his pain, and a few minutes later insisted on the IS again.

At midnight, I checked his temperature again, fully expecting it to have climbed further, but it was 98.9°F (37.2°C). At that moment, early in my practice, I became fully convinced of the power of aggressive pulmonary toilet and the ability of deep breathing to reduce and prevent atelectasis. Mr. L and I continued with his hourly IS throughout the early morning hours, and his temp was 98.3°F (36.8°C) at 4 a.m. As I drove home and reflected on the events of the shift, I thought about how easy it is for a patient to develop atelectasis, and the importance of early prevention through deep breathing and coughing. The other realization for me was how easy it probably would have been for me to prevent it entirely by starting the IS with my first shift assessment. However, by having had this experience (and happily with Mr. L's quick recovery from all aspects of his surgery, without development of post-op pneumonia!), my patient education on the rationale for use of the IS from that night forward became much more compelling.

### Frequent Repositioning

Repositioning a patient with impaired cardiopulmonary status maintains body alignment, prevents pressure injuries from low perfusion and hypoxia, and prevents foot drop and contractures. When repositioning a patient in bed, supportive devices such as pillows, rolls, and blankets can aid in providing comfort and safety. It is important to reposition patients appropriately to prevent neurological injury that can occur if a patient is inadvertently placed on their arm. Frequent repositioning also allows for respiratory secretions to mobilize rather than pool in one location (usually dependent, based on gravity). Being turned may cause deeper breaths and may inspire coughing. Position changes also enhance comfort, which reduces pain, allowing for ease of breathing and again more likelihood of full and effective breaths.

### Medication Administration

There are medications recognized as specific to the respiratory system and those associated with the cardiovascular system; some have effects on both components of the cardiopulmonary system. Medication administration for respiratory and cardiac drugs involves nurses being familiar with a variety of administration routes. Respiratory drugs may be given as nasal sprays and drops, inhalers, tablets, or capsules to be administered orally or through injections by intramuscular (IM), subcutaneous (SC), or intravenous (IV) access. Cardiac medications add the potential for topical (e.g., nitroglycerin ordered by patch or cream) application and do not include the wide variety through sprays, drops, or powders. When immediate actions are desired, drugs for cardiopulmonary emergencies are typically administered by IV or intraosseous (IO) routes, though respiratory emergencies may still require inhaled doses of certain drugs.

### Respiratory Medications

There are various drug classes to treat respiratory pathophysiological problems—all with a goal relative to improving function, whether through improved oxygenation or ventilation ([Table 19.6](#)).

Type	Drug	Mechanism of Action
Sympathetic nervous system: Beta <sub>2</sub> adrenergic agonists	Albuterol (Proventil HFA)	Capitalizes on the bronchodilation response of SNS stimulation
Parasympathetic nervous system: anticholinergics	Tiotropium (Spiriva—long acting), ipratropium (Atrovent—short acting)	Blocks the bronchoconstriction response of muscarinic PSNS stimulation

**TABLE 19.6** Commonly Used Respiratory Medications

Type	Drug	Mechanism of Action
Methylxanthine derivatives	Theophylline (Theo-24)	Smooth muscle relaxation allowing bronchodilation
Corticosteroids	Triamcinolone Nasocort Allergy—nasal; Aristospan—systemic)	Prevention of reaction or worsening reaction to inflammation, whether local or systemic depends on drug, dose, and route
Leukotriene receptor antagonists	Montelukast (Singulair)	Blockade of leukotriene receptors and related decreased inflammatory responses
Cromolyn	NasalCrom	Blocks mast cells and related inflammatory actions
Antihistamines	Diphenhydramine (Benadryl), loratadine (Claritin)	Blocks action of histamine; first generation has broader effects, including sedation
Decongestants	Pseudoephedrine (Sudafed)	Adrenergic stimulation releases norepinephrine, causing vasoconstriction
Expectorants	Guaifenesin (Mucinex)	Causes vagal response that increases fluid in the respiratory tract; thins mucous
Antitussives	Dextromethorphan (Robitussin)	Depression of cough center (medulla) and cough receptors in respiratory tract
Anti-infectives	Numerous classes of anti-infectives—selection based on type of infection (C&S results)	Cause injury or death to infectious microbial cells

**TABLE 19.6** Commonly Used Respiratory Medications

### Cardiac Medications

As varied as the potential diagnoses that affect the cardiovascular system are the drugs to treat the disorders. Medications are used to modify actions of the ANS in order to lower or raise BP; they treat dyslipidemias and often-linked CAD; antianginal drugs relieve chest pain; there are drugs to treat HF, medications to help the kidneys remove excess fluid; there are those that may treat or prevent dysrhythmias, and there are drugs to prevent and/or treat clotting problems ([Table 19.7](#)).

Type	Drug	Mechanism of Action
ACE inhibitors	Lisinopril, enalapril	Vasodilation from inhibition of angiotensin-converting enzyme, and therefore prevention of angiotensin I conversion to angiotensin II (vasoconstrictor); decreases cardiac remodeling and overt HF (some patients)
Angiotensin receptor blockers (ARBs)	Valsartan (Diovan)	Blocks angiotensin II effects of aldosterone release and vasoconstriction at the angiotensin receptors

**TABLE 19.7** Commonly Used Cardiac Medications

Type	Drug	Mechanism of Action
Antianginals	Nitroglycerin	Arterial and venous vasodilation increases perfusion and decreases O <sub>2</sub> demand
Anti-arrhythmic	Adenosine (Adenocard)	Temporarily slows or arrests AV conduction and return to NSR
Antianginals	Nitroglycerin	Arterial and venous vasodilation increases perfusion and decreases O <sub>2</sub> demand
Beta blockers	Atenolol, sotalol	Inhibits stimulation of beta receptors; prolongs cardiac cycle refractory period
Calcium channel blockers	Diltiazem (Cardizem)	Smooth muscle relaxation allows for vasodilation; decreases cardiac workload inhibition of calcium during depolarization
Cardiac glycosides	Digoxin (Lanoxin)	Improves cardiac contractility by three mechanisms: positive inotrope (increases contractility, SV, and CO), negative dromotrope (decreased cardiac conduction), and negative chronotrope (lowers HR)
Catecholamines	Norepinephrine	SNS stimulation causes vasoconstriction for enhanced organ perfusion
Diuretics (loop)	Furosemide	Inhibits reabsorption of sodium in the loop of Henle and distal tubule; increases urine and electrolyte output
Diuretics (potassium sparing)	Spirolactone (Aldactone)	Aldosterone antagonist—inhibits sodium reabsorption without loss of potassium
Diuretics (thiazide)	Hydrochlorothiazide (Microzide)	Inhibits reabsorption of sodium in the distal tubule—increases urine output
HMG CoA reductase inhibitors (a.k.a. “statins”)	Rosuvastatin (Crestor)	Inhibits production of cholesterol by inhibiting HMG CoA reductase; LDL is decreased
Neprilysin inhibitor and ARB combination	Sacubitril/valsartan (Entresto)	Inhibits neprilysin (enzyme), allowing for increased natriuretic peptides, which causes vasodilation and sodium (and water) excretion; valsartan (see ARBs)

**TABLE 19.7** Commonly Used Cardiac Medications

Type	Drug	Mechanism of Action
Potassium channel blockers	Amiodarone (Pacerone)	Prolongs repolarization through blockade of potassium channels
Sodium channel blockers	Lidocaine	Decreases influx of sodium to cardiac cells—depolarization is prolonged

**TABLE 19.7** Commonly Used Cardiac Medications

### Oxygen Therapy

O<sub>2</sub> is considered a drug and requires a prescription or healthcare provider's order for nurses to administer it. When administering oxygen to a patient, it is important to ensure that oxygen flow rates are appropriately set according to the type of administration device (Table 19.8). When administering oxygen therapy, it is important for the nurse to assess the patient before, during, and after the procedure and document the findings.

Device	Flow Rates and Oxygen Percentage	Image
Nasal cannula	Flow rate: 1 to 6 L/min FiO <sub>2</sub> : 24 to 44 percent	 <p>(credit: "Nasal Cannula" by National Library of Medicine/ National Center for Biotechnology Information, CC BY 4.0)</p>
High-flow nasal cannula	Flow rate: up to 60 L/min FiO <sub>2</sub> : up to 100 percent	 <p>(credit: "Illustration of bronchoscopy using HFNC (A) or NIV (B)" by National Library of Medicine, CC BY 4.0)</p>
Simple mask	Flow rate: 6 to 10 L/min FiO <sub>2</sub> : 28 to 50 percent	 <p>(credit: "Simple Face Mask" by Glynda Rees Doyle and Jodie Anita McCutcheon, CC BY 4.0)</p>

**TABLE 19.8** Settings of Oxygenation Devices

### Patient Education

It is important to modify patient education methods depending on the individual's knowledge, skills, and abilities. For example, some older adults readily engage in using electronic technology, but others have low digital literacy or experience difficulty when accessing electronic health resources. Nurses should adapt patient education to the needs of the individual and provide verbal, written, or electronic resources, as needed, while considering any sensory, cognitive, or functional impairments. The ultimate goal of health promotion and patient education is to improve their understanding, motivation, and engagement in self-management and promote their quality of life.

### Behavioral Modifications

Knowing there are many behaviors that can negatively impact the cardiopulmonary system, it can be important for nurses to provide patient education about behavioral modifications. As part of the nursing history and physical, behaviors like smoking, exercise, nutrition, alcohol, and other intake of drugs, should all be discussed with the patient.

Helping the patient realize how certain applicable behaviors affected overall health, and cardiopulmonary health in particular, is important and can provide the necessary first step in recognition of the action-reaction relationship. Nurses are often the first providers of such information, as so much time is spent directly with patients, and relationships are established whereby patients feel comfortable asking questions. Once identified and recognized, the nurse can begin to introduce applicable information to help modify any negative behaviors.

There is a lot of information available regarding smoking cessation and many resources to help patients quit. Dietary recommendations can be provided, including cardiac diets, and recommendations for calorie intake in the presence of COPD. Patients may need guidance and contacts for support groups in order to consider quitting alcohol or illicit drug use. If expert information is needed, such as specific dietary limitations, the nurse can discuss with the prescribing healthcare provider about a consult with a specialist, in this case, a nutritionist or dietitian.

### Pollutants

As patients are seen in outpatient settings or are preparing for discharge from acute inpatient care, exploration by the nurse should include environmental exposures the patient is prone to. Whether this is secondhand smoke, exposure to motor vehicle exhaust, coal dust, or smoke from fires of any variety, patients may not understand the importance of exposure prevention. Patients should know about warnings for poor air quality and actions to take to avoid exposure. Education about appropriate respiratory protection devices, when to don and doff them, and how to wear them correctly can be discussed. And for information beyond the scope of nursing practice, the nurse can teach patients how to find reliable resources.

### Coping Techniques to Reduce Anxiety

Coping strategies are behaviors used to manage anxiety. Effective strategies control anxiety and lead to problem-solving, but ineffective strategies can lead to use, misuse, or overuse of food, tobacco, alcohol, or drugs. Nurses teach and reinforce effective coping strategies.

The nurse should determine what techniques the patient has used historically, and together the nurse and patient can discuss which have been successful and which have not. This can lead to behavior modifications and introduce new and healthy recommendations for coping in stressful situations. Often techniques like slow, deep breaths can be helpful. Some patients respond well to distraction and imagining a pleasant place or recalling a fond memory. The nurse can also suggest to the patient and prescriber the possibility of pharmacological intervention for anxiety to be added or adjusted to the patient's care plan.

### Comfort Measures

Establishing and maintaining comfort can be vital to patients while they are battling illness, painful symptoms, and fear. Nurses should be aware that some physical problems cause pain or discomfort, and many diagnostic tests and interventions inflict pain upon patients, who may already be uncomfortable.

The nurse should remain mindful of not only the treatments and pharmacological interventions that will enhance those direct cardiopulmonary physical needs but also the addition of pain medications, anxiolytics, and hypnotics if and when needed. Sometimes the most basic of interventions can better meet a patient's most basic needs: a warm bath, preferred music, or a visit from a pet may help reduce stress, enhance comfort, and assist with rest and healing.

## Interdisciplinary Collaboration

Many patients with serious, life-limiting illnesses have common symptoms that the nurse can assess, prevent, and manage to optimize their quality of life. Good symptom management improves quality of life and functioning in all states of chronic illness. Nurses play a critical role in recognizing these symptoms and communicating them to the interdisciplinary team for optimal management.

Collaborating with physical, occupational, speech therapists, and nutrition specialists in the design and implementation of care planning truly enhances patient care and improves patient outcomes (Figure 19.26). The importance of establishing and fostering good relationships with all members of the interdisciplinary team is crucial to safe patient care. Important departments that ensure cardiovascular and pulmonary health are nutrition, cardiac rehabilitation, and chest physiotherapy.

**FIGURE 19.26** These are examples of the members of an interdisciplinary care team. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Nutrition

Healthy nutrition helps to prevent obesity and chronic diseases, such as cardiovascular disease. By proactively encouraging healthy eating habits, nurses provide the tools for patients to maintain their health, knowing it is easier to stay healthy than to become healthy after disease sets in. When patients are recovering from illness or surgery, nurses use strategies to promote good nutrition even when a patient has a poor appetite or nausea. If a patient

develops chronic disease, the nurse provides education about prescribed diets that can help manage the disease, such as a low-fat, low-salt, low-cholesterol diet for patients with cardiovascular disease.

Patients often need guidance from dietitians to understand, plan for, and follow their specific nutritional needs. Also, whether the patient is actively involved in dietary choices or limitations while hospitalized, the dietitian is involved in the preparation of menu items that meet the needs of all specific diets.

Similar to being aware of a patient's needs in regard to prescribed medications, it is important for nurses to understand patients' dietary requirements and restrictions. Awareness of a cardiac diet, for example, which has limitations relative to sodium and fats, helps nurses provide the correct diets as well as guide patients and families to understand choices and follow recommendations. Patients with significant respiratory illness, like late-stage emphysema, often have increased calorie needs and require supplements with meals to provide enough energy for the extra physiological needs. For those who have comorbidities like DM or renal disease, dietary restrictions and recommendations are added to their care plans, while in the hospital and on discharge. Nurses tend to be the providers of discharge education, so the ability to describe various diets and caloric needs is important.

### Cardiac Rehabilitation

Patients who have substantial cardiac dysfunction, whether having had an MI, or from progressive deterioration like HF, or who are postoperative after surgery for valvular disorder or CABG, are usually prescribed cardiac rehabilitation. Depending on the length of hospitalization, the patient may be quite deconditioned, with anticipated needs for a variety of interdisciplinary therapies in order to gain some strength back and be well enough to return home. Others may not have had significant damage requiring complicated rehabilitation and various therapies. Such rehabilitation may or may not involve time as an inpatient at a dedicated rehabilitation unit or facility.

Many are able to begin their cardiac rehabilitation while inpatient and be taught exercises and activities to be done after discharge. Like physical therapy (which may also be ordered), many rehabilitation actions can be carried out at home by the patient and perhaps with assistance from a family member or friend. Often, there are outpatient visits for some time after discharge, to a cardiac rehabilitation agency, in order to check in, be evaluated, and adjust activities as indicated by patient status and tolerance.

### Chest Physiotherapy

There are devices and techniques that can assist patients with maintaining pulmonary function and recuperating from illness or exacerbation of an illness. Previously introduced was the IS, which many patients receive shortly after admission, whether for a long stay in the hospital or merely an overnight stay. These devices are disposable so patients are encouraged to take the IS upon transfer or discharge and continue using it several times daily.

Other methods of chest or respiratory physiotherapy include valves like a flutter valve which use vibration or oscillation to assist with positive expiratory pressure and enhance airway clearance. There are also specialized vests that inflate and deflate and offer vibration and percussion. Percussion can also be done manually by using cupped hands and repeated dull strikes to the chest and back, or with manufactured devices that provide similar thumping to the chest and back.

## LINK TO LEARNING

This video presents a demonstration of [manual chest physical therapy \(https://openstax.org/r/77ManualChestPT\)](https://openstax.org/r/77ManualChestPT) by a respiratory therapist.

The goal of these interventions is to loosen and mobilize secretions from smaller to central airways to enable their removal by coughing or **postural drainage** (positioning the patient to use gravity to allow secretions to drain) ([Figure 19.27](#)).

**FIGURE 19.27** Postural drainage fosters drainage and removal of secretions from various locations in the lungs. (credit: reproduced by permission of Jane Whitney)

## Emergency Interventions

When things go wrong with the cardiopulmonary system, the results can quickly be devastating or fatal. Of course, not all abnormalities are lethal, but an ability to recognize normal and therefore be able to identify abnormal (whether being able to define exactly what is wrong or not) is critical for nurses. It is also important to be vigilant about assessments and know what changes in a patient's status are worthy of immediate follow-up. A few of the things that require urgent or emergent interventions follow in the next and final section of this chapter.

### Chest Tube Insertion

Depending on the reason for the insertion of a chest tube, it may be urgent or emergent; it is not typically a routine intervention. Emergent chest tube insertion is perhaps most commonly done for a pneumothorax; hemothorax (or the mixture of hemopneumothorax) and chylothorax are also possibilities that necessitate a chest tube. The lungs have a limited amount of space within the thoracic cage, so situations that alter the area for lungs to inflate and deflate, and those that change the normal pressure, are problematic.

The location for chest tube placement is based on radiography, as pneumothoraces are visible on chest x-rays ([Figure 19.28](#)). The nursing role includes reassuring and frequently assessing the patient, providing medication for pain and anxiety, and assisting the physician (or advanced practitioner) with the procedure, including the setup of the chest tube system. The insertion is done under sterile technique, either at the bedside or in an operating room. The flexible tubing from the chest tube system needs to be attached to the chest tube itself, so the nurse holds the clean tubing and the provider who inserted the tube inserts the tube end into the system's tubing.

**FIGURE 19.28** Chest drainage tubes are placed (a) higher to drain air and (b) lower to drain fluid. (credit a: modification of work “An inserted chest tube” by C. H. Chen, S. Y. Lee et al/Wikimedia Commons, CC BY 2.5; credit b: modification of work “Rib cage” by Mikael Hågström, Public Domain)

A related emergency that requires the insertion of a chest tube for ongoing management is a tension pneumothorax. This develops suddenly and impacts the lung or lungs, heart, and blood vessels. Without immediate intervention, it can be quickly life threatening. Since time is limited before the provider takes the time for chest tube insertion, a large gauge needle is inserted in the second intercostal space and midclavicular line to allow air to escape and the lung to reinflate.

The video [Chest Tubes—Nursing Management and Assessment Made Easy \(https://openstax.org/r/77ChestTubes\)](https://openstax.org/r/77ChestTubes) presents more information about chest tubes.

### Cardiopulmonary Resuscitation

According to the AHA (2023), high-quality CPR is the principal contributor to post–cardiac arrest survival. Nursing students, as well as nurses at all levels—from licensed practical nurses through advanced practice nurses, are normally certified as BLS providers and recertify every two years. Depending on the cause of the arrest, and the subsequent status of the patient, interventions include rescue breathing, chest compressions, and use of an automated external defibrillator (AED) or manual defibrillator. Not all actions are indicated for all patients. For example, a patient who has experienced a respiratory arrest but has a pulse does not need chest compressions, and asystole is not a shockable rhythm. If the patient is pulseless, CPR is indicated, in order to perfuse the body, particularly the brain.

### LINK TO LEARNING

The animation [CPR in Action \(https://openstax.org/r/77CPRinAction\)](https://openstax.org/r/77CPRinAction) shows the perfusion capabilities of high-quality CPR. It also illustrates what happens when CPR is not done adequately.

### Defibrillation

Based on the term itself, defibrillation is the delivery of an electric shock to stop fibrillation (ineffective quivering movement of the heart muscle). Fibrillation, though, can occur in the atria or the ventricles, and atrial fibrillation (A-fib) is not typified as a “deadly rhythm.” If an electrical intervention is sought for the treatment of A-fib, it involves fewer joules of electricity and is termed **cardioversion**. Ventricular fibrillation (VF) and pulseless ventricular tachycardia (VT) are nonperfusing rhythms, and defibrillation is indicated emergently. Usually, this is delivered as part of BLS or ACLS efforts and accompanies CPR.

In acute care settings, a cart for arrest situations, also called a code, or COR-0, is present on most or all patient care units. The cart contains a hard backboard to place under the patient to enhance the quality of chest compressions,

airway devices and bag-valve masks of various sizes, emergency drugs, and a manual defibrillator/monitor. In many other settings, automated external defibrillators (AEDs) are available and can be used by laypersons, as the device offers step-by-step instructions. Those who are BLS certified have practiced with AEDs. Defibrillation delivers 150 to 300 joules (depending on the type of device), in an effort to essentially reset (depolarize) the heart and resume a more normal rhythm. Refer to the AHA's guidelines and algorithms (linked in the previous heading) for defibrillator (shock) indications and timing.

## LINK TO LEARNING

---

A demonstration of [defibrillation with an AED \(https://openstax.org/r/77AEDDefibrilla\)](https://openstax.org/r/77AEDDefibrilla) is presented in this video. Watch the rhythm examples, as they are from an actual patient. Also, the [AHA guidelines and algorithms \(https://openstax.org/r/77AHAGuideAlgor\)](https://openstax.org/r/77AHAGuideAlgor) may be reviewed.

---

### Intubation

When a patient is receiving general anesthesia prior to a procedure or surgery or is experiencing respiratory failure or respiratory arrest, an ETT is inserted by an advanced practitioner, such as a respiratory therapist, paramedic, or anesthesiologist, to maintain a secure airway. The ET tube is sealed within the trachea with an inflatable cuff, and oxygen is supplied via a bag valve mask or via mechanical ventilation.

Placement is verified with a CO<sub>2</sub> detection device to ensure it is in the airway and not the esophagus. Auscultation should be done to verify equal, bilateral breath sounds. A chest x-ray will be ordered and performed for definitive placement confirmation and also to verify the ETT is in the optimal position. The ETT is attached to an Ambu bag, and the patient's ventilation is provided by squeezing the bag every six seconds to deliver breaths until a mechanical ventilator is available. At that point, the bag is disconnected from the ETT, and the mechanical ventilator circuit is attached. Nurses collaborate with RTs and healthcare providers regarding the overall care of the patient on a mechanical ventilator.

## LINK TO LEARNING

---

This video shows [intubation, bagging, placement detection, and attachment of the ETT to a ventilator \(https://openstax.org/r/77ETTVentilator\)](https://openstax.org/r/77ETTVentilator) in an emergency. Watch the technique and landmarks used with the laryngoscope, how the ETT is passed through the vocal cords, and the postintubation actions.

---

### Mechanical Ventilation

A mechanical ventilator is a machine attached to an ETT to assist or replace spontaneous breathing. Mechanical ventilation is termed invasive because it requires the placement of a device inside the trachea through the mouth, such as an ETT. Mechanical ventilators are managed by RTs via protocol or provider order. The FiO<sub>2</sub> can be set from 21 to 100 percent.

Intubation and mechanical ventilation are uncomfortable and distressing to the patient, so patients are customarily sedated with an anxiolytic (e.g., lorazepam or midazolam) or anesthetic-type (e.g., propofol) medication. These drugs help the patient achieve synchrony with the ventilator, allowing the ventilator to provide all, or most of, the ventilation support. Some ventilator settings are so contrary to normal physiological breathing that patients will require continuous IV neuromuscular blockade or chemical paralysis. This drug therapy allows for complete control of breathing by the ventilator, and it is vital to provide sedation for patients on paralytics. Intubated and ventilated patients are at increased risk for ventilator-associated pneumonia (VAP), and there are nursing care actions like maintaining patients with the head of the bed at 30 degrees minimum, frequent oral care, and proton-pump inhibitor therapy in order to prevent the occurrence of VAP.

## Summary

### 19.1 Respiratory System

The various structures of the respiratory system, from the upper to lower airway, into the lungs, and to the capillary-alveolar bed, have been identified and explored. At the capillary-alveolar bed, the primary function of the respiratory system is gas exchange. The functions of these structures have been categorized, relating specific components to the purpose relative to ventilation and perfusion. This section has delved into the physiology of the respiratory system, and how it fits in the cardiopulmonary system. Specifics as to the role this system plays in ventilation, how respiration and gas exchange transpire, and the role the lungs play in the renin-angiotensin-aldosterone system are presented. Respiration is a basic function, generated by the neurological system, with control centers within the medulla oblongata and pons. Regulation by these systems, including actions stimulating the length and depth of each breath, is controlled by opposing actions of the apneustic and pneumotaxic centers, in efforts to maintain homeostasis throughout the body.

### 19.2 Cardiovascular System

The cardiovascular system is structurally unique insofar as it contains the muscular four-chambered heart (the pump), fluid/blood volume (the tank), and the blood vessels (the pipes). It is an electrical system. Electrical impulses precede the muscular movement or contraction of the heart. When the signals and responses are normal, it functions impeccably. These structures and processes have been explored and analyzed in an effort to understand cardiovascular system physiology.

In the process of investigating the normal anatomy and physiology of the cardiovascular system, regulation of this complex and intertwined system has been reviewed as well. Because normal cardiovascular function is critical to the maintenance of homeostasis, and in anticipation of the next module exploring various aspects of impaired function, this section introduced several cardiovascular dysfunctions and disorders, some of which intertwine and affect one another. Hypertension and arteriosclerosis impact one another and are implicated in CAD. Sometimes, the electrical system does not function normally, causing dysrhythmias and even cardiac arrest, which have been elaborated on through the disorders and interventions.

### 19.3 Factors Affecting Cardiopulmonary Function

When cardiopulmonary function is not performing properly, the physiological impacts can range from asymptomatic to severe and even life threatening. Some examples of disorders and dysfunctions affecting the cardiopulmonary system have been presented and discussed. Additionally, contributors to the development of such physiological concerns, including those risk factors considered nonmodifiable, such as genetics and age, as well as lifestyle decisions and behaviors that promote or prevent the development of cardiopulmonary diagnoses are discussed. Genetic input is not something that can be erased, although some negative impacts may be slowed or prevented by positive lifestyle and behavioral actions and decisions. Similarly, negative choices and decisions can have negative physical results.

Health status is also a factor in cardiopulmonary dysfunction. Comorbidities have a negative influence on a patient's ability to physically (and perhaps mentally) come through the problems that accompany malfunctions of the cardiac or pulmonary systems. As critical as this combined system is, the impacts may not only be obvious from the primary diagnosis but may be more insidious and be based on a secondary or tertiary effect.

Finally, a variety of diagnostic tests were investigated—from laboratory blood studies like cultures to arterial or venous blood gases to analyze acid-base balance and respiratory status, to monitoring devices such as pulse oximeter and capnography. Some of the components of PFTs were presented, although this practice area is quite specialized, with many details specific to pulmonology care. Since the electrical system is so vital to cardiovascular function, electrocardiograms were explored, with a focus on the entry-level, generalist nurse.

### 19.4 Management of Impaired Cardiopulmonary Functioning

The nursing roles in care of the cardiopulmonary patient can be varied and may take place in varied settings. Care of chronic disorders may happen most often in outpatient settings: physician's offices, clinics, or home care. Acute care and emergent care involve inpatient settings, and recovery, either between exacerbations or complete, is likely

to entail rehabilitation. Nursing care may include total, intensive care, or focus more on maximizing an individual's recovery and return to best function.

Nurses caring for patients with cardiopulmonary dysfunction should be vigilant and compassionate in their care delivery. Patient status can change rapidly, so frequent assessment is necessary. Prevention of complications is important; therefore, helpful practices like assertive pulmonary toilet should be employed to prevent atelectasis and possibly pneumonia. The importance of pain and anxiety control and other comfort measures cannot be diminished throughout the provision of care.

The nurse is not alone in the provision of cardiopulmonary care but is a member of an interdisciplinary team. Team members work in concert to coordinate the various aspects of patient status and goals, as well as the different care available through specialists in medicine, nursing, and other care providers. Cardiopulmonary emergencies benefit from the fast identification of the circumstance and immediate collaboration and action of the interdisciplinary team. The nurse works very closely with advanced practitioners—physicians, nurse practitioners, and physician's assistants—collaborating during routine and emergent care. The professional interaction during emergencies offers respect and recognition for all team members, from frequent nursing assessment to chest tube placement, or necessary advanced airways and mechanical ventilation. Respiratory therapists assist with intubations and set up and manage ventilators; radiology personnel take and read x-rays; and entire collaborative teams manage arrest situations in an organized manner to maximize the patient's outcome. Throughout a patient's journey, all sorts of multidisciplinary players contribute their expertise through varied therapies and support.

## Key Terms

- advanced cardiac life support (ACLS)** enhanced training and skills beyond basic life support (BLS), primarily involving the addition of resuscitation and cardiac support medications
- afterload** the force the ventricles must generate to pump blood against the resistance in the vessels
- arteriosclerosis** stiffening of the arterial walls
- artery** a blood vessel that carries blood away from the heart
- atelectasis** the collapse of alveoli in the lungs, resulting in limited air movement and decreased gas exchange
- atherosclerosis** buildup of plaque deposits within the artery walls
- automated external defibrillator (AED)** an easy-to-use portable device available in many settings that can analyze a cardiac rhythm and defibrillate, if appropriate, in order to reestablish an effective cardiac rhythm
- automaticity** the ability of cells to initiate spontaneous action potential
- bronchiectasis** a chronic condition where airways are dilated and the lung walls are thickened due to inflammation and infection
- capnography** CO<sub>2</sub> monitor
- cardiomyocytes** heart muscle cells
- cardiopulmonary resuscitation (CPR)** combination of rescue breathing and chest compressions
- cardiopulmonary system** combination of cardiovascular and pulmonary systems
- cardioversion** use of low-dose electricity to convert the cardiac electrical system from a dysrhythmia (e.g., A-fib) to normal sinus rhythm
- carina** the ridge of cartilage at the base of the trachea that separates the openings of the left and right primary bronchi
- comorbidity** multiple medical diagnoses
- compliance** the ability of the lungs to accommodate deep and shallow breaths and maintain elastic recoil
- contractility** pumping action of the heart
- crepitus** a popping or crackling sensation when the skin is palpated; it is a sign of air trapped under the subcutaneous tissues
- cyanosis** a bluish or dusky discoloration of the skin and mucous membranes caused by hypoxia
- dysrhythmia** a rhythm abnormality
- ejection fraction (EF)** the percentage of blood within the ventricle that is expelled during a single systolic contraction
- electrocardiogram** the visual interpretation of the electrical impulses involved in the cardiac cycle
- epiglottis** a flexible piece of cartilage that covers the opening of the trachea during swallowing to prevent ingested material from entering the trachea

- esophagus** part of the gastrointestinal tract: tubular structure adjacent to trachea which transports food and fluid boluses from the mouth to stomach
- expiration** the act of exhalation or breathing out
- false vocal cords** mucosal tissue located within the glottis; also known as vestibular folds
- fibrosis** abnormal scar tissue
- gas exchange** the transfer of oxygen and carbon dioxide; takes place at the alveolar-capillary bed
- glottis** the opening between vocal folds; includes true vocal cords and the opening between them
- hypercapnia** an elevated blood CO<sub>2</sub>
- hyperventilation** rapid, deep breathing
- hypoxemia** decreased partial pressure of oxygen in the blood (PaO<sub>2</sub>)
- hypoxia** a reduced level of tissue oxygenation
- inspiration** the movement of air into the lungs
- intravascular volume** the amount of fluid within the blood vessels
- ischemia** a condition in which oxygen-rich blood flow is restricted or reduced in a part of the body
- isoelectric line** the flat horizontal line on ECG paper, reflecting no electrical voltage (positive or negative)
- laryngopharynx** lower portion of the throat, located behind the larynx
- larynx** tubular airway structure at the superior part of the trachea that connects the pharynx to the trachea and helps regulate the volume of air that enters and leaves the lungs; contains the vocal cords
- mediastinum** the space within the thoracic cavity, medially between the lungs
- metabolic syndrome** a group of disorders including high triglycerides, low high-density lipoprotein (HDL), insulin resistance, hyperglycemia, hypertension, and central obesity
- nasal turbinates** folded mucosal tissues offering protection, warmth, and humidity to the nasal cavity; also known as conchae
- nasopharynx** superior part of pharynx, connecting nose and trachea
- oropharynx** middle portion of pharynx, including tonsils and base of tongue, connecting to trachea
- perfusion** vascular circulation powered by the pumping action of the heart that delivers oxygen and other nutrients to body tissues
- pharynx** muscular tube that connects the nasal cavity and mouth to the voice box (larynx) and the esophagus (food pipe); also known as the throat
- postural drainage** use of gravity/positioning to enhance drainage of respiratory secretions
- preload** the stretch on the ventricles prior to contraction
- respiration** the action of breathing, including inhalation and exhalation
- respiratory ventilation** the act of breathing; associated with oxygenation
- rhythm strip** a tracing of the electrical cycles as seen from a selected lead, usually representing six seconds
- sinuses** cavities located bilaterally in various areas of the skull; identified by the nearby bones
- spirometry** pulmonary function test measuring the amount and speed of air movement on inhalation and exhalation
- stroke volume** the volume of blood pumped out of the left ventricle of the heart during each systolic cardiac contraction
- subcutaneous emphysema** air trapped in the subcutaneous tissue
- surfactant** a phospholipid compound that reduces surface tension of alveoli, thereby preventing alveolar collapse (atelectasis)
- tachycardia** heart rate faster than 100 beats per minute
- tachypnea** a respiratory rate that exceeds 20 breaths per minute
- tidal volume** length and depth of breaths
- trachea** the lowest structure of the upper airway, adjacent to the esophagus, that connects the lung bronchi and the larynx and provides a route for air to enter and exit the lungs; also known as the windpipe
- true vocal cords** structures within the glottis with muscular attachments to the thyroid and laryngeal cartilage; movement at the inner aspects produces sound production mechanism
- valve** promotes the unidirectional flow of blood toward the heart and prevents backflow in a vein
- vein** a blood vessel that returns blood to the heart
- venous reserve** percentage of venous blood located in venous networks within the liver, bone marrow, and integument

**ventilation** the movement of air in and out of the lungs

## Assessments

### Review Questions

1. What laboratory result is indicative of hypercapnia?
  - a. PaO<sub>2</sub> 68 mm Hg
  - b. PaCO<sub>2</sub> 24 mm Hg
  - c. HCO<sub>3</sub> 24 mEq/L
  - d. PaCO<sub>2</sub> 50 mm Hg
2. Diffusion works by which method of molecular movement?
  - a. Molecules move from the intravascular space to the surrounding tissue.
  - b. Movement of molecules is from interstitial to intravascular space.
  - c. Molecular movement is from high to low concentration along a gradient.
  - d. Molecules are moved across a filter by expenditure of ATP.
3. What substance is a powerful vasoconstrictor, synthesized by reactions of the kidneys and the lungs?
  - a. aldosterone
  - b. angiotensin II
  - c. renin
  - d. angiotensin I
4. What substance reduces alveolar surface tension, thereby preventing the collapse of alveoli?
  - a. surfactant
  - b. macrophage
  - c. bradykinin
  - d. prostaglandin
5. What patient's respiratory status would a nurse in the emergency department be *most* concerned about?
  - a. 68-year-old with fifty-pack-year smoking history
  - b. 52-year-old with brainstem infarction
  - c. 45-year-old with right lower lobe pneumonia
  - d. 34-year-old with latent tuberculosis
6. A nursing student who is preparing to educate a patient on the use of the incentive spirometer practices by telling the preceptor the patient will be told to use what technique?
  - a. "Inhale through the mouthpiece like a thick milkshake through a straw."
  - b. "Blow into the mouthpiece as hard as you can for as long as you can."
  - c. "Breathe in and out through the mouthpiece quickly ten times in ten seconds."
  - d. "Cough into the mouthpiece to see if the regulator rises to the goal."
7. Norepinephrine enhances perfusion by what mechanism?
  - a. dilates blood vessels
  - b. produces hypotension
  - c. causes vasoconstriction
  - d. normalizes temperature
8. The combined processes of cellular respiration and gas exchange are referred to by what terminology?
  - a. ventilation
  - b. perfusion
  - c. internal respiration
  - d. Krebs cycle

9. The impulse of the normal cardiac electrical cycle travels from the SA node to the AV node, then to which structure?
- Purkinje fibers
  - bundle of His
  - ventricular wall
  - interventricular septum
10. A nurse anticipates what symptom from a patient who has low CO?
- clammy skin
  - clear mentation
  - bradycardia
  - robust pedal pulses
11. Metabolic syndrome is associated with what combination of diagnoses?
- hyperglycemia, central obesity, hypertension
  - high triglycerides, high HDL, hyperglycemia
  - hypertension and severe obesity
  - high triglycerides, low HDL, hypoglycemia
12. Acid-base balance is reflected by what factor?
- $\text{PaCO}_2$
  - pH
  - $\text{PaO}_2$
  - $\text{HCO}_3$
13. A nurse is educating a patient about lifestyle choices; what behavior is of most concern for respiratory implications?
- sedentary activity level
  - high sodium intake
  - 150 minutes of moderate walking
  - smoking
14. The amount and rate of inspiration and expiration of air are measured by what test?
- oximetry
  - capnography
  - spirometry
  - PEFR
15. The telemetry nurse notices a patient's HR has slowed to 45 beats/minute; upon reviewing the continuous ECG monitor, no P-waves are visible, but the QRS complexes are regular. The nurse prepares to call to inform the cardiologist of what suspected issue?
- The patient is in HF.
  - An MI is occurring.
  - A-fib has developed.
  - The SA node is not firing.
16. A nurse reads a postintubation chest x-ray report that indicates a patient has subcutaneous emphysema in the anterior right chest, near the clavicle. What assessment finding should the nurse anticipate in this region?
- no breath sounds
  - crepitus
  - alkalosis
  - wheezing

17. A patient is admitted for an acute-on-chronic exacerbation of emphysema. What powerful class of drugs does the nurse expect to be prescribed to treat the acute inflammatory process?
  - a. decongestant
  - b. expectorant
  - c. corticosteroid
  - d. antitussive
  
18. An unresponsive patient who is not breathing and whose cardiac rhythm is identified as VF is a candidate for what emergency intervention?
  - a. cardioversion
  - b. O<sub>2</sub> by CPAP
  - c. IV sedation
  - d. defibrillation
  
19. A patient with secretions in bilateral anterior upper lobes of the lungs has been taking guaifenesin, has undergone chest physiotherapy to include percussion of the upper anterior chest, and is now to be positioned for postural drainage. In what position will the nurse place the patient?
  - a. Trendelenburg
  - b. supine and flat
  - c. prone
  - d. high Fowler

### Check Your Understanding Questions

1. How does the pneumotaxic center affect the respiratory rate?
2. What is meant by the term *automaticity*?
3. What dietary patient teaching should the nurse provide to a patient recently diagnosed with hypertension?
4. Which three techniques are helpful for removal of excess CO<sub>2</sub> and promotion of airway clearance?

### Reflection Questions

1. A nursing student notices an ICU nurse pays closer attention to a patient's cardiac index (CI) than CO on the monitor. Why is the nurse focusing more on the CI?
2. Describe the benefit of the traffic light system for patient education regarding peak flow results.
3. Consider the members who make up an interdisciplinary healthcare team. Describe which team members are likely to be involved in a cardiopulmonary arrest situation and reflect on the interaction of roles and how the players collaborate toward positive outcomes.

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #4: Part 1](#).  
Based on this Unfolding Case Study and the formula for cardiac output, what do you think is happening with the patient based on her presenting vital signs?
2. Refer to [Unfolding Case Study #4: Part 2](#).  
What risk factors might be present that are contributing to the patient's condition?

### What Should the Nurse Do?

An unresponsive patient has been brought to the emergency department, and an ABG is performed. Results indicate a pH of 7.24 and CO<sub>2</sub> of 52. The nurse notes the patient's respiratory rate is 26.

1. Based on the definition of hyperventilation, is this patient hyperventilating?
2. Why is the patient tachypneic?
3. A patient who experienced a MI with significant myocardial tissue damage two weeks ago now has a

diagnosis of HF. The nurse notes these recent test and hemodynamics results: T: 98.8°F (37.1°C), HR 122, BP 86/48, RR 16, CO 3.9, CI 1.8. Echocardiogram report includes bilateral ventricles with minimal wall motion and low SV. What results would illustrate signs and symptoms associated with HF?

4. A patient presents to the ED with complaint of 10/10 chest pain. The receiving nurse notes the patient is ashen and diaphoretic. Vital signs are as follows: temperature 98.8°F (37.1°C), HR 112, BP 84/56, RR 24, SaO<sub>2</sub> 94 percent on 2 L O<sub>2</sub> by nasal cannula (NC). As the leads are being placed for a twelve-lead ECG, the patient says to the nurse, “Please don’t let me die!” and loses consciousness. The nurse checks for a carotid pulse, but there is none, so the code button is pushed to activate the code team. While awaiting the team’s arrival and the code cart, which action should the nurse take first?

### Competency-Based Assessments

1. A nurse is caring for a patient awaiting cardiac catheterization who had 9/10 chest pain, reduced to 4/10 on a nitroglycerin IV drip. Which patient assessment findings should the nurse consider to determine whether to increase the rate of nitroglycerin? *Select all that apply.*
  - A. temperature
  - B. BP
  - C. HR
  - D. pain scale
  - E. respiratory rate
2. The new graduate nurse prepares to place leads for continuous three-lead cardiac telemetry monitoring: in addition to the ground, at which locations should leads be placed?
  - a. right arm and both legs
  - b. both arms and left leg
  - c. left and right second intercostal space
  - d. xiphoid process and left arm

## CHAPTER 20

# Fluid, Electrolyte, and Acid-Base Balance

**FIGURE 20.1** Successful regulation of fluid and electrolytes is a vital part of maintaining homeostasis within the human body. (credit: "U.S. Navy Sailors spend time working in Valleywise Medical Center supporting the community 220222-A-TV877=1003," Navy Medicine/ Flickr, Public Domain)

### CHAPTER OUTLINE

20.1 Fluid and Electrolyte Balances

20.2 Acid-Base Balances

20.3 The Nurse's Role in Patient Care Management

**INTRODUCTION** Understanding fluid, electrolyte, and acid-base balance is one of the most important concepts in nursing. Without stability in all three of these areas, cellular process cannot occur normally, and life may cease to exist. A normal fluid balance is needed to deliver oxygen and other nutrients to target tissues and to remove cellular waste. Keeping electrolytes within a narrow range is vital for muscle contractions, nerve impulses, a stable acid-base balance, and control of fluid within the body. Acid-base levels affect the function of enzymes and nearly all cellular processes, including immune function, neuronal excitability, and myocardial blood flow. Given the fact that all body systems are affected by fluid, electrolytes, and acid-base balance, it is imperative that nurses be knowledgeable about these topics (Quade et al., 2021).

## 20.1 Fluid and Electrolyte Balances

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the principles of fluid and balances in the body
- Identify principles of electrolytes and balances in the body
- Explain the regulation mechanisms of fluid and electrolyte balance

The principle of fluid and electrolyte balance is one of the cornerstones of nursing practice. The human body must

maintain strict balance between fluid levels and electrolyte concentrations in order for physiological processes to occur normally. To maintain this balance, there are multiple regulatory mechanisms that restore fluid and electrolyte balance. However, those regulatory mechanisms sometimes fail. Nurses must be knowledgeable about the signs and symptoms of a fluid and electrolyte imbalance so that they can intervene early and prevent serious complications.

## Principles of Fluids and Balances in the Body

To ensure **homeostasis** and acid-base balance, the human body must maintain a consistent balance of fluid and electrolytes. Homeostasis refers to the process by which the human body maintains its balance by adjusting to internal and external stimuli. When homeostasis is not maintained, the patient is at risk for organ system dysfunction or even death. Nurses must recognize subtle signs of fluid and electrolyte imbalances. By doing so, they can intervene early and prevent patient complications.

### Composition of Body Fluids

Body fluid is composed of water and solutes. A **solute** is any substance that is dissolved in a solution. Examples of solutes in body fluid are proteins, electrolytes, and metabolites. There are two main compartments of body fluid in the body: the intracellular compartment and the extracellular compartment. Approximately two-thirds of body fluid is found in the intracellular space and one-third is in the extracellular compartment ([Figure 20.2](#)) (Tobias & Mohiuddin, 2022).

**FIGURE 20.2** Although cerebral spinal fluid (CSF) is extremely important in protecting the brain and spinal cord, it makes up less than 1 percent of total body fluid. (credit: modification of “Cellular Fluid Content” by “Welcome1To1The1Jungle”/Wikimedia Commons, CC BY 3.0)

### Intracellular Fluids

The **intracellular fluid** is the body fluid found inside the body’s cells. Within this space, multiple chemical reactions occur. Therefore, it is important to maintain consistent solute concentrations. Alterations in solute concentration can change the acid-base balance inside the cell, which affects the structure and function of enzymes. An **enzyme** is a protein that catalyzes chemical reactions. When enzymes do not function normally, chemical reactions that normally take place inside the cells are significantly impacted (Brinkman & Sharma, 2023).

### Extracellular Fluids

The **extracellular fluid** is the body fluid found outside of cells. It is subdivided into three categories: interstitial fluid,

blood plasma, and transcellular fluid. The fluid that surrounds the cells is called **interstitial fluid**. Intravascular fluid, also known as **blood plasma**, is the liquid component of blood. It is whole blood minus the red blood cells, white blood cells, and platelets (Tobias & Mohiuddin, 2022). The fluid within epithelial-lined spaces is called **transcellular fluid**. Examples of transcellular fluid include cerebrospinal fluid, ocular fluid, and joint fluid. Transcellular fluid makes up less than 1 percent of total body fluid (Chen & Khalili, 2023).

### Body Fluid Balance

Maintenance of fluid balance is necessary for optimal health. Nurses must recognize fluid imbalances because health problems can result from a patient having too much or too little fluid. Certain physiological conditions, such as renal disease and cardiac disease, can cause an excess accumulation of fluid, known as **hypervolemia**. On the other hand, decreased oral intake or excessive fluid loss can cause a negative fluid balance, known as **hypovolemia**. An optimal fluid balance for cellular processes is a net even, or **euvolemic**, fluid balance (Simpson & McIntosh, 2021).

In addition to problems related to total body fluid balance, fluid can be in the wrong compartment. For example, the patient can have an excess of extracellular fluid. A primary sign of excess extracellular fluid is **edema**, or swelling, caused by the accumulation of fluid in the body's tissues. Extracellular fluid can also shift into the intracellular space, causing an excess of intracellular fluid. This process is seen in conditions such as cerebral edema. Having excess fluid in brain cells causes impaired neurological function. Fluid distribution in the body is largely determined by the solute concentration in both intracellular and extracellular fluid. Having a higher solute concentration in one compartment draws fluid into that compartment to maintain an equal solute concentration in both compartments (Simpson & McIntosh, 2021).

### Fluid Volume Deficit

Also referred to as hypovolemia or dehydration, **fluid volume deficit** is a medical condition in which fluid loss exceeds fluid intake. A fluid volume deficit can occur in any age group, but children under the age of two and older adults are at greater risk. Common causes of fluid volume deficit include vomiting, diarrhea, fever with excessive sweating, and inadequate oral intake. Nurses must recognize signs of dehydration to intervene early. Possible signs of dehydration in infants and young children include crying without tears, no wet diapers for three hours or more, irritability, sunken eyes, and a sunken fontanel. Mild cases of fluid volume deficit can be treated with oral rehydration. More severe cases require intravenous fluid administration.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Take Action: Recommend Laboratory Analysis

The nurse is admitting a 9-month-old infant with a three-day history of vomiting and diarrhea. When completing the admission assessment, the nurse notes the infant's eyes are sunken and anterior fontanelle (or fontanel) is depressed. Recognizing that the infant's physical assessment is concerning for dehydration, the nurse analyzes other cues to see if additional diagnostic tests may be warranted. The nurse considers possible treatment options for dehydration and determines intravenous fluid may be needed. The nurse reviews the medical orders and notes that the infant is ordered a clear liquid diet, and no baseline laboratory values were requested. The nurse pages the on-call provider to discuss the patient's clinical status. During the conversation, the nurse recommends sending a basic metabolic panel to monitor the patient's hydration status and placing a peripheral IV.

### Fluid Volume Overload

Also referred to as hypervolemia, **fluid volume overload** is a medical condition in which an excessive amount of fluid is retained in the intravascular fluid compartment. Certain medical conditions place patients at risk for developing fluid volume overload. These conditions include heart failure, kidney failure, cirrhosis, and pregnancy. Patients with fluid volume overload often present with pitting edema, ascites, and dyspnea and crackles in the lung fields. Treatment of fluid volume overload often involves restricting sodium and fluid intake. It may also include diuretic use to help remove excess fluid.

## CULTURAL CONTEXT

### Preference for Traditional Medicines

Heart failure is a common chronic condition that often improves with diet and lifestyle modifications such as sodium restriction and fluid restriction. When providing education about heart failure management, nurses should be cognizant of how cultural preferences influence the patient's response to education about diet and lifestyle modification. Many ethnic groups in the United States may prefer traditional medicine practices and be more likely to adhere to diet and fluid recommendations if the practitioner takes into consideration their cultural preferences. For example, many people in the Hispanic/Latino community may use traditional remedies such as herbal teas or treatments derived from *curanderismo* (traditional folk healing). If a practitioner acknowledges and integrates these practices, such as recommending safe herbal teas that complement medical treatments, patients may be more receptive to following dietary and fluid intake guidelines. Similarly, Chinese patients may rely on traditional Chinese medicine (TCM), which includes practices such as acupuncture, tai chi, and the use of specific herbs and foods for their medicinal properties. Practitioners who understand and respect TCM can provide dietary recommendations that align with these practices, such as suggesting foods that balance yin and yang, thereby increasing patient adherence to medical advice. Nurses should be knowledgeable about the diet and traditional medicine beliefs of the patient population they serve. By doing so, their patients are more likely to be receptive to the education (Kulakaç et al., 2022).

### Principles of Electrolytes and Balances in the Body

Electrolytes are different from other solutes because they have an electrical charge, either positive or negative, when dissolved in water. The electrical charge of electrolytes is important for multiple cellular processes, including initiation of muscle contractions, initiation of nerve signals, maintenance of acid-base homeostasis, and distribution of fluid across different compartments. There are multiple regulatory systems within the human body that maintain electrolytes within a narrow range so that they are able to fulfill their function in maintaining homeostasis.

#### Electrolyte Composition of Body Fluids

Body fluid composition is maintained in a normal physiological range by regulatory mechanisms that control water and solute concentrations in both the intracellular and extracellular spaces. There is a narrow range of normal electrolyte values that body fluid composition should stay within, and slight abnormalities can have serious consequences. For this reason, it is important for nurses to know normal electrolyte ranges, understand the cause of electrolyte imbalances, recognize the signs and symptoms of an imbalance, and identify appropriate treatments (Table 20.1).

Electrolyte	Functions in the Body	Normal Adult Range
Bicarbonate	Maintains acid-base homeostasis	22–29 mEq/L
Calcium	Necessary for muscle contractions, nerve impulses, blood clotting, and healthy bones and teeth	8.6–10.2 mg/dL
Chloride	Helps maintain fluid balance and is an important component of stomach acid	96–106 mEq/L
Magnesium	Necessary for muscle and cardiac contractions, bone strength, and muscle formation	1.5–2.4 mEq/L
Phosphate	Essential for energy production, bone and teeth formation, and cell signaling	3.4–4.5 mg/dL

**TABLE 20.1** Common Electrolytes in the Human Body and Their Function

Electrolyte	Functions in the Body	Normal Adult Range
Potassium	Helps maintain fluid balance, controls heart contractions, and regulates heart rhythm	3.5–5.1 mEq/L
Sodium	Regulates fluid balance and necessary for nerve and muscle contractions	135–145 mEq/L

**TABLE 20.1** Common Electrolytes in the Human Body and Their Function

## LIFE-STAGE CONTEXT

### Dehydration Risk in Children Under the Age of 2

Infants and young children under the age of 2 are at a higher risk of dehydration than other age groups. Children in this age group have immature immune systems and are more susceptible to infections, such as gastroenteritis, which can cause vomiting and diarrhea. Children under the age of 2 also have a higher metabolic rate, which results in more insensible fluid loss. Lastly, they are unable to communicate their needs to hydrate themselves (Vega & Avva, 2024).

### Sodium

Sodium ( $\text{Na}^+$ ) is the most abundant electrolyte in the extracellular fluid compartment. The concentration of sodium plays an important role in maintaining an appropriate fluid balance in the intravascular and interstitial spaces. Sodium ions play a pivotal role in regulating extracellular fluid volume and are essential for generating the **action potential**, which is the voltage difference across a cell membrane. The action potential is determined by the balance of ions between the intracellular and extracellular fluid. Action potentials are vital for the proper functioning of neurons, pacemaker cells in the heart, muscles, and nerves.

The normal serum sodium range is 135 to 145 mEq/L. A common phrase in fluid and electrolyte physiology is “water follows sodium.” A high serum sodium levels pulls fluid out of the intracellular space and a low serum sodium level moves fluid into the intracellular space, causing cells to swell. The brain cells are particularly sensitive to these fluid shifts in response to changes in serum sodium levels. Signs of **hypernatremia**, or an elevated serum sodium level, include mental confusion, irritability, seizures, severe thirst, and dry mucous membranes. Signs of **hyponatremia**, or a low serum sodium level include headache, confusion, nausea, seizures, and coma (Allen & Sharma, 2023; Barker & VonColln-Applying, 2023).

## PATIENT CONVERSATIONS

### Resistance to Diet Modifications

**Scenario:** Julian is a 19-year-old with type 1 diabetes, hypertension, and kidney disease. He receives health care at a family practice clinic that provides services to the uninsured. Over the last six months, his blood pressure has increased; however, he is resistant to taking new medications or making any diet or lifestyle changes. He came to the clinic today to meet with the nurse case manager for the diabetes team.

**Nurse:** Hi, Julian. My name is Rebecca. I’m a nurse who helps patients who have diabetes.

**Patient:** Hi, Rebecca. It’s nice to meet you. I’m really stressed out because I lost my insurance and it’s hard for me to buy my medications.

**Nurse:** That sounds really stressful. We have a prescription assistance program. Often, we can provide you with samples of the medications that you need until we can work out a permanent solution. In the meantime, I’d like to talk about other things you can do to help manage your condition, such as diet and exercise modification.

**Patient:** What do you mean? I’m a type 1 diabetic. I need insulin! Why are you bothering to talk to me about stupid

stuff like diet?

**Nurse:** I understand that you need insulin, and I'll make sure you leave the clinic today with the medicine you need. However, with the kidney disease and high blood pressure along with the diabetes, lifestyle modifications are oftentimes needed in addition to medications. Has anyone talked to you about the effect of sodium on blood pressure and kidney disease?

**Patient:** No. And I don't see why it matters. Having a chronic illness sucks. It's not my fault I'm a diabetic.

**Nurse:** Of course, it's not your fault. I'm not judging you or trying to make you feel bad. I just want to make sure you understand what's going on inside your body so that you can make the best decisions for yourself.

**Patient:** Hmmm, okay.

**Nurse:** High blood sugar and high blood pressure both negatively impact your kidneys. When you add a high-salt diet on top of that, it can make the kidney damage worse. You've just started showing signs of kidney disease and I want to help you protect your kidneys to minimize potential harm to your body. Does that make sense?

**Patient:** I guess so.

**Nurse:** Okay, let's talk about some things you can do at home. First of all, limiting your salt intake is important. Salt draws fluid into your bloodstream and makes your blood pressure higher. If you cut back on processed foods that contain a lot of salt—such as canned soups, bacon, chips, frozen pizzas, Ramen noodles, and things like that—you might feel better and see improvements in your blood pressure. Also, it would be great to exercise three times per week. You don't need to join a fancy gym or anything, you can just go for a thirty-minute brisk walk or maybe ride your bike. How does trying those things sound to you?

**Patient:** I don't really see why exercising and decreasing my salt intake is important for a diabetic, but I could try.

**Nurse:** Trust me, those small lifestyle changes will help. I'd like to see you back in the clinic in two weeks for another blood pressure check and to track your progress with exercise and diet. Now I'm going to talk to your provider to make sure I have the most updated information for your prescription medications. How do you feel about the plan?

**Patient:** Okay. I was scared about not being able to afford my insulin. If you can help with that I'll try to limit my salt intake and think about the exercise.

**Nurse:** Great. I know managing diabetes is stressful. I'll make sure you have the insulin sorted out before you leave today, and I'll see you back in my office in two weeks. Deal?

**Patient:** Yeah, thanks for your help.

---

### Potassium

Potassium ( $K^+$ ) is the most abundant electrolyte within the intracellular fluid. Serum potassium levels are maintained inside the cell via active transport using the sodium–potassium pump. Serum potassium levels are regulated by the hormone aldosterone in the kidneys. Normal potassium levels are needed for cardiac function, neural function, and muscle contractility (Sur & Mohiuddin, 2022).

The normal serum potassium range is 3.5 to 5.1 mEq/L. An increased serum potassium level greater than 5.1 mEq/L is referred to as **hyperkalemia**. Signs of hyperkalemia, or an elevated potassium level, include irritability, gastrointestinal cramping, diarrhea, and peaked T waves on an electrocardiogram. If hyperkalemia worsens, the patient may progress to cardiac dysrhythmias or cardiac arrest (Barker & VonColln-Appling, 2023). Common causes of hyperkalemia are kidney failure, metabolic acidosis, use of potassium-sparing diuretics, and/or administration of potassium supplements. Mild hyperkalemia often involves adjustments to medications and decreasing potassium oral intake. For more severe cases, sodium polystyrene (Kayexalate) is often administered either orally or rectally. Kayexalate binds potassium so it can be excreted via the gastrointestinal tract. For severe symptomatic hyperkalemia, temporary hemodialysis may be used (Sur & Mohiuddin, 2022).

Hypokalemia refers to a decreased serum potassium level or a level less than 3.5 mEq/L. Potential causes of hypokalemia include excessive vomiting, diarrhea, use of potassium-wasting diuretics, and a low potassium diet.

Signs of **hypokalemia**, or having a low serum potassium level, include muscle weakness, lethargy, and a thready pulse (Cleveland Clinic, 2022). Treatment of hypokalemia revolves around replacing the missing potassium. Mild hypokalemia is often treated with oral potassium supplements. More severe cases may require intravenous potassium administration. Because potassium is excreted by the kidneys, it is imperative to confirm that the patient has adequate urine output prior to giving a potassium replacement (Barker & VonColln-Applying, 2023).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: What To Do If a Patient Requires Intravenous (IV) Potassium Supplements

Disclaimer: Always follow the agency's policies.

Steps	Description/Rationale
Assess the patient's fluid status and renal function.	IV potassium should only be given to patients who are well-hydrated and who have normal renal function. Patients who are dehydrated or have decreased renal clearance of potassium could develop life-threatening hyperkalemia during IV potassium administration.
Assess and document the patient's IV access.	Potassium salts are highly caustic to veins. Ideally potassium should be administered via a central line. If it is not infused via a central line, it should be infused via a large, high-flow vein.
Place the patient on a bedside cardiac monitor and record a set of baseline vital signs prior to administration.	Intravenous potassium administration can cause cardiac arrhythmias. Continuously monitor the patient to prevent complications.
Verify the dose of IV potassium ordered with a second nurse.	An accidental overdose of potassium can be life-threatening. Always double-check the dose of potassium ordered with a second RN. Both RNs should document the administration on the medication administration record (MAR).
Start the infusion of potassium slowly, at a maximum rate of 20 mEq/hr.	Rapid administration of potassium can cause cardiac arrest.
After the infusion is complete, send a follow-up serum potassium level. Make sure the blood is not drawn from the same line used to infuse the potassium.	Following up on the patient's potassium level is important to ensure the patient's safety. High potassium levels are associated with cardiac arrhythmias and cardiac arrest. The post-infusion level must be drawn from a different line because potassium can stick to IV tubing and could alter the results of the follow-up potassium level.

### Calcium

Calcium ( $\text{Ca}^{2+}$ ) is more common in the extracellular fluid than in the intracellular fluid. However, most of the total body calcium is stored in the bones. Calcium is important for bone and teeth structure, nerve transmission, and muscle contraction. Serum calcium levels are regulated by parathyroid hormone, dietary intake, and physical activity. Physical activity promotes the incorporation of calcium into bones, contributing to bone density, whereas extended periods of immobility may lead to the release of calcium from bones into the bloodstream. Dietary sources of calcium include dairy products, green leafy vegetables, and whole grains.

The normal serum calcium range is 8.6 to 10.2 mg/dL (Barker & VonColln-Appling, 2023; Drake & Gupta, 2024). Having an elevated serum calcium level is known as **hypercalcemia**. Possible causes of hypercalcemia are prolonged immobilization that causes calcium to leach out of bones into the serum. It can also be caused by certain types of cancer, such as parathyroid tumors, that increase the secretion of parathyroid hormone (PTH). Hypercalcemia primarily affects the gastrointestinal and musculoskeletal systems. Symptoms of hypercalcemia include nausea, vomiting, constipation, and skeletal muscle weakness. Mild hypercalcemia may be treated with dietary modifications such as decreasing intake of calcium and increasing intake of phosphorus, which binds to calcium and makes it inactive. Patients with limited mobility and hypercalcemia may benefit from weight-bearing exercise to stop the leaching of calcium from the bones into the serum. More severe or chronic hypercalcemia may require hemodialysis or surgical removal of the parathyroid gland (Barker & VonColln-Appling, 2023).

Having a low serum calcium level, known as **hypocalcemia**, can be caused by hypoparathyroidism, vitamin D deficiency, and or renal disease. Without adequate levels of PTH, not enough calcium is reabsorbed by the kidneys. Vitamin D deficiency causes hypocalcemia because vitamin D is necessary for absorption of dietary calcium from the gastrointestinal tract. In patients with renal disease, the kidneys may excrete too much calcium, resulting in hypocalcemia. The primary symptom of hypocalcemia is **paresthesia**, or numbness and tingling sensation. Hypocalcemia paresthesia is felt in the lips, tongue, hands, and feet. Patients with hypocalcemia may also experience muscle cramps and **tetany**, or involuntary muscle contractions. **Chvostek's sign**, an involuntary twitching of the facial muscle when the facial nerve is tapped, is a classic sign of hypocalcemia (Omerovic & M Das, 2023). **Trousseau's sign**, or the involuntary spasm of the hand when a blood pressure cuff is inflated above the diastolic blood pressure for three minutes, is also a classic sign of hypocalcemia (Patel & Hu, 2023). Most cases of hypocalcemia can be treated with dietary modifications. Patients are encouraged to increase calcium and vitamin D intake and decrease phosphorus intake. Severe cases of hypocalcemia may be treated with intravenous calcium replacements (Drake & Gupta, 2024).

## LINK TO LEARNING

This video about [Chvostek's and Trousseau's signs \(https://openstax.org/r/77chvostek\)](https://openstax.org/r/77chvostek) helps you gain an understanding of how to elicit these signs.

### Magnesium

Magnesium ( $Mg^{2+}$ ) is an important electrolyte for cardiac, nerve, and muscle function. Approximately 50 percent of the body's magnesium is stored in the bones. The remaining magnesium is primarily stored in the intracellular fluid. The normal serum magnesium level is 1.5 to 2.4 mEq/L (Barker & VonColln-Appling, 2023). Maintaining serum magnesium levels is necessary for normal cardiac function, nerve stimulation, muscle contractions, and immune health.

Having an elevated serum magnesium level is known as **hypermagnesemia**. Many cases of hypermagnesemia are caused by medication misuse, such as taking excessive magnesium supplements or using magnesium-containing laxative or antacids. It can also be caused by renal failure. Patients presenting with hypermagnesemia may have bradycardia, lethargy, hyporeflexia, muscle weakness, and tremors. Severe cases may lead to cardiac arrest. Mild cases of hypermagnesemia can be treated by increasing fluid intake and limiting oral intake of magnesium. In severe cases, dialysis is needed to lower magnesium levels (Barker & VonColln-Appling, 2023).

Having a low serum magnesium level is referred to as **hypomagnesemia**. The most common cause of hypomagnesemia is inadequate dietary intake of magnesium. Patients with alcohol use disorder are at high risk for hypomagnesemia because they tend to have a poor diet and have impaired nutrient absorption from the gastrointestinal tract. It can also be secondary to loop diuretic use, which causes the excretion of magnesium in the urine. Common signs and symptoms of hypomagnesaemia include vomiting, lethargy, weakness, and leg cramps. Severe cases can lead to cardiac dysrhythmia, or an abnormal heart rhythm or heart rate. Mild cases of hypomagnesemia can be treated with increasing oral intake of magnesium. More severe cases require IV replacement of magnesium (Allen & Sharma, 2023).

## Chloride

Chloride ( $\text{Cl}^-$ ) is the second-most common electrolyte in the extracellular fluid. It plays a key role in regulation of body fluids, electrolyte balance, and acid-base balance. Chloride is almost always bound to other electrolytes, such as sodium, which makes it unusual for a patient to have an isolated chloride abnormality. If the serum chloride level is out of range, most often another electrolyte, such as sodium, is also out of range. The presence of a chloride deviation is most often associated with an underlying acid-base imbalance. The normal serum chloride range is 96 to 106 mEq/L (Wu & Yan, 2023).

Having an elevated serum chloride level, known as **hyperchloremia**, can occur when water loss exceeds sodium and chloride losses. Because chloride is an anion that is commonly used in chemical reactions, hyperchloremia is also seen in patients with acid-base imbalances. Symptoms of hyperchloremia are linked to the underlying cause of the electrolyte imbalance. The treatment is to treat the underlying cause (Song et al., 2022).

Having a low serum chloride level, known as **hypochloremia**, is usually caused by nasogastric suctioning, vomiting, or the excessive use of loop diuretics. Loop diuretics excrete both potassium and chloride and gastric contents contain hydrochloric acid (HCL). Therefore, losing large amounts of gastric contents causes hypochloremia. There have also been cases of hypochloremia related to malnutrition (Signorelli et al., 2020). There are no specific symptoms of hypochloremia. The treatment is to fix the underlying cause of the electrolyte disorder (Signorelli et al., 2020).

## Bicarbonate

Bicarbonate ( $\text{HCO}_3^-$ ) is one of the major anions, or negatively charged electrolytes, in the extracellular fluid. Bicarbonate is a base (a molecule that can donate a hydroxide ion ( $\text{OH}^-$ ) in chemical reactions). Its main function is to act as a buffer and uphold homeostasis in **pH**, which refers to the concentration of hydrogen ions in a given solution. Bicarbonate is generated spontaneously from carbon dioxide and water, or via the catalytic activity of the enzyme carbonic anhydrase. The kidneys help maintain optimal bicarbonate levels by either excreting or reabsorbing bicarbonate. The normal serum bicarbonate range is 22 to 29 mEq/L (Moustafa et al., 2022).

## Phosphate

Phosphate ( $\text{PO}_4^{3-}$ ) is an important electrolyte in the human body that is needed for energy production, cell membrane formation, and deoxyribonucleic acid (DNA). Bones contain about 85 percent of the body's phosphate. The remaining 15 percent is found in the intracellular fluid compartment. The body obtains phosphate from dietary intake. Foods high in phosphate include dairy products, egg yolk, and chocolate. The kidneys regulate phosphate levels by excreting phosphate in the urine.

The normal serum phosphate range is 3.4 to 4.5 mg/dL (Lewis, 2023; Sharma et al., 2024). Having an elevated serum phosphorus level is known as **hyperphosphatemia**. Having elevated phosphate levels does not cause any symptoms. However, because phosphate levels and calcium levels are inversely related, patients with hyperphosphatemia may develop symptomatic hypocalcemia. Mild hyperphosphatemia can be treated with decreasing oral intake of phosphorus. Patients may also be prescribed phosphorus-binding agents that bind phosphate and help with excretion. As a last resort, hemodialysis can be used to correct hyperphosphatemia.

Having a low serum phosphate level is referred to as **hypophosphatemia**. Chronic hypophosphatemia can be caused by parathyroid gland tumors, vitamin D deficiency, prolonged use of phosphate binders, and malnutrition. Acute hypophosphatemia can be the result of burns, diuretic use, and diabetic ketoacidosis. Mild hypophosphatemia is usually asymptomatic. However, severe cases can cause muscle weakness, seizures, and even death. The primary treatment of hypophosphatemia is to treat the underlying cause. If needed, phosphorus supplements can be given both orally and intravenously (Sharma et al., 2024).

## LINK TO LEARNING

West Coast University provides a [concise review of the principles of fluid and electrolyte balances](https://openstax.org/r/77flectrol) (<https://openstax.org/r/77flectrol>) in the human body.

## Regulation of Fluid and Electrolyte Balance

The fluid compartments of the body are interdependent. Homeostasis of the different compartments depends on their interactions with each other. Fluid and electrolytes can move between the compartments by passive or active transport. Active transport requires energy expenditure and passive transport does not. The movement of solutes through a transmembranous protein (a gatekeeper that controls what gets into and out of a cell) using energy expenditure is called **active transport**. The movement of solvents and solutes across cell membranes based on the concentration gradients, or the process of substances moving from an area of high concentration to an area of low concentration, is known as **passive transport**. Passive transport is subdivided into two categories: osmosis and diffusion. Through the principles of active and passive transport, the human body maintains fluids, electrolytes, and other solutes in optimal concentrations for chemical reactions and cellular processes to occur (Chen & Lui, 2023).

### Osmosis

The passage of a solvent, or a liquid, through a semipermeable membrane from an area of lower solute concentration to an area of higher solute concentration is called **osmosis**. The solvent passes through the membrane from the solution with the higher concentration of solutes to the side with the lower concentration until the two solutions are equal in concentration. The rate of osmosis largely depends on the osmotic pressure, which is determined by the concentration of solutes. The higher the osmotic pressure, the faster the fluid moves. The rate of osmosis is also dependent on the permeability of the membrane and the electric potential across the cell membrane (Lopez & Hall, 2023).

### Diffusion

The passage of solutes (e.g., electrolytes, proteins, and metabolites) through a semipermeable membrane that separates solutions with two different solute concentrations is called **diffusion** (Figure 20.3). It is very similar to osmosis in that the diffusion rate is driven by the concentration of solutes. However, it differs from osmosis in that diffusion is the passive transport of solutes, instead of solvents (liquids). Solute molecules move via diffusion from the solution with the higher concentration to the solution with the lower concentration until the two solutions have equal concentrations (Lopez & Hall, 2023).

**FIGURE 20.3** The structure of the cell membrane allows diffusion of uncharged substances, such as oxygen and carbon dioxide, to pass through the cell membrane down their concentration gradient in a process known as diffusion. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Active Transport

The phospholipid layer and the electrochemical gradient of cell membranes prevent the movements of some substances across the membrane. Active transport, or the movement of solutes through a transmembrane protein using energy expenditure, is the mechanism that cells use to overcome the impediment posed by the cell membrane, or to move solutes against a concentration gradient. By active transport, cells accumulate needed resources inside the cells. Examples of solutes moved via active transport include electrolytes, sugar, and amino acids (Chen & Lui, 2023). An example of active transport is the sodium–potassium pump. The sodium–potassium pump is located on the outer plasma membrane of cells and maintains a higher concentration of sodium extracellularly and a high concentration of potassium intracellularly. Without the sodium–potassium pump, the

concentrations of sodium and potassium would equalize across the cell membrane through the process of diffusion (Pirahanchi & Aeddula, 2023).

### Capillary Filtration

The process of delivering oxygen and other nutrients and removing cellular waste through the capillary system is called **capillary filtration**. Capillaries are the smallest blood vessels in the circulatory system. They connect arteries, which deliver oxygen and nutrients to target tissue, to veins, which transport waste products back to the heart and lungs. Capillaries form a bed, or network, of multiple capillaries. One end of the capillary bed is the arterial side, and the other end is the venous side. The pressure on the arterial side is greater, which pushes nutrients and oxygen from the arterial capillary bed into the surrounding tissue. The pressure on the venous side of the capillary bed is lower, which causes waste products to be reabsorbed from the tissue into the capillary bed (Pias, 2021).

### LINK TO LEARNING

This video reviews how the [capillary bed helps deliver oxygen and remove waste products \(https://openstax.org/r/77capilbed\)](https://openstax.org/r/77capilbed) in the body.

### Body Systems and Organs

In addition to active and passive transport, various body systems are responsible for regulating fluid and electrolytes to maintain body homeostasis. Hormones also play an integral role in stimulating various organ systems to either excrete or reabsorb electrolytes. Total body fluid is regulated by the renal system. In response to pressure in the renal tubules, the kidneys suppress or excrete antidiuretic hormone. When total body fluid is down, or the patient is hypovolemic, more antidiuretic hormone (ADH) is released, which causes the kidneys to reabsorb more water. When fluid volume in the renal tubules is high, the kidneys suppress ADH, resulting in hypervolemia and more dilute urine. [Table 20.2](#) explains how different body systems regulate serum electrolyte levels.

Electrolyte	Primary Fluid Compartment	Body System and Hormones that Regulate Serum Levels	Signs and Symptoms of Excess	Signs and Symptoms of Deficit
Sodium (Na <sup>+</sup> )	Extracellular	Renal system Aldosterone	Confusion, irritability, seizures, thirst, dry mucous membranes	Headache, confusion, seizures, coma
Potassium (K <sup>+</sup> )	Intracellular	Renal system Aldosterone, insulin, epinephrine, and glucocorticoids	Irritability, gastrointestinal cramping, peaked T waves on ECG, cardiac arrest	Muscle weakness, lethargy, thready pulse, flattened or inverted T waves on ECG, U wave on ECG, ST segment depression on ECG
Calcium (Ca <sup>2+</sup> )	Extracellular	Skeletal system Parathyroid hormone, vitamin D, and calcitonin	Nausea, vomiting, constipation, skeletal muscle weakness	Muscle tingling, muscle cramps, tetany

**TABLE 20.2** Electrolyte Regulation in the Human Body (Sources: Ryan & Kovacs, 2020; Merrill & Chambliss, 2020; Ito et al., 2024.)

Electrolyte	Primary Fluid Compartment	Body System and Hormones that Regulate Serum Levels	Signs and Symptoms of Excess	Signs and Symptoms of Deficit
Magnesium (Mg <sup>2+</sup> )	Intracellular	Renal system Parathyroid hormone and vitamin D	Bradycardia, lethargy, hyporeflexia, muscle weakness	Nausea, vomiting, tremors, tetany, dysrhythmias
Chloride (Cl <sup>-</sup> )	Extracellular	Renal system Aldosterone	Dependent upon the primary electrolyte that is causing the chloride excess	Dependent upon the primary electrolyte that is causing the chloride deficiency
Bicarbonate (HCO <sub>3</sub> <sup>-</sup> )	Extracellular	Renal System Aldosterone	Confusion, numbness in the face, hands, or feet, nausea, vomiting	Increased heart rate, headache, deep breathing
Phosphate (PO <sub>4</sub> <sup>3-</sup> )	Intracellular	Renal system and gastrointestinal system Parathyroid hormone and vitamin D	Bone pain, loss of appetite, weakness, irritability	Muscle cramps, bone and joint pain, rash, itchy skin

## 20.2 Acid-Base Balances

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the principles of acid-base balance
- Identify the principles of acid-base imbalance
- Explain the regulation of balance systems

Understanding principles of acid-base balance is an essential concept in nursing. Many patients are at risk for acid-base imbalance because of chronic diseases such as kidney disease, lung disease, cardiac disease, and endocrine disorders. If acid-base homeostasis is not maintained, the patient can experience severe consequences or even death. Given the severity of potential complications, nurses must be knowledgeable about acid-base disorders, recognize the symptoms of an imbalance, and know how to intervene if acid-base homeostasis is not maintained.

### Principles of Acid-Base Balance

Ensuring that the acid-base balance of human blood remains within a normal range is crucial for maintaining health. Many enzymes and cellular processes do not function normally if the blood's level of acid or base is too high or too low. Having an uncontrolled acid-base imbalance can even lead to death. There are regulatory systems within the body that correct imbalances to bring the acid-base level back into normal range. It is vital for nurses to understand the basic principles of the acid-base balance so that they can intervene early if there is an abnormality (Lewis, 2023).

#### Acid

An **acid** is a molecule that can donate a hydrogen ion (H<sup>+</sup>) in chemical reactions. There are multiple acids in the

human body that maintain the acid level at a specific concentration for enzymes to work. For example, pepsin is an enzyme that breaks down protein in the small intestine. To be activated, pepsin must be in an acidic environment. The stomach secretes HCL to activate pepsin when we eat. In this case, HCL is isolated to the gastrointestinal tract and does not affect the acid-base balance of the body as a whole (Patricia & Dhamoon, 2022).

The acid level in the blood is vitally important for homeostasis. The molecule in the human blood that regulates acid levels is  $\text{PaCO}_2$ , or the partial pressure of carbon dioxide. The normal  $\text{PaCO}_2$  level is 35 to 45 mm Hg. The act of breathing involves the exhalation of carbon dioxide ( $\text{CO}_2$ ). Consequently, the respiratory system plays a role in controlling the level of  $\text{PaCO}_2$  in the bloodstream (Lewis, 2023).

### Base

Just as the acid level in the blood is vital to homeostasis, so is the concentration of base. A **base** is a molecule that donates hydroxide ions ( $\text{OH}^-$ ) in chemical reactions. In the human body, base is represented by the bicarbonate ion ( $\text{HCO}_3^-$ ). The kidneys regulate the bicarbonate level by either excreting bicarbonate in the urine or reabsorbing it back into the bloodstream. The normal serum bicarbonate range is approximately 22 to 29 mmol/L (Hopkins et al., 2022); however, reference ranges may vary slightly by laboratory.

### pH

The pH, or potential of hydrogen, serves as the indicator for the acid-base balance in a solution. It is a numerical representation of the concentration of hydrogen ions within that particular solution. The typical pH range for arterial blood falls between 7.35 and 7.45. A pH below 7.35 indicates **acidosis**, signifying an abundance of hydrogen ions in the blood. Conversely, a pH exceeding 7.45 suggests **alkalosis**, indicating a shortage of hydrogen ions in the blood (Hopkins et al., 2022). Symptoms of mild alkalemia are related to the underlying cause of the imbalance (Lewis, 2023). Extended or severe alkalemia results in a relative hypocalcemia, as ionized calcium tends to bind more readily to proteins in an alkalotic environment (Hopkins et al., 2022). Symptoms of acidosis are related to the underlying cause. If the acidosis is mild, the patient may be asymptomatic. However, extended or severe acidosis causes potassium ions to shift out of cells to buffer the net influx of positive hydrogen ions, resulting in systemic hyperkalemia (Mount, 2024). The pH of blood and the concentration of available hydrogen ions is determined by the balance of carbon dioxide ( $\text{CO}_2$ ) and bicarbonate ( $\text{HCO}_3^-$ ). The most accurate way to measure the blood pH is through an arterial blood gas sample. Venous blood has considerably less oxygen and more carbon dioxide than arterial blood because venous blood returns cellular waste to the heart and lungs to expel carbon dioxide and pick up oxygen. Although it is also possible to monitor pH via a capillary blood gas or a venous blood gas, both of those tests tend to report more acidotic results. The type of blood gas sample must be considered when interpreting results (Figure 20.4) (Castro & Keenaghan, 2024).

RESPIRATORY <b>R</b>
OPPOSITE <b>O</b> pH ↑ PCO <sub>2</sub> ↓ Alkalosis pH ↓ PCO <sub>2</sub> ↑ Acidosis
METABOLIC <b>M</b>
EQUAL <b>E</b> pH ↑ HCO <sub>3</sub> <sup>-</sup> ↓ Alkalosis pH ↓ HCO <sub>3</sub> <sup>-</sup> ↑ Acidosis

**FIGURE 20.4** When interpreting arterial blood gas samples, many students find it helpful to remember that in a respiratory imbalance, pH and CO<sub>2</sub> move in opposite directions (Respiratory Opposite). In metabolic imbalances, pH and HCO<sub>3</sub><sup>-</sup> move in the same direction (Metabolic Equal). (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: How to Draw a Capillary Blood Gas Sample

Disclaimer: Always follow the facility's policies.

Steps	Rationale/Description
Choose the puncture site. For infants 0–12 months, puncture the outer aspect of the heel. For adults and children over age 1, puncture the outer aspect of the finger.	A capillary blood gas is a less invasive procedure than an arterial blood gas sample, which makes it a good option for infants and young children whose veins and arteries can be difficult to access. In adults, capillary blood gas sampling can be used when venous or arterial access is difficult, for noncritical assessments, in outpatient settings without ABG equipment, based on patient preference for less invasive procedures, or where ABG equipment is unavailable. However, it is important to use an appropriately sized lancet and to puncture the appropriate body part to avoid patient harm.
Attach the cap to one end of the capillary.	Capillary blood gas samples are collected in clear glass tubes. If you do not place a cap on one end of the tube, the blood will leak out while collecting the sample.

Steps	Rationale/Description
Clean the puncture site with an alcohol pad and firmly support the site (either the finger or the heel) with your nondominant hand.	Use the nondominant hand to stabilize the puncture site so that the dominant hand is free to puncture and draw the blood.
Puncture the site and wipe away the first drop of blood.	The first draw of blood can be contaminated with the alcohol that was used to clean the site, which can lead to inaccurate results.
Place the uncapped end of the tube in the center of the drop of blood. Allow the blood to flow freely into the tube without putting excessive pressure on the lanced site.	Applying excessive pressure on the finger or heel can lead to inaccurate results.
Once the capillary tube is filled with blood, run the blood gas analysis. Some units have a blood gas analysis machine on the unit. If it needs to be sent to the lab, it must be sent on ice and as a STAT lab.	If a blood gas sample cannot be run immediately, it should be stored on ice. Leaving a blood gas sample at room air temperature leads to inaccurate results.

### Principles of Acid-Base Imbalance

Acid-base imbalances can potentially have a profound impact on patients' health and well-being ([Figure 20.5](#)). Understanding acid-base imbalances is vital to quality nursing care because many patients are at risk for acid-base imbalances. If nurses understand the physiology behind the imbalance, they can recognize the cues early and intervene before the patient suffers severe complications. Acid-bases imbalances fall into two general categories: metabolic imbalances and respiratory imbalances. If an imbalance occurs in one system, the other system will compensate in order to bring the blood pH back into normal range.

**SYMPTOMS OF ACIDOSIS****Central Nervous System**

- Headache
- Sleepiness
- Confusion
- Loss of consciousness
- Coma

**Respiratory System**

- Shortness of breath
- Coughing

**Heart**

- Arrhythmia
- Increased heart rate

**Muscular System**

- Seizures
- Weakness

**Digestive System**

- Nausea
- Vomiting
- Diarrhea

**SYMPTOMS OF ALKALOSIS****Central Nervous System**

- Confusion
- Lightheadedness
- Stupor
- Coma

**Peripheral Nervous System**

- Hand tremor
- Numbness or tingling in the face, hands, or feet

**Muscular System**

- Twitching
- Prolonged spasms

**Digestive System**

- Nausea
- Vomiting

**LINK TO LEARNING**

Principles of [acid-base balance in the blood \(https://openstax.org/r/77acid-base\)](https://openstax.org/r/77acid-base) is crucial to understanding homeostasis.

**Metabolic Acidosis**

Acidosis, pH less than 7.35, is any process that increases the concentration of hydrogen ions in a solution. An increase in the hydrogen ion concentration as a result of an abnormally low serum bicarbonate level ( $\text{HCO}_3^-$ ), or a serum bicarbonate level less than 22 mEq/L is known as **metabolic acidosis** (Figure 20.6). Metabolic acidosis is never a benign process and signifies an underlying medical problem that needs to be addressed (Burger & Schaller, 2023).

**FIGURE 20.6** The level of bicarbonate in the blood determines the severity of metabolic acidosis. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The root cause of metabolic acidosis is divided into four categories: an increase in acid production, a decrease in acid excretion, acid ingestion, and renal or gastrointestinal bicarbonate loss. Another way to separate metabolic acidosis is whether or not an **anion gap** (the concentration of unmeasured serum anions) exists. Having a large number of unmeasured anions indicates that an acid has been added to the system (Burger & Schaller, 2023).

Bicarbonate and chloride are the most proliferative anions, or negatively charged ions, in the human body. To maintain homeostasis, the human body has regulatory mechanisms to keep the number of anions and cations, or positively charged ions, approximately equal. Sodium, the most common extracellular cation, is equal to bicarbonate and chloride plus the sum of the unmeasured anions. If there are a large number of unmeasured anions

in the plasma, the patient has an anion gap metabolic acidosis. The formula for calculating the anion gap is:

$$\text{Anion gap} = \text{Sodium} - (\text{Chloride} + \text{Bicarbonate})$$

A normal anion gap ranges from 4 to 12 mmol/L. Therefore, having a gap greater than 12 mmol/L indicates that the patient has a large number of additional anions in the plasma, indicating an acid has been added to the system. A common cause of an anion gap metabolic acidosis is an elevated lactate level. However, there are many other causes. A useful mnemonic to help a nurse remember the causes of an anion gap is the acronym CAT MUDPILES. Each letter in CAT MUDPILES stands for a specific acid that could be ingested or produced to cause a metabolic acidosis.

- C: cyanide or carbon monoxide poisoning
- A: arsenic
- T: toluene
- M: methanol, metformin
- U: uremia
- D: diabetic ketoacidosis (DKA)
- P: paraldehyde
- I: iron
- L: lactate
- E: ethylene glycol
- S: salicylates (Burger & Schaller, 2023)

Differentiating the type of metabolic acidosis helps determine the underlying problem that needs to be addressed. For example, if a patient presents with anion gap metabolic acidosis, the nurse must consider the possibility that the patient ingested a toxin, poison, or medication. Determining the nature of the anion gap helps guide treatment. Because metabolic acidosis is never a benign clinical state, nurses must understand the causes of metabolic acidosis so that they can make informed decisions about patient care.

The etiology of a nonanion gap metabolic acidosis is bicarbonate loss. Diarrhea and renal tubular acidosis are the two most common causes of nonanion gap metabolic acidosis. Patients with diarrhea lose bicarbonate in their stool. Patients with renal tubular acidosis excrete an excessive amount of bicarbonate in their urine. Once a probable cause of a patient's metabolic acidosis has been identified, appropriate steps can be taken to correct the underlying problem (Burger & Schaller, 2023).

## REAL RN STORIES

### Missed Diagnosis

**Nurse:** Liu, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 3

**Facility location:** Inner city of a large metropolitan area in Colorado

We serve a diverse population, but many of our patients are people with lower incomes. Our hospital is the only hospital in the city that accepts Medicaid. One day I received report from the emergency department (ED) for a new patient who I was admitting to the unit for dehydration secondary to acute vomiting and diarrhea. When the ED nurse gave me report, I thought it was odd that the patient was tachypneic. The reported respiratory rate was 40 breaths per minute. I asked why, and the reporting nurse just brushed me off because the patient's breath sounds were clear, and she had oxygen saturations greater than 92 percent on room air.

I admitted the patient to the unit and immediately noted that she was teary-eyed and anxious. I sat down with her for a few minutes so I could see what was going on. During our conversation she confessed that she had attempted suicide the night before by taking an entire bottle of aspirin. She lied about having vomiting and diarrhea because she was embarrassed.

I paged the on-call resident and informed him of the patient's confession. The resident placed the patient on a 1:1

staffing protocol, ordered a psychiatric consult, and also reexamined the patient's laboratory values. On closer review, the resident noted that the patient had a significant anion gap. A STAT arterial blood gas sample was ordered, and the resident ordered a toxicology consult regarding the aspirin ingestion.

I discussed the case with the resident, who reminded me that respiratory system compensates for the metabolic system. Because the patient had taken so many aspirin, she developed anion gap metabolic acidosis. The respiratory system compensated for the metabolic acidosis by increasing the respiratory rate to blow off more carbon dioxide and bring the pH back up. The aspirin ingestion explained the patient's tachypnea without any associated lung pathology. After reviewing the case with the resident and making sure the 1:1 staffing ratio was in place for the patient, I felt more comfortable and was confident the patient would get the care she needed.

### Metabolic Alkalosis

Alkalosis—when the pH is greater than 7.45—is any process that causes a net increase in bicarbonate ions in the plasma. A net increase in bicarbonate ions due to loss of hydrogen ions or retention of bicarbonate ions by either the renal or gastrointestinal systems is called **metabolic alkalosis** (Figure 20.7). There are three broad categories that describe how a patient develops metabolic alkalosis: gastrointestinal loss of hydrogen ions, renal loss of hydrogen ions, and retention or addition of bicarbonate (Brinkman & Sharma, 2023).

**FIGURE 20.7** Metabolic alkalosis is the most common acid-base disorder in hospitalized patients. Identifying and treating the root cause, either hydrogen ion loss or bicarbonate ion gain, is essential because the risk of mortality increases as pH increases (Tinawi, 2021). (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Gastrointestinal loss of hydrogen ions can occur as a result of vomiting or gastric suctioning. The stomach contents contain a high concentration HCL. When a patient loses a large quantity of these gastric secretions, this correlates to a relative increase in bicarbonate in the blood. Having a relative increase in bicarbonate in the blood is the cardinal feature of metabolic alkalosis (Brinkman & Sharma, 2023).

Renal loss of hydrogen is another common cause of a metabolic alkalosis. Aldosterone triggers the reabsorption of sodium into the bloodstream via a 1:1 exchange for excreting hydrogen ions into the urine. Pathologies that increase the production of aldosterone increase renal loss of hydrogen ions. For example, loop and thiazide diuretics can create a secondary hyperaldosteronism that leads to excess urine excretion of hydrogen. Genetic defects, such as Bartter syndrome or Gitelman syndrome, can also cause excessive hydrogen ion loss in the urine (Brinkman & Sharma, 2023).

The retention or addition of bicarbonate in the blood can be caused by a variety of different processes. One of the most common is overuse of antacids, which contain alkaline substances to neutralize acids. Also, because the renal system buffers for the respiratory system, patients with respiratory acidosis will develop compensatory metabolic alkalosis. As the carbon dioxide level rises in the blood, the kidneys compensate by reabsorbing bicarbonate to keep the total pH within normal limits (Brinkman & Sharma, 2023).

Metabolic alkalosis is a common diagnosis among hospitalized patients. If not corrected, it can lead to decreased myocardial contractility, arrhythmias, decreased cerebral blood flow, confusion, and even death. Given the potentially dire consequences if the condition is left uncorrected, nurses must closely monitor their patients and intervene early. Nursing knowledge of complex physiological problems, such as hospitalization-induced metabolic alkalosis, enables nurses to be better advocates for their patients (Brinkman & Sharma, 2023).

### Respiratory Acidosis

Having a blood pH less than 7.35 with a concurrent increase in carbon dioxide (CO<sub>2</sub>) is called **respiratory acidosis**. Carbon dioxide levels are normally maintained in a tight window of 35 to 45 mm Hg because chemoreceptors in the medulla sense an increase in CO<sub>2</sub> and trigger the patient to breathe more frequently. However, if ventilation is disrupted for some reason, the lungs are not able to exhale excess CO<sub>2</sub> and the patient develops respiratory acidosis (Patel & Sharma, 2023).

Respiratory acidosis is subdivided into three subcategories: acute; chronic; and acute and chronic. In acute respiratory acidosis, there is a sudden rise in carbon dioxide levels. This can be caused by an acute respiratory pathology pneumonia. It can also be caused by problems with the central nervous system (CNS), which can include things such as a stroke or the use of CNS depressants such as opioids. Acute respiratory acidosis can also be the result of diaphragm weakness. Patients with myasthenia gravis and Guillain-Barré syndrome can develop acute muscle weakness that affects their ability to breathe or ventilate (Patel & Sharma, 2023).

Chronic respiratory acidosis occurs in patients with long-standing ventilation issues. As a result of consistently elevated carbon dioxide levels, a patient's chemoreceptors become less responsive to carbon dioxide. Patients with chronic ventilation problems, such as patients with chronic obstructive pulmonary disease (COPD), can develop a new baseline range of CO<sub>2</sub> that is higher than the CO<sub>2</sub> of patients without chronic ventilation issues.

Patients with chronic respiratory acidosis can also have what is called an “acute and chronic” respiratory acidosis. This occurs when a patient has chronic respiratory pathology and develops an acute ventilation problem that makes the acidosis worse. For example, when a patient with COPD develops pneumonia, the result is an acute and chronic respiratory acidosis (Patel & Sharma, 2023).

### Respiratory Alkalosis

A systemic acid-base disorder that is caused by a reduction in carbon dioxide, which produces an elevation in pH above 7.45, is called **respiratory alkalosis**. It may be caused by a hyperventilation disorder in which the patient breathes too quickly and exhales an excess amount of CO<sub>2</sub>. Respiratory alkalosis may also occur as compensation for an underlying process, such as metabolic acidosis. Finally, respiratory alkalosis may be accidentally induced as part of medical treatment. Patients who are on mechanical ventilation need to have their carbon dioxide levels monitored regularly to ensure that the ventilator settings are appropriate. If the respiratory rate on the ventilator is too high or if the tidal volume is excessive, the patient may develop respiratory alkalosis (Singh Gill, 2019).

## REAL RN STORIES

---

### Treating Respiratory Alkalosis

**Nurse:** Bob, RN

**Clinical setting:** Outpatient community health

**Years in practice:** 15

**Facility location:** Inner city of a large metropolitan area in California

We serve a diverse population, but many of our patients are experiencing homelessness. Our clinic is as an access point for multiple community services including food stamps, Medicaid enrollment, and housing assistance. Frequently in the mornings, there is a long line of people out front hoping to get a walk-in appointment in the clinic. One morning, as I walked by the line of patients, I noticed a middle-aged woman sitting on the ground, crying hysterically. She was taking deep, labored breaths and her hands trembled as she sobbed. Seeing that she was in distress, I stopped to help.

The first thing I did was confirm that she did not have any immediate or life-threatening injuries. Then I sat with her for a minute to help her calm down. I took my brown paper lunch bag out of my backpack and asked her to place it over her nose and mouth. By doing so, she inhaled the carbon dioxide that she was exhaling with every labored breath. At my request, she covered her nose and mouth for six breaths and then removed the bag. Then I encouraged her to practice taking slow, calm breaths with me. We placed the paper bag over her nose and mouth a second time and she left it there for another six breaths.

By rebreathing her own exhaled carbon dioxide, the woman started to feel less shaky and calmed down. I sat with her for a few more minutes to make sure she was feeling better and then walked her up to the front of the line so that she could be evaluated by the triage nurse at our clinic.

## Regulation of Balance Systems

Nurses must have a firm understanding of the mechanisms that regulate acid-base homeostasis because many patients have impaired renal, respiratory, and metabolic function that can interfere with the regulation of pH. If the blood pH is not maintained between 7.35 and 7.45, complications can occur. If there are large deviations from this pH range, severe complications are likely. A pH greater than 7.8 or less than 6.8 is often associated with death. To maintain homeostasis, the human body has multiple regulatory systems that bring the pH back into the needed physiological range. The regulatory balance systems that control blood pH are the chemical buffer system, the respiratory regulatory system, and the renal regulatory system (Davies et al., 2019).

### LINK TO LEARNING

To prevent deviations in the body's pH, there are several buffer systems that regulate acid-base levels. Review the [regulation of acid-base systems](https://openstax.org/r/77regacidbase) (<https://openstax.org/r/77regacidbase>) with this video.

### Chemical Buffer Systems

Excess acids or bases must be neutralized to maintain the blood pH within a normal physiological range and protect cells. One of the primary ways of regulating this balance is through the chemical buffer system. As acids or bases enter the bloodstream, excess amounts are modified or neutralized by the chemical buffer system. Then, either the respiratory regulatory system or the renal regulatory system is activated to complete the process of eliminating the excess acid or base. The chemical buffer system has three pathways: the carbonic acid–sodium bicarbonate system, the phosphate buffer system, and the protein buffer system.

#### Carbonic Acid–Sodium Bicarbonate System

The carbonic acid–sodium bicarbonate system is the most widely mobilized buffer system in the human body, accounting for more than 50 percent of all chemical buffering (Figure 20.8). This buffering pathway takes place in the extracellular fluid compartment. Carbon dioxide, CO<sub>2</sub>, is produced as a result of normal cellular metabolism and enters the bloodstream. In the bloodstream, CO<sub>2</sub> combines with water and forms carbonic acid. The carbonic acid molecule is a weaker acid than CO<sub>2</sub> and does not cause cellular damage. The carbonic acid molecule is transported in the bloodstream to the lungs, where it disassociates back into CO<sub>2</sub> and water. The CO<sub>2</sub> is then exhaled by the lungs. Any remaining excess CO<sub>2</sub> is converted back into carbonic acid and transported via the circulatory system to the kidneys. In the kidneys, the carbonic acid is separated into H<sup>+</sup> ions and bicarbonate. At this point, the kidneys sense which molecule is in excess and excrete that substance while retaining the other. For example, if the patient is acidotic, the kidneys excrete hydrogen ions and reabsorb bicarbonate ions to be reused for further buffering.

**FIGURE 20.8** The carbonic acid–sodium bicarbonate system is a chemical buffer system that helps regulate the pH of bodily fluids. This system involves a dynamic balance between carbonic acid (H<sub>2</sub>CO<sub>3</sub>) and bicarbonate ions (HCO<sub>3</sub><sup>−</sup>) in response to changes in hydrogen ion (H<sup>+</sup>) concentration. The carbonic acid–sodium bicarbonate buffer system is the most common buffer system used in the human body. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

#### Phosphate Buffer System

In contrast to the carbonic acid–sodium bicarbonate buffer system, the phosphate buffer system neutralizes excess acid or base in the intracellular fluid, not the extracellular fluid (Figure 20.9). It is one of two buffering systems that work inside of cells to maintain intracellular acid-base homeostasis. In this system, dihydrogen phosphate acts as a

hydrogen ion donor to neutralize excess base, and hydrogen phosphate acts as an ion acceptor to neutralize excess acid. With this buffering system, the acids and bases still exist inside the cells, but the phosphates hold onto the ions and prevent them from altering the cell's pH.

**FIGURE 20.9** Phosphates are found in the blood in two forms: sodium dihydrogen phosphate ( $\text{NaH}_2\text{PO}_4^-$ ), which is a weak acid, and sodium monohydrogen phosphate ( $\text{Na}_2\text{HPO}_4^{2-}$ ), which is a weak base. Because phosphates exist as both an acid and a base, they can buffer both types of molecules. This equation shows how the weak base accepts hydrogen ions to buffer acidosis and the weak acid donates hydrogen ions to buffer alkalosis. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Protein Buffer System

The protein buffer system is the most important buffer system in the intracellular fluid. It accounts for 75 percent of buffering that occurs intracellularly. Almost all proteins can act as buffers. The building blocks of proteins are amino acids, which contain both a positively charged amino group and a negatively charged carboxyl group ([Figure 20.10](#)). Because amino acids contain both a positively and negatively charged group, they can buffer both acids and bases. The positively charged amino group acts as a hydrogen ion donor that neutralizes excess base, and the negatively charged carboxyl group acts as a hydrogen ion acceptor that neutralizes excess acid.

**FIGURE 20.10** Amino acids have both a positive and negative charge, which enables them to buffer both acids and bases. In this model, the red end is negatively charged, meaning it accepts hydrogen ions from acids to buffer against acidosis. The white end is positively charged, meaning it donates hydrogen ions to buffer against alkalosis. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Respiratory Regulation System

The respiratory system plays a crucial role in regulating acid-base balance by regulating the exhalation and retention of carbon dioxide,  $\text{CO}_2$  ([Figure 20.11](#)). Carbon dioxide reacts with water in the blood to form carbonic acid, which is the primary acid in the blood. In the lungs, carbonic acid disassociates back into carbon dioxide and water. Increasing the rate and depth of respirations allows the body to exhale more  $\text{CO}_2$ , which lowers the net carbonic acid level in the blood. On the other hand, taking shallow breaths or holding your breath retains  $\text{CO}_2$ , which causes the carbonic acid level in the blood to rise.

The respiratory regulation system acts as a counterbalance to the renal regulation system. If an acid-base imbalance develops as a result of a renal problem, the patient's respiratory system adjusts the depth and rate of respiration to compensate.

**FIGURE 20.11** The respiratory system regulates pH by removing  $\text{CO}_2$  from the bloodstream. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Renal Regulation System

The renal system regulates acid-base balance by controlling serum levels of bicarbonate,  $\text{HCO}_3^-$  (Figure 20.12). Bicarbonate is a base, and alterations in excretion or reabsorption of bicarbonate cause acid-base imbalances. If the kidneys excrete an excess of bicarbonate in the urine, the patient develops metabolic acidosis. On the other hand, if the kidneys retain too much bicarbonate, the patient develops metabolic alkalosis. Common causes of metabolic acidosis include chronic diuretic use, chronic renal insufficiency, and elevated blood ketone levels.

**FIGURE 20.12** Through the secretion and reabsorption of bicarbonate, an electrolyte, the renal system regulates the blood pH. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The renal system acts as a counterbalance to the respiratory system. If a patient develops respiratory acidosis, their body senses the increase in acid through the use of chemoreceptors, which stimulates the kidneys to reabsorb more bicarbonate. On the other hand, if a patient develops respiratory alkalosis, that stimulates the renal system to excrete more bicarbonate. Having less bicarbonate in the blood offsets the decrease of carbon dioxide, which is bound with water to form carbonic acid in the blood.

## 20.3 The Nurse's Role in Patient Care Management

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize cues for fluid, electrolyte, and acid-base balance when providing patient care
- Identify nursing tasks to prevent fluid, electrolyte, and acid-base imbalances

The human body has multiple mechanisms in place to maintain a narrow range of fluid balance, electrolytes, and acid-base levels. If any of these components of homeostasis is out of the normal range, the patient is at risk for organ dysfunction, and if left untreated, even death. It is imperative that nurses recognize subtle changes in fluid imbalance, electrolyte levels, and acid-base homeostasis so they can intervene early and prevent patient complications. To accomplish these goals, nurses are constantly evaluating their patients and updating their plan of care as their clinical condition changes. In contrast to other healthcare disciplines, bedside nurses are in a unique position to pick up on trends early in the patient's clinical course and adjust the plan of care as needed.

### Recognizing Cues of Fluid, Electrolyte, and Acid-Base Balances

Nurses use cues to recognize change in clinical status. Subjective or objective data points that are observed by the nurse are known as **cues**. Patient cues can be an indicator of a clinical improvement or a deterioration. Common cues that nurses integrate in their clinical judgement are changes in vital signs, changes in mental status, and the presence or absence of pain (Burdeu et al., 2020). Cues for fluid, electrolyte, and acid-base balance are specific to the type of imbalance that is occurring. For example, cues for a fluid imbalance include a change in the patients' weight, urine output, and skin turgor, whereas cues for an electrolyte imbalance include mental status changes, changes in muscle tone, and cardiac arrhythmias. Cues for acid-base imbalances can be seen in the two body systems that regulate acid-base levels: the respiratory system and the renal system. Nurses should also consider the possibility of gastrointestinal loss of acid (through vomiting) and base (due to diarrhea) when considering cues of acid-base imbalances.

Nurses complete a **focused assessment**, or the collection of relevant information pertaining to a change in the patient's clinical status, to monitor a condition that could potentially lead to a complication. For example, if a patient has new onset abdominal pain, the nurse completes a focused assessment of the abdomen. This exam includes a description of the pain, where the pain is located, if the pain radiates, if there are unusual abdominal exam findings, and if there are factors that either alleviate or exacerbate the pain. This same model of thinking about a focused assessment can be applied to patients experiencing fluid, electrolyte, or acid-base imbalances (Toney-Butler & Unison-Pace, 2022).

### CLINICAL SAFETY AND PROCEDURES (QSEN)

#### QSEN Competency: What To Do If Your Patient Has Dilutional Hyponatremia

Steps	Description/Rationale
Confirm the diagnosis.	Hyponatremia can be caused by excess free water, which causes dilutional hyponatremia, or sodium loss. The treatment is different depending on the cause. Understanding the patient's physiology is necessary to provide safe nursing care.
Perform an hourly neurological exam.	Hyponatremia can cause mental confusion. Closely monitoring for subtle neurological changes can provide cues to if the patient's clinical status is changing.
Monitor input and output closely.	The kidneys, in conjunction with aldosterone, regulate serum sodium levels. Changes in urine output and total fluid balance can have a significant impact on serum sodium levels.

Steps	Description/Rationale
Anticipate an order to restrict fluids.	Patients with dilutional hyponatremia have excess free water in their serum. The first line of treatment is to limit fluid intake. If fluid restriction does not fix the hyponatremia, diuretics to help remove excess water may be prescribed.
Anticipate sending frequent serum sodium levels.	Patients with dilutional hyponatremia can become severely ill if their hyponatremia does not resolve. To monitor the patient's response to treatment, it is normal to check the serum sodium level frequently until the hyponatremia resolves (Workeneh et al., 2023).

The metrics that nurses monitor in response to a change in clinical status depends on the type of imbalance noted. For example, with both a fluid volume deficit and a fluid volume excess, nurses need to pay close attention to intake, output, and daily weights. On the other hand, with an acid-base imbalance, the key assessment to monitor is the patient's blood gas. [Table 20.3](#) summarizes key assessment criteria to consider for different fluid, electrolyte, and acid-base imbalances.

Imbalance	Key Assessment Criteria
Fluid volume imbalances	<ul style="list-style-type: none"> <li>• Intake/output; net fluid balance</li> <li>• Daily weights</li> <li>• Skin condition (i.e., edema, skin turgor)</li> <li>• Serum electrolytes</li> </ul>
Sodium	<ul style="list-style-type: none"> <li>• Serum sodium level</li> <li>• Intake/output; net fluid balance</li> <li>• Neurological status</li> </ul>
Potassium	<ul style="list-style-type: none"> <li>• Serum potassium level</li> <li>• Intake/output; net fluid balance</li> <li>• Heart rate; cardiac arrhythmias</li> </ul>
Calcium	<ul style="list-style-type: none"> <li>• Serum calcium level</li> <li>• Heart rate; cardiac arrhythmias</li> <li>• Muscle tone</li> </ul>
Magnesium	<ul style="list-style-type: none"> <li>• Serum magnesium level</li> <li>• Muscle tone</li> </ul>
Respiratory acidosis or alkalosis	<ul style="list-style-type: none"> <li>• Arterial blood gas</li> <li>• Respiratory rate; work of breathing; breath sounds</li> </ul>
Metabolic acidosis or alkalosis	<ul style="list-style-type: none"> <li>• Arterial blood gas</li> <li>• Renal function; basic metabolic panel</li> <li>• Intake/output; net fluid balance</li> </ul>

**TABLE 20.3** Fluid, Electrolyte, and Acid-Base Imbalances and Parameters

An **arterial blood gas** is a blood test that measures the levels of oxygen (measured partial pressure [PaO<sub>2</sub>] and calculated saturation [SaO<sub>2</sub>]) and carbon dioxide (PaCO<sub>2</sub>) in the arterial blood, as well as the pH and levels of bicarbonate ions (HCO<sub>3</sub><sup>-</sup>) (Table 20.4). It is a crucial diagnostic tool used to assess a patient's acid-base balance and oxygenation status. Nurses play a vital role in obtaining ABG samples, ensuring accurate collection and handling, and interpreting the results in collaboration with healthcare providers.

Parameter	Normal Range
pH	7.35 – 7.45
PaO <sub>2</sub>	75 – 100 mm Hg
PaCO <sub>2</sub>	35 – 45 mm Hg
HCO <sub>3</sub> <sup>-</sup>	22 – 29 mEq/L
SaO <sub>2</sub>	95 – 100%

**TABLE 20.4** Arterial Blood Gas Values

Nurses monitor these parameters closely, recognizing deviations from normal ranges that may indicate respiratory acidosis or alkalosis, metabolic acidosis or alkalosis, or hypoxemia, which is defined as low oxygen levels in the blood. Hypoxemia can lead to compensatory mechanisms such as increased respiratory rate or cardiac output, which may affect acid-base balance. ABG results provide important cues to guide nursing interventions, such as adjusting oxygen therapy, ventilatory support, or administering medications to correct acid-base imbalances. See (Table 20.5) for a quick reference for interpreting ABG values.

Parameter	Interpretation
pH	< 7.35: acidosis; > 7.45: alkalosis
PaO <sub>2</sub>	Low: hypoxemia; High: hyperoxemia
PaCO <sub>2</sub>	High: respiratory acidosis; Low: respiratory alkalosis
HCO <sub>3</sub> <sup>-</sup>	High: metabolic alkalosis; Low: metabolic acidosis
SaO <sub>2</sub>	< 95%: hypoxemia

**TABLE 20.5** Interpreting Arterial Blood Gas Values

### Prioritizing Patient Care

By recognizing cues, nurses are able to identify patients who are at risk for clinical deterioration and prioritize their care. Prioritization of patient care revolves around ensuring patient safety. If a patient is currently stable but demonstrating cues of a worsening clinical status, the nurse must prioritize that patient. Prioritization of patient care includes monitoring the patient more frequently, sending labs to follow a concerning trend, addressing complaints of pain, and addressing any other changes in clinical status (Déry et al., 2019).

## REAL RN STORIES

### Recognizing Cues of Acid-Base Imbalance

**Nurse:** Matteo, BSN

**Clinical setting:** Medical unit

**Years in practice:** Six months

**Facility location:** Teaching hospital affiliated with a large medical school in the Midwest

We serve a diverse population; many of our patients are people with lower incomes and speak limited English. Approximately three months after completing new graduate orientation, I admitted an 18-year-old with Down syndrome for treatment of a viral upper respiratory infection (URI). When the patient arrived to the unit from the emergency department (ED), he had mottled extremities, delayed capillary refill, and moderate respiratory distress. His oxygen saturation was 88 percent on 1 L of oxygen via nasal canula. According to the report I received from the ED nurse, the patient would intermittently have periods of respiratory distress that improved with nasal suctioning.

I placed the patient on a bedside cardiac monitor, transitioned him to humidified oxygen, and completed a focused assessment of his respiratory and cardiac systems. The patient was tachycardic; however, his blood pressure was normal. He was mottled in bilateral lower extremities and his capillary refill was greater than three seconds. His respiratory exam was significant for tachypnea, diffused wheezing, nasal flaring, and supraclavicular and intercostal retractions. I immediately paged the on-call resident regarding the patient's exam findings.

The resident came to assess the patient and recommended giving an albuterol nebulizer followed by deep nasal suctioning. After completing the ordered treatments, the patient's exam minimally improved. However, the resident wanted to monitor the patient before trying any additional treatments. I called the charge nurse and asked for assistance in managing this patient's care. The charge nurse came to the bedside and recommended placing an IV, ordering baseline labs, and obtaining a chest x-ray. I called the resident back to express my concerns and suggested the additional diagnostic tests.

The resident ultimately agreed to order more diagnostic tests including a capillary blood gas, a basic metabolic panel, a complete blood count, and a chest x-ray. The capillary blood gas was significant for a pH of 7.28, PaCO<sub>2</sub> of 70 mm Hg, and a HCO<sub>3</sub><sup>-</sup> of 30 mEq/L. The chest x-ray showed diffuse bronchial thickening. Based on the capillary blood gas and physical exam findings, the decision was made to transfer the patient to the intensive care unit (ICU) for an escalation in respiratory support.

---

### Potential versus Actual Problems

The importance of recognizing cues cannot be understated. Recognizing cues of possible clinical deterioration and intervening early prevents a potential problem from becoming an actual problem. Consider the following example: A patient is dehydrated and presents with no urine output for more than eight hours. Routine laboratory studies show that the patient has mild metabolic acidosis and a serum potassium of 5.2 mEq/L. At the time the patient presents for medical care, they have an actual problem of dehydration and low urine output. However, if the low urine output and elevated potassium level are not addressed, then the patient is at risk of developing hyperkalemia with associated cardiac arrhythmias. In this situation, it is imperative the nurse recognize the cue of possible future deterioration given the fact that the patient has inadequate urine output and a slightly elevated serum potassium level.

### Impact on Other Areas of Functioning

Fluid, electrolyte, and acid-base imbalances can impact other areas of functioning. The human body has mechanisms in place to maintain homeostasis; however, those mechanisms only provide a solution in acute clinical situations. They do not prevent problems from developing if the patient has a chronic condition that affects fluid, electrolyte, or acid-base imbalances.

All areas of homeostasis are impacted by chronic conditions. For example, a patient with end-stage renal disease will have electrolyte abnormalities because the kidneys are unable to filter fluid and solutes normally. Patients with chronic fluid volume excess with edema will ultimately develop decreased mobility and impaired skin integrity, whereas patients with fluid volume deficit are at risk for orthostatic hypotension, dizziness, and electrolyte abnormalities resulting in chronic fatigue and mental confusion. Lastly, patients with chronic acid-base imbalances develop alternation in the regulatory system that counterbalances the root cause of their imbalance. For example, a patient with chronic metabolic alkalosis will develop a lower respiratory rate to retain more carbon dioxide and offset the alkalosis.

### Preventing Fluid, Electrolyte, and Acid-Base Imbalances

The keys to preventing fluid, electrolyte, and acid-base imbalances are recognizing which patients are at risk for

those imbalances, screening for abnormalities, and intervening early if there are indications of a problem. Young children and older adults are at an increased risk for these imbalances because of their metabolic rates, ratio of fluid-to-body surface area, and increased risk of organ dysfunction related to their age. Also, certain medical conditions such as cancer, cardiovascular disease, and kidney disease place patients at an increased risk for developing an imbalance. Patients with known risk factors should have routine laboratory work done to screen for abnormalities. Intervening early can prevent more serious complications (Shrimanker & Bhattarai, 2023).

### Nursing Interventions

Nursing interventions for patients who have a fluid, electrolyte, or acid-base imbalance depend on the abnormality being treated and the root cause of the problem identified. Nursing interventions include education about diet modifications, monitoring the patient's vital signs and weight, reviewing laboratory values, adjusting the patient's respiratory support, and administering medications and intravenous fluids. Specific examples of appropriate nursing interventions for different diagnoses may include the following:

- Electrolyte and fluid volume excess secondary to chronic kidney disease:
  - developing a dietary plan
  - educating the patient about which foods to avoid or minimize
  - recommending a daily fluid intake
  - monitoring the patient's weight
  - reviewing laboratory values
- Respiratory acidosis secondary to an acute illness:
  - sending and reviewing serial ABG samples
  - making adjustments to the patient's respiratory support according to the ABG result
- Electrolyte and fluid volume deficit secondary to diarrhea:
  - sending and reviewing chemistry analysis to evaluate electrolytes and renal function
  - infusing intravenous fluids (IVFs) to correct fluid volume deficit
  - making recommendations to adjust IVFs based on laboratory results
  - monitoring patient's vital signs and weight

### Age-Related Considerations

Both older adults and young children are at higher risk for fluid, electrolyte imbalances, and acid-base imbalances. Patients in both age groups require more monitoring to enable nurses and other healthcare professionals to intervene early if an imbalance develops. Young children under the age of two are at an increased risk for imbalances because they have a higher metabolic rate, an increased rate of insensible fluid losses, and an inability to communicate their needs. Young children also have an immature immune system and are more prone to gastrointestinal illnesses that cause fluid loss (Vega & Avva, 2024). On the other hand, older adults are at increased risk for electrolyte and acid-base imbalances secondary to chronic disease, medication use, and decreased muscle mass that can impair breathing.

## LIFE-STAGE CONTEXT

---

### Electrolyte and Fluid Balance in Older Adults

Older adults' risk for dehydration is multifactorial. For many it is related to a decreased thirst sensation. Older adults are also more likely to be disabled or experience cognitive impairment, such as dementia or delirium, and forget to drink adequate water (Li et al., 2023). Furthermore, many older adults take medications, such as diuretics, that increase their fluid loss or affect their judgement (Masot et al., 2018).

---

### Patient Education

Patient education is an important factor in preventing fluid, electrolyte, and acid-base imbalances. Many patients who develop an imbalance have risk factors. Identifying those risk factors and providing anticipatory guidance helps prevent complications.

For example, nurses play a crucial role in educating older adults and the parents of young children about the increased risk of fluid and electrolyte imbalances in these age groups. Nurses also play a pivotal role in making sure

that patients who are taking medications that could cause an imbalance know what side effects to look for and when to seek medical attention. Patients with chronic disease such as congestive heart failure, renal disease, or COPD need to understand how their chronic illness affects fluid, electrolyte, and acid-base imbalances.

## PATIENT CONVERSATIONS

---

### What If Your Patient Is Reluctant to Go to the Emergency Department for an Evaluation?

**Scenario:** A telephone triage nurse at an outpatient pediatrician's office takes a phone call from a mother requesting an order for rectal Zofran to help her daughter stop vomiting.

**Nurse:** Thank you for calling Dr. Smith's after-hours line. My name is Serena, I'm a registered nurse, and this is a recorded line. How can I help you?

**Patient:** Hi, Serena. My name is Heidi; I'm Eleni Papadopoulos's mom. She has been vomiting nonstop all day. I can't even get her to hold down sips of water. When my son was her age, the doctor gave me a prescription for Zofran and that really helped. Can the doctor call something like that in for me tonight?

**Nurse:** I'm sorry to hear Eleni isn't feeling well. Before we jump to prescribing a medication, I'd like to get some more information from you. Can you tell me Eleni's date of birth so that I can look up her chart?

**Patient:** Sure. It's 2/4/2022.

**Nurse:** Great. I found her chart. It looks like she's been healthy, no major illness or past medical history. How long has she been vomiting? Are there any other symptoms such as a fever or diarrhea?

**Patient:** She woke up around midnight vomiting and has been vomiting off and on for the past twelve hours. At first, she was only vomiting food, but for the past five or six hours I can't get her to keep anything down. She spiked a temperature up to 103°F (39.4°C). I gave a dose of Motrin three hours ago and her temperature has come down a little. Now she's grabbing her stomach and crying and won't let me give her anything to eat or drink.

**Nurse:** I see. Abdominal pain, fever, and vomiting could be a lot of different things. Because of her age she's at risk for dehydration and could get worse quickly. Because it is after our office hours, it is best for you to take her to the emergency department so she can be seen by a provider who can figure out what is going on.

**Patient:** I know it's nothing serious. If I could just get her to stop vomiting, I'm sure she would be fine. Can't you page the on-call provider and ask for a prescription?

**Nurse:** Your daughter's symptoms concern me. It is best for her to be seen in the emergency department. She could have a serious infection that requires antibiotics. Also, she's at risk for dehydration and may need intravenous fluid.

**Patient:** This is ridiculous! She's just got a stomach bug. I can't afford an emergency room visit for something as simple as a stomach bug.

**Nurse:** It may be a stomach bug; however, it could also be something more serious. Children under the age of 2 can get behind on their fluid intake and get sick quickly. What you are describing to me sounds serious. If she's not taking any fluids by mouth, she could easily need IV fluids to get through this illness. I strongly encourage you to take her to the emergency department. Zofran is not a magic pill that will make her feel better. Something has triggered the fever, abdominal pain, and vomiting, and she needs to see a provider to get checked out.

**Patient:** I see. I certainly don't want her to get any worse. I'll get her ready and take her in.

**Nurse:** I'm glad to hear that. I'll let the on-call provider know that you're on the way to the emergency department so they can follow up with the emergency room provider. I hope she feels better soon.

---

### Evaluation of Outcomes

Evaluation of patient outcomes is a critical step in providing optimal patient care. To successfully measure **patient outcomes**, the nurse must set measurable goals that can be met within a specific time frame. Once a goal, or outcome, has been established, evaluation of the outcome requires critical thinking by the nurse. The nurse must analyze the reassessment data and determine if the expected outcome was met. If the expected outcome was not

met or was only partially met, the nurse needs to modify the nursing intervention in order to meet the patient's clinical goals. Having measurable outcomes and analyzing those outcomes improves patient care and ensures the patient's clinical goals are being met (Rørtveit et al., 2020).

Examples of measurable goals for patients at risk for fluid, electrolyte, or acid-base imbalances include the following:

- Patient will have a net even fluid balance within the next twelve hours.
- Patient's serum sodium level will increase by 1 mEq/L every eight hours until within normal limits.
- Patient's PaCO<sub>2</sub> will increase by 5 mm Hg within the next two hours.
- Patient will decrease sodium intake by 50 percent within the next two weeks.

## Summary

### 20.1 Fluid and Electrolyte Balances

The human body regulates fluid and electrolyte balance by adjusting to internal and external stimuli to maintain homeostasis. When homeostasis is not maintained, the patient is at risk for organ system dysfunction and even death. One of the primary mechanisms by which homeostasis is maintained is through regulation of body fluid within the different fluid compartments. The two fluid compartments in the human body are the extracellular and intracellular fluid compartments. Approximately two-thirds of the total body fluid is found in the intracellular space and one-third is in the extracellular space. For cellular processes to occur normally, the balance of fluid in these two compartments must be maintained and the patient needs to have a net even, or euvolemic, total fluid balance.

Body fluid composition is maintained in a normal physiological range by regulatory mechanisms that control water and electrolyte concentrations in both the intracellular and extracellular spaces. The intracellular and extracellular spaces have different electrolyte concentration levels and there is a narrow window of normal electrolyte ranges. Slight abnormalities in electrolyte levels can have serious consequence; for this reason, it is important for nurses to recognize the signs and symptoms of an electrolyte imbalance and identify appropriate treatments for imbalances. The most common electrolytes in the human body are sodium, potassium, calcium, magnesium, chloride, bicarbonate, and phosphate.

Keeping electrolytes within a narrow range is necessary for energy production, muscle contractions, stimulation of nerve impulses, and maintenance of a normal fluid balance. Nurses need to recognize how specific changes in electrolyte levels can affect the patient's overall health. For example, signs of hypernatremia include mental confusion, irritability, and seizures. Patients with hyponatremia may present with confusion, nausea, and a headache. Normal potassium levels are needed for cardiac and muscle cell function. Signs of hyperkalemia included peaked T waves and cardiac dysrhythmias. Patients with low potassium levels may present with muscle weakness, lethargy, a thready pulse, flattened or inverted T waves, U waves, and prolonged ST segments. Normal calcium and magnesium levels are needed for nerve transmission and muscle contraction. Signs of hypercalcemia include nausea, vomiting, and muscle weakness. Signs of hypocalcemia include paresthesia and tetany. Both Chvostek's sign and Trousseau's sign are classic physical exam findings in patients with hypocalcemia. Patients with abnormal magnesium levels may present with both cardiac and neuromuscular findings. Common symptoms of hypermagnesemia include bradycardia, muscle weakness, and tremors. Patients with hypomagnesemia may present with vomiting, weakness, and leg cramps. In severe cases, patients may develop dysrhythmias.

Fluid and electrolyte concentrations are maintained in normal ranges through different regulatory mechanisms, passive transport, active transport, and capillary filtration. Passive transport is the movement of water and electrolytes using the principle of concentration gradients. Passive transport is subdivided into two subcategories: osmosis and diffusion. Osmosis is the movement of water of liquid down a concentration gradient whereas diffusion is the movement of solutes, such as electrolytes, down a concentration gradient. Active transport requires energy expenditure and move solutes against their concentration gradients. A prime example of active transport is the sodium–potassium pump, which uses energy to pump sodium to the extracellular space and potassium into the intracellular space. Sodium is the most common extracellular electrolyte and potassium is the most common intracellular electrolyte. Without active transport, the concentration of sodium and potassium would equalize across cell membranes, which would impede the conduction of action potentials and alter fluid balance concentration in both the extracellular and intracellular compartments. Capillary filtration is a regulatory mechanism that delivers oxygen and other nutrients from the arterial blood flow through the capillaries to target tissue. It is counterbalanced by capillary reabsorption, which is the removal of waster products from tissue to the capillaries into the venous blood flow.

### 20.2 Acid-Base Balances

Maintaining the human blood in a normal range of acid-base balance is essential for health. Many cellular processes do not function normally if the blood's acid-base levels are off. The normal pH for the human blood is between 7.35 and 7.45. If the pH is less than 7.35, the patient has an acidosis, and if the pH is greater than 7.45, the patient has an alkalosis. There are multiple processes inside the human body that help maintain the pH within this narrow window.

Understanding acid-base imbalances is a key concept in nursing because lack of acid-base homeostasis can have a profound impact on patients' health. Acid-base imbalances are broken down into two general categories: metabolic imbalances and respiratory imbalances. Within these two broad categories, acid-base imbalances are further described as either causing an acidosis or an alkalosis, making a total of four subtypes: metabolic acidosis, metabolic alkalosis, respiratory acidosis, and respiratory alkalosis.

The chemical buffer system is a key regulatory mechanism that maintains acid-base levels within a normal range in the intracellular fluid compartment and in the extracellular fluid compartment. The carbonic acid–sodium bicarbonate buffer system is the most widely used buffer system in the human body, accounting for 50 percent of all chemical buffering. However, this buffer system only maintains acid-base balance in the extra cellular fluid compartment.

In the intracellular fluid compartment, there are two different buffering systems: the phosphate buffering system and the protein buffering system. The protein buffering system is more common than the phosphate buffering system. Almost all proteins can act as a chemical buffer because amino acids, which are the building blocks of protein, have both a positive and negative end. By having both electrical charges on one molecule, proteins can neutralize both acids and bases. The phosphate buffering system uses two different molecules: dihydrogen phosphate and hydrogen phosphate. Dihydrogen phosphate neutralizes excess base whereas hydrogen phosphate neutralizes excess acid.

In addition to chemical buffers, there are two systems in the human body that play an integral role in regulating acid-base homeostasis: the respiratory system, and the renal system. The respiratory system helps maintain acid-base balance by either exhaling or retaining carbon dioxide. Carbonic acid reacts with water to form carbonic acid, which is the most common acid in the bloodstream. The renal system regulates acid-base balance by either reabsorbing or excreting bicarbonate. Bicarbonate is a base. The renal system compensates for the respiratory system if there is an acid-base imbalance that is caused by a respiratory problem. Likewise, the respiratory system compensates for the renal system if there is an alteration in serum bicarbonate levels.

### 20.3 The Nurse's Role in Patient Care Management

Recognizing cues about fluid, electrolyte, and acid-base imbalances is a cornerstone of providing safe nursing care. By recognizing cues, nurses can intervene early before serious complications occur. The cues that alert nurses to an impending imbalance depend on the alteration that the patient is facing. Nursing interventions to prevent fluid, electrolyte, and acid-base imbalances should target the specific imbalance the patient has or is at risk of developing. Nurses are also responsible for patient education and evaluating patient outcomes.

#### Key Terms

**acid** a molecule that can donate a hydrogen ion ( $H^+$ ) in chemical reactions

**acidosis** having a blood pH less than 7.35

**action potential** the voltage across a cell membrane that is determined by the ratio of ions in the intracellular and extracellular fluid

**active transport** the movement of solutes through a transmembrane protein using energy expenditure

**alkalosis** having a blood pH greater than 7.45

**anion** a negatively charged electrolyte

**anion gap** the concentration of unmeasured serum anions; having a large number of unmeasured anions indicates an acid has been added to the solution

**arterial blood gas** a blood test that measures the levels of oxygen, carbon dioxide, pH, and bicarbonate ions ( $HCO_3^-$ ) in the arterial blood

**base** a molecule that can donate a hydroxide ion ( $OH^-$ ) in chemical reactions

**blood plasma (also, intravascular fluid)** the liquid component of blood

**capillary filtration** the process of delivering oxygen and other nutrients and removing cellular waste through the capillary system

**cation** a positively charged ion

**Chvostek's sign** an involuntary twitching of the facial muscle when the facial nerve is tapped

**concentration gradient** the process of substances moving from an area of high concentration to an area of low concentration

- cue** a subjective or objective data point that is observed by the nurse
- diffusion** a transport process that involves molecular movement involving a concentration gradient
- edema** swelling caused by excessive buildup of fluid in tissue spaces or a body cavity
- enzyme** a protein that catalyzes chemical reactions
- euvolemic** at net even fluid balance
- extracellular fluid** the body fluid found outside of cells; subdivided into three categories: interstitial fluid, blood plasma, and transcellular fluid
- fluid volume deficit (also, hypovolemia or dehydration)** a medical condition in which fluid loss exceeds fluid intake
- fluid volume overload (also, hypervolemia)** a medical condition in which an excessive amount of fluid is retained in the intravascular fluid compartment
- focused assessment** the collection of relevant information pertaining to a change in the patient's clinical status
- homeostasis** the process by which the human body maintains balance by adjusting to internal and external stimuli
- hypercalcemia** an elevated serum calcium level ( $> 10.2$  mEq/L)
- hyperchloremia** an elevated serum chloride level ( $> 106$  mEq/L)
- hyperkalemia** an elevated serum potassium level ( $> 5.1$  mEq/L)
- hypermagnesemia** a high serum magnesium level ( $> 2.4$  mEq/L)
- hypernatremia** an elevated serum sodium level ( $> 145$  mEq/L)
- hyperphosphatemia** an elevated serum phosphorus level ( $> 4.5$  mg/dL)
- hypervolemia** an excess of body fluid
- hypocalcemia** a low serum calcium level ( $< 8.6$  mg/dL)
- hypochloremia** a low serum chloride level ( $< 96$  mEq/L)
- hypokalemia** a low serum potassium level ( $< 3.5$  mEq/L)
- hypomagnesemia** a low serum magnesium level ( $< 1.5$  mEq/L)
- hyponatremia** a low serum sodium level ( $< 135$  mEq/L)
- hypophosphatemia** a low serum phosphorus level ( $< 3.4$  mg/dL)
- hypovolemia** a deficit of body fluid
- interstitial fluid** the fluid that surrounds cells
- intracellular fluid** the body fluids found inside the body's cells
- metabolic acidosis** an increase in the hydrogen ion concentration as a result of an abnormally low serum bicarbonate level ( $\text{HCO}_3^-$ )
- metabolic alkalosis** a net increase in bicarbonate ions due to loss of hydrogen ions or retention of bicarbonate ions by either the renal or gastrointestinal systems
- osmosis** the passage of a solvent (liquid) through a semipermeable membrane from an area of lower solute concentration to an area of higher solute concentration
- paresthesia** a sensation of numbness and tingling
- passive transport** the movement of liquid and solutes across cell membranes using principles of concentration gradients
- patient outcome** a measurable goal that can be met within a specific time frame
- pH** the concentration of hydrogen ions in a given solution
- respiratory acidosis** having a blood pH less than 7.35 with a concurrent increase in carbon dioxide ( $\text{CO}_2$ )
- respiratory alkalosis** a systemic acid-base disorder that is caused by a reduction in carbon dioxide and a pH greater than 7.45
- solute** any substance that is dissolved in a solution
- tetany** involuntary muscle contractions
- transcellular fluid** the fluid within epithelial-lined spaces
- Trousseau's sign** an involuntary spasm of the hand when a blood pressure cuff is inflated above the diastolic blood pressure for three minutes; a classic sign of hypocalcemia

## Assessments

### Review Questions

1. What statement describes distribution of fluid balance in the human body?

- a. Approximately two-thirds of body fluid is found in the extracellular space.
  - b. Total body fluid is split evenly between the intracellular space and the extracellular space.
  - c. Transcellular fluid makes up about 25 percent of total body fluid.
  - d. The intracellular space has the highest percentage of total body fluid.
2. While assessing a new patient admission, the nurse notes that the patient has ascites and crackles in the lung fields. What fluid imbalance should the nurse suspect?
- a. hypervolemia
  - b. fluid volume deficit
  - c. increased transcellular fluid
  - d. euvolemia
3. What physical exam finding would the nurse expect in a patient experiencing hyponatremia?
- a. confusion
  - b. thirst
  - c. muscle twitching
  - d. tachycardia
4. What suggestion from a nursing student would be appropriate for a patient experiencing hypercalcemia?
- a. Limit fluid intake to concentrate the urine and encourage urinary excretion of calcium.
  - b. Stop eating dried fruit and nuts to prevent excess calcium intake.
  - c. Increase weight-bearing exercises to stop leaching of calcium from the bones.
  - d. Decrease foods high in phosphorus to prevent phosphorus from binding to calcium.
5. What statement correctly describes the process of active transport?
- a. Active transport is dependent on solutes moving down a concentration gradient.
  - b. Through active transport, the concentration of sodium and potassium remains equal across cell membranes.
  - c. Oxygen and other nutrients are delivered via the capillary bed using active transport.
  - d. Active transport uses energy expenditure to move solutes from an area of lower concentration to higher concentration.
6. What statement describes why it is important to maintain the blood pH within a narrow range?
- a. Alterations in the blood pH leads to increased vascular permeability and capillary leak.
  - b. Many cellular processes do not function normally if there is an acid-base imbalance.
  - c. Having an acid-base imbalance speeds up the body's metabolism, requiring patients to consume more energy.
  - d. Failure to maintain acid-base homeostasis results in accumulation of intracellular fluid.
7. What comment by a nurse explains why patients with acidosis are at risk for developing hyperkalemia?
- a. Intracellular potassium shifts into the extracellular space to counterbalance the net influx of positive hydrogen ions.
  - b. Prolonged acidosis causes cells to lyse, releasing intracellular potassium into the extracellular fluid compartment.
  - c. Potassium-containing acids interact with bases, releasing potassium.
  - d. Acidosis shifts potassium from the muscles into the bloodstream to bind to bicarbonate.
8. What is one cause of metabolic acidosis?
- a. gastrointestinal loss of bicarbonate
  - b. carbon dioxide retention secondary to hypoventilation
  - c. increased secretion of hydrogen ions into the urine
  - d. loss of HCL from the gastrointestinal tract

9. What happens to the patient's blood acid level if the patient takes deeper, faster breaths?
  - a. The patient develops respiratory acidosis.
  - b. The patient's blood acid level will not change.
  - c. Respiratory alkalosis will develop.
  - d. The patient's blood pH will increase.
  
10. What is a cue that a patient has developed hyperkalemia?
  - a. mental confusion
  - b. increase thirst
  - c. cardiac arrhythmias
  - d. paresthesia
  
11. The nurse anticipates what change in urine output in a patient with a fluid volume deficit?
  - a. decreased urine output
  - b. no change in urine output
  - c. presence of blood in urine
  - d. increased urine output
  
12. What nursing intervention would the nurse use to prevent electrolyte abnormalities in a patient with chronic kidney disease?
  - a. dietary education
  - b. education on electrolyte supplements
  - c. administration of intravenous fluid
  - d. daily weights

### Check Your Understanding Questions

1. Explain the difference between osmosis and diffusion.
2. Explain what happens to the blood pH if the kidneys reabsorb an excess amount of bicarbonate.
3. What is the formula to calculate a patient's anion gap, and what does an anion gap greater than 12 indicate?

### Reflection Questions

1. Explain why it is important for nurses to understand acid-base physiology.
2. Describe appropriate patient education about how vomiting causes an acid-base imbalance.
3. Why is it imperative for nurses to recognize cues when assessing patients' fluid, electrolyte, and acid-base levels?

### What Should the Nurse Do?

1. What should the nurse do if they triage a patient with a seven-day history of diarrhea who presents with dry mucous membranes and mental confusion?
2. What should the nurse do if a patient is ordered an IV potassium replacement, and their urine output has declined over the last four hours?
3. Peggy is a 74-year-old patient with chronic renal disease who presents to the emergency department with fluid overload, a headache, and peaked T waves on the cardiac bedside monitor. A basic metabolic panel is drawn that shows the following: a sodium level of 128 mEq/L, a potassium level of 6 mEq/L, a BUN of 40 mg/dL, a creatinine level of 2 mg/dL, a chloride level of 85 mEq/L, and a calcium level of 8 mg/dL. Which electrolyte abnormality should the nurse associate with the patient's peaked T waves? Why would this electrolyte abnormality cause this finding?
4. A patient who is sedated and on mechanical ventilation has a routine arterial blood gas (ABG) drawn that shows the following:

- pH: 7.5
- PaCO<sub>2</sub>: 28 mm Hg
- HCO<sub>3</sub><sup>-</sup>: 23 mEq/L

What acid-base imbalance is the patient experiencing? What should the nurse do to correct the acid-base imbalance?

## Competency-Based Assessments

1. Use the internet to research dietary practices to improve electrolyte abnormalities in patients with renal disease. Describe common dietary guidelines for patients with chronic kidney disease.

Marika, a 45-year-old patient, presents to the emergency department with complaints of persistent vomiting, diarrhea, and abdominal pain for the past 24 hours. She reports feeling weak and lightheaded.

Laboratory Results:

- pH: 7.28
- PaCO<sub>2</sub>: 32 mm Hg
- HCO<sub>3</sub><sup>-</sup>: 18 mEq/L
- sodium (Na<sup>+</sup>): 140 mEq/L
- potassium (K<sup>+</sup>): 3.2 mEq/L
- chloride (Cl<sup>-</sup>): 96 mEq/L

2. Identify whether each lab is normal or abnormal.
3. Based on the lab results, does Marika's pH suggest acidosis or alkalosis?
4. According to Marika's labs, which acid-base balance is she experiencing?
5. Many patients with chronic obstructive pulmonary disease (COPD) have chronic respiratory acidosis. Spend fifteen minutes reviewing COPD signs and symptoms. What trends in acid-base imbalance would nursing expect in a patient with COPD who presents with a productive cough and fever?
6. A patient with chronic kidney disease presents to the emergency department with a decrease in urine output from baseline and evidence of fluid overload. An electrolyte panel is sent that shows the following: Na<sup>+</sup> of 130 mEq/L, K<sup>+</sup> of 5.4 mEq/L, Ca<sup>+</sup> of 10.2 mg/dL, and a phosphate level of 4.3 mmol/L. Based on the laboratory values, what is the highest priority for this patient?

# CHAPTER 21

## Nutrition

**FIGURE 21.1** Proper nutrition, which includes a balanced diet, is linked to improved health and bodily functioning. (credit: “Fresh cut fruits and vegetables.jpg” by Peggy Greb, U.S. Department of Agriculture, Public Domain)

### CHAPTER OUTLINE

- 21.1 Nutritional Concepts
- 21.2 Factors Affecting Nutrition
- 21.3 Specialized Diets
- 21.4 Nutritional Assessment

**INTRODUCTION** Good nutrition is essential to healthy living and disease prevention. Nutritious meals provide nutrients to power all the cells of the body and enable biochemical processes that humans need to engage in an active, satisfying life. While nutritional needs across a person’s life span vary, the need for quality, nutrient-rich food never changes. Regardless of their cultural, religious, or economic background, everyone benefits from healthy lifestyle choices and dietary patterns.

Unfortunately, unhealthy dietary patterns not only risk immediate health needs but are also associated with the development of chronic disease. In the United States, 60 percent of the population has been diagnosed with at least one chronic medical condition due to unhealthy dietary practices (USDA, 2020). Whether it is diabetes, heart disease, obesity, or eating disorders, no one is immune from the consequences of poor nutrition. Nurses are on the forefront of health promotion; thus, it is essential for nurses to have a clear understanding of the relationship between food and health. Nurses must teach the importance of good nutrition and understand how specialized diets are used to promote optimal health. Most importantly, nurses must be competent in the skill of nutrition assessment and evaluation across a person’s life span.

## 21.1 Nutritional Concepts

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain how nutrition supports energy production
- Recognize nutrients used for energy in the body
- Recall nutrients used for regulation in the body
- Describe optimal nutritional status for proper bodily functioning

The science of nutrition has impacted clinical care in significant ways. As scientists learn more about the roles and uses of nutrients in health and medicine, new and improved nutritional guidelines and recommendations are developed. The **dietary reference intake (DRI)** are scientifically developed reference values that set baseline standards and guide recommendations for daily nutritional intake. The U.S. Department of Agriculture (USDA) uses **recommended dietary allowances (RDAs)**, which provide general guidelines for consuming the nutrients that make up a healthy diet each day. RDAs help guide mealtime planning and food choices and aid in the development of food labels. They are based on DRIs to guide nutrition policy in the United States. **reference daily intake (RDI)** is the average daily intake of a population. It is important for nurses to develop a sound understanding of nutrition science and clinical judgment skills regarding the implementation of healthy dietary practices. This section provides an overview of nutrient metabolism and regulation.

### Energy Production

Human life cannot exist without energy. Energy fuels all the physiological demands of the human body. It is required for cellular growth, development, and regulation. It powers musculoskeletal movement, cognitive function, and neuromuscular reflexes. All living cells in the human body depend on energy derived from adenosine triphosphate (ATP). ATP is a molecule that releases energy when converted to adenosine diphosphate (ADP). This stepwise process is known as **cellular respiration**. Energy-rich nutrients (carbohydrates, fats, and proteins) are chemically broken down to provide ATP. ATP is then oxidized and converted to ADP, carbon dioxide, and water. Energy release in the form of ADP fuels all cellular functions within the body. To meet the body's metabolic demands, carbohydrates, proteins, and fats must be consumed and either digested or stored to meet the ongoing energy demands of the body.

### Metabolic Requirements

The process by which substances are chemically broken down to meet the body's nutrient and energy needs is **metabolism**. The energy needs of the body require the consumption and metabolism of carbohydrates, proteins, and fats in significant quantities. These three energy-rich nutrients provide a consistent amount of energy per gram of nutrient. The **calorie** is a unit of measure for energy. Both carbohydrates and proteins provide four calories of energy per gram of nutrient, while fats provide nine calories per gram. The rate at which calories burn is called the basal metabolic rate (BMR). A high metabolic rate burns calories faster than a slow metabolic rate. Many factors influence metabolic rates, including age, sex, activity level, genetics, and overall fitness. Underlying medical conditions also significantly affect both metabolic rates and needs. Nutritional wellness occurs when cells burn calories efficiently and excess energy is stored effectively, thus achieving metabolic homeostasis.

The goal of metabolic homeostasis is to balance caloric intake with caloric need. Metabolic imbalance negatively impacts overall wellness and can occur when either too many or too few calories are consumed to meet the body's immediate needs. When calories consumed exceed caloric need, excess energy is stored as fat, which can lead to weight gain and the development of obesity, metabolic syndrome, and other chronic medical conditions. Caloric deficits can be just as detrimental. When caloric need outweighs caloric intake, a caloric deficit occurs, and the body turns to energy stores to meet energy needs. Carbohydrates, stored as glycogen in the liver, are metabolized first, followed by energy stored in fat cells. If a caloric deficit is prolonged and starvation ensues, the body will metabolize proteins, which can lead to life-threatening medical conditions and death. Metabolic homeostasis is essential to healthy living.

### Body Weight Standards

Across a person's life span, body weight is greatly affected by caloric imbalances. Overconsumption and underconsumption of calories can result in body weight alterations that negatively impact overall health. Thus, it is

important for individuals to achieve and maintain an ideal body weight. The measure of **ideal body weight (IBW)** correlates with positive health benefits. An individual's IBW is influenced by individual characteristics such as height, weight, body frame, age, and sex. General guidelines have been developed using these characteristics to identify IBW standards. IBW can be a helpful tool when analyzing nutritional health based on generalized standards.

The measure of **body mass index (BMI)** is a commonly used tool that analyzes height and weight to provide a measurement relative to generalized standards. The Centers for Disease Control and Prevention (CDC) classifies BMI into the following categories: underweight, healthy weight, overweight, and obese ([Table 21.1](#)). A calculated BMI is based on an individual's height, weight, age, and sex and can be a helpful tool in determining an individual's relative fitness and overall wellness. Since body fat distribution can naturally differ by ethnicity, and other factors (such as exercise) can impact BMI, it should not be used as the only determination of nutritional and related health. There are many BMI calculators available on the web.

BMI	Weight Status
Below 18.5	Underweight
18.5–24.9	Healthy weight
25.0–29.9	Overweight
30.0 and above	Obese

**TABLE 21.1** BMI Interpretation for Weight Status (Centers for Disease Control and Prevention, 2022.)

## LINK TO LEARNING

BMI is a tool commonly used to provide a measurement relative to the IBW standard. The CDC provides a [BMI calculator \(https://openstax.org/r/77BMIconc\)](https://openstax.org/r/77BMIconc) to make calculating BMI easy.

Waist circumference is another commonly used measure. Waist circumference is a relative indicator of excess fat storage deposited in the midsection; it is often used as a relative measure to gauge overall caloric balance. Growth charts are used to analyze body height and weight standards across the continuum of growth and development in children through adulthood. The CDC and the World Health Organization (WHO) have developed growth charts for use in clinical settings to track physical growth trends.

## LINK TO LEARNING

The CDC has developed [growth charts \(https://openstax.org/r/77growthcharts\)](https://openstax.org/r/77growthcharts) to track physical growth trends in infants and children. These charts are used to promote pediatric health.

Growth charts for infants include measurements of length, weight, and head circumference; charts for children and adolescents include measures of weight and height. Growth charts trend measurements according to percentiles, which compare a measure to an average. Thus, for a child in the fiftieth percentile for weight, 50 percent of children will be above and 50 percent of children will be below that child's measure. Growth and BMI charts are useful tools for studying trends involving growth, development, and general nutrition.

### Caloric Requirements

Energy is measured in calories. The energy-rich nutrients (carbohydrates, fats, and proteins) provide a substantial number of calories per unit of weight: Carbohydrates provide 4 cal/g, proteins provide 4 cal/g, and fats provide 9 cal/g. The USDA provides guidance on daily dietary recommendations including energy requirements. According to the USDA, human energy requirements range between 1,000 and 3,200 calories per day depending on the

individual. Individual estimates of energy needs vary based on a variety of characteristics including age, sex, height, weight, health status, and level of physical activity.

## LIFE-STAGE CONTEXT

---

### Caloric Needs of Older Adults

People age 65 years and older are considered older adults. Older adults are more likely to experience chronic illness and disease. They have lower caloric needs than younger people, though they still need a diet full of nutrient-dense foods because their nutrient needs increase. The caloric needs of older adults decrease due to decreases in activity, metabolic rates, and muscle mass. Chronic disease and medication can contribute to decreased nutrient absorption.

Protein and vitamin B12 are commonly underconsumed in older adults. Protein is necessary to prevent loss of muscle mass. Vitamin B12 deficiency can be a problem for older adults because absorption of vitamin B12 decreases with age and with certain medications. Adequate hydration is also a concern for older adults because feelings of thirst decrease with age, which can lead to poor fluid intake. Additionally, older adults may be concerned with bladder dysfunction so they may consciously choose to limit fluid intake. Loneliness, diminished ability to chew and swallow, and poverty can also decrease dietary intake in older adults. Organizations such as Meals on Wheels, local senior centers, and other community programs can provide socialization and well-balanced meals to older adults.

---

### Nutrients for Energy

Carbohydrates, proteins, and fats are energy-rich nutrients consumed on a daily basis to meet the body's caloric needs. Each of these three nutrients is considered a **macronutrient** because large quantities of each are consumed daily to meet the body's energy needs. Each of these energy-rich nutrients is metabolized at the cellular level to release energy used to fuel cellular functions. Carbohydrates break down into sugars for quick release of energy to meet immediate caloric needs. Excess sugars are converted to glycogen and stored in the liver; they can be converted back to glucose for release in the bloodstream as glucose when needed. When blood glucose levels drop, fat cells, also known as lipids, break down to meet immediate caloric needs. Fat cells are complex molecules that provide a slow but very efficient release of energy. Proteins are larger molecules made up of amino acids that also provide a slow release of energy. When carbohydrate and fat energy stores are depleted, proteins are metabolized to provide needed energy. These three energy-rich macronutrients are essential to life and work in concert to meet the body's need for fuel.

#### Carbohydrates

A macronutrient used to fuel the immediate energy needs of the body is a **carbohydrate**. Carbohydrates are classified as simple (monosaccharides and disaccharides) or complex (oligosaccharides and polysaccharides). Simple carbohydrates are also known as sugars. Glucose, a monosaccharide, is the body's primary energy source; it is used to meet immediate energy needs. When glucose is transported into a cell, it undergoes cellular metabolism, which releases ATP and energy. Larger, complex carbohydrates are broken down by enzymes into monosaccharides to be metabolized for energy. Every gram of carbohydrate provides 4 calories of energy. Carbohydrates should make up 45 to 65 percent of a healthy diet.

Simple and complex carbohydrates differ in significant ways, though all are made up of carbon, hydrogen, and oxygen. Sugars typically taste sweet and are found in foods like honey and fruits. Complex carbohydrates are longer sugar chains that are digested in the intestines and broken down into monosaccharides that can then be used by the cells. They release energy more slowly than simple sugars. Starches, fiber, and glycogen are complex carbohydrates. Starches are polysaccharides that are digested by enzymes in the intestinal tract. Rice and potatoes are examples of starches. Dietary fiber is broken down in the large intestine by bacteria rather than metabolized by enzymes. Soluble fiber is found in fruits, vegetables, whole grains, and legumes; it helps control blood sugar by reducing absorption of postprandial blood sugar in the gut. Insoluble fiber, such as cellulose, is a bulking agent for stool.

#### Proteins

A macronutrient made up of amino acids is a **protein**; they are much larger molecules than carbohydrates. There are

twenty different amino acids used by the human body. Nine of these amino acids must be consumed within the diet. These are referred to as essential amino acids. The other amino acids can be synthesized within the body. All proteins are made of strings of amino acids called polypeptides. During digestion, proteins are broken down into smaller units that can then be used to make new proteins. Proteins are essential to human life. They are the main building blocks for muscle, skin, and connective tissue and are involved in the growth, maintenance, and repair of body tissues. Enzymes, hormones, and hemoglobin are proteins. While proteins are not a primary source of energy, they can be broken down for glucose metabolism if cells are starved for energy. Proteins yield 4 calories of energy for every gram of nutrient.

Dietary proteins should make up 10 to 15 percent of an individual's daily caloric intake. There are situations where protein needs are higher, such as in growing children or when a person is pregnant, lactating, or experiencing a critical illness. However, excessive dietary protein can be harmful to individuals with underlying kidney impairment. Thus, it is important to maintain a protein intake that is healthy and also balanced for individual nutritional needs. Meat, poultry, eggs, and seafood are all good sources of animal protein. Unfortunately, some of these protein sources are associated with high levels of saturated fat, which can negatively impact health and should be limited in a healthy diet. Protein from plants, such as soy products, nuts, seeds, and legumes, can supply adequate amounts of protein as well, though these sources are not metabolized as efficiently as animal protein. The USDA recommends a balanced intake of animal and plant protein. [Table 21.2](#) compares the protein content of animal- and plant-based foods, information that is useful for developing a balanced diet while reducing saturated fat content.

Type	Source	Measure	Protein Content
Animal based	Whey powder	3 scoops	50 g
	Beef	3 oz	29 g
	Turkey	3 oz	26 g
	Lamb	3 oz	25 g
	Pork	3 oz	25 g
	Salmon	3 oz	23 g
	Chicken	3 oz	20 g
	Cod	3 oz	19 g
	Milk	8 oz	9 g
	Yogurt	4 oz	9 g
	Egg	1 whole	6 g
Plant based	Black beans	1 cup	42 g
	Peanuts	1 cup	36 g
	Pumpkin seeds	1 cup	35 g
	Almonds	1 cup	29 g

**TABLE 21.2 Protein Content** (Source: U.S. Department of Agriculture, Agricultural Research Service, Beltsville Human Nutrition Research Center, 2024.)

Type	Source	Measure	Protein Content
	Tofu	0.5 cup	22 g
	Edamame	1 cup	13 g
	Kidney beans	1 cup	8 g
	Peas	1 cup	8 g
	Broccoli	1 cup	6 g
	Spinach	1 cup	5 g

**TABLE 21.2 Protein Content** (Source: U.S. Department of Agriculture, Agricultural Research Service, Beltsville Human Nutrition Research Center, 2024.)

### Fats

A large, complex molecule made up of fatty acids and glycerol is a **fat**. Fats, also known as lipids, are a highly efficient source of stored energy, releasing energy when needed at a very slow, measured rate. Each gram of fat releases 9 calories of energy.

Cholesterol and triglycerides are important lipids within the body. They are associated with essential functions including brain function, hormone regulation, and energy production. Adipose tissue, commonly found in subcutaneous fat, is composed of fat cells that help regulate energy supply within the body. Energy, in the form of excess blood sugar, is converted to lipids and stored as adipose tissue for future use. When glucose stores are depleted, the body turns to these fat stores for energy by breaking down the triglycerides in adipose tissue into simple sugars, which then release energy for immediate use within the body. Cholesterol is a key component of cell membranes; it is transported, along with triglycerides, throughout the body by protein-based compounds called lipoproteins. Lipoproteins, which are classified according to the ratio of lipid to protein, bind to cholesterol and triglycerides for transport through the body. Low-density lipoproteins (LDLs) are essential for healthy cellular function but in excess are associated with increased cardiovascular risk. LDL is often referred to as “bad cholesterol” and can be found in high-fat diets that contain fried foods, red meat, high-fat dairy products, and processed baked goods. High-density lipoproteins are considered “good cholesterol” and are beneficial to cell function. Examples of good cholesterol include nuts, seeds, fish, and legumes.

Lipids are either saturated or unsaturated; unsaturated fats may be monounsaturated or polyunsaturated. Saturated fats are associated with increased cardiovascular risk, leading to atherosclerosis, coronary artery disease, and stroke; they should be limited in a healthy diet. Animal products contain saturated fat, while fat derived from plants typically contains unsaturated fat. Trans fats are human-made fats derived from partially hydrogenated oil. Eliminating trans fats from the diet is recommended because these fats are associated with development of atherosclerosis and adversely affect cholesterol levels. The USDA recommends limiting the consumption of dietary fat to 28 percent or less of daily caloric intake. Saturated fat should be limited to 8 percent or less.

### Nutrients for Regulation

Energy-dense macronutrients are not the only nutrients needed to regulate body function. Other nutrients, such as electrolytes, vitamins, minerals, and water, are required for growth, development, and maintenance of regulatory processes in the human body. Electrolytes, such as sodium, potassium, and calcium, are considered macronutrients because they are needed in relatively large quantities. Water is also a macronutrient. A **micronutrient** is a nutrient found in small quantities within the body but which is still necessary for physiological functions. Vitamins and minerals are examples of micronutrients. [Table 21.3](#) lists the RDA of vitamins and minerals for children, and [Table 21.4](#) lists the RDA of vitamins and minerals for adults.

Age	6–11 Months	1–2 Years	2–3 Years	4–8 Years	9–13 Years	14–18 Years
Calories (kCal)		800	1,000	1,200–1,400	1,600–1,800	1,800–2,200
Protein (g)	11	13	13	19	34	46–52

### Vitamins

A **vitamin** is an essential micronutrient, vital to biochemical regulation within the human body. Vitamins are exogenous (not made by the body) and must be ingested as part of a healthy diet. They are classified by solubility. Vitamins are either absorbed and transported in water (water soluble), or they are absorbed and transported in fat (fat soluble). The body's ability to absorb both fat- and water-soluble vitamins can be affected by various medical conditions. Many drugs can interfere with absorption and metabolism of vitamins. Vitamins can be toxic if taken in excess, but vitamin deficiencies can also have detrimental effects. Therefore, scientists have determined RDA for

many vitamins to help reduce associated risks.

Vitamin C and the complex of B vitamins are examples of water-soluble vitamins: that is, they dissolve in water. Water-soluble vitamins are eliminated in the urine fairly quickly, so toxicities are rare. Deficiencies are often due to lack of access to quality food. Vitamin C is found in citrus fruits, vegetables, and potatoes. It helps regulate collagen, hormone, and amino acid production and assists with iron absorption and wound healing. The complex of B vitamins helps regulate a variety of physiological and neurological processes. Common B vitamins include B1 (thiamine), B2 (riboflavin), B3 (niacin), and B12 (cyanocobalamin). Foods rich in B-complex vitamins include meat, fish, eggs, and legumes.

Fat-soluble vitamins dissolve in lipids. Common fat-soluble vitamins include vitamin A, vitamin D, and vitamin K. Vitamin A is essential to maintain vision and healthy skin and is found in fish liver oils, egg yolks, and vegetables. Vitamin D helps build and maintain healthy bones and is not found naturally in food. Instead, vitamin D is absorbed through direct sunlight, though many fortified foods now contain vitamin D. Vitamin K promotes blood clotting and reduces bleeding risk and is found in dark green, leafy vegetables. Vitamin E is a fat-soluble vitamin with antioxidant properties, protecting cells against the effects of free radicals. Foods rich in vitamin E include vegetable oils, peanuts, and leafy greens. Many fat-soluble vitamins are stored in the liver and can have toxic effects on the body if taken in excess.

### Minerals

Another essential component of physiological processing is the **mineral**. Some minerals are macronutrients, and some are micronutrients. Electrolytes are macronutrient minerals that are essential to cardiac, musculoskeletal, and neurological functions. They help maintain water balance and acid-base balance. Important electrolytes include sodium, potassium, calcium, phosphorous, and magnesium. Each of these electrolytes must be balanced within a tight therapeutic range to maintain homeostasis and avoid harmful effects.

Some minerals are micronutrients and are found in minute quantities within the body. These minerals, also known as trace minerals, have RDA to avoid toxicities. Important trace minerals include iodine, iron, and zinc. Iodine is essential to thyroid hormone production and is mainly found in sea salt. Iron is an important component of blood, specifically hemoglobin. It is found in animal products. Zinc is essential to immune and metabolic processes and can be found in many meat products.

### Water

Water is an essential macronutrient that must be maintained in homeostatic balance to avoid the detrimental effects of both over- and underhydration. Two-thirds of the volume of total body water (TBW) are found inside body cells (intracellular). The other third is extracellular and found in the vascular system and interstitial fluids ([Figure 21.2a](#)). TBW is roughly 50 to 60 percent of overall body weight, but the amount is age dependent ([Figure 21.2b](#)). Water is ingested and absorbed in the digestive tract and regulated by various mechanisms: the thirst mechanism, kidney function, pituitary function, and osmosis. The body loses about a liter of fluid a day through urine, sweat, and so on. Thus, the average recommended daily intake of water is 2.5 L to maintain adequate kidney function and vital capacity.

**FIGURE 21.2** (a) Total body water is a critical component of a person's health. Many structures of the human body are mostly water. (b) As people age, the percentage of their bodies that consists of water decreases. K. (2023). Body water percentage from childhood to old age. *Kidney Research and Clinical Practice*, 42(3), 340–348. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## Optimal Nutritional Status

The human body performs best under conditions of optimal nutrition. Nutrient deficiencies can compromise the body and affect both physical and mental functioning. Likewise, excessive nutrient intake can result in toxicity. Homeostatic balance is the goal for both macro- and micronutrients. The USDA provides recommendations for daily nutrient intake and guidance on how to support daily patterns of healthy eating to promote optimal health across the life span.

Optimal nutrition begins before birth. During pregnancy, higher levels of macronutrients are needed to support the growth and development of the fetus. Following birth, good nutrition is vital to maintaining the rapid growth and development of the infant. Throughout each life stage, (infancy, toddlerhood, childhood, adolescence, adulthood, pregnancy/lactation, and older adulthood), optimal nutrition is foundational to healthy living and human flourishing. When optimal nutrition is not achieved, over time malnutrition occurs, which can lead to various negative outcomes depending on the nutritional deficit.

## PATIENT CONVERSATIONS

### What If Your Patient Is on a Fad Diet?

**Scenario:** Nurse is completing an admissions assessment on a patient being admitted with anemia, beginning with height and weight measurement. The patient sees that she weighs 140 pounds and smiles at the nurse.

**Nurse:** Ms. Erving, I see you're happy with your weight, huh?

**Patient:** Yes, I am! I've been on a diet for two months now, and I've lost over 30 pounds!

**Nurse:** Really? That's a lot of weight very quickly. What diet are you currently on?

**Patient:** I'm only eating fruits. It's called a fruitarian diet. I can eat all the fruit I want.

**Nurse:** So, you just eat fruit? Nothing else? No protein, dairy, grains, or vegetables?

**Patient:** Yes, that's right.

**Nurse:** Did you know that your body requires optimal nutrition to remain healthy? That includes a healthy balance of macronutrients and micronutrients. When your body doesn't get these important things in your diet, you can develop nutritional deficits.

**Patient:** I didn't know that. I thought my weight was the most important thing to be healthy, and being overweight was unhealthy.

**Nurse:** Sure, being overweight can be unhealthy, but you can be an average weight for your height and still be unhealthy. I saw in your initial lab tests that your calcium, iron, vitamin B12, and vitamin D are all low. Have you been feeling tired since you started your diet?

**Patient:** Actually, I have, but I didn't think it was related to what I was eating because fruit is healthy, and I was losing weight.

**Nurse:** Restricting your diet to only one food group is not a healthy way to lose weight. Your body needs a variety of vitamins and minerals to stay healthy. If it's OK with you, I'd like to have the nutritionist come and talk to you about how you can incorporate healthy foods into your diet for optimal nutrition and maintain a healthy weight.

**Patient:** Thank you, that would be great.

---

### Malnutrition

An imbalance between the nutrients consumed and nutrients needed leads to **malnutrition**. These nutritional imbalances can result in both undernutrition and overnutrition and can involve both macronutrients and micronutrients. The RDA are a helpful tool to identify individuals at risk (see [Table 21.3](#) and [Table 21.4](#)). However, malnutrition is multifactorial, and careful clinical follow-up is necessary to minimize long-term negative impacts of poor nutrition.

#### Undernutrition

Undernutrition is a state of malnutrition in which there is inadequate intake or impaired absorption of nutrients in the body. Undernutrition can be experienced across a person's life span. It often refers to calorie or protein deficits (macronutrient undernutrition), but it also includes deficiencies in vitamins and minerals (micronutrient undernutrition). Low calorie intake is a common cause of undernutrition and is commonly associated with poverty, homelessness, mental disorders, and cognitive disorders. Caloric intake can also be affected by medical conditions that restrict ingestion of food, such as dysphagia, or conditions that interfere with absorption in the gastrointestinal tract.

Caloric deficits result in the breakdown of fats to meet the body's energy needs. Prolonged caloric deficits will deplete fat stores and stimulate the metabolism of proteins, thus causing the breakdown of muscle and tissues. Prolonged caloric deficits can lead to starvation and the visible wasting of muscle and fat. In the same manner, poor caloric intake will lead to deficiencies in essential vitamins and nutrients. The negative impact of these deficits on the body depends on the cause and severity of the deficiency. Populations most at risk include individuals with low income and those living in poverty, those who are chronically ill, children, and older adults.

#### Overnutrition

The WHO now includes overnutrition as a form of malnutrition. Overnutrition results from an excessive intake of nutrients, far beyond the body's need. Overnutrition results in excessive weight gain and obesity. Obesity is associated with a BMI of thirty or higher; severe obesity is associated with a BMI of forty or higher. Increasingly, children are experiencing obesity, causing the CDC to develop growth charts for children that extend the BMI-for-age (see [Link to Learning: Pediatric Growth Charts](#)). Obesity affects many aspects of health. It is associated with low socioeconomic conditions and discrimination, as well as mental stress resulting in depression and anxiety. It is a lead indicator for the development of cardiovascular disease, metabolic syndrome, diabetes, and various respiratory and musculoskeletal disorders. The population most at risk includes individuals with low incomes and those living in poverty due to the scarcity of nutritious whole, unprocessed foods. Individuals with sedentary lifestyles are at risk as well.

### Hydration

As shown in [Figure 21.3](#), the human body maintains water homeostasis through a balance of ingestion and

elimination. Most water is ingested by drinking fluids, such as plain water, juices, and caffeinated beverages. Ingested water also comes from food, especially fruits and vegetables. Water that is visible and measurable as it is lost is called sensible fluid loss. Urination is an example of sensible fluid loss. Insensible fluid loss cannot be measured. An example of insensible loss is water vapor lost through breathing. Adequate hydration will balance the water that enters and exits the human body. An imbalance in hydration can lead to either a fluid volume deficit or fluid volume overload. Both of these conditions present problems, but for very different reasons.

**FIGURE 21.3** The human body maintains water homeostasis by ingesting and producing water and eliminating it through a number of processes. Water loss can be increased in dry climates or when a patient has diarrhea. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Dehydration

A fluid volume deficit is called **dehydration**; this occurs with inadequate water intake or excessive water loss or both. Conditions associated with dehydration include vomiting, diarrhea, prolonged fevers, and excessive sweat due to heat stroke. Some neurological conditions can impair the thirst mechanism or impair the ability to swallow, which can lead to poor fluid intake. In some cases, sodium levels are altered. Volume depletion can lead to kidney and cardiac impairment, and severe shock can result. Populations most at risk include infants and children, the chronically ill, and older adults.

### Overhydration

Fluid volume overload, or overhydration, occurs with excess water intake or poor water elimination. These can lead to volume expansion affecting cardiac, respiratory, and kidney function. Impaired elimination of water in the body is a common consequence of chronic disease and is often associated with an alteration in sodium levels. The three chronic conditions that most commonly lead to overhydration are heart failure, kidney failure, and liver failure; pregnancy is another common cause of overhydration. Symptoms of fluid overload include pitting edema, ascites, and dyspnea and crackles from fluid in the lungs. Edema is swelling in dependent tissues due to fluid accumulation in the interstitial spaces. Ascites is fluid retained in the abdomen. Treatment depends on the cause of the fluid retention. Sodium and fluids are typically restricted, and diuretics are often prescribed to eliminate the excess fluid.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety

Competent nurses will employ assessment skills to identify patients in fluid overload and to detect when they are improving or deteriorating. Take the example of Nurse Rita who works at an outpatient wound care clinic. Rita is taking care of 42-year-old Mr. Mahoney who has weekly wound care dressings scheduled for the next six weeks with labs. She has been his nurse for over five years at this same clinic.

Week 1: Blood pressure 110/65, heart rate 72, lungs clear bilaterally, Respirations 12, nonpitting edema on right lower extremity. Sodium 139, Potassium 4.2, Calcium 9.

Patient is calm, cooperative, and considers himself “a funny guy. Rita you are the best nurse here.”

Week 4: Blood pressure 130/75, heart rate 80, fine crackles in bilateral lower lung bases, Respirations 16, 2 + edema on lower extremities. Pt is calm, cooperative and stated “I love your new haircut Rita.”

Week 6: Blood pressure 160/85, heart rate 80, crackles heard in lower and upper lung fields bilaterally, Respirations 32, 3+ edema on lower extremities, clear drainage from right lower leg. Sodium 120, Potassium 3.1, Calcium 9.

Reports not sleeping well at night and using three pillows or sleeping in the recliner. Out of breath all the time. Produces little urine. When Rita asks about how he is sleeping, patient states “Who are you again?”

This patient has had several changes in his assessment. The competent nurse will recognize when a patient’s assessment changes and report these findings to the healthcare team. This patient needed further assessment and interventions at each assessment to prevent further deterioration.

## 21.2 Factors Affecting Nutrition

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the physiological factors affecting nutrition
- Understand the sociocultural, behavioral, and lifestyle factors affecting nutrition
- Examine the psychological factors affecting nutrition

Good nutrition is associated with a high quality of life. This is true for all people, whether young or old, wealthy or poor, athletic or sedentary. Nutrient-rich foods and fluids must be available in adequate amounts to meet the specific metabolic needs of each individual. Meeting these needs is a dynamic process involving the ingestion, digestion, absorption, and metabolism of each nutrient according to its biochemical makeup. There are many factors that influence these biological processes. Some factors have direct, physiological effects on these processes, such as the stage of growth and development or the presence of underlying medical conditions. Some factors have subtler effects, such as cultural or religious influences. The meaning of food and its association with self-image can have psychological effects that influence a person’s relationship to nutrition. This module explores some of the physiological and psychological factors that positively or negatively impact nutritional health.

### Physiological Factors

Nutrition impacts many physiological processes. The physiology of digestion involves the breakdown of foodstuffs

into absorbable nutrients. Digestive processes include mechanical digestion, propulsion, chemical digestion, and absorption (Figure 21.4). The process of breaking down, or metabolizing, nutrients is influenced by many factors, including the following:

- digestive organ function responsible for the breakdown, absorption, and metabolism of nutrients
- kidney function responsible for fluid balance
- cardiovascular function responsible for transportation of nutrients
- endocrine function responsible for the production of hormones that control metabolic processes
- neurocognitive function responsible for perceptions of hunger, satiety, and thirst

Bones, muscles, and sensory organs are all involved in nutrient pathways. In fact, every cell in the body utilizes nutrients. Any process that disrupts the metabolic pathways in the body has the potential to negatively impact nutritional health.

**FIGURE 21.4** There are four phases of digestion, beginning with the ingestion of food and ending with the elimination of waste. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Some physiological factors have a profound effect on metabolic pathways. A person's genetic makeup, stage of growth and development, medications, and underlying medical conditions all directly impact how their body processes nutrients. Other factors, such as environment, socioeconomic conditions, and personal preferences, can directly influence food choice and nutrient availability. Consequently, it is important for the nurse to consider the holistic needs of every patient, including the many factors that influence the nutritional demands on the human body.

### Developmental Level

The human body is engineered to grow and develop through structured, organized, time-sensitive processes. These processes occur naturally within the body and follow predictable patterns for physiological and cognitive maturity. Across a person's life span, nutritional requirements differ based on the unique developmental needs at each stage of development. For example, caloric needs are based on body weight, activity level, and metabolic demands. As growth and development occur, these factors change. For example, in utero body weight is low, but metabolic demands are high. At birth, growth measures, such as head circumference, length, and weight, help identify individual risk for malnutrition. As the child grows, body weight increases, activity levels vary, and metabolic demands continue.

Growth charts are tools for measuring healthy growth trends based on established height and weight norms. At each life stage, developmental markers can be tracked to help with early identification of developmental delays and abnormalities. Timely nursing intervention along the growth and development path can dramatically improve health outcomes and prevent long-term negative health effects associated with early nutritional deficits.

## REAL RN STORIES

---

### Encouraging Diet Modifications in a Family

**Nurse:** Julie, RN

**Clinical setting:** Community clinic

**Years in practice:** 10

**Facility location:** Texas

I remember when I was a student nurse, and we were assigned clinical rotations in the local community clinic. One day a mom came into the clinic to seek care for her 10-year-old. She reported her daughter had been having increased fatigue and was steadily gaining weight over the last year. The mom said, "Last year she was in volleyball and soccer and was so active; now all she wants to do is lay around watching TV and eating junk food. I am concerned she is developing unhealthy habits at an early age."

Upon further assessment, I noticed the girl's diet consisted of excessive amounts of salt, sugar, and fat. I was able to educate the mom how at this age, almost one-fourth of all American children have elevated cholesterol. We also discussed the need for increased vitamin D and calcium. I explained how these are vital requirements as her bones enlarge to prevent osteoporosis later in life. The physician ordered lab work and provided the family a referral to a nutritionist. The family and I discussed activities that sparked their interest in trying them out together, and they verbalized different diet modifications they planned to incorporate immediately. That day I left clinical feeling like I truly made a difference in this young child's life.

---

### Age

If typical growth and development patterns occur, chronological age can predict generalized nutritional needs. Recommended DRIs provide guidelines for nutrient needs across an individual's life span. [Table 21.5](#) provides an example. Note that the recommendations are based on weight (kilograms) and age. Consider the needs of a child versus the needs of an adult. Protein, calories, and calcium are needed in greater amounts as children grow, then level off in adulthood. There are also unique recommendations for older adults, who experience loss of muscle and bone mass and lower activity levels due to declining mobility and thus require fewer calories than their younger counterparts. Older adults also have unique dietary needs due to their higher risk of chronic disease, development of poor dentition, and socioeconomic changes that affect the type and amount of nutrients consumed.

Macronutrient	Age (years)						
	2–3	4–8	9–13	14–18	19–30	31–50	50+
Protein (g)	13	19	34	52	56	56	56
Protein (% kcal)	5–20	10–30	10–30	10–30	10–35	10–35	10–35
Carbohydrate (g)	130	130	130	130	130	130	130
Carbohydrate (%)	45–65	45–65	45–65	45–65	45–65	45–65	45–65
Fat (% kcal)	30–40	25–35	25–35	25–35	20–35	20–35	20–35
Fiber (g)	14	20	25	31	34	31	28

**TABLE 21.5** Comparison of Male Macronutrient Needs: Toddler to Adult (Source: U.S. Department of Agriculture & U.S. Department of Health and Human Services, 2020.)

### Sex

Nutritional needs differ between sexes largely due to hormone differences. A chemical mediator that circulates in the body and has a specific stimulating or inhibiting action on the target organs is called a hormone. [Table 21.6](#) lists some of the hormones that control growth and development, metabolism, adrenal function, and stress. Sex hormones are responsible for the majority of differences between the biological sexes. These differences can result in distinctive caloric and other nutritional needs, particularly beginning in adolescence. For example, females require higher levels of iron during childbearing years due to the hormonal influences of menstruation and pregnancy. Pregnancy also changes caloric needs. More information regarding specific pregnancy-related nutritional needs is provided later in this chapter.

Endocrine Gland	Associated Hormones	Chemical Class	Effect
Pituitary (anterior)	Growth hormone (GH)	Protein	Promotes growth of body tissues
Pituitary (anterior)	Prolactin (PRL)	Peptide	Promotes milk production
Pituitary (anterior)	Thyroid-stimulating hormone (TSH)	Glycoprotein	Stimulates thyroid hormone release
Pituitary (anterior)	Adrenocorticotropic hormone (ACTH)	Peptide	Stimulates hormone release by adrenal cortex
Pituitary (anterior)	Follicle-stimulating hormone (FSH)	Glycoprotein	Stimulates gamete production
Pituitary (anterior)	Luteinizing hormone (LH)	Glycoprotein	Stimulates androgen production by gonads
Pituitary (posterior)	Antidiuretic hormone (ADH)	Peptide	Stimulates water reabsorption by kidneys

**TABLE 21.6** Endocrine Glands and Their Major Hormones

Endocrine Gland	Associated Hormones	Chemical Class	Effect
Pituitary (posterior)	Oxytocin	Peptide	Stimulates uterine contractions during childbirth
Thyroid	Thyroxine (T4), triiodothyronine (T3)	Amine	Stimulates basal metabolic rate
Thyroid	Calcitonin	Peptide	Reduces blood $\text{Ca}^{2+}$ levels
Parathyroid	Parathyroid hormone (PTH)	Peptide	Increases blood $\text{Ca}^{2+}$ levels
Adrenal (cortex)	Aldosterone	Steroid	Increases blood $\text{Na}^+$ levels
Adrenal (cortex)	Cortisol, corticosterone, cortisone	Steroid	Increases blood glucose levels
Adrenal (medulla)	Epinephrine, norepinephrine	Amine	Stimulates fight-or-flight response
Pineal	Melatonin	Amine	Regulates sleep cycles
Pancreas	Insulin	Protein	Reduces blood glucose levels
Pancreas	Glucagon	Protein	Increases blood glucose levels
Testes	Testosterone	Steroid	Stimulates development of sex characteristics including a deeper voice, increased muscle mass, development of body hair, and sperm production
Ovaries	Estrogens and progesterone	Steroid	Stimulates development of sex characteristics including the development of adipose and breast tissue, and prepares the body for childbirth

**TABLE 21.6** Endocrine Glands and Their Major Hormones

### Pregnancy

Nutritional requirements increase during pregnancy and lactation. The growing fetus puts increased nutritional demands on the body. Increased caloric needs require a nutrient-dense diet to maximize nutrition. Prenatal vitamins are advised to meet increased requirements for micronutrients such as iron, folic acid, iodine, choline, and

vitamin D. Optimal nutritional requirements continue during lactation, when the mammary glands produce and release milk for breastfeeding. Increasing intake of pasteurized dairy, eggs, and lean proteins is a healthy way of increasing these nutrients.

### Health Status

An individual's health status is greatly influenced by their overall nutritional status, and vice versa. Individuals in good health experience high levels of well-being and life satisfaction. Healthy people are physically active within their environment and engage in rewarding relationships. Physiologically, good nutrition and hydration balance lead to healthy growth and development patterns. The maintenance of a healthy body weight protects individuals by reducing the risk of chronic disease. Conversely, chronic disease states often present with significant nutritional demands that increase the risk of compromised nutritional health and negative outcomes.

Chronic illness and declining health impact nutritional status in various ways. Some chronic illnesses interfere with an individual's ability to ingest food properly. For example, a child with a cleft palate may have trouble eating enough calories, or an older adult who suffers a stroke may develop dysphagia (difficulty swallowing) and be unable to swallow food. Some chronic illnesses affect absorption of nutrients within the body. A child with cystic fibrosis may develop pancreatic insufficiency and be unable to absorb fats and proteins. Inflammatory bowel disease can result in poor vitamin B12 absorption. Many chronic diseases cause metabolic dysfunction leading to poor utilization of nutrients. Diabetes, Addison disease, and chronic kidney disease are examples of chronic diseases with significant impact on nutrient metabolism and utilization.

Every chronic disease provides a nutritional challenge. Treatment for heart disease includes restrictions on sodium and fat. Increased calcium and vitamin D are needed to treat bone disorders such as osteoporosis. Treatment for gastroesophageal reflux disease includes limiting acidic foods, spicy foods, and alcohol. There is a nutritional aspect associated with the prevention or treatment of nearly every chronic disease. Avoiding excess calories is important to both the prevention and treatment of obesity and heart disease. Controlling fat consumption reduces the risk of obesity, stroke, and heart disease. Adequate fiber in the diet reduces the risk of colon cancer. Good nutrition, as prevention or treatment, leads to better health outcomes.

### Sociocultural, Behavioral, and Lifestyle Factors

Healthy lifestyles are key to wellness and reduction of chronic disease. However, lifestyles are strongly influenced by sociocultural factors that differ for different people. Culture, religion, and economic status play a significant role in food preferences and often give food and mealtimes meaning beyond the ingestion of nutrients. Environmental factors influence availability and quality of food and water. Unhealthy behaviors, such as alcohol and substance abuse, directly influence nutritional status. Many people rely on supplements to counteract the ill effects of unhealthy lifestyles and perceived nutritional deficits. In this section, we briefly explore how these sociocultural factors can influence overall nutritional health.

#### Culture

Cultural competence is a hallmark of patient-centered care. Culture describes the unique patterns of behavior and thought belonging to an identified group or organization. Nutrition and dietary patterns are often an integral part of cultural identity. The United States is home to a vast number of cultures. Cultural beliefs affect types of food eaten and when they are eaten. Some foods may be restricted due to beliefs or religious rituals, whereas other foods may be viewed as part of the healing process or have significant meaning to the celebrations of life. It is essential to consider cultural food preferences when planning nursing care and encourage healthy habits within the context of these foods.

## CULTURAL CONTEXT

---

### Cultural Variations

Cultural and religious beliefs often influence food selection and food intake. It is important for nurses to conduct a thorough patient assessment, including food preferences, to ensure adequate nutritional intake during hospitalization. Every culture has variations that make them unique, yet there are also similarities among many. Although a certain dish or ingredient might have originated in one country or culture, global trade has transported

fruits, vegetables, and culinary practices to the entire world. For this reason, nurses must never make assumptions about their patients' diet based on culture or ethnicity. Instead, ask every patient about their food preferences and offer as many healthy choices as possible.

---

### Religion

Religious practices can influence nutritional intake, often due to restrictions in specific foods or meal preparation. Both Jewish and Muslim laws prohibit the consumption of pork products, and Hindu scriptures promote a vegetarian diet. Restrictions may vary even within a given religion as people practice varying degrees of strictness to dietary doctrines. Some individuals may observe food restrictions in association with specific religious celebrations. For example, Catholics may observe dietary restrictions during Lent, while practicing Muslims may fast during Ramadan. Food preparation can also be influenced by religious beliefs. Some Jewish people observe Kosher laws which govern the preparation of certain foods (e.g., beef), the prohibition of certain foods (e.g., pork and gelatin), or the combination of some food (e.g., beef served with dairy products), while some Muslim people observe Halal (the Arabic word meaning "permissible" or "lawful") which restricts the consumption of pork, alcohol, and blood products, and calls for minimal suffering when preparing animal products. Religious practices and beliefs can be complex. It is important to support the nutritional goals of the individual patient by understanding and respecting the religious dietary practices of every patient.

### Economic Status

Economic status refers to a combination of economic and social indicators that describe an individual's overall scale of wealth and status. Factors that contribute to economic status include income, educational level, occupation, and place of residence. Economic status predicts a person's ability to obtain nutritious food on a routine basis. Individuals with lower incomes have less means to obtain and prepare nutritious foods. Some individuals may live in a **food desert**: a geographical area where fresh produce and foodstuffs are either too expensive or unavailable. Federal supplemental assistance programs are available to help meet the nutritional needs of underserved and marginalized low-income populations. These include the Supplemental Nutrition Assistance Program (SNAP) and the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC). There are also private organizations such as Meals on Wheels America. Individuals with higher incomes are not immune from nutrition concerns. Excess calories and intake of nutrient-poor foods can lead to obesity and other metabolic disorders due to easy access to food, especially fast food.

### LINK TO LEARNING

---

The USDA developed a [Food Access Research Atlas \(https://openstax.org/r/77foodaccess\)](https://openstax.org/r/77foodaccess) to show how food access varies for certain subpopulations in the United States. It can be used for research or community planning to increase supermarket access.

---

### Environment

Community environments have a large impact on nutritional health. As stated earlier, food deserts can create areas of food insecurity among at-risk populations. This has its greatest impact on infants, children, and older adults, who are often dependent on others for meal preparation and shopping. Urbanization and industrial effects can have detrimental consequences on clean water supplies and spaces for meal preparation. War zones and refugee camps often deal with undernutrition and lack of access to safe, quality food and water.

Along with geographical environments, family structures within communities have a profound effect on nutritional status. People in a state of **food insecurity** have limited access to adequate food, typically due to economic or social factors. People experiencing the uncertainty of food insecurity or family discord find it difficult to maintain healthy eating routines. School lunch programs are a helpful resource to families in low-income neighborhoods. Older adults often experience isolation, which leads to poor nutrition habits and negative health trends. As patient advocates, nurses must gain understanding of federal and local nutrition assistance programs and implement timely referrals for their at-risk patients.

## LINK TO LEARNING

---

Older adults can be an at-risk population. Medicare is a federal program that provides access to health care for older adults, but it is not meant to meet physiological needs such as food. Unfortunately, food insecurity is a significant problem among older adults. Read the [USDA's Nutrition Programs for Seniors \(https://openstax.org/r/77nutritionprog\)](https://openstax.org/r/77nutritionprog) and review the various programs in place to address food insecurity in the older adult population. Research one of the programs and consider how it could be incorporated into a nutrition teaching plan for an older adult.

---

### Alcohol Use

Because alcohol is high in calories and low in nutrient value, it can negatively impact nutritional health even when consumed in acceptable levels. The use of alcohol can increase the risk of chronic disease and injury. Alcohol consumption is linked to elevated triglycerides. Excessive use of alcohol can lead to chronic nutrient deficiencies due to poor absorption of nutrients, fluid imbalance, gastrointestinal disorders, and liver disease. According to Healthy People 2030, binge drinking (consuming four or more drinks per day for females or five or more drinks per day for males) is a significant problem in the United States (CDC, 2022). The USDA recommends that males limit consumption to two drinks per day and females to one drink per day.

### Overuse of Supplements

Supplementation of macronutrients and micronutrients has become increasingly popular due in part to marketing and fitness claims as well as easy access to over-the-counter supplements. Supplements are pills, capsules, and liquids that contain vitamins, minerals, amino acids, or other nutrients. The U.S. government does not require manufacturers of dietary supplements to prove their safety or efficacy, and thus the industry is poorly regulated. Even when supplements are accurately labeled and safely produced, their overuse can lead to toxicities, particularly in fat-soluble vitamins such as vitamin A and vitamin D. Large doses of vitamin C, vitamin B6, and niacin can also lead to toxicities. Performance-enhancing dietary supplements contain amino acids that in excess can cause liver and kidney impairment. It is important for nurses to be familiar with the RDI, RDA, and other standard nutrient recommendations and know how to assess for potential toxicities in patients taking supplements.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Evidence-Based Practice (EBP)

**Definition:** Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.

**Knowledge:** Explain the role of evidence in determining best clinical practice

**Action:** It is important for the nurse to ask the patient about any over-the-counter supplements they may be taking. Many patients do not realize that certain supplements can interact with prescription medication or that too much supplement can cause toxicity. Completing a comprehensive health assessment ensures the nurse is providing evidence-based practice.

---

### Medications

Some medications enhance metabolic processes and impact nutritional status in a variety of ways. For example, exogenous insulin brings needed glucose into body cells. Antiglycemic medications, such as sulfonylureas and biguanides, assist in improving insulin sensitivity, thus improving utilization of blood glucose by the cells in the body. Thyroid hormone maintains thyroid function, which sets the body's metabolic rate. Other medications affect gastric function by lowering levels of acid production. Still other medications, such as psyllium and glycolax, alter absorption of nutrients and water in the gut. Statin drugs lower lipids levels. It is important to know how medications are used within the body and how they directly influence metabolic processes.

Many medications have an indirect effect on nutritional status. For example, diuretics are used to increase elimination of water and thus will affect body water levels as well as sodium and potassium balance. Medications

with gastric upset as a side effect can decrease nutrient intake and absorption. Some psychotropic medications interfere with appetite, leading to either weight gain or weight loss, depending on the drug. Nurses must be familiar with the side effects of all drugs administered to patients under their care, anticipating long-term effects on nutritional status.

Some nutrients interfere with the mechanism of action of different drugs. For example, vitamin K, found in green leafy vegetables, can decrease the effectiveness of some anticoagulants. In contrast, some drugs should be taken with food to increase absorption. For example, vitamin C improves the absorption of iron. The pharmacokinetics of a drug—the study of the drug’s absorption, metabolism, and distribution within the body—determine the probability of a food-drug interaction. Food and drug interactions can cause deficiencies or toxicities depending on the drug and the food. Nurses must always review administration requirements for each drug, noting whether the drug should be taken with or without food.

## PATIENT CONVERSATIONS

---

### Educating a Patient About Medications Before Discharge

**Scenario:** The nurse is discharging his patient and reviewing the discharge paperwork with her. He notices that the patient is prescribed warfarin, a new medication that she will have to continue to take at home after discharge.

**Nurse:** Okay, Ms. Embiid, while in the hospital you’ve been taking warfarin. Do you know why you were taking this?

**Patient:** Oh, yes. It’s to keep my blood from forming a clot, right?

**Nurse:** That’s right. You’ll have to continue to take this medication at home, and follow up with your doctor in two weeks. Do you know how to take this medication?

**Patient:** Well, I’ve been taking it at night here, so I guess I’ll take it at night at home, too.

**Nurse:** That’s right. The best way to take this medication is to take it at the same time every night. It’s also very important to avoid cranberry juice and grapefruit juice and try to maintain the same level of vitamin K consumption every week.

**Patient:** Really? Why?

**Nurse:** Certain foods, such as cranberries and grapefruit, can actually increase the levels of warfarin absorbed by your body. High doses of vitamin K, found in green leafy vegetables, can decrease the effectiveness of warfarin. It’s very important to maintain a consistent diet and not make any major changes without checking with your doctor.

**Patient:** Thanks for letting me know! I’ll be sure to monitor what I eat while on warfarin.

---

## Psychological Factors

Physiological factors, such as growth and development, health status, and medication use, have a direct effect on nutritional status within the body. Psychological factors can influence nutritional status as well. Emotional well-being is often closely associated with food preferences and intake. Self-image impacts nutritional well-being. Cultural trends in beauty and health provide context for self-image and give meaning to food and dietary traditions. Conversely, overall nutrition can have a significant impact on psychological well-being.

### Food Meaning

Nutrition is a basic necessity of life. Maslow’s hierarchy of needs ([Figure 4.5](#)) lists food as an essential physiological need. It is important to note, however, that food consumption is highly influenced by cultural and environmental factors that have a profound effect on psychological well-being. Thus, food to most people is more than a nutrient. Food is tied to family traditions and celebrations in life. Americans traditionally celebrate Thanksgiving with turkey and pumpkin pie. Many Italian Americans celebrate the Feast of Seven Fishes on Christmas Eve, and Jewish tradition serves challah bread at the Sabbath and potato latkes at Hanukkah. Similarly, vegans avoid meat and other animal products due to personal beliefs related to animal cruelty and exploitation. Many cultures have food traditions that transcend nutritional science, giving food meaning beyond its chemical composition.

Emotional responses are invoked when food meaning goes beyond mere nutrition. Most celebrations that involve food evoke feelings of comfort, happiness, and belonging. Memories, both good and bad, are often tied to the sight and smell of specific foods. Associations with sadness and grief can lead to food aversions, while foods tied to comfort can lead to food excesses as the desire to re-create moments of comfort and celebration override judgment. This can lead to binge eating and obesity. It is important for nurses to identify and reinforce healthy patterns of eating and recognize nutritional risks related to emotional eating habits.

### Self-Image

Nutritional status is tied to weight trends, weight trends are tied to body image, and body image is tied to self-image. A person's **body image** is the perception that person has about their physical body, including any feelings associated with that perception, whereas self-image is broader, encompassing feelings about one's whole self. Individuals who maintain a healthy body weight are more likely to have a positive self-image—particularly given cultural norms, reinforced by media, that stigmatize bodies perceived to be over- or underweight. Distorted perceptions of body image can lead to severe eating disorders, such as anorexia nervosa and bulimia.

### Depression

As stated earlier, food often evokes an emotional response. It can provide feelings of comfort and belonging or feelings of sadness and grief. It is easy for food to become an emotional outlet for psychological discomfort, especially when the foods consumed promote feelings of comfort and belonging. Emotional eating is common among individuals who are depressed or stressed as they seek emotional responses they find lacking elsewhere in their life. The consumption of “comfort foods” is an emotional response to stress and is common among most individuals. When the dietary pattern includes a high degree of emotional eating, negative outcomes, such as binge eating and overeating that leads to obesity, are more likely to occur. It is important to assess the underlying emotional state of individuals experiencing nutritional impairment. A holistic approach to nursing care is needed.

## 21.3 Specialized Diets

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine the standard dietary recommendations for optimal health
- Recognize specific therapeutic diets for diseases or conditions
- Describe consistency modification diets
- Identify what enteral nutrition is and how to administer it
- Understand what parenteral nutrition is and how to administer it

Sometimes dietary intake must be adapted to meet individual nutrient needs. This may include restricting or increasing specific nutrients in the diet. It may also include modifying the consistency of the food when there is impaired swallowing or a need to give rest to the digestive tract. Sometimes nutrition must be administered via alternate means, such as directly into the stomach or via a central line. Nurses must be skilled in identifying, implementing, and evaluating therapeutic diets of all types across a person's life span and in both acute and chronic settings.

### Standard Dietary Recommendations

Good nutrition is essential to healthy living. A healthy diet is key to obtaining optimal nutrition. Holistic nursing care includes routinely assessing a patient's nutritional status and providing the patient with sound instruction and coaching regarding their dietary needs for optimal nutrition intake. This should occur in all patient care settings. Whether the patient maintains a healthy lifestyle, partakes in unhealthy dietary habits, or has a chronic illness that requires a specialized diet, nutritional health promotion must be made available to all patients. It is essential that nurses understand nutritional principles and be skilled in teaching healthy dietary habits. This section reviews the standards for a healthy diet and discusses MyPlate, an eating strategy designed by the Center for Nutrition Policy and Promotion at the USDA to simplify and standardize dietary eating patterns. Food labels and food safety concerns are also discussed.

### Standards for a Healthy Diet

A healthy diet is one that meets the daily recommended intake for macronutrients and micronutrients. Based on the Healthy Eating Index, the USDA recommends the following pattern for dietary intake:

- carbohydrates: 50 to 60 percent of calories per day with less than 10 percent added sugars
- fat: 20 to 30 percent of calories per day with less than 10 percent saturated fat
- protein: 10 to 20 percent of calories per day
- fiber: 25 grams per day
- fluids: 2.5 liters per day

The USDA recommends daily allowances for sodium, calcium, and vitamins D and B12 as well. A healthy diet must take into consideration individual caloric needs. Caloric needs are based on biological sex, age, and activity level. Some diets require strict adherence to the USDA recommendations, including calorie counting; however, the average patient will benefit from teaching related to general principles. Here are some general guidelines for healthy eating:

- Eat a variety of foods, including plenty of vegetables, fruits, and whole grains.
- Choose healthy proteins such as lean meats, fish, poultry, low-fat dairy products, and legumes.
- Drink plenty of water.
- Limit salt, alcohol, saturated and trans fats, and added sugar.
- Eat whole foods as much as possible and avoid highly processed foods.

A healthy diet prioritizes the consumption of sufficient amounts of vegetables and fruits on a daily basis. Vegetables and fruits should be eaten whole whenever possible. There are different categories of vegetables: dark green, red and orange, beans, nuts and seeds (legumes), and starches such as potatoes and cassava. Fruits may be fresh or frozen, canned, or dried. It is best to limit fruit juices, which may be high in calories.

Whole grains are an important part of a healthy diet; they include products made from wheat, rice, or oats that have not been refined. Refined grains, such as white rice and white flour, are grain kernels that have been processed to remove the bran and germ covering of the grain. This refining process removes important nutrients, such as fiber, iron, and vitamins. Whole grains use the entire grain kernel and are more nutritious than refined grains.

Foods that are high in protein include animal products such as seafood, beef, poultry, and eggs, as well as plant-based foods such as beans, peas, seeds, and nuts. Protein choices should be lean and varied. Dairy is a good source of protein, vitamins, and minerals, but low-fat versions of milk, yogurt, and cheese are typically healthier choices. Fats should be limited to 20 to 30 percent of calories, with strict limits on saturated fats. Oils are liquid fats that provide important nutrients. Oils are classified as unsaturated, polyunsaturated, or saturated. A healthy diet will include unsaturated or polyunsaturated fats and limit saturated fats.

Dietary teaching for everyone should focus on developing consistent eating patterns that include healthy amounts of carbohydrates, proteins, fats, and plenty of fresh water. A healthy diet should limit added sugars, saturated fats, sodium, and alcohol. Due to the variety of foods available, dietary choices can easily be adapted to meet cultural, religious, or budgetary preferences.

### **MyPlate**

MyPlate ([Figure 21.5](#)) is a dietary tool developed by the USDA to help individuals maintain healthy eating patterns throughout life. MyPlate uses a 9-inch plate as a visual tool for meeting the USDA's general guidelines. Using the MyPlate method, vegetables and fruits make up half the plate, grains make up roughly a quarter of the plate, and proteins make up the final quarter. A serving of low-fat dairy is included as well. A personalized MyPlate plan is based on age, sex, height, weight, and activity level. The MyPlate website and MyPlate app are available to identify calorie needs and provide simple planning recommendations based on individual needs.

USDA Food and Nutrition Service  
U.S. DEPARTMENT OF AGRICULTURE

# Start simple with MyPlate

Healthy eating is important at every life stage,  
with benefits that add up over time, bite by bite. Small changes matter.

Make half your plate fruits and vegetables.

Focus on whole fruits.

Vary your veggies.

Choose foods and beverages with less added sugars, saturated fat, and sodium.

Limit

Move to low-fat or fat-free dairy milk or yogurt (or lactose-free dairy or fortified soy versions).

Make half your grains whole grains.

Vary your protein routine.

Being active can help you prevent disease and manage your weight.

Activity

## LINK TO LEARNING

Go to the [MyPlate website \(https://openstax.org/r/77myplate2\)](https://openstax.org/r/77myplate2) and explore the USDA’s recommendations for a nutritious diet.

### Food Labeling

Scientists and government agencies have developed food labels to improve decision-making regarding nutrition intake. The USDA Dietary Guidelines provide recommended daily intakes based on DRIs for macronutrients, micronutrients, and fiber. Food labels report the recommended daily allowances for specific nutrients as a percent daily value per serving. A serving is not a regulated amount but rather a typical volume of food consumed. Food labels always identify the number of servings per container, the number of calories per serving, and the percent daily value per serving for specific nutrients.

## LIFE-STAGE CONTEXT

### Poor Vision and Reading Labels

The food label is a tool used to educate the public about the nutritional value of a product, but what if a person cannot read the label? It is important to remember that people often develop poor vision as they age. As nurses, we should assess our patients’ vision using a Snellen chart to determine the need for a referral for further investigation by an ophthalmologist. We can educate our patients on the use of a handheld magnifier to enhance the print of

nutritional labels. We can also encourage them to use the online Myplate.org feature to predetermine which foods to purchase before shopping. Many of the healthier foods such as whole fruits, vegetables, and pure animal protein do not require food labels.

Sometimes, manufacturers will choose to include daily values per container. Labels must include, but are not limited to, the following nutrients: carbohydrates, calcium, iron, potassium, vitamin D, fat, and protein. Fats are broken down into total fat, percent saturated fat, and cholesterol. Carbohydrates are broken down into total carbohydrates, fiber, total sugar, and added sugar. In general, a serving with a percent daily value of 5 percent or less for a nutrient is considered to have a low nutrient value. A serving with a percent daily value of 20 percent or more is considered to have a high nutrient value. A law passed in 2016 required food manufacturers to update their labels. [Figure 21.6](#) details the changes.

**FIGURE 21.6** Updated food labels now list added sugars and potassium, clarify the meaning of percent daily value, and have been reformatted to improve readability. (credit: modification of work "What's on the Nutrition Facts Label?" by U.S. Food and Drug Administration, Public Domain)

## LINK TO LEARNING

Food labels have become more sophisticated over the years, incorporating nutrition science in a way that is more relevant and easily accessible. Information on [how to understand and use the Nutrition Facts label](https://openstax.org/r/77nutrifacts) (<https://openstax.org/r/77nutrifacts>) is provided by the USDA.

### Food Safety

Food safety is an important part of healthy living. The goal of food safety is to prevent foodborne illnesses such as bacterial infections. The following organisms are the cause of most foodborne infections: *Campylobacter*, *Salmonella*, and *Escherichia coli*. Symptoms common to these infections are nausea, vomiting, diarrhea, abdominal pain, and fever. Public health departments have foodborne surveillance programs that include a national reporting system to track outbreaks. *Salmonella*, *Shigella*, and *Listeria* are organisms commonly included in the national reporting system. *Shigella* is a highly contagious intestinal infection. *Listeria* is caused by improper processing or pasteurization and is most harmful to individuals who are pregnant, older, or immunocompromised. Surveillance

helps track infections and identify outbreaks for public health intervention.

Prevention is key to food safety and reducing the effects of foodborne illness. Whether food is being prepared in the home, a restaurant, or an institution, the same four principles of food safety apply:

1. Keep hands, utensils, and surfaces clean.
2. Separate raw meat, seafood, and eggs from other foods.
3. Cook foods to the appropriate internal temperature.
4. Chill cooked foods within two hours.

Healthy food practices are essential to good health. Nurses should reinforce these prevention strategies by encouraging good hygiene and appropriate food handling practices and providing resources for patient education.

## LINK TO LEARNING

Maintaining safe practices for handling and cooking food is vital for good health. Review the [recommendations for food safety \(https://openstax.org/r/77foodsaferecs\)](https://openstax.org/r/77foodsaferecs) provided by the CDC. What strategies would you advise for counseling patients about safe eating practices?

## Therapeutic Specific Diets

Standard dietary recommendations guide individuals to make nutritious choices, maintain a healthy weight, and reduce the risk of chronic disease. The development of chronic disease affects nutritional goals and complicates nutritional intake. For example, individuals who develop diabetes or heart disease have new nutrient demands depending on the severity of the disease. Someone with diabetes may be advised to maintain stricter calorie or carbohydrate goals, while someone with heart disease will be encouraged to pursue a low-fat, low-sodium dietary pattern. Physiological conditions, such as stroke and reflux disease, can result in difficulty swallowing (dysphagia), requiring changes in food texture. Some disease states and medications can impair nutrient absorption, requiring supplementation of nutrients. Many chronic diseases include specialized diets in the treatment plan. It is important for nurses to know the differences between these diets, know why the specialized diets are ordered, and work closely with dietitians and the clinical team to ensure optimal nutrition outcomes.

### Consistent Carbohydrate Diet

Carbohydrates are often misunderstood. Many people limit carbohydrates as a means of calorie control, yet both simple and complex carbohydrates are healthy and important nutrients. There are conditions under which carbohydrates must be controlled, however. An example of a diet focused on carbohydrate control is the consistent carbohydrate diet, which is recommended as a treatment for diabetes. Diabetes is a metabolic disorder affecting the utilization of glucose by the body cells. Poor glucose utilization can lead to acute acid-base disturbances and chronic effects including immune dysfunction, cardiovascular disease, and neurovascular changes. The negative effects of diabetes can best be prevented by effective blood sugar control.

The consistent carbohydrate diet maintains the recommended amount of carbohydrates per day (40 to 60 percent of the diet) but is designed to meet metabolic goals through the consumption of consistent carbohydrates at each meal. This consistency spreads out the carbohydrates over all daily meals with the goal of maintaining steady glycemic control throughout the day, avoiding hypoglycemic and hyperglycemic blood glucose swings. This mimics the healthy body's natural tendency toward glucose control and insulin release. The consistent carbohydrate diet limits the use of added sugars and encourages healthy carbohydrate choices at each meal. The emphasis is on controlling carbohydrates rather than calories. This diet supports healthy dietary patterns for all individuals, encouraging regular consumption of whole grains, whole fruits and vegetables, and low-fat dairy products, and avoiding added sugars and refined and processed foods.

### Fat-Restricted Diet

Twenty to 30 percent of a healthy diet should include fat, an essential, energy-dense macronutrient. Unfortunately, not all fat is considered “good” fat. In general, individuals eating a healthy diet should limit saturated fat to 10 percent of calories consumed. Most saturated fat comes from animal proteins. Because fat is associated with increased risk of obesity, heart disease, hypertension, and stroke, individual treatment plans may include fat-

restricted diets to limit risk or decrease disease progression.

Fat-restricted diets adhere to the same USDA recommendations for a healthy diet, which is to consume between 20 and 30 percent of calories as fat but limit the types of fat consumed by avoiding saturated and trans fats. Saturated fat is typically solid at room temperature and is high in cholesterol. High-fat meats, butter, whole milk products, and coconut oil are common saturated fats. Trans fats are artificially produced by a process called hydrogenation. Partially hydrogenated fats are found in processed foods such as cookies, crackers, and margarine spreads. For patients with heart disease or at risk for developing heart disease, the American Heart Association recommends eliminating trans fats and limiting saturated fats to 5 to 6 percent of calories consumed, which is significantly lower than the dietary standard of 10 percent. Substituting more monounsaturated and polyunsaturated fats, such as canola, olive, and corn oils, is a healthy way to obtain needed fat in the diet while reducing the risk associated with “bad” fats.

### High-Fiber Diet

Dietary fiber is a type of carbohydrate that adds bulk to aid in digestion. Fiber is found in plant foods and is categorized as soluble or insoluble. A high-fiber diet is recommended for most individuals, as it improves digestive health, aids in weight control, and reduces the risk of colon cancer and other intestinal disorders. Foods high in fiber include whole fruits and vegetables, whole grains, and legumes. High-fiber foods are known to decrease risk of gastrointestinal disorders, cardiovascular disease, and many metabolic disorders and should be included in all healthy diet routines.

### Low-Fiber Diet

There are a few conditions that contraindicate a high-fiber diet. Limiting the fibrous content of foods eases digestion. Medical conditions that require periods of gastrointestinal rest benefit from a short-term reduction in fiber intake. Gastrointestinal rest allows for limited stimulation and processing in the intestinal tract, and a low-fiber diet is often included in the treatment plan. Eggs, creamy nut butters, low-fiber whole grain cereals, vegetable and fruit juices, applesauce, and canned fruits and vegetables can be included in a low-fiber diet. This diet should avoid all raw or undercooked vegetables, whole grains, nuts, seeds, and fibrous meats. A low-fiber diet is often used following intestinal surgeries or radiation treatments to the abdomen. Fiber should be slowly added back into the diet as digestive health returns.

### Sodium Restriction Diet

The general population should limit sodium intake to less than 2,300 mg/day. Sodium is an essential element needed for many basic physiological processes. Sodium aids in food processing as a flavor enhancer, a curing agent and preservative, and a thickening agent. It also helps regulate the moisture content of food. Because of its versatility, many processed foods are high in sodium content. Unfortunately, high sodium levels increase the risk of cardiovascular disease and hypertension and negatively impact fluid balance within the body. Therefore, sodium-restricted diets are commonly prescribed for individuals with heart disease or at risk for heart disease and chronic fluid retention.

The first step in maintaining a low-sodium diet is to eliminate processed foods from the diet. Eating whole, natural foods keeps the diet naturally low in sodium. Next, all food labels should be carefully monitored for sodium content. Products with less than 200 mg per serving are healthy choices for this diet. Eating a diet high in fresh fruits and vegetables and fresh lean meats, reading food labels, and substituting herbs and spices for added salt are important ways to maintain a low-sodium diet and manage health risks.

### Kidney Diet

The kidneys regulate fluid and electrolyte balance in the body. The kidneys are made up of nephrons, which filter the blood to produce urine. A kidney diet is prescribed when kidney function becomes chronically impaired and restricting certain nutrients is necessary to preserve kidney function. Foods high in protein, sodium, and potassium are limited in a kidney diet. Protein metabolism leads to waste products that must be filtered by the kidneys; therefore, a kidney diet will limit protein (animal or plant based) to small portions (2–3 oz). Because water follows sodium in the body, high sodium in the blood can lead to excess fluid volume and increased blood pressure. Because high blood pressure adversely impacts the function of delicate nephrons, sodium restrictions are placed to help preserve kidney function. With advanced kidney disease, phosphorous and potassium are also restricted. While most people on a kidney diet should have 2,000 mL intake of fluid daily, in advanced disease fluid may be restricted

even further based on individual need. Routine lab work is required to monitor kidney function, fluid status, and electrolytes.

### High-Calorie, High-Protein Diet

A high-calorie, high-protein diet may be prescribed when there is a need for extra nutrition to aid healing. Individuals with extensive burns or poor healing wounds may be placed on a diet rich in quality proteins, providing needed energy and nutrients to speed healing and tissue repair. This diet minimizes carbohydrate intake and increases protein intake. Proteins with high amounts of saturated fats should be avoided. Egg whites, fish, fowl, dairy, and legumes are excellent protein choices. Avocados, cheese, nuts, and dried fruit make excellent calorie-dense snack choices. Weight trends must be closely monitored; also, because high protein levels can negatively impact kidney function, kidney labs must be routinely followed.

### Consistency Modification Diets

Some diets are designed to alter the texture and consistency of foods rather than the nutritional content. Anatomical abnormalities, such as cleft palates, may prevent normal mastication. Neurological dysfunction can impede swallow reflexes. Gastroesophageal reflux disease can cause esophageal strictures that can cause dysphagia (difficulty swallowing). These conditions often require changes in food texture to improve nutritional access and decrease the risk of aspiration of food particles into the lungs. Typically, a speech pathologist will make recommendations to the clinical team regarding the need for modified diets based on the results of swallow studies. Nurses must collaborate with the whole clinical team, as they are responsible for managing the dietary intake of patients on modified diets. It is essential to understand, maintain, and monitor outcomes for all patients on modified diets.

### Liquid Diet

Liquid diets are used to meet short-term clinical goals. Liquids are classified by the consistency of the fluid. Clear liquids melt to a transparent fluid that contains no pulp. A full liquid is a fluid that contains sufficient residue but still maintains a fluid form. Sometimes the consistency of liquids is restricted based on viscosity. Liquid diets are implemented for a variety of reasons and are often an essential part of the treatment plan.

#### Clear Liquid

A clear liquid diet is often used as short-term treatment with specific clinical goals. Clear liquids are necessary before and after certain medical procedures (including after surgery) and for patients who need to rest their bowels or replace fluid and electrolytes, for example, due to severe diarrhea. This is not a diet that can be maintained long term because it has little nutritional value. A clear liquid diet includes transparent liquids with minimal residue. This includes broths, tea, clear juices, clear gelatin, popsicles, and sport drinks. The liquids cannot contain any pulp or substance.

Clear liquids can be thickened to improve the consistency for individuals who aspirate on thin liquids. A thickening agent is added to the clear liquid to increase the viscosity, allowing for the thickened liquids to move more slowly and improve swallowing. The viscosity can be varied as needed. Common consistencies include nectar thick, honey thick, or pudding thick. Nurses often collaborate with speech pathologists when thickened liquids are being considered.

#### Full Liquid

A full liquid diet contains residue and is not transparent. It includes foods that become liquid at room temperature. While it contains a sufficient amount of nutrition, it can be difficult to meet daily nutritional needs and should only be used short term. Full liquid diets include cream soups, ice cream, pudding, and juices with pulp. A full liquid diet is part of the treatment plan when restarting oral feeding following a period of enteral or parenteral feeding or for short-term care when a patient is unable to tolerate a mechanical soft diet.

### Soft Diets

Soft diets are diets in which the consistency and texture of the food are manipulated to improve swallowing or digestion. These diets typically contain lower fiber (less than 2 grams per serving) and a soft texture. They exclude fibrous meats, raw vegetables and fruits, beans, shellfish, and whole grains. The texture is dependent on the specific impairment. Soft diets are often used for patients with some degree of dysphagia or for postsurgical care.

### Mechanical Soft

A mechanical soft diet is most often used with individuals who have a chewing or swallowing deficit. This is commonly seen in patients with dysphagia or dental impairment. The food is processed to a soft texture. Vegetables and meats should be tender, well cooked, and chopped or ground to the texture of mashed potatoes. Eggs, white rice and pasta, applesauce, and dairy products work well in a mechanical soft diet. Teaching patients to chew slowly and thoroughly and to ingest frequent small meals is helpful.

### Pureed Diet

Pureed diets are processed to a smooth liquid consistency. Unlike a full liquid diet, pureed foods can come from a variety of sources, though it is best to avoid nuts and raw fruits and vegetables. It is best to puree foods separately. A pureed diet is prescribed for patients with an inability to chew and for some types of dysphagia. It is typically used for a short-term period following acute illness or injury but may be used for the long term when dysphagia cannot be resolved or when frailty or dementia limit nutritional intake at the end of life.

### Enteral Nutrition

An alternate form of nutrition, **enteral nutrition**, utilizes a tube or catheter for administration. Enteral feedings are liquid and come in a variety of formulas to meet specific needs. These feedings are prescribed for individuals who have lost the ability to ingest food orally but who otherwise have a functioning digestive tract, capable of absorption and digestion of nutrients. Enteral nutrition typically has two routes of administration: nasogastric (NG) tube and percutaneous enteral gastrostomy (PEG) tube. Care of the patient on enteral feedings requires the expertise of an interdisciplinary team. Nurses are integral members of the enteral nutrition team and must be skilled in the administration, management, and evaluation of nutritional status when enteral nutrition is prescribed. [Figure 21.7](#) shows the different access points for enteral tubes.

**FIGURE 21.7** An enteral tube can access the digestive system via the nose or the abdomen. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Nasogastric and Orogastric Tubes

NG tubes are sometimes placed when food cannot be safely ingested. They are utilized for the short term only, typically less than four weeks. The NG tube is a single- or double-lumen tube that is passed through the nares, pharynx, and esophagus and into the stomach; it can be used for suctioning stomach contents and administering medications in addition to providing enteral nutrition. Orogastric (OG) tubes work in the same manner except they are inserted through the mouth into the esophagus and then into the stomach. OG tubes are typically used with mechanically intubated and sedated patients and should never be used in conscious patients because they can induce a gag reflex and cause vomiting.

### Percutaneous Enteral Gastrostomy Tube

A PEG tube is placed directly through the abdominal wall via endoscopy. The PEG tube is placed in the stomach for direct administration of formula feeds and medications. In some situations, the tube can be advanced through the gastric pouch into the proximal part of the small intestine (jejunostomy). PEG tubes and jejunostomies are utilized when alternative nutrition is needed long term. PEG tubes may also be used when there is an obstruction to the esophagus, or the esophagus has been removed. Percutaneous endoscopic jejunostomy (PEJ) tubes are inserted through the abdominal wall directly into the jejunum, bypassing the esophagus and stomach. PEJ tubes are used when all or part of the stomach has been removed or if the provider determines PEJ placement would best suit the patient's needs.

### Nursing Considerations for Administration

Nursing considerations for enteral nutrition involve management of care concerning placement and maintenance of the tube, administration of formula feeds and medications, and prevention and monitoring of complications. Care is dependent on the type of tube being used and the underlying medical conditions of the patient.

## REAL RN STORIES

---

### Communicating about NG Tube Insertion

**Nurse:** Rosa, BSN

**Clinical setting:** ICU

**Years in practice:** 1

**Facility location:** Vermont

I was caring for a patient who had been in an automobile accident where he sustained multiple injuries all over his body, including an injury to his mouth and jaw. His eyes were swollen shut, and he was rarely conscious. The last nurse attempted to insert the NG tube twice, but both times, Mr. Zhu resisted by twisting and turning his head and pulling it out with his hands. During report, my supervisor told me that in order to insert the tube, I might need to increase Mr. Zhu's sedation or request for an order for wrist restraints. I considered all of these options and decided to try another way. I gathered the supplies and approached Mr. Zhu's room. I knocked on the door and began talking to Mr. Zhu, even though he seemed unconscious and unaware of my presence. I told him who I was and why I was there, and I let him know where I was going to touch him to do his assessment and care. Then, I explained that he had an injury to his mouth and jaw. These injuries meant that he could not chew his food or have anything in his mouth for a while. In order to give him nutrition, he needed a tube from his nose to his stomach. This was better for him than any other option right now. I told him it would be uncomfortable but quick. Mr. Zhu did not move or indicate understanding of what I told him. However, when I began to insert the NG tube, it went in smoothly, and Mr. Zhu did not resist. Once I was finished, I thanked Mr. Zhu and told him that I had secured the tube so that it would not be pulled out and he would not have to have it reinserted again. I thanked him again and exited the room.

---

An NG tube can be placed by a nurse but requires a clinician's order. Once placed, the NG tube is anchored to the nose or cheek, and the length of the external tubing is documented. Placement must be verified via x-ray imaging prior to use. A PEG tube or jejunostomy is placed by a physician via endoscopic procedure. Placement is also verified by x-ray imaging prior to use. The placement of NG and PEG tubes must be verified prior to every subsequent use, per facility protocol. The tubing is monitored for migration every shift and with every use. If placement of the tube is in question, gastric contents can be aspirated and their pH tested for appropriate acidity. Follow-up x-rays can be ordered for reevaluation of placement if needed. Incorrect placement can lead to aspiration or perforation.

The registered dietitian determines the type of formula needed following patient assessment. The nurse administers the enteral feeding as prescribed. Enteral nutrition can be administered via bolus or pump with a set volume and rate of administration. Free water flushes are commonly administered prior to and following administration or in tandem with an enteral feeding pump. Tubing should be assessed for migration and obstructions with every formula feed. The nurse should monitor for leakage and skin breakdown. The tubing should be cleansed routinely according to facility protocol, typically using water or saline and soft gauze. Any redness or purulent drainage should be documented and reported.

Enteral feedings are associated with complications. It is the nurse's responsibility to mitigate these types of risk:

- To reduce the risk of aspiration,
  - maintain slow, steady administration rates;
  - keep the patient's head of bed elevated 30° to 45° as tolerated;
  - monitor for migration of visible NG/OG tubing; and
  - assess for residual gastric contents and follow facility policy for rate reduction protocols.
- To reduce the risk of clogged tubing,
  - flush the tube with water every shift and prn (as needed),
  - flush tubes before and after administration of feedings or medication,
  - assess for any residual gastric contents and follow facility policy for rate reduction protocol, and
  - irrigate tubing per facility protocol.
- To reduce the risk of gastric distress,
  - administer feedings at room temperature;
  - maintain prescribed rate of administration;
  - assess placement every shift and prior to feeding or medication administration; and
  - assess for signs of gastric distress including nausea, diarrhea, abdominal pain, and distension.

## Parenteral Nutrition

A form of alternative nutrition is **parenteral nutrition (PN)**, in which a nutrient formula is administered intravenously. PN has a high osmolality and causes irritation to veins, so it should always be administered through a central venous catheter. A central venous catheter provides intravenous access directly to the vena cava, which empties into the heart. PN is reserved for individuals who do not have a functional gastrointestinal tract. This includes children with congenital gastrointestinal malformations, individuals with severe ulcerative colitis or bowel obstruction, and those who are critically ill with organ failure. The formula is composed of macronutrients and micronutrients. The three major macronutrients are dextrose (a form of glucose), proteins, and fat (lipid) emulsions. Vitamins, trace minerals, and electrolytes are also added. There are two types of PN: peripheral parenteral nutrition (PPN) and total parenteral nutrition (TPN).

### Types of Parenteral Nutrition

PN requires central venous access. A central venous catheter is inserted in the jugular or subclavian vein and terminates in the vena cava. Central lines can be tunneled for long-term use (months to years) or nontunneled for intermittent use. Peripherally inserted central catheter (PICC) lines are long catheters inserted through a vein in the arm. Commonly, the basilic vein is used, terminating in the superior vena cava. PICC lines are used for intermediate use, typically weeks to months. Standards of care must be followed to reduce complication rates and improve patient outcomes. Policies regarding the care and use of central lines should follow facility protocols.

### Peripheral Parenteral Nutrition

PPN is administered through a PICC line using a pump. PPN is intended for short-term use, typically less than ten days. The peripheral insertion reduces risk and irritation by limiting osmolality, which can lead to higher volume per feeding. Care of the PICC line should follow standard guidelines and facility protocols.

### Total Parenteral Nutrition

TPN is administered through a central venous catheter. TPN is administered when the gastrointestinal tract is not functional or when the patient needs to rest their bowels. Energy and nutrient needs are calculated based on individual need and body weight. Nutrients include amino acids, fatty acids, vitamins, minerals, and electrolytes. Carbohydrates are provided as dextrose. Lipid emulsions are often administered separately. In recent years, the use

of three-in-one admixtures, which are composed of dextrose, proteins, and lipid emulsions, has improved patient care by streamlining TPN administration and reducing complications.

TPN is administered through a central line into the vena cava of the heart for long-term access. Close monitoring is required whenever a patient is receiving TPN. Weight, intake and output, and blood glucose must be monitored carefully. Bloodwork must be evaluated and documented to follow trends involving complete blood count, electrolytes and blood urea nitrogen (BUN), prealbumin, and albumin. Complications associated with TPN include central line infections, fluid volume overload, glucose and electrolyte disturbances, and liver and gallbladder dysfunction.

### Nursing Considerations for Administration

Nursing considerations related to PN include catheter care, administration of parenteral nutrition (PN), preventing and responding to complications, and ongoing assessment of nutritional status. Nurses should follow these guidelines for central line care and administration of PN:

- PICC dressings should be changed every seventy-two hours using sterile technique.
- PN should be administered through a dedicated lumen.
- Parenteral tubing should be changed every twenty-four hours.
- The PN label should be verified against the documented order.

Complications associated with PN include central line infections, sepsis, poor blood sugar control, hepatic dysfunction, and fluid and electrolyte imbalance. Nursing interventions should be geared toward prevention:

- Maintain strict sterile technique for central line care.
- Monitor vital signs routinely.
- Monitor blood sugar and administer insulin per protocol.
- Assess for fluid imbalance.
- Monitor labs for trends involving electrolytes, kidney, and liver function.

## 21.4 Nutritional Assessment

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe steps of the nursing assessment for nutritional status
- Understand diagnostic testing for nutritional assessment
- Recall conditions causing imbalanced nutritional status

Nutritional assessment is an important skill in nursing. The assessment begins with the gathering of subjective data, focusing on individual lifestyle behaviors and underlying medical conditions. A thorough health history is vital. The nurse must also collect physical cues that help determine overall nutritional status and trends. These include anthropometric measures such as BMI and growth charts. Weight trends are vitally important, as are underlying conditions that affect the digestion, absorption, and metabolism of nutrients. Lab work helps confirm and prioritize nutritional concerns and hydration status. Last, the results from pertinent diagnostic tests, such as swallow studies and x-rays, should be reviewed and recorded. Once all data are collected, the nurse can analyze both subjective and objective cues and develop a prioritized plan of care that is individualized for the patient.

This section describes the steps of a nutrition assessment and discusses specific medical conditions associated with impaired nutrition. Because many conditions impact nutritional status, it is important for the nurse to understand the physiological adaptation that occurs with a given health condition and anticipate the nutritional needs required to restore homeostasis. Having a sound understanding of how nutrition impacts the human body is an essential aspect of nursing care.

### Nursing Assessment for Nutritional Status

A thorough nursing nutrition assessment is foundational to the holistic care of all patients. A nutrition assessment includes subjective data, including demographic and sociocultural data, lifestyle cues, and medical history. It also includes objective data gathered from physical exams, labs, and diagnostic tests. The physical exam should focus on data from anthropometric measures (such as height, weight, and BMI), skin integrity, and gastrointestinal and

urinary functions. Lab trends must be noted and results from pertinent diagnostic tests documented if indicated. When conducting a nutrition assessment, it is vital to know the overall state of health, including all chronic diseases, and to allow this holistic understanding to guide critical thinking, especially those disease states that promote the greatest risk in association with malnutrition or chronic disease progression.

### Collecting Subjective Data

A thorough health history provides needed subjective data to guide nutritional planning and intervention. A health history begins with demographic data, which are important when considering nutritional status as nutrient needs differ based on biological sex and age. Sociocultural factors have a significant effect on access and food choice. The patient's religious preference, ethnicity and culture, educational level, occupation, and geographic location should all be documented as they impact overall health and nutritional status. Support systems, including food assistance programs and weight control support groups, should be reviewed.

A thorough discussion of dietary patterns and lifestyle behaviors is essential. Dietary patterns can be assessed using a variety of patient-friendly tools. A twenty-four-hour food recall is a simple measure to gauge usual daily food intake. A three-day food tracker is an even better measure, as it helps identify eating patterns and trends. There are a variety of apps and website food trackers that provide a structured way to document and review intake over time. The health history should reflect usual dietary patterns and include information related to food access or food insecurity, food shopping trends, utilization of food assistance programs, and attitudes toward cooking and food preparation.

In addition to dietary patterns, lifestyle behaviors must be reviewed and documented. Assessment of activity levels or levels of assistance needed with activities of daily living is vital to understanding caloric and nutritional needs as well as barriers to care. Utilization of health tracker apps with activity logs and stress level recordings can be insightful. Document any sensory impairment (vision or taste) that impacts activity or affects the ability to shop or cook safely. Ask about smoking history and use of alcohol or illicit drugs.

Identify past medical history that impacts nutritional health. Ask about weight trends and whether there is a history of dieting, utilization of weight loss programs, or bariatric surgery. Medical conditions to note include gastrointestinal disease, food allergies, history of diabetes, heart disease, liver disease, history of chemotherapy or radiation, and mental illness. Document if there is a family history of diabetes, heart disease, or obesity. Review all medications and discuss any medication effects on nutrition or hydration status.

Last, allow time to discuss the patient's current health concerns. These include unintentional weight loss, weight gain, change in appetite, difficulty chewing or swallowing, nausea, vomiting, stool changes, and abdominal pain. Discuss current life stressors (divorce, unemployment, recent hospitalization) that present as obstacles to a healthy lifestyle. Explore attitudes toward healthy eating and assist the patient in identifying barriers to healthy living. All documentation must be accurate and professional, devoid of any bias or personal opinion.

### Collecting Objective Data

The physical exam begins with assessment of vital signs, height, and weight. Compare findings to those previously documented, if available. Complete a head-to-toe assessment, emphasizing systems that relate to nutritional status ([Table 21.7](#)).

Category	Areas to Assess
General	Body frame, hygiene, coordination, adequate vision and hearing, dentition
Mentation	Orientation, alertness, ability to converse and follow commands, mood stability
Skin	Turgor, pallor, cyanosis, nonhealing wounds, bruising or bleeding, edema, condition of hair and nails
Gastrointestinal/ genitourinary	Abdominal girth, abdominal distension, epigastric or abdominal tenderness, ascites, bladder distension, urine output

**TABLE 21.7** Objective Data for a Nutritional Status Assessment

Category	Areas to Assess
Musculoskeletal	Muscle tone and strength, gait
Anthropometric measures	BMI, waist circumference, skinfold test
Other	Presence of enteral tubes, twenty-four-hour intake and output

**TABLE 21.7** Objective Data for a Nutritional Status Assessment

### Diagnostic Tests for Nutritional Status

There are several diagnostic procedures specific to nutrition. Imaging studies include routine x-rays used to verify placement of NG and PEG tubes. Computed tomography scans can identify anatomical anomalies, such as intestinal blockages and tumors. A dual-energy x-ray absorptiometry (DEXA) scan is a bone density test performed under low-dose x-ray. The DEXA is a measure of calcium and other mineral deposits that provide a relative measure of bone strength. A **modified barium swallow study (MBSS)** views the anatomical and swallowing physiology of a bolus of food under video fluoroscopy. The MBSS allows for real-time evaluation of swallowing function and safety under the guidance of a speech-language pathologist.

An **esophagogastroduodenoscopy (EGD)** is an invasive procedure performed under anesthesia. During an EGD, an endoscopic tube is advanced through the pharynx, esophagus, and gastric pouch to check for anomalies such as esophageal strictures and peptic ulcers. In some cases, an upper-gastrointestinal endoscopy can advance into the upper jejunum and obtain a biopsy of the intestinal wall to identify celiac disease.

### Laboratory Tests

Diagnostic and lab work results can provide important clues about a patient's overall nutritional status and should be used in conjunction with a thorough subjective and objective assessment to provide an accurate picture of the patient's overall health status. Common lab tests include hemoglobin (hgb), hematocrit (HCT), white blood cell (WBC) count, albumin, prealbumin, and transferrin.

Anemia is a medical condition diagnosed by low hemoglobin levels. Hemoglobin is important for oxygen transport throughout the body. Anemia can be caused acutely by hemorrhage, but it is often the result of chronic iron deficiency, vitamin B12 deficiency, or folate deficiency. Iron supplements, vitamin B12 injections, folate supplements, and increased iron or folate intake in the diet can help increase hemoglobin levels.

Albumin and prealbumin are proteins in the bloodstream. They maintain oncotic pressure so that fluid does not leak out of blood vessels into the extravascular space. The most abundant protein circulating in the blood is **albumin**, which is used as a marker for protein status. Albumin and prealbumin levels are used as markers of malnutrition, but these levels can also be affected by medical conditions such as liver failure, kidney failure, inflammation, and zinc deficiency. Low albumin levels can indicate prolonged protein deficiency intake over several weeks, whereas prealbumin levels reflect protein intake over the previous few weeks. For this reason, prealbumin is often used to monitor the effectiveness of PN therapy.

Transferrin is a protein required for iron transport on red blood cells. Transferrin levels increase during iron deficiency anemia and decrease with kidney or liver failure and infection.

A patient's amount of muscle wasting due to malnutrition is measured by a twenty-four-hour urine creatinine level (Hood, 2020). If insufficient calories are consumed, the body begins to break down its own tissues in a process called catabolism. BUN and creatinine are released as a by-product. A twenty-four-hour urine collection measures these by-product levels to assess the degree of catabolism occurring.

WBCs will decrease with malnourishment, specifically with protein and vitamins C, D, and E and B-complex deficiencies. Low WBCs place the patient at risk for infection because adequate WBCs are necessary for a fully functioning immune system. See [Table 21.8](#) for a description of selected lab values associated with nutritional status. As always, refer to facility lab reference ranges when providing patient care.

Lab	Normal Range	Nursing Considerations*
Hemoglobin (hgb)	Females: 12–16 g/dL Males: 14–17.4 g/dL	Hemoglobin measures the oxygen-carrying capacity of blood. Decreased levels occur due to hemorrhage or deficiencies in iron, folate, or vitamin B12. <b>10–14: mild anemia</b> <b>6–10: moderate anemia</b> <b>&lt;6: severe anemia</b>
Hematocrit (HCT)	37–50 percent	Hematocrit is normally three times the patient's hemoglobin level during normal fluid status. Increased levels occur with dehydration, and decreased levels occur with fluid overload or hemorrhage.
White blood cells (WBCs)	5,000–10,000 mm <sup>3</sup>	Increased levels occur due to infection. Decreased levels occur due to prolonged stress, poor nutrition, and vitamins C, D, and E and B-complex deficiencies. <b>&lt;4,000: at risk for infection or sepsis</b> <b>&gt;11,000: infection present</b>
Magnesium	1.6–2.6 mEq/L	Decreased level with poor nutrition or alcohol misuse. Increased levels due to kidney dysfunction. Critical values can cause cardiac complications: <b>&lt;1.2 mg/dL or &gt;4.9 mg/dL</b>
Albumin	3.4–5.4 g/dL	Increased with dehydration. Decreased level due to zinc deficiency, corticosteroid use, protein deficiency over several weeks, or conditions resulting in muscle wasting/muscle loss.
Prealbumin	15–36 mg/dL	Increased levels with corticosteroid or contraceptive use. Decreased levels due to inflammation, poor immunity, protein depletion over a few weeks.
Transferrin	250–450 mcg/dL	Increased levels due to dehydration and iron deficiency. Decreased levels due to anemia; vitamin B12, folate, and zinc deficiency; protein depletion; and conditions resulting in muscle wasting/muscle loss.
24-hour urine creatinine	Males: 0.8–1.8 g/24 hours Females: 0.6–1.6 g/24 hour	Increased levels with kidney disease and muscle breakdown. Decreased levels with progressive malnutrition as muscles atrophy.

\*Bolded items are critical conditions and require immediate healthcare provider notification.

**TABLE 21.8** Selected Lab Values Associated with Nutritional Status

### Conditions Causing Imbalanced Nutritional Status

Every cell in the body is affected by nutrition. Nutrient deficiencies and excesses affect every body system. Some disease states cause nutritional imbalances, while others result from a nutritional imbalance. Disease states that affect metabolic rates result in significant physiological compromise and increase the risk of developing chronic disease. Infections, inflammatory disease, metabolic conditions, and eating disorders are all medical conditions that have a direct effect on nutritional status. This section reviews the effects that infections, inflammatory disease, metabolic conditions, and eating disorders have on nutritional status.

### Infections

Infectious organisms in the body increase demand for energy. Healing from an infectious disease occurs when metabolic conditions allow the immune system to control and limit the effects of the disease. Healing is compromised when nutritional deficits are present, preventing immune-modulating cells from functioning properly. Foodborne organisms can cause infection when hygiene and safety standards are not followed. Viruses, bacteria, and protozoa are all organisms that can create an infectious state.

In some cases, chronic infections can develop, stressing the nutritional demands of the body. Chronic infections commonly occur in the urinary tract, in chronic wounds, and in both the upper and lower respiratory tracts. When increased nutritional demands are not met, the patient's nutritional status becomes compromised, and the body is unable to overcome the infectious agent. Chronic infectious states often benefit from a high-calorie, high-protein diet to meet elevated energy demands.

### Inflammatory Diseases

Inflammatory disease occurs when the body's natural defenses are hyperreactive and cause damage to tissues. Inflammation is caused by organisms, injuries, and toxins in the environment. Inflammatory disease affects every body system and is a driving force for malnutrition. Inflammation can decrease appetite and lead to decreased dietary intake and anorexia. It can cause catabolic metabolism of muscle tissue, reduce insulin sensitivity of body cells, and impair nutrient absorption. Food allergies, Crohn disease, and celiac disease are all associated with inflammatory processes. Many chronic illness states have an inflammatory component. This often presents as low-grade inflammation and leads to unintentional weight loss, decreased muscle mass, and poor quality of life. Heart disease, chronic obstructive pulmonary disease, and rheumatoid arthritis are examples of chronic disease states associated with low-grade inflammation.

### Metabolic Conditions

Metabolic conditions are multifocal and associated with digestive dysfunction, malabsorption, and poor utilization of nutrients. Disorders that result in poor digestion include cognitive dysfunction, dysphagia, and mental illness that leads to poor dietary intake. Acute gastrointestinal distress (nausea, vomiting, and diarrhea) can interfere with intake and digestion. Poor digestion and decreased intake over time lead to malnutrition. Some disorders affect the absorption of nutrients within the small intestines. Bowel obstructions, diabetes, pernicious anemia, cystic fibrosis, and celiac disease cause malabsorption leading to nutrient deficits. Some diseases affect the metabolic rate, such as thyroid disease. An overactive thyroid can lead to a hypermetabolic state, while an underactive thyroid can lead to a hypoactive metabolic rate. It is important to review every patient's medical history and identify medical conditions and treatments that have a direct effect on nutritional status.

Metabolic abnormalities can be risk factors for heart disease, diabetes, and stroke. Metabolic syndrome is a cluster of conditions known to increase risk of chronic disease when presented together; it is characterized by abdominal obesity, elevated lipid levels, elevated blood glucose, and elevated blood pressure. When three of these four symptoms are present, the individual is considered to be at metabolic risk. Fortunately, metabolic syndrome can be reversed with consistent lifestyle changes, including healthy dietary patterns of eating and increased physical activity, thereby decreasing overall health risks.

### Eating Disorders

Eating disorders are often associated with maladaptive coping skills. Anorexia nervosa and bulimia are two diseases that have direct effects on patient nutrition. Patients who have anorexia nervosa are very focused on their weight to the point that they obsess about their diet. They will appear underweight and have great fear about gaining weight. Bulimic patients will eat in secret and then engage in self-induced vomiting to get rid of the food they ate. It is a cycle of secret bingeing, shame, and then self-induced vomiting called purging. It is episodic but recurrent. Patients with bulimia typically maintain weight but experience dental caries due to loss of tooth enamel. They also have menstrual irregularities and electrolyte imbalances as a result of persistent purging and laxative overuse. Both anorexia and bulimia can have severe consequences on the patient's physical, mental health, and self-image.

## LIFE-STAGE CONTEXT

---

### Eating Disorders in Young Adults

While eating disorders can affect all people, they are more common in females between the ages of 12 and 35 years. Research has indicated that eating disorders among teens have doubled since the pandemic. Increased social media use has been linked to higher incidences of body dysmorphia and eating disorders in adolescents and young adults (Harriger et al., 2022).

---

Eating disorders can lead to physiological complications and are often accompanied by anxiety and guilt. Anorexia nervosa is a life-threatening body image disturbance that results in a state of emaciation. Anorexia is often associated with control and an intense fear of becoming obese. Bulimia is a compulsive eating disorder associated with binge eating followed by purging. It is episodic but recurrent. Patients with bulimia typically maintain weight but have dental caries due to loss of tooth enamel, menstrual irregularities, and electrolyte disturbances as a result of persistent purging (forced vomiting and laxative overuse).

Eating disorders are complex and require the nurse to consider both physiological and psychological stressors in the body. Nursing care is prioritized according to safety needs and risk reduction. Maladaptive eating patterns often accompany stress, anxiety, and depression. It is important to analyze underlying stressors and utilize physiological and psychological interventions when caring for all patients with eating disorders.

## Summary

### 21.1 Nutritional Concepts

Good nutrition includes ingestion of quality macronutrients such as carbohydrates, proteins, and fats. These provide adequate calories to meet the body's daily energy needs. Dietary patterns also need to include adequate water regulation to maintain hydration balance and sufficient quantities of micronutrients, like vitamins and minerals, to meet metabolic demands. Weight and BMI trends help track growth and development and identify early risks to nutritional health. Understanding the role of nutrition in the daily health and wellness needs of people across their life span is key to the achievement of optimal nutrition and health.

### 21.2 Factors Affecting Nutrition

Physiological and psychological factors significantly affect nutritional status. Physiological factors affecting nutrition include basic human factors such as age, developmental stage and activity level, biological sex, physical health, and the presence of chronic disease, pregnancy, or lactation. Physiological factors also include environmental factors such as socioeconomic status, food insecurity, and lifestyle behaviors. Psychosocial factors are highly influential because mealtimes in all cultures tend to be social events, giving food meaning beyond basic nutritional need. This meaning can be positive, connected with celebrations and traditions, but it can also result in emotional eating that leads to negative health outcomes. It is important to take a holistic view when analyzing patient cues related to nutritional status.

### 21.3 Specialized Diets

A healthy diet includes quality nutrients such as carbohydrates, proteins, fats, vitamins, and minerals, all in sufficient amounts to meet individual needs. Nutritional teaching should address food safety, food label reading, and healthy eating strategies, for example, by utilizing the MyPlate.gov tool. Specialized diets may be implemented to reduce health risks or optimize nutrition during acute or chronic illness. Common specialized diets include the consistent carbohydrate diet, restricted fat diet, low-sodium diet, and high-fiber diet. Kidney diets, low-fiber diets, and high-calorie, high-protein diets are less common but extremely useful in certain medical conditions. Some specialized diets modify the consistency of the food for improved consumption and/or digestion. These include the mechanical soft diet, pureed diets, and various liquid diets. Enteral nutrition and PN require strict nursing care to provide controlled nutritional intake via enteral tubes such as the NG, OG, and PEG or via central lines like PPN and TPN.

### 21.4 Nutritional Assessment

A nutrition assessment begins with a collection of subjective data, including a history of weight trends, nutrition intake, lifestyle behaviors, demographics, and past medical history. Objective data should include anthropometric measures and a focused physical assessment. Diagnostic and lab work results can provide important clues about a patient's overall nutritional status and should be used in conjunction with a thorough subjective and objective assessment to provide an accurate picture of the patient's overall health status. Common lab tests include hgb, HCT, WBC count, albumin, prealbumin, and transferrin.

Infections, inflammatory disease, metabolic conditions, and eating disorders are all medical conditions that have a direct effect on nutritional status. It is important to review every patient's medical history and identify medical conditions and treatments that have a direct effect on nutritional status. Analyzing underlying stressors and utilizing physiological and psychological interventions are important when caring for all patients with eating disorders.

## Key Terms

**albumin** the most abundant protein circulating in the blood, with many functions within the body; used as a marker for protein status

**body image** perception a person has about their physical body, including any feelings associated with that perception

**body mass index (BMI)** a value that is calculated from an individual's height and weight to provide as measurement relative to the standards for ideal body weight

**calorie** a unit measure of energy

**carbohydrate** macronutrient used to fuel the immediate energy needs of the body

**cellular respiration** the breakdown of energy-rich nutrients (carbohydrates, fats, and proteins) to provide ATP, which fuels cellular functions within the body

**dehydration** a fluid volume deficit that occurs with inadequate water intake or excessive water loss or both

**dietary reference intake (DRI)** scientifically developed values for essential nutrients and other food components

**enteral nutrition** nutrition that is directly administered into the stomach

**esophagogastroduodenoscopy (EGD)** imaging study used to evaluate the esophagus, stomach, and duodenum for abnormalities such as ulcers, inflammation, or tumors

**fat** large, complex molecule made up of fatty acids and glycerol

**food desert** a geographical area where fresh produce and foodstuffs are either too expensive or unavailable

**food insecurity** the state of having limited access to adequate food

**ideal body weight (IBW)** weight at which a person maintains optimal health benefits

**macronutrient** nutrient consumed in large quantities to meet the body's energy needs

**malnutrition** an imbalance between the nutrients consumed and nutrients needed; includes both undernutrition and overnutrition and involves both macronutrients and micronutrients

**metabolism** the process by which substances are chemically broken down to meet the body's nutrient and energy needs

**micronutrient** nutrient found in small quantities within the body but still necessary for physiological functions

**mineral** essential to physiological processing; some are macronutrients, and some are micronutrients

**modified barium swallow study (MBSS)** a procedure for viewing the anatomical and swallowing physiology of a bolus of food under video fluoroscopy

**parenteral nutrition (PN)** nutrition delivered intravenously by a central line

**protein** macronutrient made up of amino acids

**recommended dietary allowances (RDAs)** guidelines developed by the U.S. government for consuming the nutrients that make up a healthy diet

**reference daily intake (RDI)** average daily intake of a population

**vitamin** essential micronutrient vital to biochemical regulation within the human body

## Assessments

### Review Questions

1. A nurse is teaching a patient with a nutritional deficit about nutrient-dense foods. What nutrient provides the most energy per gram of nutrient?
  - a. carbohydrates
  - b. fats
  - c. protein
  - d. fiber
2. A nurse is caring for an older adult patient who is dehydrated. The nurse understands that the majority of water in the human body is found where?
  - a. inside the body cells
  - b. in the vascular system
  - c. in interstitial fluids
  - d. in the urinary tract
3. A nurse is reviewing a patient's medication list and notes the patient takes vitamin D tablets once a day. What does the nurse know is true about vitamin D?
  - a. found naturally in many foods
  - b. found only in animal products
  - c. absorbed through direct sunlight
  - d. a trace mineral
4. A nurse in long-term care is reviewing charts for weight loss trends. Which patient is most at risk for developing

malnutrition?

Patient	BMI	Weight Change
Patient A	25	Gained 5 pounds in twelve months
Patient B	20	Lost 6 pounds in twelve months
Patient C	18.5	Lost 10 pounds in six months
Patient D	16	Gained 2 pounds in six months

- Patient A
  - Patient B
  - Patient C
  - Patient D
- A nurse is working with patients in a public health clinic and is assessing for food insecurity in a local immigrant population. What observation would be most concerning for food insecurity?
    - an immigrant woman applying for SNAP and WIC benefits
    - an immigrant man who is unable to find foods specific to the culture
    - an immigrant couple without personal transportation
    - an immigrant child who does not live near a grocery store
  - A nurse is working with a patient on implementing healthy dietary patterns. The patient decides to develop a healthy weekly menu. What response by the patient indicates understanding of the nutrition guidelines?
    - “RDA values tell me the daily intake for nutrients to guide meal planning.”
    - “Proteins are the most important nutrient group.”
    - “I should eat the same number of calories at every meal.”
    - “I should avoid all simple carbohydrates.”
  - A nurse is teaching about nutrition during pregnancy and lactation. What foods would be the healthiest option to meet nutritional goals during this time?
    - whole milk and red meat
    - rice and beans
    - eggs and low-fat dairy
    - fresh fruits and fruit juices
  - A home health nurse is visiting a patient with multiple chronic diseases. The patient is experiencing unintentional weight loss. The nurse considers the role of nutrition in chronic illness. What conditions will not lead to unintentional weight loss in patients with chronic illness?
    - conditions that interfere with nutrient absorption
    - conditions that interfere with ingestion of nutrients
    - conditions that alter the daily allowance of nutrients needed
    - conditions that decrease metabolic rate
  - A nurse is developing a program to promote healthy eating for a local community center. What nutrient should make up the largest daily percentage of intake in a healthy diet?
    - carbohydrates
    - proteins
    - fats
    - simple sugars

- 10.** A patient is learning to read food labels to help with healthy meal planning. How can the patient identify high nutrient values?
- These nutrients will be listed first.
  - The percent daily value per serving will be at least 20 percent.
  - The per serving percentage will be at least 50 percent.
  - These nutrients will be identified as “added.”
- 11.** A patient with a history of chronic constipation is placed on a high-fiber diet. What food or drink should the nurse recommend?
- vegetable juice
  - eggs
  - peanut butter
  - black beans
- 12.** Why does PN require administration through a central venous catheter?
- All liquid nutrients are delivered via central line.
  - PN must be delivered quickly.
  - PN has a high osmolality and causes vein irritation.
  - A central line provides direct access to the gastrointestinal tract.
- 13.** A patient has been newly diagnosed with anemia. The goal of treatment is to maintain stable hemoglobin levels. What supplement can help increase hemoglobin levels?
- vitamin C
  - folate
  - magnesium
  - calcium
- 14.** A nurse is taking a health history. The patient reports that they have a chronic cough, smoke one pack per week, have food allergies, and have a history of dieting. Which has the most impact on nutritional status?
- has a chronic cough
  - smokes one pack per week
  - has food allergies
  - has a history of dieting
- 15.** A nurse is discussing the relationship between metabolic syndrome and chronic disease. What activity would help reverse metabolic syndrome?
- increase physical activity
  - increase lipid levels
  - maintain a high-protein diet
  - drink 2 L of water daily

### Check Your Understanding Questions

- Recall nutrients used for regulation in the body. What is the difference between calorie or protein deficiencies and deficiencies in vitamins and minerals?
- Which three nutrients are considered macronutrients because the large quantities of each are needed daily to meet the body’s energy needs?
- Describe the process known as cellular respiration.
- What role do culture, religion, and economic status play in food preferences?
- Identify five nutrients that can be found on a food label.
- Describe the differences between anorexia nervosa and bulimia.

## Reflection Questions

1. When optimal nutrition is not achieved, malnutrition can happen. What are the negative effects of malnutrition on the body?

## What Should the Nurse Do?

Mr. Curtis is a 47-year-old patient admitted to the hospital with increased weakness, fatigue, and dehydration. His skin appears dry, and tenting occurs when skin turgor is evaluated. He is currently undergoing chemotherapy treatment for multiple myeloma and has experienced weight loss of ten pounds within the last two weeks. He describes that “nothing tastes good,” and he feels as if there is “a metal taste in his mouth.” When he does eat small meals, he reports that he is often nauseous. The patient’s serum protein level is 3.1 g/dL.

1. What assessment cues should the nurse recognize?
2. Based on the assessment information that has been gathered, what are some nursing interventions that can be created for Mr. Curtis?

Mr. Jones is a 67-year-old patient on the medical-surgical floor who recently underwent a bowel resection. He is post-op Day 2 and has been NPO since surgery. He has been receiving intravenous fluids but has been asking about when he can resume eating.

3. What assessments should be performed to determine if the patient’s diet can be progressed?
4. What are the first steps during dietary transition from NPO status?

Mrs. Casey is a 78-year-old widow who recently had a stroke and continues to experience mild right-sided weakness. She is currently receiving physical therapy in a long-term care facility and ambulates with the assistance of a walker. Mrs. Casey confides, “I am looking forward to going home, but I will miss the three meals a day here.” Her height is 5'2" and she weighs 84 pounds. Her recent lab work results include the following: hgb 8.8 g/dL; WBC 3,500; magnesium 1.4 mg/dL; albumin 10 g/dL.

5. What is Mrs. Casey’s BMI, and what does this number indicate?
6. Analyze Mrs. Casey’s recent lab work, and interpret the findings.
7. Describe focused assessments the nurse should perform regarding Mrs. Casey’s nutritional status.

## Competency-Based Assessments

1. Using the CDC’s [BMI calculator \(https://openstax.org/r/77BMIcalc\)](https://openstax.org/r/77BMIcalc), calculate and assess your own BMI. Develop a one-week meal plan to promote optimal nutrition based on your personal results.
2. A nurse is caring for an older adult with dysphagia. What should the nurse consider when assisting with planning meals?

## CHAPTER 22

# Activity

**FIGURE 22.1** Activity, movement, and the capacity to care for oneself help determine a person's functional ability. Activity and movement of any kind is beneficial, including chair yoga that incorporates gentle movements, stretches, and breathing exercises to promote flexibility, strength, and relaxation. (credit: "Yoga @ Wylam" by Birmingham Public Library/Flickr, CCBY 2.0)

### CHAPTER OUTLINE

- 22.1 Importance of Activity, Movement, and Alignment
- 22.2 Factors Affecting Activity Level
- 22.3 Activities of Daily Living (ADLs)

**INTRODUCTION** What does the ability to brush your hair and get dressed have to do with the ability of human beings to move, maintain their bodily position, and be physically active? Consider the following scenario. Martina is a 75-year-old Latina female. She cared for her family and worked full time in an office job her whole life. Martina struggled with arthritis in her joints but tried not to let it bother her and did not seek treatment. She did not have time or motivation to exercise and always thought she would start after she retired. After retirement at age 65, Martina spent much time caring for her grandchildren and still did not take time to exercise. Her arthritis worsened, and she moved less and went out less often. After a stroke when she was 70, Martina could not use the right side of her body, the dominant side, for several months; she never regained full use of her right upper body. She also never fully recovered the ability to walk steadily. After several falls, she began using a wheelchair. Now she relies on home healthcare workers to assist her with activities of daily living, such as grooming and dressing.

Martina's story is not an uncommon one. Through no fault of their own, most people do not realize the complex relationship between their bodies, physical activity, and their ability to perform the essential tasks of daily living. For nurses, however, it is critical to understand all these aspects to provide high-quality education, care, and patient advocacy. This chapter explores these related issues.

## 22.1 Importance of Activity, Movement, and Alignment

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the physiology of activity, movement, and alignment in the body
- Identify functions of activity, movement, and alignment in the body
- Explain ergonomics in patient care
- Describe exercise and its effect on the body systems

What do running, jumping, dancing, typing on a keyboard, and watching television have in common? All these activities require a complex interplay between the skeletal, muscular, and central nervous systems, which work together to hold the body upright, allow it to move, and protect it from harm. Understanding how the body is designed and how it functions enables nurses to provide care safely for themselves and their patients. It also offers a way to begin a discussion of exercise and the importance of movement for the body's functioning.

### Physiology of Activity, Movement, and Alignment

Purposeful movement, or **activity** refers to walking, eating, or playing an instrument. To safely perform an activity, the body must be in proper position, or **alignment**. The physiology of activity, movement, and alignment is a complex process requiring multiple body systems to work together. For example, wiggling your fingers is a simple movement that requires the combined efforts of joints, bones, muscles, and the nervous system. The bones provide the underlying structure of the fingers, the joints allow them to bend, the muscles perform the actual action, and the nervous system controls the wiggle by sending the appropriate signals from the brain. Through this section, we will explore the physiological systems that allow for movement and alignment.

#### Skeletal System

The **skeletal system** consists of bones, joints, and other structures that allow for movement and perform other critical functions in the human body. It supports the body, shields organs, makes blood cells, and provides space for minerals and fat. No activity or movement can occur without the skeletal system.

The primary component of the skeletal system is **bone**, which is a hard tissue composed primarily of calcium, with other minerals such as magnesium, fluoride, and sulfates mixed in. The adult human body has 206 bones divided into five types ([Figure 22.2](#)). Each type plays a different role in activity and movement.

- Long bones, such as the femur, provide leverage.
- Short bones provide stability and support and enable limited motion.
- Flat bones protect internal organs and provide surfaces to which muscles attach.
- Sesamoid bones function as shock absorbers for tendons.
- Irregular bones protect internal organs and provide support for movement.

**FIGURE 22.2** Bones are classified by their shape: long, short, flat, sesamoid, or irregular. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Bone surfaces come into contact at a **joint**, often allowing for movement. At the joints, bones are separated by **cartilage**, a spongy, smooth surface that decreases friction and acts as a shock absorber between bones. A tough but flexible fibrous tissue, called a **ligament**, connects bones or hold joints together. A **tendon** is a tough, flexible band of connective tissue that attaches muscles to bones, facilitating the transmission of muscle contractions and allowing for joint movement. Injury to bones, joints, cartilage, ligaments, or tendons can make movement painful or even impair the body's ability to move altogether.

### Joints

The hyoid bone of the neck is the only bone in the human body not connected to other bones. All other bones articulate, or connect to each other, at joints. Joints can be classified by the amount and type of movement they allow between adjacent bones ([Table 22.1](#)).

Type of Joint	Amount of Movement	Example
Amphiarthrosis	Limited movement	Intervertebral discs between vertebrae in the spine
Biaxial joint	Type of diarthrotic joint allowing movement along two lines	Knuckle joints (where the fingers meet the palm of the hand), which allow for bending, straightening, and spreading apart of fingers
Diarthrosis	Free movement	Most joints in the arms and legs
Multiaxial joint	Type of diarthrotic joint allowing movement in multiple directions	Hip and shoulder joints, which can move and rotate in all directions
Synarthrosis	Unmovable or almost unmovable	Where the bones of the skull meet
Uniaxial joint	Type of diarthrotic joint allowing movement in a back-and-forth direction along a single line	Elbow and knee joints, which allow for bending and straightening along a single line

**TABLE 22.1** Types of Joints

### Types of Joint Movement

A diarthrotic joint is most likely a **synovial joint**. Synovial joints are the most common joints in the body; they are movable and characterized by a fluid-filled cavity in the space where bones articulate. This fluid, called **synovial fluid**, allows bones to move against each other freely without causing pain or eroding from the friction. Friction in synovial joints is also diminished by **articular cartilage**, a thin, spongy layer of cartilage that covers the surface of bones where they articulate. There are six types of synovial joints, defined by the ways the bones articulate with and move against each other ([Figure 22.3](#) and [Table 22.2](#)).

**FIGURE 22.3** Synovial joints are classified based on the type of movement they allow. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Type of Synovial Joint	Characteristics	Example
Ball-and-socket joint	The round end of one bone fits into a large concave space in another—like a baseball fitting into a baseball glove.	Hips and shoulders
Condylloid joint	A shallow depression on one bone articulates with the rounded end of another, allowing for biaxial movement.	The joints located in the knuckles of the hands
Hinge joint	An outwardly rounded end of one bone articulates with the inwardly rounded end of another, allowing for bending and straightening.	Elbows, knees, certain parts of the ankles, and fingers
Pivot joint	The rounded end of one bone articulates within a ring of another bone and rotates within that ring.	Allows the turning of the neck
Plane joint	Articulating points slide against each other within a small range of movement bound by ligaments.	Joints of the wrist and in certain parts of the ankle
Saddle joint	Both bones are concave on one side and convex on the other and fit together like puzzle pieces, allowing biaxial movement.	What allows human thumbs to be opposable thumbs

TABLE 22.2 Types of Synovial Joints

## LINK TO LEARNING

Joints can be complex to understand. Watch the Crash Course Anatomy & Physiology video to develop a better understanding of [how joints work with bones \(https://openstax.org/r/77jointbone\)](https://openstax.org/r/77jointbone) to facilitate movement.

### Muscular System

The human body contains three types of muscles, each performing different actions as they contract and relax. The heart is composed of **cardiac muscle**, which acts to pump blood through the heart. A **smooth muscle** makes up the internal surface of arteries and veins, internal organs, and other internal passageways. It acts by pushing substances through the system—for example, food down the esophagus or blood through the veins and arteries.

Cardiac and smooth muscle movements are entirely unconscious and almost totally outside of the control of the individual. In contrast, **skeletal muscle** attaches to bone and creates intentional movement as it contracts and relaxes. Skeletal muscles allow the human body to resist the force of gravity and help keep the skeletal system stable. Most importantly for the purposes of this chapter, people use these muscles to start and stop movement.

Skeletal muscle is called **striated muscle** because it appears striped. [Figure 22.4](#) shows a microscopic image of skeletal muscle. Note how the muscle appears to be banded. When muscles contract and relax, those bands slide across each other as the muscle shortens (contracts) or lengthens (relaxes). In **contraction**, the muscle works, the bands slide toward each other and become more tightly woven, and the joint bends. In **relaxation**, the muscle no longer works, the bands return to their resting position, and the muscle lengthens back out.

**FIGURE 22.4** This microscopic image of skeletal muscle shows the striations in the muscle, which appear as stripes or bands. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

A muscle's strength is determined by the amount of work it gets. Muscle fibers and muscles grow and become stronger when they are worked; the more work they do, the stronger they become. Conversely, when muscles are worked less or not at all, they begin to **atrophy**, or shrink, losing both size and strength.

### Relationship between Muscles, Joints, and Bones

There are more than 640 skeletal muscles in the body; some muscles perform only single movements, and others can move in multiple ways. However, there is always a main muscle, the **prime mover**. A muscle that helps the prime mover, providing assistance or stability to the movement, is considered a **synergist**. Because skeletal muscles work only when they contract, there are generally other muscles that contract in the opposite direction to a prime mover. A muscle that performs this function is known as an **antagonist**. Antagonists have two functions: they maintain the body's alignment by keeping joints at their "normal" angle, and they return the body to its proper alignment when the work of the prime mover is completed.

Try this: hold your arm out straight with your palm facing up. Flex the forearm toward your head. Your biceps brachii muscle is the prime mover, contracting to shorten the angle at your elbow and pull the forearm toward your face. Your upper arm does not move. Now, straighten your arm back out. Your triceps brachii muscle is the antagonist, extending your arm back out and widening the angle at the bend of your elbow. The biceps and triceps brachii muscles attach to opposite sides of the humerus in the upper arm and to opposite sides of the lower arm, causing flexion and extension.

### LINK TO LEARNING

Watch this video to learn more about [how skeletal muscles work, receive energy, and differentiate](https://openstax.org/r/77skelmusc) (<https://openstax.org/r/77skelmusc>) between big and small tasks.

### Body Movements

The body can make many movements, depending on the type of synovial joint and the muscles that attach on either side of the joint ([Table 22.3](#)). Most commonly, each movement in one direction also has an opposite movement. Movement can be understood by looking at the changes in the angles between the two bones when the muscles are at rest and when they have contracted, as well as the angles of the bones to the center of the body. All these movements combine to allow a person to run, dance, type, engage in hobbies, play sports, eat food, dress, and climb into bed at night.

Type of Movement	Characteristics	Example	Illustration
Flexion	Bending: a decrease in the angle between two bones	Bending the neck forward, backward, or to the side	 <p>(credit: modification of work from <i>Anatomy and Physiology 2e</i>. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>
Extension	Straightening: an increase in the angle between two bones (usually up to 180 degrees, or a straight line)	Straightening the neck back to center	
Abduction	Side-out: a movement away from the body's midline or center	Moving arms or legs out to the side	 <p>(credit: modification of work from <i>Anatomy and Physiology 2e</i>. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>
Adduction	Side-in: a movement toward the body's midline or center	Moving arms or legs in toward the body	
Circumduction	The combination of flexion, abduction, extension, and adduction at a joint in a circular motion	Moving wrists, ankles, or neck in a circular motion	

**TABLE 22.3** Types of Body Movements

Type of Movement	Characteristics	Example	Illustration
Rotation	Movement of one bone around another at the articulation point	Turning the neck from side to side; making large circles at the shoulder or hip	 <p>Rotation</p> <p>Lateral rotation</p> <p>Medial rotation</p> <p>(credit: modification of work from <i>Anatomy and Physiology 2e</i>. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>

TABLE 22.3 Types of Body Movements

Type of Movement	Characteristics	Example	Illustration
Dorsiflexion	Movement of the ankle joint so the top of the foot moves toward the front of the leg	These movements are specific to the ankles; they are the only movements of the ankle joints.	 <p>(credit: modification of work from <i>Anatomy and Physiology 2e</i>. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>
Plantar flexion	Movement of the ankle joint so the toes are pointed as far away from the front of the leg as possible		
Protraction	Forward movements of the shoulder blade or mandible	Throwing an object forward (causes the shoulder blade to move forward)	 <p>(credit: modification of work from <i>Anatomy and Physiology 2e</i>. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>
Retraction	Backward movements of the shoulder blade or mandible	Squeezing the shoulder blades together causing them to move backward	
Depression	Downward movement of the shoulder blade or mandible	These movements allow you to shrug your shoulders and open and close your mouth.	 <p>(credit: modification of work from <i>Anatomy and Physiology 2e</i>. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>
Elevation	Upward movement of the shoulder blade or mandible		

**TABLE 22.3** Types of Body Movements

## Nervous System

The nervous system is the human body's computer hard drive. It controls most of the body—both voluntary and involuntary processes—through communication that happens (via nerves) between portions of the brain and specific organs (Figure 22.5).

- The brain and spinal cord, which comprise the **central nervous system**, are the processing centers. The brain is protected by the bones of the skull; the spinal cord is protected by the vertebrae that make up the spine.
- All nerves that run through the body are part of the **peripheral nervous system (PNS)**. One of the many functions of the cranial nerves is to control the movement of skeletal muscles in the face. The movement of most other skeletal muscles, particularly those involved in skeletal movement, is controlled by spinal nerves attached to the spinal cord.
- The part of the peripheral nervous system that controls purposeful movement, recognition of the environment, and voluntary actions is the **somatic nervous system**. The somatic nervous system allows for interplay between sensory neurons, motor neurons, and conscious thought.

**FIGURE 22.5** The nervous system, which includes both central and peripheral components, controls the movement of the skeletal muscles. (credit: based on modification of "Divisions of the nervous system" by Cenvo on AnatomyTool.org, CC-BY-3.0, retrieved from Neurotechedu.com)

The thirty-one spinal nerves extend from the spinal cord and run throughout the body, branching into smaller nerves as they move outward. A **neuron** stretches out throughout the system like a spiderweb and attach to muscles and other organs. Every nerve is composed of many neurons. Each spinal nerve receives information (for example, feelings of pain or hunger) through sensory neurons and sends information (for example, instructions to move or breathe) through motor neurons. The location where a motor neuron meets a muscle fiber is called a **neuromuscular junction (NMJ)**. The motor neurons signal the muscle fibers (the muscle) to contract. Muscles stop contracting when they become fatigued or when the signal from the motor neurons stops.

## Functions of Activity, Movement, and Alignment

Now that we have reviewed the major body systems responsible for activity, movement, and alignment, let us delve deeper and explore why they are important for the human body. Beyond simply allowing people to move their body, the organs involved in movement also aid the body in remaining healthy and sustaining a state of equilibrium and

stability, or homeostasis. This section explores some of the major functions of activity, movement, and alignment.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Analyze Cues: The Risks of Physical Inactivity

Nurses must be able to analyze some of the risks posed by immobility before they can generate solutions. Lack of physical activity is a significant risk factor for cardiovascular health as well as the health of many other body systems; it accounts for almost 75 percent of the healthcare costs in the United States. Risks of immobility include the following:

- 45 percent elevated risk of coronary artery disease
- 60 percent higher risk of stroke
- 30 percent higher risk of hypertension
- 59 percent higher risk of osteoporosis
- type 2 diabetes mellitus and other metabolic disorders
- cancers such as colon and breast
- depression and anxiety
- dementia
- cognitive impairment
- falls
- systemic inflammation and pain
- higher mortality rates

Recognizing the relationship between inactivity and serious health conditions allows the nurse to identify what inactivity means for a particular patient and consider how to target some interventions (Maestroni et al., 2020).

#### Circulation

The continuous, controlled movement of blood throughout the body is called **circulation** and is facilitated by the heart, blood vessels, and blood. This process ensures the delivery of oxygen, nutrients, hormones, and other essential substances to various tissues and organs while removing waste products, promoting overall metabolic function, and maintaining homeostasis within the body. Regular physical activity promotes a healthy heart. For adults, there is strong evidence that activity helps to improve blood flow and levels of good cholesterol in the body (American Heart Association [AHA], 2017). Consequently, it lowers blood pressure and decreases the risks of hypertension and early death from heart disease (Carini et al., 2017). Individuals who are largely sedentary—who engage in minimal to no activity—have a substantially higher and earlier mortality rate than those who are active (Lane-Cordova et al., 2022).

#### Balance

Postural stability or equilibrium, or **balance** is the ability to maintain an alignment that prevents an individual from falling and allows them to catch themselves if they trip. It involves the work of the nervous system, muscles, bones, and joints, as previously discussed, as well as the inner ear and the eyes (Harvard Medical School, n.d.). It allows individuals to be physically active and can usually be improved by physical activity. Balance is critically important to preventing injury, particularly in older adults.

Many conditions and symptoms can cause balance difficulties. For example, patients who have suffered a stroke often struggle with balance related to changes in their ability to control one side of their body. Parkinson disease causes tremoring of the extremities, making it difficult to control balance. Muscle weakness, particularly in the core (abdomen and back) and upper legs, diminishes a body's stability. Other issues impacting balance include multiple sclerosis, inner ear conditions, and nerve damage. Balance can also be impacted by medications (such as pain medication or sleeping pills), alcohol, and illicit drugs, all of which can impair the body's ability to remain upright and protect itself from falling.

## LINK TO LEARNING

Recognizing how well a patient can balance is only one part of how nurses assess the patient's ability to move safely, particularly in hospital situations. The [Bedside Mobility Assessment Tool \(BMAT 2.0\)](https://openstax.org/r/77bedside) (<https://openstax.org/r/77bedside>) offers a proven, nurse-driven strategy to rapidly assess a patient's mobility level and gauge how safe it is for them to be active.

### Coordination

While balance is the ability to maintain a position, **coordination** is the ability to change position effectively and intentionally. Coordination requires the synchronized efforts of the nervous system, muscles, and joints. Coordination must occur between the brain and the muscles and between groups of muscles to make movement happen. Think about answering a cell phone. The brain recognizes the need to answer the phone and alerts the various muscle groups. Then one arm and hand generally pick up the phone and hold it in the correct position, so that the other arm and hand can work the controls on the phone. This requires coordinated movement as muscles in both arms, hands, fingers, and shoulders all work together to answer the phone. Imagine the level of coordination that occurs on a daily basis.

Coordination can be impacted by many factors, including vision and vision changes, age-related changes (coordination tends to decline with age), and conditions of the central nervous system, such as stroke and Parkinson disease (Gonzalez-Usigli, 2022). Common symptoms of coordination disorders include the following:

- **ataxia**, or loss of coordination
- **dysmetria**, or the inability to control or judge the range needed for a motion
- **dysarthria**, or the slurring of speech or changing of vocal volume
- **tremor**, or uncontrolled shaking when attempting purposeful movement or resting

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Fall Prevention Strategies

Falling is one of the most frequent causes of serious injury in patients older than 65 years of age. Almost one-third of older adults fall each year, and the risk of injury increases with age (Sherrington et al., 2020). For example, hip fractures are a serious concern for older patients; 95 percent of these injuries happen after a fall (National Center for Injury Prevention and Control, 2021). For nurses, recognizing fall risk and prioritizing fall prevention strategies are core functions of providing safe patient care. While there are many interventions that can be used to decrease the number of patient falls in inpatient situations, some simple ones include the following:

- Ensure patients always have call lights in reach, and respond when they call.
- Place patients who are at high risk of falling near the nursing station.
- Use bed alarms that will notify staff when patients are getting out of bed.
- Place imagery on the doors of patients who are at high risk of falling (such as a leaf representing falling leaves) to remind all personnel to help monitor the patient.
- Provide ample time for supervised movement and activity to prevent boredom.
- Ensure patient needs are met consistently and in a timely fashion (such as offering toileting assistance).
- Check for safety precautions, such as sufficient light in the hallway, handrails along the hallway, and the availability of assistive devices.

### Posture

The key to alignment is **posture**; it is how an individual holds their body. There are two types of posture (Medline, 2017):

- The way an individual holds their body at rest is called **static posture**.
- The way an individual holds their body during movement is called **dynamic posture**.

Posture is dependent on the spine, which holds the body upright. [Figure 22.6](#) shows three natural curves in the spine, which can be seen from side to side but not from front to back. These are natural curves and indicate correct posture: the head is naturally above the shoulders, and the tops of the shoulders are over the hips. Correct posture is the position that applies the least stress on each joint.

**FIGURE 22.6** The three natural curves in the spine function as both positioners and shock absorbers. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Faulty posture is any position that increases stress on the joints and thus negatively affects health, such as slouching and slumping over ([Figure 22.7](#)). Over time, faulty posture may impact other body systems, including the digestive and respiratory systems (MedlinePlus, 2017). It can also cause serious issues with the musculoskeletal system, including the following:

- moving the spine out of alignment
- causing pain in the neck, shoulders, and back
- decreasing **flexibility**, the ability to move a joint effectively through its entire range of motion
- eroding vertebrae, causing spinal degeneration and arthritis
- decreasing balance and increasing the risk of falls
- incontinence for people with vaginas

**FIGURE 22.7** (a) Scoliosis, (b) kyphosis, and (c) lordosis are common faulty postures that can be related to a variety of conditions, whether genetic, age-related, or temporary. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Postural Reflexes

A **postural reflex** is an unconscious, involuntary correction that the nervous and musculoskeletal systems make together to keep postural alignment when something threatens to change it. They happen continuously in reaction to Earth's gravitational forces. They also happen in more noticeable ways. For example, when people encounter an unexpected environmental stimulus, such as uneven footing, their postural reflexes kick in to prevent them from falling. Without those reflexes, balance and coordination would be impossible (Phu et al., 2022).

Postural reflexes develop as the human body develops and the spine grows and curves (Carini et al., 2017). Vision aids postural reflexes by allowing a forward visual field with adjustments to allow for stable sight and reduce the risk of falls. The **vestibular system** in the inner ear also plays a part in maintaining balance. Chronic diseases diminish postural reflexes and increase the chances of falling. Some of these diseases are stroke, Parkinson disease, diabetes, HIV, and chronic pain (Phu et al., 2022).

### Ergonomics

The study of movement and body position in work is called **ergonomics**. A basic understanding of ergonomics is important to keeping patients and staff safe during patient care and transferring. Healthcare-acquired injuries and illnesses are all too common nationally. These happen when patients fall, develop infections, or are injured while transferring, during procedures, or through poor body positioning. Techniques for **safe patient handling and mobility (SPHM)** are a set of interconnected techniques designed to allow high-quality care for patients safely and to encourage safe movement without injury to patients or staff (Association of periOperative Registered Nurses [AORN], 2019).

#### Safety in the Workplace

Proper ergonomics is crucial to healthcare workers, who are at high risk for musculoskeletal injuries because they regularly care for patients who may not be able to move themselves. Sprains and strains occur frequently in the workplace but can be prevented by using proper ergonomics and body positioning (Karwowski & Zhang, 2022). These disorders most often occur because of manual activities related to patient care, including heavy lifting and working in awkward positions. In health care, nurses' bodies are in constant motion, and understanding how to protect themselves from injury is critically important. By studying ergonomics and how nurses interact with their environments, patients, and everything around them, researchers have developed evidence-based strategies to improve performance, patient outcomes, and safety while minimizing staff injuries (Karwowski & Zhang, 2022).

#### Assistive Devices

An **assistive device** is available in most facilities to facilitate SPHM ergonomics (Figure 22.8). These devices allow for safe movement of patients between locations—for example, from bed to stretcher or wheelchair, within a bed, or between a bed and bath—and even to assist with standing. Each of these devices is intended to decrease the risk of injury to patient or provider during care.

(a)

(b)

(c)

**FIGURE 22.8** (a) Sliding sheets or boards are friction-reducing surfaces that can be inserted beneath a patient to allow for easier movement between surfaces. (b) Lifts can attach to ceilings or move on the floor; slings go under patients and then attach to lifts. They are used together to lift patients. (c) Mechanical beds often consist of distinct sections that can separately be adjusted. For example, their heads and feet can be raised or lowered, or they may tilt from side to side or convert into chairs. Some beds can even take a patient's weight without the patient having to get up. (credit a: modification of work "Stretcher and slider board" by Glynda Rees Doyle and Jodie Anita McCutcheon, CC BY 4.0; credit b: modification of work "U.S. Navy Medical Team Integrates with Spokane Hospital 211017-A-KC249-1093" by Navy Medicine/Flickr, Public Domain; credit c: RDNE Stock project/Pexels, CC 0)

It is important never to use assistive devices without proper training; assistive personnel should also have been trained. Without proper training, the device could accidentally hurt patients or staff rather than help them (AORN, 2019; Veterans Health Administration, 2022).

### Safe Patient Handling and Mobility

SPHM includes a variety of techniques designed to protect patients' safety and dignity while also protecting staff's safety (AORN, 2019). For patients, the techniques reduce patient falls and skin tears, increase satisfaction, and encourage mobility. For staff, they decrease the risk of acute and chronic musculoskeletal injuries, improve worker morale, and decrease worker fatigue.

Proper preparation for patient care or transfer is hugely important for the safety of patients and staff alike. With every patient-handling activity, take the time to complete the following steps *before* performing the activity.

1. Assess the patient's needs and gather the assistive devices necessary to provide their care.
2. Ensure there are enough staff available to assist with care.
3. Ensure the environment has been properly prepared. For example, move bedside tables and chairs, and ensure that devices that should be locked are locked and those that should be unlocked are unlocked.
4. Make sure team members understand their roles.
5. Explain to the patient the plan, and coach them if they can assist.
6. Apply proper **body mechanics**—intentional movements and muscle use designed to maintain an individual's posture and alignment—to decrease the chance of injury.

Once these preparations have been made, it is much easier to safely handle or transfer the patient, minimizing the injury risk for patients and staff.

### LINK TO LEARNING

The U.S. Veterans Health Administration (VA) has developed [a free app called Safe Patient Handling \(https://openstax.org/r/77safe\)](https://openstax.org/r/77safe) to assist with safe patient handling. Users can explore a variety of patient issues and conditions and receive algorithms and feedback regarding techniques and equipment to use. After downloading the app, click on "Comprehensive Patient Assessment and Algorithms" and try it out with a few hypothetical patients.

### Safe Patient Transfers

Most SPHM professionals aim to eliminate all unnecessary manual patient transfer (National Institute for Occupational Safety and Health, 2023). But when a transfer is necessary, what is the safest way to proceed? Putting all the ideas about SPHM and body mechanics together to use at one time when providing care for a patient can be complicated and feel overwhelming, particularly early in a nurse's career. However, over time these activities will come to feel completely normal. Until then, using formulas and algorithms can help nurses make safe decisions and determine what steps and equipment need to be used.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competencies: Patient-Centered Care and Safety: Transferring a Patient from a Bed to a Stretcher

When transferring a patient from a bed to a stretcher, follow these steps.

1. Let the patient know why the transfer is being made and allow them to ask questions.
2. Determine the following conditions:
  - What does the patient weigh?
  - Will the patient be cooperative with the transfer?
  - Will the patient be able to assist with or perform the transfer?
3. Verify that the receiving surface can hold the patient's weight. If not, obtain a stretcher that will.
4. If the patient is cooperative and can perform the transfer:
  - Ensure the bed and stretcher are both in the lowest possible position.
  - Coach the patient to move between the surfaces.
5. If the patient is cooperative and can assist with the transfer, ask them how they can help and work with them to determine the best strategy.
  - Always allow patients to perform as much as possible without putting anyone's safety in danger.
  - For example, if the patient can roll over, encourage them to roll from side to side while placing the sliding sheet beneath them.
6. If the patient is uncooperative:
  - Try to determine why they are not cooperative. If there is a reasonable expectation that they will be cooperative at another time, try to reschedule the transfer for that time.
  - If the transfer cannot be postponed, request assistance from additional staff as needed.
7. Position the patient on assistive equipment (such as a sliding sheet or sling), with help from additional staff as needed.
  - This will generally be accomplished by "log rolling" the patient from one side to the other while placing the equipment beneath them.
  - Remember, the heavier the patient, the more staff will be needed to position the patient on the sliding sheet or sling.
  - Ensure no tubes or lines are trapped between the patient and the equipment.
8. Ensure the bed and stretcher are both locked in position and the receiving surface is about a half-inch lower than the surface the patient is currently on.
9. Transfer the patient to the receiving surface:
  - With a sliding sheet: push/pull the patient between the surfaces.
  - With a lift: lift the patient with the sling, move over the receiving surface, and lower the sling.
10. Return the patient to a comfortable position.
  - Ensure no lines or tubes are between the patient and surface.
  - Raise the head of the bed, if appropriate.
  - Ensure a call light is within the patient's reach.
11. Before leaving, determine whether the patient is comfortable or has any questions.

### Exercise

Purposeful, structured, and repetitive physical activity that requires sustained effort is called **exercise**. It is well known to decrease the chances for major illnesses and early death and improve the quality of life for most patients. However, people exercise at different levels. Some people do lots of exercise, others do less, and some do none. In the last several years, the scientific understanding of exercise has expanded substantially. Gone are the days when healthcare providers recommended 30 to 60 minutes of continuous, vigorous activity to obtain cardiac benefits. Today, there is a more nuanced understanding of how different types of exercise help different body systems and how much exercise is needed. In this section, we will explore exercise types, recommendations, and some specific exercises to suggest to patients.

## PATIENT CONVERSATIONS

### Discussing a Patient's Physical Activity Level

**Scenario:** The nurse is assessing a patient's activity level. When assessing a patient's activity level, nurses should ensure that patients are considering activity they perform at work, at home, via transportation, or at leisure. Too often, assessments neglect the level of physical activity occurring in settings other than leisure (such as the gym or basketball court). There are often ways to help patients include more physical activity in a variety of settings, such as bicycling to work, using a standing desk, or dancing while doing housework.

**Nurse:** Hi Sarah, I'm Chandra. I wanted to talk to you about physical activity for a bit, if you agree.

**Patient:** Sure, that sounds great.

**Nurse:** So, Sarah, what kind of physical activity do you do?

**Patient:** I like to walk my dogs. I take them on thirty-minute walks two to three days a week, weather permitting.

**Nurse:** Do you do any other types of physical activity?

**Patient:** Well, not much else for fun.

**Nurse:** Can you tell me what you do at work?

**Patient:** I work for a large shipping company.

**Nurse:** Do you get much physical activity on the job?

**Patient:** Actually, I do. I spend several hours a day, five days a week, moving heavy boxes from one location to another.

**Scenario follow-up:** Without a more in-depth assessment, the nurse assessing Sarah's activity level would miss a large piece of her actual activity.

### Types of Exercise

There are several types of exercise, each of which is important for different body systems (Johnston, 2023). Each type impacts multiple systems as well as the body's **core**, or lower torso (particularly the abdomen and lower back). The core controls lower body postural stabilization.

### Stretching and Flexibility

A slow, steady exercise or movement called a **stretch** is designed to extend or lengthen specific muscles or muscle groups in the body (Figure 22.9). They should never be painful and should not be pushed to the point of pain. Flexibility describes the body's ability to bend safely at its joints. Exercises that involve stretching and flexibility improve **range of motion** (the extent and direction of movement that a joint or a group of joints can achieve), muscle relaxation, and comfortable engagement in other activities (Johnston, 2023). They also improve balance and movement coordination and decrease fall risk (Riverra-Torres et al., 2019) and are beneficial for treating and managing pain, particularly chronic pain such as in the lower back (Kim & Yim, 2020).

**FIGURE 22.9** (a) An individual stretches the piriformis muscle that affects hip movement. (b) The hip flexor stretch stretches the hips and improves balance and coordination. (c) The child's pose stretch stretches the hips, lower back, and upper body. (credit a: modification of work "Stretching Fitness Workout" by ThoroughlyReviewed/Flickr, CC BY 2.0; credit b: modification of work by FocusFitness, Public Domain; credit c: modification of work by FocusFitness, Public Domain)

### Aerobic Exercise

A continuous physical activity called **aerobic exercise** increases the heart rate and improves the function of the cardiovascular system—thereby improving the body’s ability to take in oxygen, increasing the amount of blood the heart pumps (stroke volume), decreasing the heart’s workload at rest (resting heart rate), and improving both cardiac and overall mortality rates (Johnston, 2023). The key is to perform aerobic activity for at least several minutes at a time and accumulate enough active minutes over the course of a day to impact the cardiovascular system (Figure 22.10).

**FIGURE 22.10** Aerobic activities include running, walking, dancing, and even vacuuming. (credit: “Aerobic exercise” by CDC/James Gathany/Wikimedia Commons, Public Domain)

### Strength Training

Resistance training, sometimes referred to as **strength training**, involves contracting a muscle against a load, such as free weights, elastic bands, water, or one’s body weight (Riverra-Torres et al., 2019). In addition to improving muscle strength, endurance, and size, strength training improves cartilage health, bone strength, and the individual’s overall functional ability (Maestroni et al., 2020; Johnston, 2023). It can also be used to decrease pain; improve cardiovascular endurance, posture, and flexibility; improve sleep; and help mitigate the effects of metabolic diseases, such as type 2 diabetes, and mental health and neurocognitive disorders, such as dementia (Maestroni et al., 2020).

There are two basic types of strength training: isometric and isotonic (Figure 22.11). Exercise that involves contracting a muscle against an unmoving force (such as a floor or wall) is called **isometric training**. Thus, the muscle cannot shorten or lengthen. It becomes fatigued by the pressure applied against the unmoving object. On the other hand, **isotonic training** involves contracting a muscle against a force that moves (such as a barbell or a weight machine). Users may gradually increase the weight to further strengthen the muscle, but this need not be a priority of a training program.

**FIGURE 22.11** (a) This individual is performing strength training with resistance bands. (b) The plank pose strengthens muscles in the shoulders, back, core, buttocks, and legs. (c) Exercises such as the bird dog strengthen the core. (credit a: “Personal training shoulder exercise” by Tyler Read/PTI Pioneer, CC BY 2.0; credit b: PX here, CC0; credit c: “Woman Doing Bird Dog Exercise To Strengthen Core”/FocusFitness, Public Domain)

### Balance Training

An activity called **balance training** is specifically used to improve an individual’s ability to remain upright while stationary or moving and to decrease the chance of falling (Riverra-Torres et al., 2019). It has also been shown to improve mobility, reaction time, and strength and to assist with postural control, both static and dynamic (Lal, 2022). Balance training frequently occurs in physical therapy and rehabilitation settings where the focus is to retrain the body to maintain its own center of gravity by challenging the individual’s stability (Johnston, 2023). Common techniques include having patients stand on one leg or use balance beams or wobble boards to improve balance in unstable settings. Many poses in the practice of yoga are also excellent for balance training ([Figure 22.12](#)).

**FIGURE 22.12** (a) These people are working on balance during a yoga class by practicing the pose called downward-facing dog. (b) Standing on one leg strengthens postural stability, balance, and ankle strength. (credit a: “Spouses practice the crescent pose during a yoga workshop” by Defense Visual Information Distribution Service/Nara & DVIDS Public Domain Archive, Public Domain; credit b: PX Here, CC0)

## LIFE-STAGE CONTEXT

### At-Risk Populations and Activity

People in marginalized communities—such as people with low incomes, immigrants, and people experiencing homelessness—are much less likely to participate in physical activity. Regular struggles with barriers such as cost, transportation, childcare needs, time, and basic financial and housing insecurity negatively impact their ability to be physically active in a purposeful way, which can profoundly affect their cardiovascular, mental, and physical health. Developing individual or community-level strategies to improve the physical activity of marginalized groups can have substantial impacts. For example, it might be possible to organize walking or aerobics groups in the community or distribute walking or running shoes to patients who have lower incomes (Creagh et al., 2023).

## 22.2 Factors Affecting Activity Level

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe physiological factors affecting activity level
- Recognize psychological factors affecting activity level
- Identify external factors affecting activity level

A profound interplay exists between physical activity and a person's body, mind, and environment. For most people, much of the time, physical activity is beneficial. However, during any physical body movement, a simultaneous feedback loop attaches physical and emotional responses and mental images to the movement. The total experience—physical, emotional, social, and mental—may be stored in the brain as unpleasant and negative, or pleasant and positive. These past experiences with physical movement can impact an individual's willingness to be physically active in the present.

Current conditions, including barriers to activity, can have a similar impact. Consider these two scenarios. Have you ever been sad, taken a walk to shake it off, and felt better after the walk? Alternatively, have you ever been sad and thought about taking a walk but not done it—perhaps you were physically unable to, or perhaps you simply did not feel up to it? These scenarios illustrate the double-edged nature of physical activity: there are many situations in which it will help, but only if the individual can overcome whatever barriers—whether past experiences or current health or environmental conditions—they experience to engage in it. Because physical activity has such enormous potential to positively impact the totality of a patient, it is important to help patients recognize and overcome their internal and external barriers.

### Physiological Factors Affecting Activity Level

Despite the many well-known benefits of exercise, many people are reluctant to begin and stick with a prescribed exercise regimen. For many patients who are chronically ill, pain, weakness, and fatigue may negatively impact their activity (U.S. Department of Health and Human Services [DHHS], 2017). Others may be concerned that they are already too out of shape to be successful or that they will worsen preexisting conditions (American Diabetes Association, n.d.).

As the body ages, certain problems in the musculoskeletal system can have a negative impact on proper alignment and movement. Similarly, illness or trauma involving other body systems may interfere with movement because of either the underlying pathology or the treatment regimen. Nurses must be sensitive to how both acute and chronic health problems affect a patient's general appearance and their ability to purposefully perform even the most basic self-care activities. For instance, patients experiencing pain may present with a lack of visible energy and enthusiasm. Body posture also may be affected. For example, a person with chronic pain may often sit with their head bowed and shoulders slumped and may lack the energy to eat or even to use the toilet.

### Growth and Development

Physical activity depends on muscle growth and development. For example, babies do not have the muscle strength to carry their body weight until they are about a year old. All children in the United States are screened for development on a regular schedule as part of the recommendations from the American Academy of Pediatrics (Centers for Disease Control and Prevention [CDC], 2022b). Children who show delays in development may be referred for further screening or therapy, such as occupational or physical therapy. It is important to remember that every child develops at their own pace. However, a child who consistently misses milestones or loses skills should be evaluated by their healthcare professional for underlying conditions that might be contributing to the delays.

### LINK TO LEARNING

The CDC's [Milestones in Action \(https://openstax.org/r/77milestone\)](https://openstax.org/r/77milestone) website offers a wonderful collection of pictures and short videos regarding a variety of age appropriate milestones.

### Physical Health

Physical health is directly correlated to one's physical activity level. Patients may experience any number of physical

problems with the musculoskeletal system, which can all negatively influence their physical activity level. For example, trauma such as sprains and soft tissue injuries and chronic conditions such as degenerative bone disease all limit one's level of activity. Nurses must perform comprehensive assessments to determine appropriate activity for each patient.

It is critically important that patients progress toward targets rather than trying to jump directly to them (DHHS, 2021). Pushing patients to perform at a higher level than they are capable of can lead to injury, frustration, and unwillingness to continue. For example, patients who are totally inactive should begin activity slowly, performing light-intensity activities such as slow walks (less than 2 mph). As their **stamina** (physical and mental capacity to endure prolonged periods of exertion or activity without experiencing fatigue) and **endurance** (ability to withstand or tolerate prolonged physical activity or hardship over time) improve, they can move up to faster walks. Nurses serve the unique role of understanding each individual patient's limitations and can assist in developing a tailored plan of care.

### Postural Abnormalities

Postural abnormalities such as contractures, scoliosis, or kyphosis often restrict range of motion and cause balance issues that make physical activity uncomfortable. Patients with postural abnormalities who have experienced a related fall, with or without injury, are often less willing to exercise because they do not want to risk further injury (Sherrington et al., 2020). As a result, their issues frequently become worse over time.

When working with these patients, educate them based on their health literacy and encourage them to find exercise opportunities in supervised group settings (where they may feel safer) that target strength and balance. These exercises can help patients be less likely to experience another fall (Sherrington et al., 2020). Yoga, tai chi, and qigong have all been shown to be effective in working with a variety of conditions, including postural abnormalities and balance issues. These types of exercises involve a variety of gentle movements that stretch muscles and encourage postural correction and stability. They are also modifiable for use with patients using a wheelchair or experiencing other disabilities.

### Bone or Joint Abnormalities

A measurement of **bone density** studies the amount of hard minerals—specifically calcium and phosphorous—present in bone; these minerals account for bone's strength and resilience. Patients who have lost bone density are at increased risk for fracture. Often, patients who have already experienced a fracture related to bone density are very careful not to engage in activities that may put them at risk of additional fracture. For patients who also have low health literacy, careful education is required to teach that age-related loss of bone density can be slowed down by regular physical activity, including aerobic, muscle-strengthening, and bone-strengthening activities. Studies indicate that the most significant changes are seen in patients who perform at least ninety minutes of these activities weekly (DHHS, 2021).

Joint abnormalities, such as osteoarthritis and various rheumatic conditions, result in pain. Studies have shown that participating in at least 150 minutes per week of aerobic activity and muscle-strengthening exercises decreases pain and improves overall joint function and patient quality of life (DHHS, 2021). However, it is frequently difficult to begin exercising because the idea that the exercises will decrease pain is counterintuitive for many patients, particularly those who have a history of pain with exercise.

## LIFE-STAGE CONTEXT

---

### Osteoporosis Prevention in Older Adults

A common bone disease called **osteoporosis** makes bones weak and more likely to break, is characterized by low bone density and deterioration of bone tissue—particularly in the hips, wrists, and vertebrae (Figure 22.13). Ten million Americans currently have osteoporosis, including half of all adults over age 50; another forty-four million Americans with low bone density are at risk of developing it (Bone Health & Osteoporosis Foundation, 2022). The disease is more common in women than in men, and the chance of developing it increases with age (Pinheiro et al., 2020). Often it stays undiagnosed until an individual breaks a hip, vertebra, or wrist.

**FIGURE 22.13** Note the difference in curvature between the normal bones and the bones with osteoporosis. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Patients with osteoporosis may have bone deformities that affect their posture. They may appear to be hunched over and frail from bone loss. To combat or prevent this, weight-bearing exercises are encouraged. These exercises stimulate the absorption of calcium back into bones, thus strengthening bones, stopping the loss of bone mass, and preventing fractures (Pinheiro et al., 2020).

### UNFOLDING CASE STUDY

#### Unfolding Case Study #4: Part 3

Refer back to [Chapter 19 Oxygenation and Perfusion](#) for Unfolding Case Study Parts 1 to 2 to review the patient data. Mrs. Jenson, a 72-year-old female, presents to the emergency room with worsening shortness of breath, fatigue, and swelling in her lower extremities over the last week. She reports increasing difficulty performing activities of daily living due to weakness and increased dyspnea. She has been admitted to the hospital and has just arrived in her room on the telemetry unit.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, heart failure (class III), osteoarthritis</p> <p><b>Family history:</b> No significant family history reported.</p> <p><b>Social history:</b> Widowed ten years ago, currently living in an assisted care facility. No children.</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Lisinopril 20 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Metoprolol 50 mg PO once daily</li> <li>• Aspirin 81 mg PO once daily</li> <li>• Furosemide 40 mg PO once daily</li> <li>• Losartan 25 mg PO once daily</li> <li>• Ibuprofen 400 mg PO Q6 hours PRN mild arthritic pain</li> </ul>
Flow Chart	<p><b>Time: 1300</b></p> <p>Blood pressure: 142/80 mm Hg</p> <p>Heart rate: 98 beats/minute</p> <p>Respiratory rate: 20 breaths/minute</p> <p>Temperature: 98.9°F (37.1°C)</p> <p>Oxygen saturation: 94 percent on 2 L nasal cannula</p> <p>Pain: 6/10 (joint pain)</p>
<ol style="list-style-type: none"> <li>1. Recognize cues: What cues are the priority for the nurse to recognize?</li> <li>2. Analyze cues: Based on the priority cues recognized in the first question, what other information would the nurse want to obtain from the patient at this time?</li> <li>3. Prioritize hypotheses: How do you think the patient's osteoarthritis affects her quality of life and physical activity level?</li> </ol>	

### Muscle Abnormalities

One of the most common disorders related to muscle abnormalities is muscular dystrophy, which describes a group of disorders that cause skeletal muscles to weaken and atrophy, and the **myopathy**, which is characterized by failure of the muscle fibers, causing muscular weakness (Siciliano et al., 2019). Traditionally, patients with these disorders have been discouraged from participating in physical activity, as it was thought to speed up the degeneration and dysfunction of the muscles. However, the newest guidelines encourage physical activity (Siciliano et al., 2019). The benefits of gentle balance, stretching, or aerobic activity to the muscles may outweigh the risks. Still, no single exercise prescription fits these patients due to variations in the disorders. Decisions about physical activity should be made under a physician's supervision because, for these patients, inappropriate exercise can cause permanent damage.

The following guidelines are key when caring for patients with muscular abnormalities:

- Do not perform aerobic activities while moving downhill.
- Do not exercise to exhaustion.
- Do not exercise during acute exacerbations of the disorder.
- Do not force or try to hyperextend any muscle movement or muscle group.

### Central Nervous System (CNS) Abnormalities

Diseases or injuries that affect a patient's central nervous system (CNS) have a direct impact on their ability to perform exercise. This is because the CNS controls movement and balance. CNS abnormalities may occur because of diseases that affect neurons, such as multiple sclerosis (MS), a progressive disorder of the CNS characterized by weakness, numbness, decreased muscle coordination, and intermittent exacerbations. Other CNS disorders are related to injuries and problems with the spinal cord, such as paralysis. These and many more neuromuscular abnormalities affect the messaging and mechanics of movement, creating barriers to physical activity.

## REAL RN STORIES

### A Patient with Multiple Sclerosis

**Nurse:** Ashley, RN

**Clinical setting:** Ortho-neuro unit

**Years in practice:** 15

**Facility location:** Thibodaux, Louisiana

We used to have this patient, Livia. She was my age (around 43 then) and a single mother—like me. She was on disability because her multiple sclerosis was severe enough that she was unable to work consistently. She used many of the outpatient services available at my hospital, so I would occasionally see her then, or sometimes she would even drop by the unit to say hello. When she was in good condition, she did great. She used a cane, but it was almost exclusively for some balance help. When her MS was exacerbated, however, she could barely walk and needed to use a wheelchair for days or even weeks. She often visited the hospital for several days of high-dose steroids when she had a bad flare-up. It was always hard to see. She would feel so frustrated with herself—like she had done something wrong.

Livia and I spend a lot of time discussing her illness and her life’s stressors. Many things can cause MS to flare up, such as stress, infections, too much activity, and even getting your period. For a single mom with younger kids, it was like living in a minefield of things that could trigger her. I spent a lot of time considering how I would manage being in her situation. Her ability to adapt and overcome always amazed me. She pushed through barriers to activity and even engagement with the world—barriers that I often felt would have stopped me. Eventually, Livia met a lovely man, they married, and he adopted her children. She had fewer flare-ups after that. I heard that they moved out of state a while back. I still think of her and hope she is doing well.

### Psychological Factors Affecting Activity Level

Have you ever heard that the whole is more than the sum of its parts? A concept called **quality of life (QoL)** reflects the meaning of that expression. In health care, QoL seeks to capture an individual’s overall well-being. It consists of the totality of the patient’s mental and physical health, as well as their beliefs and values about their health.

Physical activity is a key component of QoL—done properly, it improves both physical and mental health.

Unfortunately, as with purely physiological factors, patients must often overcome psychological barriers to exercise before they experience the positive effects to their QoL ([Table 22.4](#)).

Barrier	Strategies to Overcome
Feelings of isolation or loneliness	<ul style="list-style-type: none"> <li>• Encourage patients to work with a family member or friend or participate in group activities.</li> <li>• Encourage patients to discuss their needs or goals with family or friends and ask for support.</li> <li>• Describe the benefits of joining a gym or activity club to meet other people like them.</li> <li>• Suggest patients seek out others in their fitness groups to “buddy” with for support.</li> </ul>
Fear of injury	<ul style="list-style-type: none"> <li>• Provide education regarding equipment and assistive devices.</li> <li>• Encourage structured settings with supervision.</li> <li>• Suggest balance and strength exercises to reduce the risk of falling.</li> <li>• Recommend starting slowly and simply to build confidence.</li> <li>• Encourage warming up and cooling down.</li> </ul>

**TABLE 22.4** Psychological Barriers to Exercise (Sources: DHHS, 2017; CDC, 2022b; AHA, 2021.)

Barrier	Strategies to Overcome
Feelings of embarrassment (e.g., regarding weight, ability, or current inactivity level)	<ul style="list-style-type: none"> <li>• Suggest exercising independently in the patient’s home using equipment or videos.</li> <li>• Encourage joining a class designed for beginners so everyone is at the same level.</li> <li>• Ask if they have a friend or colleague who might be similarly active and willing to work together.</li> <li>• Suggest joining a social activity (such as bowling or a dance class) rather than more traditional forms of exercise.</li> </ul>
Lack of motivation	<ul style="list-style-type: none"> <li>• Discuss activities the patient enjoyed when younger and might enjoy again.</li> <li>• Suggest trying several types of activities.</li> <li>• Encourage them to retrain how they think of exercise—not as drudgery but as fun—and to identify activities they enjoy.</li> <li>• Suggest exercise equipment that can be used while they do things they enjoy, such as watch TV.</li> <li>• Encourage getting an exercise buddy to work with consistently and motivate each other.</li> </ul>

**TABLE 22.4 Psychological Barriers to Exercise** (Sources: DHHS, 2017; CDC, 2022b; AHA, 2021.)

### Mental Health

Mental health and physical activity have a complicated relationship. Poor mental health is frequently a barrier to physical activity; however, physical activity can improve mental health conditions. A study performed during COVID-19 shows this relationship—and the related barriers to physical activity—quite clearly. This study found that people were less likely to be physically active during the pandemic than before it (Marashi et al., 2021). The respondents who had decreased their activity the most reported the greatest increases in anxiety, depression, and stress. These same people listed anxiety and lack of motivation as primary barriers to exercising. In contrast, the study participants who remained physically active experienced substantial relief from anxiety.

### Lifestyle Variables

A **lifestyle variable** refers to the daily actions and activities related to work, leisure, and diet. For example, a diet largely consisting of processed foods may not provide enough energy or the increased metabolism needed for health-promoting activities. These variables can have a direct effect on health and exercise. People who do not exercise or remain seated for most of their daily activities have a sedentary lifestyle. On the other hand, people who incorporate exercise and physical activity into their daily life have an active lifestyle. These people will generally have more muscle mass and be stronger and in better health than those who are sedentary. Occupations that require an extended amount of sitting can contribute to a sedentary life in the same way that choosing energetic leisure activities such as hiking contribute to an active lifestyle.

### Attitudes and Beliefs

The way individuals perceive physical activity greatly impacts their willingness to participate in physical activity (Quicke et al., 2017). Individuals who do not believe they can successfully be physically active, or who believe that activity will increase their pain, fatigue, or likelihood of injury, are less likely to participate in prescribed exercise. Thus, the expectation of a negative outcome may be a barrier to physical activity. When working with these patients, focus on the positive outcomes from physical activity, such as its positive impact on an individual’s self-concept, psychological well-being, and body satisfaction, which contribute to improving psychological well-being and overall QoL (Fernández-Bustos et al., 2019).

### Fatigue

Fatigue is one of the classic double-edged swords of physical activity. It can be substantially decreased through regular physical activity. Unfortunately, it also poses one of the most common reasons individuals give for being

unable to exercise. When working with patients, encourage them to think about when they are most fatigued and when they have the most energy. Suggest that they begin small by planning activities during times when they generally have the most energy. Educate them about the feedback loop in which sedentary behavior can make fatigue worse, whereas physical activity can make it better. For many this may be counterintuitive, and it is certainly possible to be physically active to the point of exhaustion. However, in general, when individuals start slowly, well within the level of their abilities, and advance their activity over time, they feel less fatigued all the time. Remind patients that they can perform physical activity in short bursts. They do not have to walk continually for sixty minutes; they can walk around the outside or even in their living room for two minutes at a time throughout the day.

### Stress

Exercise and stress have an interesting relationship. Exercise decreases stress levels. Yet, high-stress levels decrease the likelihood of exercising (Burg et al., 2017). Even anticipation of stress the following day can decrease the likelihood of an individual engaging in physical activity. Further, high levels of psychological stress predict lower levels of physical activity and higher levels of sedentary behavior (Stults-Kolehmainen & Sinha, 2014). This holds true whether the stress is related to objective, external life events or to subjective internal states. People who are stressed may believe they have no time to exercise due to work schedules, family obligations, study obligations, or other commitments.

When working with individuals who are experiencing high levels of stress or who provide stress as a reason for lack of physical activity, try the following strategies:

- Remind them that any exercise is better than no exercise.
- Encourage them to lower the exercise intensity when they are feeling particularly stressed.
- Suggest they move a little daily, even if only by taking a few minutes during sedentary sessions to stretch their legs.
- Encourage them to plan their physical activity and schedule it as they do other parts of their lives.

## PATIENT CONVERSATIONS

### Helping Patients Overcome Barriers to Physical Activity

**Scenario:** Nurse Susan Schindler is 44 years old and works in an outpatient clinic in Lexington, Kentucky. She has worked at the clinic for five years and is currently working with a new patient regarding physical activity. The patient has stated that she would like to be more physically active, but she does not have the time or know where to begin, and she is worried about how activity will impact her lower back pain. The physician has asked the nurse to give the patient the results of her x-rays and discuss options for physical activity.

**Nurse:** Hello, Ms. Mayberry. My name is Susan. Dr. Brunner asked me to come and chat with you about physical activity and exercise. Your back x-rays came back and there are no contraindications to a normal exercise program. If you are interested, Dr. Brunner would like to refer you to physical therapy. They can work with you on back pain, do manual manipulation, and teach you stretching and strength exercises if you would like.

**Patient:** Well, I guess that's okay. I'm just not sure I have the time to go to physical therapy.

**Nurse:** If you don't have time for physical therapy, you can try several other options, such as tai chi or yoga, that you can do with videos at home. Just be careful not to push yourself past the point where you feel any pain.

**Patient:** I just don't know where to start. It has been a long time since I've been at all active.

**Nurse:** There are several places around town that offer low-impact aerobics or other types of group fitness classes for beginners. Maybe you could attend one of those once a week and then find some ways to do a few minutes of exercise at other times of the day. All it takes is a few minutes at a time to have a positive effect on your body.

**Patient:** Really? I thought I had to work out for at least an hour each time. I don't know how I would do that even if I wanted to—between my pain and my schedule.

**Nurse:** Yes, really! Just a few minutes at a time, here and there, will go a long way to helping you feel better. Simple things, like parking farther away from stores to give yourself a bit longer to walk or walking around your yard for a

few minutes with your dog or kids, are great ways to start.

**Patient:** Yes, I can do that easily. My daughter loves to run around the yard, but I never go out with her.

**Nurse:** She would probably like to have you out there with her occasionally. I also recommend seeing the physical therapist at least a couple of times. We work with a good one who has extended hours and can work around almost any schedule. May I schedule an initial consultation for you? Even a few sessions might give you the tools to really help your pain.

**Patient:** Yes, I think so. I would like that. Thank you.

**Nurse:** Excellent. If you have any other questions, feel free to call the office.

---

## External Factors Affecting Activity Level

In addition to physical and psychological factors specific to the individual, external factors influence whether an individual engages in physical activity. Sadly, socioeconomic and environmental factors result in clear differences in the amount of physical activity performed by different groups of people.

### Socioeconomic Factors

Physical activity is often presented in our culture as a luxury, requiring considerable time, expensive equipment, and a gym membership. Patients concerned about the perceived high costs of physical activity may avoid exploring inexpensive or even free options, such as jogging or working out with resistance bands, jump ropes, and water bottles as free weights. Lack of childcare can also be a significant barrier to physical activity. Simple activities such as walking and dancing can be ways to involve the whole family in exercise. Patients may also explore cooperative relationships with friends or relatives, trading babysitting for exercise time.

### Environment

Environmental factors can also facilitate or inhibit physical activity. For example, access to safe walking paths, facilities, or trails may encourage local people to be physically active, just as lack of access may discourage them (Riverra-Torres et al., 2019). Individuals living in rural areas may not have walking paths or access to facilities (free or paid) where they can exercise (Pelletier et al., 2021). Understanding the local conditions and available resources enables the nurse to provide higher-quality education regarding physical activity in any environment.

### Weather

An important component of the environment that is often overlooked when planning an exercise regimen is weather. Bad weather can completely derail an individual's fitness plan, particularly if it is exclusively based on outdoor activities. Encourage patients to develop various fitness options, including ones that can be done indoors, such as exercise videos, walking around a mall, or dancing classes. That way, when they cannot bike, walk, run, or play tag with their kids outside, they do not have to miss their daily physical activity goals (CDC, 2022b).

## 22.3 Activities of Daily Living (ADLs)

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize the types of ADLs
- Describe the causes of limitations with performing ADLs
- Identify measurement tools for the performance of ADLs

A functional performance activity, also called an **activity of daily living (ADL)**, is an essential, routine task that most people can do independently most of the time. If you are reading this and going to nursing school with the intent to practice as a nurse, you probably perform all your ADLs independently. You can dress, shop, and cook for yourself without help. However, perhaps you have had an occasion—maybe during an illness—when you needed help with those basic functions.

A great deal of nursing care, particularly in hospitals and long-term care facilities, is centered around aiding patients with ADLs or completely performing ADLs for patients who cannot perform them independently. Individuals with disabilities or chronic illness, patients recovering from recent surgeries, and even many older adults may regularly require assistance with ADLs. In long-term facilities, staffing decisions are frequently made based on the number of

patients needing assistance with ADLs and the number of ADLs each patient needs. Even funding agencies such as the Centers for Medicare & Medicaid Services use ADLs to estimate a patient's time for rehabilitation after an illness, and the performance measures used to evaluate and rank care facilities are often partly based on ADLs. Many insurers decline to provide permanent nursing home care unless the patient has lost three or more ADL abilities.

The inability to perform basic routine tasks can lead to safety and health risks for individuals and decrease their quality of life (QoL). Even in outpatient care, regular assessment of ADL ability is an important part of ensuring that patients receive the care they need. Gradual decline in ADLs over a long period of time is not unusual, particularly in patients over 85 years—sometimes called the oldest old. The 2011 U.S. National Health Interview Survey revealed that 20.7 percent of all adults over 85 required ADL assistance, whereas only 3.4 percent of those between 65 and 74 required help (Edemekong et al., 2022). However, a rapid decline in ADL ability in any patient is cause for alarm. Thus, understanding and recognizing ADL ability is important in all healthcare settings.

## Types of ADLs

There are two types of ADLs: basic and instrumental. A physical ADL is also considered a **basic activity of daily living (BADL)**. They are things that most individuals learn as children when they are reaching various developmental milestones, and they make up the basic skills necessary to manage one's physical body. A complex activity called an **instrumental activity of daily living (IADL)** makes up the skills required to live independently in community settings. These are everyday activities typically learned as adolescents.

### Basic ADLs

Healthcare providers generally recognize the following BADLs:

- **Transferring:** the ability to move one's body from one location to another, such as from a bed to a wheelchair and vice versa.
- **Continence:** the ability to maintain control of one's own bowel and bladder functions.
- **Eating:** the ability to feed oneself and use utensils without assistance from others.
- **Dressing:** the ability to make appropriate clothing choices for the occasion or weather and put on the clothes (including zippers and buttons) without assistance.
- **Bathing:** the ability to wash oneself and provide for one's basic cleanliness.
- **Grooming:** the ability to brush one's teeth and care for one's nails and hair.
- **Toileting:** the ability to move to and from the toilet, use it correctly, and clean oneself afterward.

Note that there are some variations in BADLs depending on the source or the measurement instrument being used. For example, some agencies combine toileting and continence or list walking as a separate BADL.

When a patient begins to lose their BADLs, the chances of gaining a nursing home admission increase dramatically—especially upon loss of the abilities to bathe, feed, or dress oneself. It is very difficult for families to provide full-time care for individuals who need extensive assistance with their BADLs. In a 2018 study of long-term care providers in the United States, 251,100 individuals were using an **adult day service** to meet their needs when their caregivers are working. Of those individuals, 64 percent needed help with three or more BADLs (Lendon & Singh, 2021).

### Instrumental ADLs

IADLs are higher-order skills requiring complex physical or mental processes. They include the following:

- **Transportation:** the ability to either arrange for transportation, such as a cab or bus, or provide one's own transportation.
- **Shopping:** the ability to acquire items needed for daily life, such as food, medication, and clothing.
- **Managing finances:** the ability to pay bills and manage bank accounts.
- **Meal preparation:** the ability to plan meals and cook for oneself.
- **House cleaning:** the ability to maintain one's living space by completing tasks such as cleaning dishes after eating, taking out the trash, and straightening up living areas.
- **Laundry:** the ability to wash and dry one's clothing.
- **Home maintenance:** the ability to keep one's home in good repair, either by performing tasks oneself or by arranging for others to do them.
- **Managing communication:** the ability to communicate as needed via phone, mail, or computer.

- Managing medications: the ability to obtain medications and take them as ordered.

The loss of an individual's ability to perform IADLs is often the trigger when families recognize a cognitive decline in their loved ones; it may be one of the first noticeable signs of dementia.

### Limitations with Performing ADLs

Individuals who cannot perform ADLs independently and lack assistance are at risk for a variety of health and safety concerns, including malnutrition, poor hygiene, illnesses such as urinary tract infections, and injuries from falls. Unidentified ADL limitations are associated with higher chances of mortality, added healthcare costs, and admission to institutional care (Huntsberry-Lett, 2023). These limitations can have many causes, including musculoskeletal, CNS, circulatory, sensory, and respiratory disorders; impairment can also result from aging, medication side effects, and cognitive decline (such as dementia). Regular physical activity can prevent or delay the loss of ADL functioning (DHHS, 2021).

### Aging

By 2030, there will be seventy-two million people in the United States over age 65—that will be 20 percent of the population (Tatum et al., 2018). As individuals live longer, their chances of experiencing multiple chronic illnesses and disabilities also increase. For older adults with Medicare, ADL assessment can be included in the yearly primary care wellness visit as part of a more extensive health risk assessment and testing for functional status and safety (Tatum et al., 2018). ADL skills assessments can be provided to patients or their caregivers to complete prior to seeing the physician, who can then review the results and discuss any implications and needs for community or rehabilitation assistance.

When working with older patients, particularly those with multiple comorbidities, exploring their desire for ongoing care is important. For many older adults, **aging in place**—remaining in their home, with or without caregivers—is a major priority. Many agencies are designed to allow older adults to remain at home for as long as possible. However, some strategies may require advanced planning by the patient and their family (National Institute on Aging [NIA], 2019). Exploring options early and planning for possibilities is key to ensuring an older adult can remain at home even when they begin to lose some of their ADL skills.

## CULTURAL CONTEXT

---

### ADLs, Multiple Chronic Conditions, and Older Mexican Americans

Individuals of Hispanic heritage now make up the largest minority group in the United States; they include more than 3.1 million individuals aged 65 and over, the majority of whom are Mexican Americans. Older Mexican Americans tend to have more chronic health conditions, such as arthritis, stroke, and cognitive decline, than their non-Hispanic White counterpart; those with three or more health conditions are likely to have severe ADL limitations (Collins et al., 2018). At the same time, they have longer life expectancies than non-Hispanic Whites. While both Hispanic and non-Hispanic populations experience loss of QoL due to limited BADLs and IADLs, older Mexican Americans may experience the limitations longer and with greater severity due to their greater life expectancy and number of chronic health conditions.

*Familismo* is a cultural practice common to many of Hispanic heritage; it refers to the connections within one's family, both emotionally and in terms of responsibility. As a result of *familismo*, older Mexican Americans are less likely to be placed into long-term care situations, such as nursing homes, and less likely to use home health services (Collins et al., 2018). These individuals are more likely to look to families to meet their healthcare needs rather than rely on external resources.

The combination of longer life expectancy and expectation of family responsibility can be a heavy burden on Hispanic families no matter how much they love their older relatives, particularly as the caregivers themselves age. When working with patients of Hispanic or Mexican American heritage, it is important to ensure that ADL and functional limitations are being identified and that their families and caregivers are being offered and given the support they are eligible for in a fashion that is culturally appropriate for them (Collins et al., 2018).

---

### Cognitive Decline

Some minor cognitive decline is considered normal in older adults, and the chances of cognitive impairment increase with age (Tatum et al., 2018). However, a dementia is not a normal part of aging; they are irreversible, progressive disorders of the brain characterized by loss of cognitive and physical functioning. One of the most common causes of dementia is Alzheimer disease, a progressive cognitive disorder of the CNS that destroys the abilities to remember, problem solve, and eventually to manage even simple tasks; the disease may also cause personality and mood changes (NIA, n.d.). An estimated six million Americans have Alzheimer disease, although many have not yet been diagnosed (NIA, n.d.). Assisting these patients to establish early and long-term plans and connecting them with other agencies that can assist them are important parts of their healthcare team's obligations.

Taking longer to complete BADLs and difficulty managing IADLs are often the first signs that family members, and sometimes the patients themselves, begin to notice. By the time a patient reaches the late stage of Alzheimer disease, they are generally entirely dependent on others for all their ADLs (NIA, n.d.).

Suppose a patient has been diagnosed with early-stage dementia. In that case, they and their family should begin planning for their future. Many will be able to remain in their homes initially, some for years, before needing long-term care. However, they must establish strategies for managing IADLs—such as taking medications, purchasing groceries, and paying bills—as limitations in those activities often appear before limitations in BADLs. The patient should develop strategies to help themselves remember important things they need daily, such as using calendars or notebooks and keeping items together in a prominent place. They should also set up ways to pay bills, such as automatic bill pay, or ask someone they trust to pay their bills instead. Safety measures such as automatic cutoffs on stoves and emergency call buttons should be installed, and smoke detectors should be inspected and upgraded if necessary.

### Acute Illness

Particularly among older adults, an acute illness often causes a loss of ADLs. Nurses can improve these outcomes through individualized plans of care. For example, nurses can actively encourage providers to order physical therapy and participate in early mobilization efforts. Additionally, nurses can ensure that call lights are answered promptly to decrease patients' reliance on adult briefs and discourage the use of urinary catheterization when possible.

### LINK TO LEARNING

---

Many agencies offer home health services to individuals to allow them to remain in their homes and live as independently as possible for as long as possible. Adult day care programs are excellent options for many older adults who want to age in place and be as independent as possible but are unable to manage all their ADLs or lack the cognition to be safely alone. Check out this short video about [using adult day care \(https://openstax.org/r/77adultcare\)](https://openstax.org/r/77adultcare) to facilitate aging in place.

---

### Delirium

If patients experience episodes of delirium while in the hospital, their chances of losing ADL function increase dramatically. An acute cognitive change called delirium resembles dementia in many ways; it is most often related to medical illnesses, substance use, surgery, chemical imbalances, or withdrawal from medications (Bellelli et al., 2021). However, unlike dementia, delirium is reversible if identified and treated appropriately.

Delirium is more common in older adults. For patients, the risk of delirium increases with the length of hospitalization, severity of illness, frailty of the patient, and number of medications and treatments provided. Additional risks include sensory deprivation, urinary catheterization, and preexisting dementia (Bellelli et al., 2021). Patients experiencing delirium are often too confused to provide self-care and lose their ADL abilities. Those losses can be permanent if not identified early and treated promptly (Weng et al., 2019).

### Measurements for Performance of ADLs

Measuring ADL performance is an important part of evaluating an individual's health status and needs. Measurement can assist in identifying safety risks and the kinds of living environments or assistance strategies that are appropriate for a patient. Medicaid, the U.S. Department of Veterans Affairs (VA), and other insurers consider a

patient's **functional ability**—the ability to independently perform expected tasks, including ADLs—when determining whether they are eligible for benefits such as home health aides or long-term care (American Council on Aging [ACA], 2023).

A measurement of ADL performance is called a **functional assessment**. They aid in determining an individual's capacity to perform BADLs and IADLs. They are used in a variety of settings. Primary care and acute hospital providers may use them to decide the types of care a patient requires upon discharge or the onset of acute functional changes. Short-term rehabilitation specialists may use them to assist in developing care plans and establishing a baseline between where a patient was prior to an illness or surgery, where they are currently, and where they would like to be. Long-term care facilities may use them to validate the need for a patient's continued admission. Third-party payers, such as Medicaid and the VA, use them to confirm a patient's need for services.

There are a variety of common functional assessments that may be used independently or in conjunction with each other, depending on the purpose of the assessment. They include the Katz Index of Independence in Activities of Daily Living (Katz ADL Index), the Lawton-Brody Instrumental Activities of Daily Living Scale (Lawton Scale for IADL), the Klein-Bell Scale (the most complex), the Cleveland Scale (for individuals who have Alzheimer disease), the Bristol Scale (for individuals with dementia), and the Barthel Index. The most common are the Katz ADL Index, the Lawton Scale for IADL, and the Barthel Index (ACA, 2023).

### Katz Index of Independence in Activities of Daily Living (Katz ADL Index)

The Katz ADL Index measures the ability of an individual to perform six BADLs. It can be given periodically to identify whether changes to the individual's functioning have occurred. It is one of the most used indexes, particularly for patients transferring from hospital to home (Liebzeit et al., 2018). It is effective in identifying large declines but not incremental declines or improvements (Witt & Hoyt, 2023).

## LINK TO LEARNING

The Hartford Institute offers an example of a [Katz ADL Index \(https://openstax.org/r/77katz\)](https://openstax.org/r/77katz) worksheet. Check it out to see how it works in practice.

The Katz ADL Index contains six items: the BADLs of dressing, toileting, bathing, transferring, continence, and feeding (Liebzeit et al., 2018). It is a yes-or-no instrument; either the patient can perform a task independently or they require assistance. If the patient can perform the task independently, they score a 1 for that item and if they cannot perform the task independently, they score a 0 for that item. Assessment is usually done either through self-report by the patient or by their caregivers. A score of 6 indicates the patient is independent, 4 indicates the patient has moderate impairment, and 0 indicates the patient is very dependent.

## PATIENT CONVERSATIONS

### How to Perform a Katz ADL Index Assessment

**Scenario:** Mr. Solomon is a 69-year-old Black male who has recently moved and is having an initial appointment with a new primary care provider. During his intake, the nurse collects much of his history and pertinent data and uses the Katz ADL Index assessment to evaluate Mr. Solomon's ADLs.

**Nurse:** Okay, Mr. Solomon, I'm going to move on to some other types of questions about your daily life and activities. Are you able to bathe yourself?

**Patient:** Yes.

**Nurse:** Do you dress yourself?

**Patient:** Depends on who you ask. My granddaughter says I have no fashion sense.

**Nurse:** My daughter says the same about me. How about toileting? Do you ever need help with that?

**Patient:** Only for a few weeks after I broke my leg. That was so embarrassing to have to get my wife to wipe me after

I stooled. Now I'm fine again.

**Nurse:** Do you ever have problems getting to the toilet? Or do you have issues controlling your bladder?

**Patient:** Since my prostate surgery, I sometimes have problems getting to the toilet quickly enough and pee myself. I wear pads for that.

**Nurse:** That is more common than you may realize. I see that you walk with a cane. Do you ever have problems getting from one place to another?

**Patient:** Only if I do not have my cane. I can get off balance easily, you see. But if I have my cane, I can get wherever I need to go.

**Nurse:** Finally, are you able to feed yourself?

**Patient:** Yes.

**Scenario follow-up:** The nurse has quickly completed the Katz ADL Index scale with Mr. Solomon; being unable to reliably control his bladder, he scored 5 out of 6 possible points. Also, he has a strategy to manage the one issue for which he is not fully independent without assistance: pads for when he can't get to the toilet in time. This information provides the new provider with a baseline for Mr. Solomon's physical functioning. The nurse performed the same type of questions with Mr. Solomon about his IADLs and discovered he has no difficulties there.

### Lawton-Brody Instrumental Activities of Daily Living Scale (Lawton Scale for IADL)

The Lawton Scale for IADL was developed to measure more complicated ADLs. Interestingly, the original scale, developed in 1969, reflected the expected gender roles of the time (Liebzeit et al., 2018). It had 8 points for women: the abilities to use a telephone, prepare food, do laundry, shop, and manage transportation, medications, housekeeping, and finances. It had only 5 points for men: the abilities to use a telephone, shop, and manage transportation, medications, and finances. Today's version includes 8 points for all genders—those on the original scale for women (Liebzeit et al., 2018). It is a self-reported questionnaire that can either be filled out by a patient or family member or given orally by a nurse.

### The Barthel Index

The Barthel Index (BI) is another common instrument frequently used in rehabilitation centers to gauge patient progression. It allows for a more nuanced and expanded examination of the BADLs (Liebzeit et al., 2018). It expands and separates some categories. For example, controlling one's bowel and bladder are separate activities, as are bathing and grooming (e.g., caring for one's face, hair, and teeth) and mobility on flat surfaces and on stairs. It also allows for more nuanced reporting of abilities: users may be rated as independent, in need of assistance, or dependent (Liebzeit et al., 2018). BI is scored from 0 to 100, with 0 being totally dependent and 100 being totally independent.

### Levels of ADL Performance

It is possible—indeed, probable—that a given individual will perform different ADLs at different levels. The various activities are relatively distinct from each other. For example, the same patient who cannot transfer themselves from their bed to their wheelchair may be able to button the buttons on their shirt, brush their teeth, and feed themselves. Thus, for each ADL, providers may gauge a patient to be fully independent, in need of supervision or assistance, or fully dependent.

### Independent

An **independent ADL** requires no assistance; the patient can perform them with no help or coaching. Individuals who perform a given ADL independently may use an assistive device, such as a wheelchair or scooter for mobility or a Provala cup to prevent aspiration when drinking. They still perform the activity without the assistance of other individuals. For example, Susan is a 45-year-old female who uses a wheelchair because of a traumatic lower leg amputation in a car wreck three years ago.

- Susan easily transfers between surfaces such as her bed and wheelchair, and she can move around her home independently.
- Susan cannot drive yet because she has no car adapted to her prosthesis. However, she is adept at arranging

transportation via ride-sharing apps and has also used local buses. Therefore, she can manage her transportation needs independently.

### Supervised

A **supervised ADL** describes an activity that an individual can safely perform with supervision or with coaching or reminders of what to do. Individuals who require supervision may technically be able to perform all the skills needed for the action; however, they may lack either the physical ability to do it consistently without harming themselves or the cognitive ability to remember how to do it. For example, Eduardo is a 65-year-old male with the early stages of Alzheimer disease who also has some mobility issues.

- Eduardo gets bored easily and loves to walk but has an unsteady gait and needs a cane. However, he forgets to use his cane, and he falls often. He requires coaching and reminders to use his cane to walk without falling.
- Eduardo is from Puerto Rico but now lives in the Northeast. He prefers to wear shorts and lightweight button-up shirts, which he always chooses, even when the temperature is quite cold. He requires coaching and someone to restrict his clothing options to seasonally appropriate ones.

### Assisted

An **assisted ADL** describes an activity that an individual cannot perform independently or with supervision but can participate in and do some of the work. Individuals who require some assistance with ADLs are frequently able to perform all the movements required for the skill but lack the strength to do it independently. They may also be unable to perform all the movements required or be confused and require direct coaching and hands-on help to perform ADLs. For example, Frederica is a 51-year-old female who recently broke her ankle and upper arm on the right side, her dominant side. She cannot put any weight on her broken ankle or use her right arm. She can maneuver herself from a chair into her wheelchair to get to the bathroom and use her left leg and arm to move the wheelchair around.

- Frederica can stand on one leg and pivot to the toilet without help. However, she cannot stand on one leg, support herself with one arm, and clean herself after toileting. She requires assistance with toileting.
- Frederica can get her wheelchair up to the sink with assistance and perform a partial sponge bath on her upper body with her left hand. However, she cannot bathe the left side of her upper body with her right hand or effectively clean her lower legs, back, and bottom. She requires assistance with bathing.

### Dependent

A **dependent ADL** must be done entirely for an individual because they cannot or will not do them for themselves. These individuals may be sedated and not know that care is being provided, or unaware or uncaring that the care is necessary; they may be passive participants who follow instructions but provide no active assistance; or they may actively discourage ADL care. For example, John is 75 years old and lives in a nursing home. He has advanced Alzheimer disease.

- John no longer feeds himself. He will open his mouth when asked and chew and swallow food when placed in his mouth. However, someone else must feed him. He is dependent for feeding.
- John also no longer dresses himself. He does not fight when someone is dressing him; however, he does not offer any assistance by bending his arms or legs. He must be fully dressed by someone else. He is dependent for dressing.

## UNFOLDING CASE STUDY

### Unfolding Case Study #4: Part 4

Refer back to [Unfolding Case Study #4: Part 3](#) for a review on the patient data.

Nursing Notes	<b>Time: 1315</b> Patient reports experiencing persistent joint pain, particularly in the shoulders and wrists, rated at 6/10 on the numerical pain scale. Patient states that pain interferes with daily activities, such as getting dressed and cooking. Patient also reports stiffness in affected joints, especially in the morning or after prolonged periods of rest, which improves with movement throughout the day.
Provider's Orders	<b>Time: 1400</b> <ul style="list-style-type: none"><li>• Occupational therapy referral</li><li>• Acetaminophen 1,000 mg PO Q6 hours PRN moderate arthritic pain</li></ul>

---

4. Generate solutions: How could the nurse further assess the patient's functional status and ADL performance?
5. Take action: After performing a functional assessment and determining that the patient requires assistance with several ADLs, what actions should the nurse take?
6. Evaluate outcomes: What findings would indicate that interventions were effective and optimal patient outcomes were achieved?

## Summary

### 22.1 Importance of Activity, Movement, and Alignment

Activity, movement, and alignment are critical to an individual's health and well-being. They require the coordinated effort of multiple organ systems, including bones, joints, muscles, and the nervous system. The physiology of activity, movement, and alignment in the body is managed through the skeletal system. Functions of activity, movement, and alignment in the body are managed through an intertwined system of bones, muscles, and joints. These systems work together to improve cardiovascular circulation, balance, coordination, posture, and even postural reflexes, which work unconsciously.

When providing care for patients, healthcare staff must use safe practices such as ergonomics and safe patient handling and mobility to prevent injury for each other and patients. Ergonomics in patient care can be accomplished through proper body mechanics such as safe lifting and transferring. Patients should also stay healthy through purposeful activity and exercise. There are a wide range of exercises that improve the functioning of different body systems including stretching and flexibility exercises, aerobic exercises, strength training, and balance exercises.

### 22.2 Factors Affecting Activity Level

While physical activity has positive benefits for almost every person, many factors determine whether someone is able to be physically active. An individual's level of physical activity may decrease due to physiological factors such as pain, injury, and health conditions or to psychological factors such as fear and anxiety. Finally, external factors, such as socioeconomic and environmental conditions, further impact physical activity. When educating or working with patients regarding physical activity, always assist them in developing strategies to overcome their barriers to exercise.

### 22.3 Activities of Daily Living (ADLs)

Activities of daily living (ADLs) are important indicators of a patient's functional ability and decline. No matter the setting, all nurses will evaluate and assist patients with ADLs. ADLs include basic and instrumental activities. Performance of ADLs can be limited due to aging, cognitive decline, and chronic or acute illness. There are various tools for assessing ADLs, including the Katz ADL Index, the Lawton Scale for IADL, and the Barthel Index, which providers and insurers use to ensure patients receive the appropriate level of care. Finally, individuals can need several levels of assistance, ranging from no assistance needed, to supervision or assistance from others required, to complete dependence on others to perform the tasks for them.

## Key Terms

**activity** purposeful movement, such as walking

**activity of daily living (ADL)** an essential, routine task that most people can do independently most of the time

**adult day service** a facility where adults who are unable to support all their ADL needs or who are unsafe to be alone for long periods can go for care during the day while their families or caregivers work

**aerobic exercise** continuous physical activity that increases the heart rate and improves the function of the cardiovascular system

**aging in place** the state of growing older in one's home, with or without caregivers, rather than moving to a nursing home

**alignment** proper body position

**antagonist** a muscle that moves in the opposite direction of the prime mover

**articular cartilage** thin, spongy layer of cartilage that covers articulations

**assisted ADL** an ADL that an individual can help with, but they need hands-on help from another to perform fully

**assistive device** equipment, such as a lift or sliding sheets, that enables healthcare professionals to care for patients more safely

**ataxia** loss of coordination

**atrophy** the shrinking of a muscle due to lack of exercise or activity

**balance** the ability to maintain an upright alignment that prevents an individual from falling

**balance training** a practice used to improve an individual's ability to remain upright while stationary or moving and to decrease the chance of falling

- basic activity of daily living (BADL)** a physical ADL learned as children that allows individuals to care for their bodies: transferring, continence, eating, toileting, dressing, bathing, and grooming
- body mechanics** intentional movements and muscle use designed to maintain an individual's posture and alignment, decreasing the chance of injury
- bone** hard, dense connective tissue that form most of the adult skeleton, the primary support structure of the body
- bone density** a measurement of the amount of hard minerals that are present in bone and that account for its strength and resilience
- cardiac muscle** muscle specifically related to cardiac tissue
- cartilage** type of connective tissue that provides structural support and flexibility and helps reduce friction during joint movement
- central nervous system (CNS)** the primary processing center of the body; includes the brain and spinal cord
- circulation** the continuous, controlled movement of blood throughout the body, facilitated by the heart, blood vessels, and blood
- contraction** the act of a muscle working by shortening the muscle fibers to make a joint bend
- coordination** the ability to change position effectively and intentionally
- core** the lower torso, including the abdomen and lower back, that controls lower body postural stabilization
- dependent ADL** an ADL that an individual is unable to help with at all and requires someone else to do for them
- dynamic posture** how an individual holds their body during movement
- dysarthria** the slurring of speech or changing of vocal volume
- dysmetria** the inability to control or judge the range needed for a motion
- endurance** ability to withstand or tolerate prolonged physical activity or hardship over time
- ergonomics** the design and arrangement of workspaces, tools, equipment, and tasks to optimize comfort, efficiency, and safety for employees
- exercise** purposeful, structured, repetitive physical activity that requires sustained effort
- flexibility** the ability to move a joint through its entire range of motion
- functional ability** the ability to independently perform expected tasks
- functional assessment** a measure of ADL performance
- independent ADL** an ADL that an individual can do with no help or coaching
- instrumental activity of daily living (IADL)** a more-complex skill needed to function independently in a community, such as shopping for and preparing food, paying bills, and managing medications
- isometric training** exercise that involves contracting a muscle against an unmoving force
- isotonic training** exercise that involves contracting a muscle against a force that moves
- joint** a location where bones come into contact, allowing for movement
- lifestyle variable** a daily action or activity related to work, leisure, and diet
- ligament** tough but flexible fibrous tissue that connects bones or holds joints together
- myopathy** the name for a set of health conditions characterized by failure of the muscle fibers to work effectively, causing pain, stiffness, and weakness
- neuromuscular junction (NMJ)** the site where a motor neuron's terminal meets the muscle fiber and responds to motor signals
- neuron** a component of a nerve that passes information to and from the spinal cord and brain
- osteoporosis** a condition characterized by loss of bone density, making bones weak and prone to fracture
- peripheral nervous system (PNS)** the portion of the nervous system located on the periphery of the central nervous system containing peripheral structures including ganglia and nerves
- postural reflex** an unconscious, involuntary correction that the nervous and musculoskeletal systems make together to keep postural alignment when something threatens to disrupt it
- posture** how an individual holds their body
- prime mover** the main muscle making a movement happen
- quality of life (QoL)** an individual's overall enjoyment of life and sense of well-being
- range of motion** the extent and direction of movement that a joint or a group of joints can achieve
- relaxation** the act of muscle fibers returning to their resting state as a muscle stops working
- safe patient handling and mobility (SPHM)** a series of interconnected techniques designed to allow high-quality patient care, decreasing the risk of injury to both patients and staff
- skeletal muscle** muscle that attaches to bone and creates intentional movement as it contracts and relaxes,

causing the bones to move

**skeletal system** the bones, joints, and other structures that allow for movement, form the body, make blood cells, and shield organs

**smooth muscle** muscle in the walls of hollow organs such as the urinary bladder, uterus, stomach, and intestines

**somatic nervous system** the part of the peripheral nervous system that controls voluntary movements of skeletal muscle

**stamina** physical and mental capacity to endure prolonged periods of exertion or activity without experiencing fatigue

**static posture** how an individual holds their posture when still

**strength training (resistance training)** the practice of contracting a muscle against a load, such as free weights, elastic bands, water, or one's body weight

**stretch** a slow, steady exercise or movement designed to extend or lengthen specific muscles or muscle groups in the body

**striated muscle** muscle that appears striped, allowing for the muscle fibers to slide apart or together during movement

**supervised ADL** an ADL that an individual can do themselves, but they require coaching or supervision to perform them safely and effectively

**synergist** a muscle that helps the prime mover muscle by providing stability or assistance

**synovial fluid** liquid in joints that allows bones to glide over each other freely with decreased friction, preventing pain and erosion at the articulations

**synovial joint** a movable joint characterized by a fluid-filled cavity in the space where bones articulate

**tendon** a tough connective tissue located on each side of a joint that controls joint movement

**tremor** uncontrolled shaking when attempting purposeful movement or resting

**vestibular system** the body system located in the inner ear that functions to maintain homeostasis in balance

## Assessments

### Review Questions

- What part of the skeletal system allows a finger to bend when moved?
  - bone
  - cartilage
  - ligament
  - joint
- What unconscious, involuntary corrections do the nervous and musculoskeletal systems make together to maintain alignment?
  - postural reflexes
  - body mechanics
  - antagonists
  - synergists
- The collection of techniques and strategies used to prevent patients or staff from being injured are known collectively as what?
  - assistive devices
  - ergonomic body positioning
  - proper body mechanics
  - safe patient handling and mobility
- An older patient has come to the office complaining of falls. In addition to a medical workup, what type of exercise is the provider most likely to suggest?
  - stretching
  - strength
  - aerobics

- d. balance
5. Sampson's nurse is discussing physical activity with him, but he is quick to shake his head and say, "I've tried exercising, but I travel too much, hurt when I exercise for longer than fifteen minutes, worry that I'll fall and break another bone, and frankly, I'm just too tired." What barrier that Sampson expressed is a psychological barrier?
- traveling too much
  - pain when exercising longer than fifteen minutes
  - fear and concern about injury
  - feeling tired
6. A patient who has been experiencing pain and postural abnormalities has asked for a recommendation for ways to increase their physical activity. What type of exercise would be the most appropriate for this patient?
- tai chi
  - running
  - strength training
  - dancing
7. A nurse is working with a patient who has questions about physical activity but also several barriers to overcome. The patient reports they do not have enough money for a gym membership, feel unsafe in their neighborhood, experience pain when exercising for too long, and do not know where to start. What should the nurse suggest that would best address the barriers listed by the patient?
- enroll in the Silver Sneakers Senior class for 50 percent off
  - join a gym in another neighborhood
  - stretch until the pain goes away
  - participate in a short beginners' exercise class on YouTube
8. A nurse is assisting a patient with mild dementia to get dressed and groomed for the day. The nurse offers the patient three options for the day's clothing and reminds the patient to brush their teeth, comb their hair, and put on their shoes. What level of care does this patient need with their ADLs?
- They are independent.
  - They require supervision.
  - They require assistance.
  - They are dependent.
9. An independent patient's family member has come with the patient to their primary care provider and notes concern that the patient is struggling to care for themselves but is otherwise healthy. When the nurse asks the family member why they are concerned, what ADL is the family member most likely to mention?
- The patient smells because they are not bathing.
  - They found the patient wearing shorts outside when walking the dog in January.
  - They found several late notices for bills on the entrance table.
  - The patient can no longer get out of bed.
10. A nurse in the emergency department is triaging a 75-year-old Black patient who was brought in by her daughter due to acute confusion, inability to recognize family members, and inability to transfer, eat, or toilet herself independently since she woke up this morning. The family is worried that the patient has developed Alzheimer disease. What is the most appropriate response by the triage nurse?
- "I am sure the provider will run several tests. However, Alzheimer disease is normally something that progresses over time, and all of this is new as of this morning. It may be related to an illness of some kind. We will know more after the provider sees her and gets some tests run."
  - "Maybe, does Alzheimer disease run in your family?"
  - "It certainly looks like Alzheimer disease or one of the dementias, but I am surprised it happened so quickly."

- d. “This looks like a classic case of delirium. Your mother must have some kind of underlying illness. Once we figure out what that illness is and treat it, the symptoms will probably go away.”
- 11.** Aging in place is important for many older adults to retain their quality of life (QoL) and independence. However, as patients become older, aging in place is often difficult to manage. What is the best way for the nurse to help initially?
- Provide counseling to let the patient and family down easily because there comes a time when older family members need more care than families can provide in their homes.
  - Encourage older adults and family members to plan for ways to pay for twenty-four-hour care.
  - Suggest that a family member move in with the older adult to care for them twenty-four hours a day.
  - Provide resources for local agencies skilled in modifying homes and providing services that assist older adults to age in place.
- 12.** Pedro is a 75-year-old Hispanic male with dementia who lives at home with his adult daughter and her children. He feeds himself without coaching or help, bathes himself when reminded, wears adult briefs for incontinence issues, and either his daughter or her children pick out his clothes and help him put on his socks and shoes. What level of ADL care does Pedro need?
- He is independent for eating, needs supervision for bathing and grooming, and requires assistance for dressing.
  - He requires supervision for eating and bathing and is dependent for dressing.
  - He needs help with eating and dressing and is independent for continence and transferring.
  - He is independent for eating and needs supervision for bathing, grooming, toileting, and dressing.

### Check Your Understanding Questions

- Describe the relationship between balance, postural reflexes, and the vestibular system.
- List at least eight health risks of physical inactivity.
- What information might you offer to a patient concerned that exercising would increase their pain?
- How can exercise help prevent osteoporosis?
- What is the difference between BADLs and IADLs?

### Reflection Questions

- Consider working with a patient who is from an at-risk, underrepresented group or who has a disability. Describe how you would approach an exercise conversation with that patient.
- Safe patient handling and mobility techniques take time to perform, as does ensuring there are enough staff available for tasks. You may encounter situations where other nursing staff encourage you to just lift or move patients without taking the time to use assistive devices. How might you, as a new nurse, manage this situation?
- Consider the issue of age and motor-related developmental milestones. When helping a young adult determine appropriate types of physical activities, why might it be helpful to have information about their early childhood development?
- Section 22.2 explored several socioeconomic and environmental barriers to activity. Identify two additional external barriers based on your own experience or that of your friends or family. How might someone overcome these barriers and exercise more regularly?
- This chapter briefly explored the ways that agencies such as the Centers for Medicare & Medicaid Services and the VA use ADLs to decide whether patients require services. Do you think functional assessments should be used to determine a patient’s need for care? Support your response with two scenarios: one in which the process works effectively and another in which it does not.

## Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #4: Part 3](#).  
What psychological barriers to exercise may be affecting the patient? How should the nurse assess for these barriers?
2. Refer to [Unfolding Case Study #4: Part 4](#).  
Does the patient struggle with basic ADLs or instrumental ADLs? What is the difference between the two types?

## What Should the Nurse Do?

A 65-year-old patient who weighs 400 lb (181 kg) is admitted to the unit for high blood pressure. They have recently broken a hip, which has healed, but they remain unsteady. Despite their weight, the patient has always been active. However, now the patient fears falling because of their unsteady balance and has become much more sedentary.

1. The charge nurse has asked you to prepare the patient's room. Describe the types of equipment this patient might need in their room.
2. Which sets of muscle groups might be causing the patient's unsteadiness, and why?
3. What are some health risks this patient now faces related to being more sedentary?
4. Which types of exercises might you encourage the patient to perform to assist them in managing the unsteadiness in their leg?
5. Nurse Henderson is working with a patient, Ms. Rosa, who is experiencing some severe mental health concerns, such as depression and stress, which she states are barriers to her ability to perform physical activity. However she realizes that she needs to be active. What should the nurse do?
6. Nurse Roman is performing an assessment on Mr. Green, an outpatient, who has come to the clinic for a follow-up after an emergency room visit. The patient's adult child is with them, and Mr. Green has agreed to have the child in the room during the assessment. The patient states that they were driving their car, became confused and lost, and had a wreck. His child is with him because he is now afraid to drive. What should the nurse do?
7. Nurse Jorge is assessing Ms. Scrim, a patient who has come in for her annual physical. Ms. Scrim is very anxious and begins crying when Nurse Jorge asks questions related to functional assessment. Ms. Scrim states that she is struggling to do things she has always been able to do, such as remembering important dates and shopping. She states she is terrified that she is developing Alzheimer disease like her father-in-law. These issues have only been going on for a brief time. What should the nurse do?

## Competency-Based Assessments

Consider that you are caring for a patient with cancer who is asking about whether they can safely be physically active. Refer to the article [Cancer and Exercise \(https://openstax.org/r/77cancerexer\)](https://openstax.org/r/77cancerexer) for information that will help you answer the following questions.

1. What types of physical activity are recommended?
2. What exercise tests can be used to determine appropriate activities?
3. Describe the exercise prescription for patients with cancer.
4. What are the contraindications for exercising?
5. How would you respond to this patient?
6. What types of psychological effects can this patient receive from aerobic exercise?
7. What types of exercise suggestions would you make for a patient who is confined to a bed?
8. You have a patient with newly diagnosed Alzheimer disease who wants to age in place for as long as possible. Identify four resources you could provide this patient and explain why you have chosen each resource. Ensure the resources you provide are available in your current location.

Consider using these websites to begin your search for resources:

- [Aging in Place \(https://openstax.org/r/77ageplace\)](https://openstax.org/r/77ageplace)
- [National Institute on Aging \(https://openstax.org/r/77nataging\)](https://openstax.org/r/77nataging)

- [Habitat for Humanity \(https://openstax.org/r/77habitat\)](https://openstax.org/r/77habitat)
9. Download the [Lawton Scale for IADL \(https://openstax.org/r/77lawtonIADL\)](https://openstax.org/r/77lawtonIADL) and the [Katz ADL Index \(https://openstax.org/r/77KatzADL\)](https://openstax.org/r/77KatzADL) and prepare for a skill checklist with your instructor on the use of these instruments.

## CHAPTER 23

# Neuromuscular Function

**FIGURE 23.1** The nurse assesses the patient’s ability to use his muscles to lift his leg in response to neurological impulses, demonstrating how the musculoskeletal and neurological systems work effectively together. (credit: Maria Christina Yager/DVIDS, Public Domain)

### CHAPTER OUTLINE

- 23.1 Foundations of Neuromuscular Functioning
- 23.2 Factors Affecting Neuromuscular Functioning
- 23.3 Considerations for Care of Neuromuscular Impairment

**INTRODUCTION** Imagine you are about to take a shower in the morning before going to school. You have turned on the faucet to start the water as you prepare to get in the shower. After a few minutes, you expect the water to be at a temperature that will be comfortable to enter. So, you put your hand into the spray of water to test it. What happens next depends on how your nervous system interacts with the stimulus of the water temperature and what your muscles do in response to that stimulus. To be able to respond to these kinds of stimuli, the neurological and musculoskeletal systems must both be functioning and working together efficiently. Impairments in either of these body systems can cause an inability to respond to external stimuli, which can result in bodily injury and poor health. This chapter discusses the foundations of the neurological system, factors that may affect function of the neurological system, and ultimately how care can be tailored based on that information.

## 23.1 Foundations of Neuromuscular Functioning

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify structures and functions of the neurological system
- Recognize structures and functions of the musculoskeletal system
- Describe primary functions of the neuromuscular system

The neuromuscular system is composed of both the neurological system and the musculoskeletal system. These systems work effectively together to respond to internal and external stimuli, allowing the body to remain healthy and safe from injury. This section describes the structure and function of the different parts of the neuromuscular system, so that you will have a solid foundation of knowledge about normal anatomy and physiology before discussing alterations in function and specific disease states that affect these systems.

## Structures and Functions of the Neurological System

The nervous system includes the **brain** (the central organ of the nervous system responsible for controlling bodily functions, processing sensory information, and enabling cognitive processes such as learning and memory) and the **spinal cord** (a long, thin, tube-shaped bundle of nerves that extends from the base of the brain through the vertebral column). Within the brain, a variety of regions are responsible for many different and separate functions.

### Central Nervous System

The nervous system can be divided into two major regions: the central and peripheral nervous systems. The **central nervous system (CNS)** is the brain contained within the cranial cavity of the skull and the spinal cord contained within the vertebral cavity of the vertebral column. The **peripheral nervous system (PNS)** is everything else; although, some elements of the PNS are located within the cranial or vertebral columns ([Figure 23.2](#)). The CNS plays a crucial role in the neuromuscular system by coordinating and regulating voluntary and involuntary movements. It receives sensory input from peripheral nerves, processes this information, and sends motor commands back to muscles via motor neurons, allowing for coordinated muscle contractions and movement control. Additionally, the CNS facilitates reflex actions that protect the body from harm by quickly responding to stimuli without conscious effort. The PNS is so named because it is on the periphery—meaning beyond the brain and spinal cord. Depending on different aspects of the nervous system, the dividing line between central and peripheral is not necessarily universal. The PNS is discussed later in this section.

**FIGURE 23.2** The CNS is composed of the brain and spinal cord, whereas the PNS contains peripheral structures including ganglia and nerves. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Brain

The adult brain has four major regions: cerebrum, diencephalon, brain stem, and cerebellum. The iconic gray matter of the human brain, which appears to make up most of the brain mass, is the **cerebrum** ([Figure 23.3](#)). Many of the higher neurological functions (e.g., memory, emotion, consciousness, voluntary muscle movement) are the result of

cerebral function. The **gyri** (folds) and **sulci** (grooves) formed by convolutions in the surface of the brain give the **cerebral cortex**, the outer covering of the brain, a wrinkled appearance. The rest of the cerebrum is beneath that outer covering. The large separation between the two sides of the cerebrum is called the **longitudinal fissure**. It separates the cerebrum into two distinct halves, a right and left **cerebral hemisphere**. Deep within the cerebrum, the **corpus callosum** provides the major pathway for communication between the two hemispheres of the cerebral cortex.

**FIGURE 23.3** The cerebrum is a large component of the human CNS. Its most obvious aspect is the folded surface called the cerebral cortex. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **diencephalon** is the region of the adult brain that connects the cerebrum to the rest of the nervous system ([Figure 23.4](#)). The rest of the brain, spinal cord, and peripheral nervous system (PNS) all send information to the cerebrum through the diencephalon. Output, including motor commands, language expression, and emotional responses, from the cerebrum also passes through this structure. The two major regions of the diencephalon are the thalamus and the hypothalamus.

**FIGURE 23.4** The diencephalon is composed primarily of the thalamus and hypothalamus. The hypothalamus is inferior and anterior to the

thalamus, culminating in a sharp angle to which the pituitary gland is attached. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **thalamus** is a collection of nuclei that relay sensory and motor information between the cerebral cortex and the brain stem, spinal cord, or periphery. All sensory signals, except for the sense of smell, and motor signals pass through the thalamus before being processed by the cortex. The thalamus is also responsible for regulating sleep, wakefulness, and consciousness and also emotion and memory. The thalami are two elongated, ovoid structures on either side of the midline that make contact in the middle. The **hypothalamus** is a collection of nuclei that are largely involved in regulating homeostasis. It is the executive region in charge of the autonomic nervous system and the endocrine system through its regulation of the anterior pituitary gland. Other parts of the hypothalamus are involved in memory and emotion as part of the limbic system.

The brain stem emerges from the ventral surface of the forebrain as a tapering cone that connects the brain to the spinal cord (Figure 23.5). The midbrain and hindbrain (composed of the pons and the medulla oblongata) are collectively referred to as the **brain stem**. The **pons** (connection point between the medulla and the thalamus) and the **medulla** (connection point between the brain stem and spinal cord) regulate several crucial functions, including the cardiovascular and respiratory systems.

**FIGURE 23.5** The brain stem comprises three regions: the midbrain, the pons, and the medulla. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **cerebellum** is the “little brain.” It is covered in gyri and sulci like the cerebrum and looks like a miniature version of that part of the brain (Figure 23.6). The cerebellum is largely responsible for comparing information from the cerebrum with sensory feedback from the periphery through the spinal cord. It accounts for approximately 10 percent of the mass of the brain (Van Essen et al., 2018).

**FIGURE 23.6** The cerebellum is situated on the posterior surface of the brain stem. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LIFE-STAGE CONTEXT

### Neurological Changes in Older Adults

Several neurological changes occur with aging that affect the brain's functioning. These changes include the following:

- shrinking of certain areas of the brain, which can result in decreased ability to learn new things or perform difficult mental activities
- decreased communication between neurons within the brain
- decreased blood flow to the brain
- atrophy of mass and loss of nerve cells in the brain and spinal cord
- slower neuron message processing, resulting in slower muscle reactions
- accumulation of waste products or chemicals in brain tissues after cellular breakdown

### Spinal Cord

The spinal cord is the second major organ of the CNS. The length of the spinal cord is divided into regions that correspond to the regions of the vertebral column. Immediately adjacent to the brain stem is the cervical region, followed by the thoracic, then the lumbar, and finally the sacral region ([Figure 23.7](#)). The spinal cord is not the full length of the vertebral column because the spinal cord does not grow significantly longer after the first or second year of life, but the skeleton does continue to grow. The nerves that emerge from the spinal cord pass through the intervertebral foramina at the respective levels.

**FIGURE 23.7** There are four regions of the spinal column including the cervical, thoracic, lumbar, and sacral regions. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

As the vertebral column grows, these nerves grow with it and result in a long bundle of nerves that resembles a horse's tail. This is named the **cauda equina** ([Figure 23.8](#)).

**FIGURE 23.8** The bundle of nerve roots located at the end of the spinal cord is called the cauda equina because it resembles a horse's tail. (credit: "Cauda Equina" by Daniel Donnelly/Flickr, CCBY 4.0)

### Neural Pathways

The **gray matter** of the spinal cord, a butterfly-shaped structure, is subdivided into regions that are referred to as horns ([Figure 23.9](#)). Gray matter consists of neuronal cell bodies and is involved in processing information in the

brain. The **posterior horn** (or dorsal horn) is responsible for sensory processing. The **anterior horn** (or ventral horn) sends out motor signals to the skeletal muscles. The **lateral horn**, which is only found in the thoracic, upper lumbar, and sacral regions, contains motor neuron cell bodies of the autonomic nervous system. The myelinated nerve fibers that facilitate communication between different regions of the brain are called **white matter**. Just as the gray matter is separated into horns, the white matter of the spinal cord is separated into columns. A column of nervous system fibers called an **ascending tract** carries sensory information up to the brain, whereas a **descending tract** carries motor commands from the brain.

**FIGURE 23.9** The thoracic spinal cord segment shows the posterior (dorsal), anterior (ventral), and lateral horns of gray matter and columns of white matter. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Peripheral Nervous System

As mentioned previously, the peripheral nervous system (PNS) is the part of the nervous system that lies outside of the brain and spinal cord. The PNS is responsible for transmitting sensory information from the body to the CNS and for sending motor commands from the CNS to the muscles and glands. The PNS contains cranial and spinal nerves, both of which are important for optimal neuromuscular functioning.

### Cranial Nerves

A nerve attached to the brain is called a **cranial nerve**, which is primarily responsible for the sensory and motor functions of the head and neck. There are twelve cranial nerves, which are designated CNI through CNXII, using Roman numerals for 1 through 12 ([Figure 23.10](#)).

**FIGURE 23.10** The anatomical arrangement of the roots of the cranial nerves can be observed from an inferior view of the brain. (credit: modification of work from Anatomy and Physiology 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Cranial nerves can be classified as sensory nerves, motor nerves, or a combination of both (mixed). Sensory axons enter the brain to synapse in a nucleus. Motor axons connect to the skeletal muscles of the head or neck. Nurses should be able to name the cranial nerves and provide a brief description of their function and their source (sensory ganglion, motor nucleus, or mixed) ([Table 23.1](#)).

Number/Name	Function	Source
I. Olfactory	Smell	Sensory
II. Optic	Vision	Sensory
III. Oculomotor	Eye movement and pupil reflexes	Motor
IV. Trochlear	Eye movement	Motor
V. Trigeminal	Sensory/motor—face, chewing	Mixed
VI. Abducens	Eye movement	Motor
VII. Facial	Face movement, taste	Mixed
VIII. Vestibulocochlear (Auditory)	Hearing, balance	Sensory
IX. Glossopharyngeal	Swallowing, throat sensations, taste	Mixed
X. Vagus	Movement and sensations of abdominal organs	Mixed
XI. Accessory (Spinal)	Head and neck movement	Motor
XII. Hypoglossal	Tongue movement	Motor

**TABLE 23.1** Functions of the Twelve Cranial Nerves

### Spinal Nerves

A **spinal nerve** is a nerve that is connected to the spinal cord. There are thirty-one spinal nerves, named for the level of the spinal cord at which each one emerges. There are eight pairs of cervical nerves designated C1 to C8, twelve pairs of thoracic nerves designated T1 to T12, five pairs of lumbar nerves designated L1 to L5, five pairs of sacral nerves designated S1 to S5, and one pair of coccygeal nerves. The nerves are numbered from the superior to inferior positions, and each emerges from the vertebral column through the intervertebral foramen at its level. Spinal nerves extend outward from the vertebral column to innervate the periphery. The nerves in the periphery are not straight continuations of the spinal nerves, but rather the reorganization of the axons in those nerves to follow different courses ([Figure 23.11](#)).

**FIGURE 23.11** Each vertebrae is numbered and each numbered spinal nerve emerges from the vertebral column and branches off into alternate pathways to innervate different parts of the body. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Autonomic Nervous System

The **autonomic nervous system (ANS)** is a component of the peripheral nervous system (PNS) that is responsible

for involuntary control of the body. This involuntary control is usually for the sake of homeostasis, a steady state of body systems that living organisms maintain by regulating their internal environment. Sensory input for autonomic functions can be from sensory structures tuned to external or internal environmental stimuli. The motor output extends to smooth and cardiac muscle as well as glandular tissue, which results in involuntary muscle or tissue action. The role of the ANS is to regulate the organ systems of the body to control homeostasis. Sweat glands, for example, are controlled by the ANS. When you are hot, sweating helps cool your body down. That is a homeostatic mechanism. But when you are nervous, you might start sweating also. That is not homeostatic; it is the physiological response to an emotional state. The ANS is divided into two different systems: the sympathetic nervous system and the parasympathetic nervous system.

### Sympathetic Nervous System

The **sympathetic nervous system** becomes activated during times of tension or stress, resulting in “fight or flight” types of reactions. When the body senses an external danger or threat, the sympathetic nervous system causes involuntary reactions in the body that help combat the perceived threat. These reactions include the following:

- increased heart rate, which increases the amount of oxygen being delivered to the rest of the body
- airway muscle relaxation, allowing improved oxygen delivery to the lungs
- pupil dilation, resulting in improved vision
- slowed digestion, allowing for energy to be used for more important tasks such as running or fighting

### Parasympathetic Nervous System

The **parasympathetic nervous system** is the part of the ANS that results in involuntary “rest and digest” types of reactions. These reactions include the following:

- pupil constriction to limit the amount of light entering the eyes, allowing for a state of rest
- saliva production in the mouth to aid with digestion
- tightening of airway muscles to reduce the work of breathing while at rest
- decreased heart rate to lessen the workload on the heart, allowing for rest and recovery
- increased rate of digestion to break down food to store as energy for later use

## Structures and Functions of the Musculoskeletal System

The musculoskeletal system is composed of bones, muscles, joints, and connective tissue. These structures are connected and allow the body to move and function while also protecting internal organs from injury.

### Muscles

Muscle is one of the four primary tissue types of the body. The three different types of muscle tissue are cardiac muscle, smooth muscle, and skeletal muscle. The three muscle tissues have some properties in common; they all exhibit a quality called **excitability**, which occurs when the plasma membranes change their electrical states (from polarized to depolarized) and send an electrical wave called an action potential along the entire length of the membrane. The nervous system can influence the excitability of cardiac and smooth muscle to some degree. Skeletal muscle, however, completely depends on signaling from the nervous system to work properly. On the other hand, both cardiac muscle and smooth muscle can respond to other stimuli, such as hormones and local stimuli.

### Cardiac Muscle

The **cardiac muscle** tissue is found only in the heart. Highly coordinated contractions of cardiac muscle pump blood into the vessels of the circulatory system. Contractions of the heart (heartbeats) are controlled by specialized cardiac muscle cells called pacemaker cells that directly control heart rate. Although cardiac muscle cannot be consciously controlled, the pacemaker cells respond to signals from the ANS to speed up or slow down the heart rate. The pacemaker cells can also respond to various hormones that modulate heart rate to control blood pressure.

### Smooth Muscle

The **smooth muscle** is present in the walls of hollow organs such as the urinary bladder, uterus, stomach, and intestines. The walls of passageways (e.g., arteries and veins of the circulatory system) and the tracts of the respiratory, urinary, and reproductive systems also contain smooth muscle. Smooth muscle present in the eyes functions to change the size of the iris and alter the shape of the lens. Smooth muscle in the skin causes hair to stand erect in response to cold temperature or fear.

### Skeletal System

The **skeletal system** forms the rigid internal framework of the body. The skeletal system is divided into axial and appendicular skeletons. The adult **axial skeleton** consists of eighty bones that form the head and trunk of the body. The **appendicular skeleton** consists of the limbs, which are attached to the axial skeleton. The appendicular skeleton has 126 bones. The skeletal system consists of bones, joints, muscle, and different types of connective tissue.

### Bones

A hard, dense connective tissue that forms most of the adult skeleton is called a **bone** and it is the primary support structure of the body ([Figure 23.12](#)). There are 206 bones in the adult human body. The bones of the skeletal system perform the following critical functions for the human body:

- body support
- movement facilitation
- internal organ protection
- blood cell production
- mineral and fat storage and release

**FIGURE 23.12** There are 206 bones within the adult skeletal system. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Joints

Except for the hyoid bone in the neck, each of the bones in the body is connected to at least one other bone. A **joint** is the location where bones come together. Many joints allow for movement between the bones. A **ligament** and a **tendon** are tissues that support a joint; the articulating surfaces of the adjacent bones can move smoothly against each other. However, the bones of other joints may be joined to each other by **cartilage**, a specific type of connective tissue that provides structural support and flexibility. These joints are designed for stability and provide for little or no movement. Importantly, joint stability and movement are related to each other. This means that stable joints allow for little or no mobility between the adjacent bones. Conversely, joints that provide the most movement between bones are the least stable. Understanding the relationship between joint structure and function will help to explain why particular types of joints are found in certain areas of the body.

The articulating surfaces of bones at joints considered stable with little or no mobility are strongly united to each other. For example, most of the joints of the skull are held together by fibrous connective tissue and do not allow for movement between the adjacent bones. This lack of mobility is important because the skull bones serve to protect

the brain. Similarly, other joints united by fibrous connective tissue allow for very little movement, which provides stability and weight-bearing support for the body. For example, the tibia and fibula of the leg are tightly united to give stability to the body when standing.

At other joints, the bones are held together by cartilage, which permits limited movements between the bones. Thus, the joints of the vertebral column only allow for small movements between adjacent vertebrae, but when added together, these movements provide the flexibility that allows your body to twist, or bend to the front, back, or side.

In contrast, at joints that allow for wide ranges of motion, the articulating surfaces of the bones are not directly united to each other. Instead, these surfaces are enclosed within a space filled with lubricating fluid, which allows the bones to move smoothly against each other. These joints provide greater mobility, but because the bones are free to move in relation to each other, the joint is less stable. Most of the joints between the bones of the appendicular skeleton are this freely moveable type of joint. These joints allow the muscles of the body to pull on a bone and thereby produce movement of that body region. Your ability to kick a soccer ball, pick up a fork, and dance the tango depends on mobility at these types of joints.

### Skeletal Muscle Tissue

The best-known feature of **skeletal muscle** is its ability to contract and cause movement. Skeletal muscles act not only to produce movement but also to stop movement, such as resisting gravity to maintain posture. Small, constant adjustments of the skeletal muscles are needed to hold a body upright or balanced in any position. Muscles also prevent excess movement of the bones and joints, maintaining skeletal stability and preventing skeletal structure damage or deformation. Joints can become misaligned or dislocated entirely by pulling on the associated bones; muscles work to keep joints stable. Skeletal muscles are located throughout the body at the openings of internal tracts to control the movement of various substances. These muscles allow functions, such as swallowing, urination, and defecation, to be under voluntary control. Skeletal muscles also protect internal organs (particularly abdominal and pelvic organs) by acting as an external barrier or shield to external trauma and by supporting the weight of the organs.

### Connective Tissue

As indicated by its name, one of the major functions of **connective tissue** is to connect tissues and organs. The different types of connective tissue found in the musculoskeletal system include cartilage, ligaments, and tendons ([Table 23.2](#)).

Type	Description
Cartilage	<ul style="list-style-type: none"> <li>• Tough elastic fibrous tissue that covers bone surfaces at joints</li> <li>• Provides structural support and flexibility and helps reduce friction during joint movement</li> </ul>
Ligaments	<ul style="list-style-type: none"> <li>• Tough elastic bands of tissue surrounding joints that connect bones together</li> <li>• Provides stability and limits joint movement</li> </ul>
Tendons	<ul style="list-style-type: none"> <li>• Tough connective tissue located on each side of a joint that connects muscles to bones</li> <li>• Controls joint movement</li> </ul>

**TABLE 23.2** Types of Connective Tissue Found in the Musculoskeletal System

## Functions of the Neuromuscular System

The nervous system and musculoskeletal system work together to form the neuromuscular system. Signals within the nervous system act on the muscular system to provide body movement, posture control, breathing, and maintenance of homeostasis.

### Essential Body Movement

The defining characteristic of the **somatic nervous system** is that it controls skeletal muscles. Somatic senses

inform the nervous system about the external environment, but the response to that is through voluntary muscle movement. The term *voluntary* suggests that there is a conscious decision to make a movement. Another specialization of the skeletal muscle is the site where a motor neuron's terminal meets the muscle fiber—called the **neuromuscular junction (NMJ)**. This is where the muscle fiber first responds to signaling by the motor neuron. Every skeletal muscle fiber in every skeletal muscle is innervated by a motor neuron at the NMJ. Excitation signals from the neuron are the only way to functionally activate the fiber to contract.

### Control of Posture

Maintaining good body posture is not as simple as it sounds. Even when muscles are not producing movement, they are contracted at least a small amount to produce muscle tone. The tension produced by muscle tone allows muscles to continuously stabilize joints and maintain posture. Muscle tone is accomplished by a complex interaction between the nervous system and skeletal muscles that results in the activation of a few motor units at a time, most likely in a cyclical manner. As a result, muscles never fatigue completely, because some motor units can recover while others are active.

### Breathing

Unless you actively practice yoga and meditation, you may never have consciously thought about breathing. That is because breathing is an involuntary process controlled by the ANS. Signals from the external environment as well as internal signals from your body are sent to the brain, which acts as the command center to control breathing. Nerves from the spinal cord send these messages to breathing muscles such as the diaphragm and intercostal muscles to adjust breathing rates and patterns as needed. This all occurs without any conscious thought about breathing on your part—isn't the human body amazing?

### Maintaining Homeostasis

Maintaining homeostasis requires that the body continuously monitor its internal conditions. From body temperature to blood pressure to levels of certain nutrients, each physiological condition has a particular set point. A **set point** is the physiological value around which the normal range fluctuates. A normal range is the restricted set of values that is optimally healthy and stable. For example, the set point for normal human body temperature is approximately 98.6°F (37°C). Physiological parameters, such as body temperature and blood pressure, tend to fluctuate within a normal range that is a few degrees above and below that point. Control centers in the brain and other parts of the body monitor and react to deviations from homeostasis using negative feedback. A mechanism that reverses a deviation from the set point is called **negative feedback**. Therefore, negative feedback maintains body parameters within their normal range. The maintenance of homeostasis by negative feedback is continuously occurring throughout the body and is overseen by the neuromuscular system. For example, skin contains thermoreceptors that can detect an increase in body temperature. These receptors then use negative feedback mechanisms to send messages to the brain to initiate measures to cool down the body such as sweating or hyperventilating.

## 23.2 Factors Affecting Neuromuscular Functioning

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify diagnostic testing for neuromuscular functioning
- Discuss common disorders that affect neuromuscular functioning
- Describe the effects of neuromuscular impairment

Now that we have outlined how the neuromuscular system should function normally, we can discuss potential abnormal findings and conditions that affect this system. This section will provide an overview of various diagnostic tests that can be used to detect abnormalities as well as discuss several neuromuscular disorders in more detail.

### Diagnostic Testing for Neuromuscular Functioning

There are several diagnostic tests that can be used to help diagnose specific neuromuscular disorders or rule out other conditions that may be causing similar symptoms. These include blood tests, electromyography, radiographic imaging, nerve conduction velocity testing, muscle biopsies, and genetic tests.

### Blood Tests

No specific blood tests are available that diagnose disorders of the neuromuscular system with absolute certainty, however several tests are typically performed to assist with confirmation of the disorder or to rule out other causes. Nurses should understand some of the most common blood tests used to help diagnose neuromuscular disorders ([Table 23.3](#)).

Test	Description
Erythrocyte sedimentation rate (ESR)	<ul style="list-style-type: none"> <li>Measures the rate at which red blood cells settle at the bottom of a test tube containing blood.</li> <li>Higher values indicate inflammation, which could be consistent with a neuromuscular disorder.</li> <li>Note: Many conditions cause elevated ESR, so this is not the most accurate diagnostic test.</li> </ul>
Creatine kinase (CK)	<ul style="list-style-type: none"> <li>Normal muscle enzyme that leaks out into the blood when muscle damage occurs.</li> <li>Elevated values may be indicative of a neuromuscular disorder that has caused muscle damage.</li> <li>Note: Many conditions cause muscle damage, so this is not the most accurate diagnostic test.</li> </ul>
Electrolytes	<ul style="list-style-type: none"> <li>Any of various ions (e.g., sodium, potassium, chloride) that have a positive or negative electrical charge when dissolved in water.</li> <li>Crucial for many body processes (e.g., regulating chemical reactions, conducting nerve impulses, contracting muscles, regulating pH levels, maintaining the balance between fluids inside and outside the cells).</li> <li>Key method to diagnose a wide range of medical conditions and diseases.</li> <li>Imbalances in electrolytes can cause muscle weakness or paralysis, so this test can be used to rule out other causes of symptoms.</li> </ul>
Antibody tests	<ul style="list-style-type: none"> <li>Several antibody tests can be performed to determine whether the patient has an infection.</li> <li>Many neuromuscular disorders are caused by a virus, so this test can help determine a potential cause.</li> </ul>

**TABLE 23.3** Blood Tests Used to Assist with Diagnosis of Neuromuscular Disorders

### Electromyography

An **electromyography (EMG)** is used to evaluate how muscles respond to nervous system stimulation. An EMG is performed by inserting small needles, called electrodes, through the skin until they are in the underlying muscles ([Figure 23.13](#)). After the needles are placed, the provider asks the patient to perform certain movements of the extremity (e.g., contraction, relaxation). When the muscles contract, the electrical activity in the muscles is recorded by the needle electrodes. This information is sent to a computer where the provider can review the test results in real time. This procedure takes anywhere from sixty to ninety minutes and typically does not cause the patient much pain. However, some patients do report pain with insertion of the needle and lingering soreness in the muscles for a few days after the procedure.

**FIGURE 23.13** During an electromyography test (muscle test), a small needle is inserted into the muscle of the arm and electrical activity associated with voluntary muscle movements is recorded as waves on the monitor. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

During the test, the provider is looking for abnormal electrical activity patterns with various muscle movements. Some of the neuromuscular conditions that can be diagnosed with this type of testing include the following:

- peripheral neuropathy
- carpal tunnel syndrome
- sciatica
- pinched nerves,
- muscular dystrophy
- amyotrophic lateral sclerosis (ALS)
- myasthenia gravis

### Radiographic Imaging

Several radiographic imaging tests can be used to help diagnose neuromuscular conditions. The most common are computed tomography (CT) scans and magnetic resonance imaging (MRI). The images obtained from these scans can help identify changes or abnormalities in muscle or nervous tissue that may be indicative of neuromuscular disorders. Although these tests are not usually conclusive for specific disorders, they can be used to show changes within the tissue that warrant additional follow-up and testing (Figure 23.14). Also, these scans can be used periodically after diagnosis of a neuromuscular condition to monitor the progression of the disorder over time.

**FIGURE 23.14** An MRI scan shows injury to the muscle, indicating the need for additional diagnostic testing. (credit: Aydemir G, Cakmak S, Aydinöz S/NIH, CC BY 2.0)

### Nerve Conduction Velocity Testing

A nerve conduction study, or **nerve conduction velocity (NCV) testing**, shows how quickly electrical signals move through nerves in the body. Two electrodes are placed on the skin over the patient's nerves (Figure 23.15). One electrode delivers the electrical stimulus, and the other electrode records the speed of the impulse, or how quickly

the electrical stimulus moves from one electrode to the other.

**FIGURE 23.15** Two electrodes are placed on the skin over nerves as part of nerve conduction velocity testing. A very mild electrical impulse is sent through a patch or a handheld device to stimulate the nerve. (credit: Alex Durbin/Joint Base Langley-Eutis, Public Domain)

Often, this test is completed during the same visit as the EMG testing described earlier because they are performed with similar techniques and allow for more information to be obtained about the patient's condition. The main reason that NCV testing is used is to determine whether the disorder is caused by nerve issues or muscle problems. If the NCV testing is normal, it is likely that the disorder has a muscular cause. On the other hand, if the NCV testing is abnormal (slow), the cause of the issue is more likely stemming from the nervous system. Some of the disorders that NCV testing can help diagnose include the following:

- Guillain-Barré syndrome
- carpal tunnel syndrome
- Charcot-Marie-Tooth disease
- herniated discs
- neuropathy
- sciatica

## LINK TO LEARNING

Learn more about [electromyography and nerve conduction studies and how to prepare a patient \(https://openstax.org/r/77emg\)](https://openstax.org/r/77emg) for these tests.

### Muscle Biopsies

Muscle biopsies involve removing muscle tissue from the body for microscopic laboratory examination. The muscles used most often include the biceps or deltoids in the arms and shoulders or the quadriceps in the legs. This procedure is not used often because it is more invasive than other types of diagnostic testing, such as blood tests or imaging scans. However, it can be useful for determining specific types of muscle disorders if other tests come back inconclusive. Some examples of disorders that might be diagnosed using muscle biopsy include inflammatory myopathies (e.g., polymyositis, dermatomyositis) and specific types of muscular dystrophy.

### Genetic Testing

Many neuromuscular disorders have a genetic component, meaning they can be inherited from parents. Often, when a parent or other close family member has a neuromuscular disorder, a genetic test is ordered to determine whether the disorder could have been passed on to the next generation. These tests can be performed by obtaining a swab from the cheek or a blood sample from which DNA can be analyzed. The DNA is examined for genetic mutations that are indicative of specific neuromuscular disorders. This type of test is the most accurate for diagnosing neuromuscular disorders that are genetic in nature.

### Common Neuromuscular Disorders

Many disorders can affect the neurological and musculoskeletal systems simultaneously. Some of the conditions are common, whereas others are quite rare. Disorders of the neuromuscular system include Charcot-Marie-Tooth disease, congenital myopathy, muscular dystrophy, amyotrophic lateral sclerosis, myasthenia gravis, multiple sclerosis, cerebral palsy, and spinal cord injuries.

#### Charcot-Marie-Tooth Disease (CMT)

A progressive neuromuscular disorder, **Charcot-Marie-Tooth disease** affects one out of every 2,500 people in the United States, and more than three million people worldwide (CMT Research Foundation, n.d.). It is caused by genetic mutations, passed down from parent to child. CMT affects the peripheral nerves, most often those of the arms, hands, legs, and feet. As the disease progresses, the patient experiences worsening numbness and muscle weakness ([Figure 23.16](#)). Other symptoms of CMT include the following:

- weak grip
- tripping or imbalance
- shuffling or dragging feet while walking
- cold hands and feet
- numbness and tingling of hands and feet
- curled toes (“hammertoes”)
- high arches in the feet

**FIGURE 23.16** Charcot-Marie-Tooth disease causes hammertoes in addition to other possible symptoms. (credit: Liao YC, Liu YT, Tsai PC, Chang CC, Huang YH, Soong BW, Lee YC/NIH, CC BY 4.0)

Currently, there is no cure for this disease. Symptom management is attempted with pain medications, foot splints, shoe inserts, and physical and occupational therapy, but these efforts do not treat the underlying disorder.

#### Congenital Myopathy

A genetic muscle deformity that is present from birth is called **congenital myopathy**. These conditions are rare but serious because they result in lack of muscle tone and severe muscle weakness. There are several subtypes of congenital myopathy, but they all cause similar symptoms including the following:

- decreased muscle tone, known as **hypotonia**
- muscle weakness, particularly in the neck, shoulders, and pelvis
- breathing and feeding issues
- developmental delays, such as being unable to sit up or roll over

- falling or stumbling

Treatment for congenital myopathy typically focuses on managing symptoms and improving quality of life. This may involve physical therapy to maintain muscle strength and mobility, occupational therapy to assist with daily activities, and respiratory therapy to address breathing difficulties. In some cases, medications such as corticosteroids or medications to improve muscle function may be prescribed. Assistive devices such as braces, walkers, or wheelchairs might also be used to aid mobility. Additionally, genetic counseling may be offered to families to understand the inheritance pattern and provide information about potential risks for future generations.

### Muscular Dystrophy

A group of muscular disorders called **muscular dystrophy** are caused by genetic mutations. All types of muscular dystrophies result in progressive muscle weakness. Nurses should be aware of some of the more common types of muscular dystrophies and their key differences ([Table 23.4](#)).

Type	Characteristics
Duchenne muscular dystrophy (DMD) and Becker muscular dystrophy (BMD)	<ul style="list-style-type: none"> <li>• Most common types of muscular dystrophy.</li> <li>• Primarily affects males with onset between ages 2 and 3.</li> <li>• Primary symptom is muscle weakness, first affecting the proximal muscles and later affecting muscles of the extremities.</li> <li>• Other symptoms include calf enlargement, waddling gait, and inward curvature of the spine.</li> <li>• Results in eventual respiratory failure due to scoliosis and diaphragmatic muscle weakness.</li> <li>• Life expectancy for DMD is early 20s; BMD life expectancy is about 30 to 40 years of age.</li> </ul>
Myotonic (DM)	<ul style="list-style-type: none"> <li>• Affects males and females equally.</li> <li>• Muscle weakness typically begins between 10 and 30 years of age.</li> </ul>
Limb-girdle (LGMD)	<ul style="list-style-type: none"> <li>• Affects males and females equally.</li> <li>• Upper arms and legs are the first areas to experience muscle weakness.</li> </ul>
Facioscapulohumeral (FSHD)	<ul style="list-style-type: none"> <li>• Affects males and females equally.</li> <li>• Muscle weakness typically begins in early adulthood and affects the face, shoulders, and upper arms first.</li> </ul>
Congenital (CMD)	<ul style="list-style-type: none"> <li>• Rare, affecting 1 in 100,000 people.</li> <li>• Affects males and females equally.</li> <li>• Symptoms begin at birth or in early infancy.</li> </ul>

**TABLE 23.4** Characteristics of the Most Common Types of Muscular Dystrophy (Source: Centers for Disease Control and Prevention, 2024.)

### Amyotrophic Lateral Sclerosis (ALS)

Previously known as Lou Gehrig disease, **amyotrophic lateral sclerosis (ALS)** is a progressive neurological disorder that affects motor neurons. Onset of ALS is variable but may occur between 40 and 70 years of age. A nerve cell that receives signals from the brain and spinal cord that cause voluntary skeletal muscle movements and breathing is called a **motor neuron**. As ALS progresses, more motor neurons die, resulting in muscle weakness, twitching, and atrophy. Eventually, ALS causes complete loss of control over voluntary movements including walking, talking,

eating, and even breathing. Some of the early symptoms of this condition include the following:

- muscle twitching, especially in the arms and legs
- muscle cramping
- spasticity of the muscles
- muscle weakness
- slurred speech
- difficulty swallowing

Other symptoms may develop later such as drooling, inability to form words and speak, unintended emotional displays (e.g., crying or laughing at inappropriate times), and severe weight loss. Unfortunately, there is no current cure for ALS; however, there are several medications available that have been shown to improve symptoms and slow the progression of the disease (e.g., riluzole [Exservan], edaravone [Radicava]). The majority of patients with ALS only survive two to five years after diagnosis (ALS Association, n.d.).

### Myasthenia Gravis

An autoimmune disorder, **myasthenia gravis** is a disorder in which antibodies attack the neuromuscular junction (NMJ) of skeletal muscles, resulting in progressive muscle weakness (e.g., arms, hands, fingers, legs, neck) and fatigue. Initial symptoms of myasthenia gravis happen suddenly; although initial symptoms may be so mild that diagnosis is delayed. Symptoms of myasthenia gravis include the following:

- eyelid drooping, known as **ptosis** ([Figure 23.17](#)).
- double vision, known as **diplopia**
- difficulty swallowing, known as dysphagia
- difficulty changing facial expressions
- difficulty speaking
- weak neck muscles, making it difficult to support the head

**FIGURE 23.17** Progressive muscle weakness in myasthenia gravis results in ptosis (i.e., drooping eyelids). (credit: Andrewya/Wikimedia Commons, Public Domain)

Several pharmacological therapies are available for the treatment of myasthenia gravis. These include cholinesterase inhibitors to improve communication between the nervous and musculoskeletal systems. Corticosteroids or immunosuppressants can also be used to help limit production of antibodies.

### Multiple Sclerosis

A neurological disorder, **multiple sclerosis (MS)** causes immune system cells to attack **myelin**, the protective coating on nerves. MS symptoms typically begin between the ages of 20 and 40; however, the course of the disease varies from person to person. Some patients with MS may have a mild type, causing minimal symptoms. On the other hand, some patients may have a severe case that progressively worsens over time. In many cases, patients with MS have periods of exacerbation where symptoms are worse and periods of remission where symptoms improve temporarily. Nurses should understand the different subtypes of MS ([Table 23.5](#)).

Type of MS	Description
Relapsing-remitting	<ul style="list-style-type: none"> <li>• Symptoms occur as exacerbations or “attacks.”</li> <li>• Between attacks, symptoms improve or resolve completely, resulting in remission.</li> <li>• Remission times between attacks vary from weeks to years.</li> </ul>
Secondary-progressive	<ul style="list-style-type: none"> <li>• Occurs after being diagnosed with relapsing-remitting type.</li> <li>• Symptoms begin to worsen over time with significant deterioration in physical functioning.</li> </ul>
Primary-progressive	<ul style="list-style-type: none"> <li>• Progressively worsening symptoms from the beginning without any exacerbations or periods of remission.</li> </ul>
Progressive-relapsing	<ul style="list-style-type: none"> <li>• Most rare subtype.</li> <li>• Steadily worsening symptoms from the beginning with acute relapses that further worsen symptoms.</li> </ul>

**TABLE 23.5** Subtypes of Multiple Sclerosis

The earliest signs and symptoms of MS include the following:

- blurry or double vision
- muscle weakness, most often in the hands and legs
- muscle spasms
- tingling or numbness
- clumsiness when walking
- inability to control bladder
- dizziness
- fatigue

In the later course of the disease, cognitive dysfunction is common. Patients may have trouble focusing on tasks, thinking, learning new things, or remembering memories. Unfortunately, there is no definitive cure for MS at present. There are, however, many treatments available for symptom control. Specifically, corticosteroids are used in an attempt to prevent the body from attacking its own myelin cells. Several disease-modifying medications have been approved for treatment of MS that work similarly to steroids to suppress the immune system.

## PATIENT CONVERSATIONS

### Your Patient Has Received a New Diagnosis of Multiple Sclerosis

**Scenario:** Nurse walks into the patient’s room to check vital signs. The patient has just been diagnosed with relapsing-remitting multiple sclerosis (MS).

**Nurse:** Hi, my name is Dana, and I’ll be your nurse today. Please confirm your name and date of birth before we get started.

**Patient:** Sure. It’s Serena James and my birthday is 11/24/1986.

**Nurse:** Great, thank you. Before I check your vital signs, I just wanted to check in and see how you’re feeling. I know that you were recently diagnosed with multiple sclerosis, which may be difficult to process. How are you doing?

**Patient:** I've definitely been better. I'm only in my 30s, so it's really unfair! I didn't have any questions when the doctor was in here but now that I've had a little time to think, I have a million things to ask. Would you be able to answer some of my questions?

**Nurse:** Of course. And if there's any question I don't know the answer to, I'm happy to relay the question to your doctor for you.

**Patient:** Thank you so much. For starters, what is MS? Like, how in the world did I get it when I'm so young and healthy?

**Nurse:** That's a really good question. Unfortunately, so far science hasn't shown a specific cause of MS, so we don't really know. In most cases though, there is some kind of autoimmune action occurring in your body. That means that your immune system is attacking the outside coating of your nerves, which eventually slows down brain signals to your muscles.

**Patient:** That sounds terrifying! What will happen to me when those signals are slowed down?

**Nurse:** It's hard to say because symptoms vary from person to person depending on the form of MS that you have, but most of the time symptoms of MS include blurry vision, muscle weakness, tingling in the hands and feet, and dizziness. Later on, you might start dealing with confusion or have trouble focusing on tasks.

**Patient:** What do you mean, the "form" I have?

**Nurse:** There are several different types of MS and thankfully, you were diagnosed with the mildest type. It's called relapsing-remitting MS. This means that you'll have periods of time where you have exacerbations, or "attacks" during which your symptoms get worse, but you'll also have periods of remission where your symptoms improve. Remission times can last anywhere from a few weeks to a few years.

**Patient:** I suppose that's reassuring. Are there any treatments available for it?

**Nurse:** There's no cure at the moment, but there are a lot of treatment options to help the symptoms and slow down the progression of the disease. A lot of patients with MS benefit from being on steroids that can slow your immune system down, which in turn slows down the disease. I think you would really benefit from a support group where you can talk about these things with other people your age who have also been diagnosed with this condition. Would it be okay if I print some resources and phone numbers for you to connect with these groups?

**Patient:** Yes, I would love that. Thank you so much!

**Nurse:** You're very welcome. I'm so sorry that you're dealing with this. Please let me know if there is anything else I can do to help you.

---

### Cerebral Palsy

An umbrella term for a group of disorders that affect the ability to move and stay balanced is **cerebral palsy (CP)**, which occurs because of damage to the brain during pregnancy, childbirth, or in early infancy. There are several subtypes, each with their own associated signs and symptoms. Some early signs that a baby may have one of the forms of CP include the following:

- head lag when being picked up from lying on the back
- overly stiff or floppy extremities
- overextension of back and neck, making it seem as if the baby is pushing themselves away from the caregiver when being held
- leg stiffening or scissoring when being picked up
- inability to roll over after 6 months of age
- lopsided crawling or inability to crawl at all

Currently, there is no cure for CP; however, several interventions are available to treat symptoms of the condition. These interventions include medications, braces and adaptive devices, physical and occupational therapies, and potentially surgery in severe cases.

## Spinal Cord Injuries

When there is damage to the spinal cord, a **spinal cord injury** occurs, often as a result of trauma (e.g., a motor vehicle accident, a fall) or cancer. The rest of the body below the damaged level of the spinal cord is affected and often results in irreversible damage and limited mobility. In some cases, the damage to the spinal cord is incomplete, leaving some sensation and mobility below the level of damage. However, in complete spinal cord injury, all feeling and ability to control movement are lost. This complete loss of sensation and mobility is called **paralysis**. Paralysis can be further classified as **tetraplegia** (quadriplegia), which is paralysis from the neck down, or **paraplegia**, which is paralysis of the legs and portions of the trunk but not the arms. Common symptoms of spinal cord injuries include the following:

- immobility of affected extremities
- loss or changes in sensation (e.g., feeling extreme temperatures)
- loss of bowel or bladder control
- involuntary muscle spasms
- hyperactive reflexes
- sexual dysfunction
- trouble breathing (more common with higher spinal cord injuries)

Treatment for spinal cord injuries depends on the extent of the damage but typically involves intense physical and occupational therapy.

## REAL RN STORIES

---

### Spinal Cord Injury

**Nurse:** Frankie, BSN

**Clinical setting:** Intensive care unit (ICU)

**Years in practice:** 5

**Facility location:** The inner city of a large metropolitan area in California

I arrived at work for my night shift at 1700 hours and was told that I'd be floating to the emergency department (ED). After I arrived in the ED, I was told by the charge nurse that a patient with suspected spinal cord injury would be arriving any minute and that I was being assigned to that patient. Not even three minutes later, paramedics rushed through the door with the patient.

The paramedics looked very concerned as they wheeled my patient into his assigned room. I could see that the patient was already intubated, on a ventilator, had a cervical collar on, and was not moving any of his extremities. Adhering to cervical spine precautions, we moved the patient from the stretcher onto the hospital bed. The paramedics then gave me a quick report of what happened.

“This is Josh Myers, 17-year-old male. He was swimming with friends and dove into shallow water. He was underwater for a few minutes before his friends realized he wasn't coming up to the surface. His friends pulled him out and called 911. They did CPR and by the time we got there he had a pulse, but we immediately had to intubate the patient. We have not seen any purposeful movement in any of his extremities, so we're worried about a high spinal cord injury. His parents have been contacted and they're on their way here now.”

I began to assess the patient, confirming that there was no purposeful movement in his extremities. The trauma provider ordered a STAT CT scan, which showed a cervical spinal cord injury. I cared for this patient for three days in a row, ultimately learning that he would need to be on a ventilator for the rest of his life because the injury occurred so high in the spinal cord. The patient's mental state remained intact, which made this situation quite difficult for him to process, being only 17 years old. As a nurse, it was difficult for me as well to see a healthy teenager be permanently disabled from a completely preventable accident.

---

## Effects of Neuromuscular Impairment

There are many disorders that can adversely affect the neuromuscular system, all with different causes and symptoms. However, many of these disorders share similar symptoms, including loss of balance; muscle weakness

and stiffness; muscle atrophy; pain; and breathing, swallowing, and vision impairment.

### Loss of Balance

Loss of balance in neuromuscular conditions occurs via two main mechanisms. First, neuromuscular disorders cause muscle weakness, which in turn makes it difficult to maintain balance and posture. When muscles of the trunk and core are weak, the center of gravity of the body is off, making it difficult to stay balanced. The other mechanism behind loss of balance is related to slow nerve signals being sent to the muscles, such as seen in multiple sclerosis. Essentially, the muscles are not receiving signals from the brain in a timely manner, making it difficult to move in a way that consciously or unconsciously maintains balance and posture. Loss of balance can be dangerous, especially in older adults, who are already more prone to falls. For neuromuscular conditions that cause a loss of balance, adaptive devices may be required to assist with ambulation and other movements to decrease the risk of a fall and subsequent injury.

### Muscle Weakness and Stiffness

Muscle weakness and/or stiffness are hallmark symptoms of many neuromuscular conditions. In fact, they are often the presenting symptom that indicates the need for follow-up, which leads to eventual diagnosis of the disorder. In some conditions, such as with myasthenia gravis, muscle weakness is related to the direct muscle damage that occurs as part of an autoimmune system attack on muscle tissue. In many other neuromuscular conditions, brain or nerve damage results in slowing of nerve signals sent to muscles. With a lack of nerve signals being sent to skeletal muscles, they are not used as often or as efficiently, resulting in weakness related to immobility. Most neuromuscular conditions that cause muscle weakness require extensive physical and occupational therapy in conjunction with adaptive devices to preserve and improve the patient's mobility.

### Muscle Atrophy

Wasting and breakdown of muscle tissue, **muscle atrophy**, is another common clinical manifestation of many neuromuscular disorders ([Figure 23.18](#)). When muscles are not being used often enough, they become weak and waste away. This wasting away of muscles further contributes to the cycle of muscle weakness, resulting in an inability to effectively move and maintain balance and posture.

**FIGURE 23.18** Muscle atrophy occurs as a manifestation of many neuromuscular conditions. (credit: “Case of progressive muscular atrophy”/Wellcome Images, CC BY 4.0)

### Pain

Chronic pain is a common clinical manifestation of many neuromuscular conditions. In some conditions, such as Charcot-Marie-Tooth disease, pain can be severe and debilitating, affecting all aspects of everyday life. Other conditions, such as mild forms of multiple sclerosis, may cause some pain but not enough to significantly affect activities of daily living (ADLs). As with all patients, it is important for the healthcare team to recognize that “pain is

what the patient says it is,” and treat them accordingly. It is also important to know that patients with neuromuscular disorders often have good days where pain is minimal and bad days where pain is debilitating. Pain management should be an included component in the care plan for every patient who is diagnosed with a neuromuscular disorder.

### Breathing Impairment

Breathing impairment may occur with some neuromuscular disorders, most often at the end of the course of the disease. In conditions that cause muscle weakness and atrophy, muscles such as the diaphragm and intercostal muscles are eventually affected, resulting in an inability to breathe effectively. In fact, respiratory muscle weakness is one of the leading causes of death in patients with neuromuscular disorders (Khanbabaei et al., 2023). Additionally, in conditions that affect the cervical spinal cord, such as with high spinal cord injury, the nerves that innervate the breathing center of the brain may be affected, which inhibits the patient’s ability to breathe. These patients often require a **tracheostomy** (an opening in the trachea into which a tube is placed that allows for mechanical ventilation to be delivered) for the course of their life because they are no longer able to breathe or breathe adequately on their own.

### Swallowing Impairment

Difficulty swallowing, or dysphagia, is a common clinical manifestation of many neuromuscular disorders. Muscles of the mouth, pharynx, and upper esophagus become weakened, making it difficult for the patient to chew and swallow effectively. This is a concern for many reasons. First and foremost, dysphagia increases the risk of **aspiration**, which occurs when food or other foreign particles enter the airway. Aspiration can become life-threatening when it limits the patient’s ability to breathe effectively. Another concern with dysphagia is that it can significantly and adversely affect the patient’s quality of life. Dysphagia can cause malnutrition and can also take the enjoyment out of eating, resulting in depression and negative feelings toward food.

### Vision Impairment

Vision impairment is not quite as common as the symptoms discussed in the previous sections but can still occur as a clinical manifestation of some neuromuscular disorders. In most cases, there is damage to the optic nerve, which results in pain and decreased vision. This is especially true for conditions such as multiple sclerosis that cause demyelination of nerve cells. When the optic nerve is attacked, vision is negatively affected.

## 23.3 Considerations for Care of Neuromuscular Impairment

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe nursing considerations for impaired neuromuscular functioning
- Discuss collaborative care considerations for impaired neuromuscular functioning
- Identify environmental considerations for impaired neuromuscular functioning

Regardless of the setting you choose to practice in as a nurse, it is highly likely that you will at some point encounter a patient with neuromuscular impairment. When caring for these patients, nurses should keep in mind the nursing considerations specific to patients with neuromuscular conditions, the goals of collaboration between disciplines, and the importance of maintaining a safe environment to promote optimal outcomes.

### Nursing Considerations

Nursing considerations for patients with neuromuscular impairment include physical needs such as maintaining respiratory function, promoting mobility, managing pain, ensuring optimal nutrition, and monitoring elimination and skin integrity. Beyond the physical needs, it is also important for nurses to consider the emotional needs of the patient because these disorders can negatively affect overall quality of life. The nurse can help by teaching coping strategies and providing family support. Infants and children with neuromuscular impairment also have developmental needs that nurses must be prepared to handle.

### Physical Needs

Because the primary symptom of most neuromuscular disorders is muscle weakness, these patients have many physical needs. Specifically, they will need help maintaining respiratory function; preventing adverse effects of immobility; managing pain; and monitoring nutrition status, elimination, and skin integrity. Another significant role of

the nurse when caring for patients with neuromuscular impairment is assisting with activity of daily living (ADL).

### Maintaining Respiratory Function

The muscle weakness that occurs with neuromuscular disorders eventually affects the diaphragm and intercostal muscles, resulting in impaired breathing. This typically occurs later in the course of the disease progression, and it is important for the nurse to be prepared to intervene in an effort to maintain respiratory function. First and foremost, it is important to always ensure airway patency. With weak muscles, it may be difficult for the patient to cough effectively and keep the airway clear of secretions. If secretions cannot be cleared, the patient is at high risk for aspiration and subsequent aspiration pneumonia, which can be life-threatening.

In some cases, patients with neuromuscular disorders may require supplemental oxygen to breathe effectively. In more mild situations, the patient may only need a few liters of oxygen via nasal cannula ([Figure 23.19](#)).

**FIGURE 23.19** Patients with certain neuromuscular disorders may require supplemental oxygen to be delivered through a nasal cannula. (credit: *Nursing Skills [Internet]. 2nd edition/NIH, CC BY 4.0*)

In more severe situations, such as with higher level spinal cord injuries, the patient may require lifelong mechanical ventilation through a tracheostomy ([Figure 23.20](#)). For patients with tracheostomies, it is important for the nurse to provide “trach” care as ordered to keep the airway clear and prevent infection. Additionally, the nurse should have familiarity with the ventilator settings and be able to intervene appropriately for various alarms.

**FIGURE 23.20** A patient with a neuromuscular disorder may have a tracheostomy, which is connected to a mechanical ventilator. This surgically created opening in the trachea helps provide oxygen to the lungs. (credit: National Heart Lung and Blood Institute/Wikimedia Commons, Public Domain)

### Dealing with Immobility Considerations

Patients with muscle weakness from neuromuscular conditions often spend an extended period of time in bed and thus can develop a variety of complications related to loss of muscle strength. Regardless of the cause, immobility can cause degradation of cardiovascular, respiratory, gastrointestinal, and musculoskeletal functioning. Promoting mobility can prevent these complications from occurring. Studies have shown several benefits of mobilization, including less delirium, pain, urinary discomfort, urinary tract infection, fatigue, **deep vein thrombosis (DVT)**, skin breakdown, and pneumonia, as well as an improved ability to void (Alaparathi et al., 2020). (Figure 23.21).

Additionally, the use of adaptive equipment and assistive devices (e.g., wheelchairs, walkers, canes) can restore some mobility, allowing for increased independence and participation in self-care activities.

**FIGURE 23.21** The patient's leg is red and swollen; the arrow points to the deep vein thrombosis that has developed as a complication of

prolonged immobility. (credit: Seyahi E, Yurdakul S/NIH, CC BY 2.0)

Nurses should understand the effects of immobility on these body systems as well as the complications. It also is important for nurses to be prepared to implement associated nursing interventions related to immobility ([Table 23.6](#)).

Body System	Immobility Effects	Nursing Interventions
Cardiovascular	<ul style="list-style-type: none"> <li>Decreased systemic vascular resistance, causing venous pooling in extremities</li> <li>Decreased cardiac output</li> </ul>	<ul style="list-style-type: none"> <li>Monitor blood pressure regularly.</li> <li>Encourage fluids for adequate hydration.</li> <li>Administer prophylactic anticoagulant, as ordered.</li> </ul>
Gastrointestinal	<ul style="list-style-type: none"> <li>Decreased peristalsis</li> <li>Anorexia</li> <li>Decreased fluid intake</li> <li>Increased intestinal gas</li> <li>Altered swallowing</li> </ul>	<ul style="list-style-type: none"> <li>Offer high-calorie foods such as protein shakes.</li> <li>Encourage fluid intake.</li> <li>Puree foods as needed.</li> </ul>
Genitourinary	<ul style="list-style-type: none"> <li>Urinary discomfort</li> <li>Urinary retention</li> <li>Urinary calculi</li> <li>Urinary tract infections</li> </ul>	<ul style="list-style-type: none"> <li>Implement toileting schedule.</li> <li>Use a bladder scan and straight catheterization techniques as needed.</li> <li>Encourage adequate hydration.</li> </ul>
Integumentary	<ul style="list-style-type: none"> <li>Decreased delivery of oxygen and nutrients to tissues</li> <li>Tissue ischemia</li> <li>Inflammation over bony prominences</li> <li>Friction and shear</li> </ul>	<ul style="list-style-type: none"> <li>Turn the patient every two hours.</li> <li>Monitor for skin breakdown and intervene immediately if noticed.</li> </ul>
Musculoskeletal	<ul style="list-style-type: none"> <li>Reduced muscle mass and strength</li> <li>Decreased endurance</li> <li>Impaired joint mobility</li> </ul>	<ul style="list-style-type: none"> <li>Perform active and passive range of motion exercises as tolerated.</li> <li>Encourage ambulation and movement as tolerated.</li> </ul>
Psychological	<ul style="list-style-type: none"> <li>Depression</li> <li>Anxiety</li> <li>Distress</li> </ul>	<ul style="list-style-type: none"> <li>Provide support.</li> <li>Connect patient to social worker, support groups, and other resources.</li> </ul>
Respiratory	<ul style="list-style-type: none"> <li>Decreased strength of respiratory muscles</li> <li>Diminished lung expansion</li> <li>Hypoventilation</li> <li>Impaired gas exchange</li> <li>Decreased cough reflex</li> <li>Pulmonary secretion pooling</li> </ul>	<ul style="list-style-type: none"> <li>Provide supplemental oxygen, as ordered.</li> <li>Encourage incentive spirometer use.</li> <li>Ambulate patient as tolerated to facilitate lung expansion.</li> </ul>

**TABLE 23.6** Nursing Considerations for Body Systems Affected by Immobility

### Managing Pain

Pain is another common clinical manifestation of neuromuscular disorders. Pain management requires collaboration with the interdisciplinary team, including nurses, healthcare providers, pharmacists, and sometimes pain specialists. There are many different types of pain medications (called analgesics) that can be administered by various routes. Analgesics are classified as nonopioids, opioids, or adjuvants. An adjuvant is a medication that has been found in clinical practice to have either an independent analgesic effect or additive analgesic properties when administered with opioids. Examples of adjuvant medications include antidepressants (e.g., amitriptyline) and anti-seizure medications (e.g., gabapentin). It is important for the nurse to be familiar with analgesic medications, especially their potential side effects before administering them. For example, overuse of opioids can lead to constipation, which can cause more pain for a patient experiencing muscle weakness from a neuromuscular disorder.

In addition to medications, numerous nonpharmacological interventions can be used to treat pain associated with neuromuscular disorders. Some of these interventions include the following:

- distraction (e.g., playing games, watching television)
- relaxation through meditation, hypnosis, prayer, breathing, or music therapy
- comfort measures including repositioning and massage as tolerated
- application of heat or cold
- exercise or physical therapy as tolerated
- aromatherapy

### Monitoring Nutritional Status

Monitoring nutritional status is important for all patients but is especially important for patients with neuromuscular disorders. These patients experience severe muscle weakness, which can be exacerbated by malnourished states. If the patient is unable to eat enough, the muscles are not getting the nutrients they need, further contributing to their weakened state. To improve this, the nurse should try to encourage the patient to eat when they are able to, and to consume high-calorie, nutrient-dense foods when possible. It may be beneficial for these patients to increase their intake of protein as well to help repair muscle tissue. It is important to note that although consuming more protein and calories can help alleviate some muscle weakness, it is not a cure for the underlying disorder. And in some cases, altering nutrition will still not help symptoms significantly. Some patients with neuromuscular disorders may have difficulty swallowing (known as dysphagia), making it even more difficult to eat. In these cases, enteral or parenteral nutrition therapies may be ordered. It is important for the nurse to collaborate effectively with the care team, including dietitians and speech therapists, to ensure the patient is receiving appropriate nutrition, especially if they are experiencing dysphagia.

### Monitoring Elimination

Muscles of the bowel and bladder often become weak in neuromuscular conditions, especially in the later stages of disease progression. This can lead to urinary or bowel **incontinence**, which is the involuntary expulsion of urine or feces from the body. Nurses should use therapeutic communication with patients experiencing incontinence to help them feel comfortable in expressing their fears, worries, and embarrassment about incontinence and work toward improving their quality of life. Nurses should be prepared to provide education about pelvic floor muscle training exercises, timed voiding, lifestyle modification, and incontinence products. Encourage patients to learn more about their condition so they can optimally manage it and improve their quality of life. In more severe cases where the patient cannot manage the incontinence themselves, it is important for the nurse to check the patient frequently to ensure they are clean and dry to help prevent skin breakdown or the development of a urinary tract infection. If the patient is being discharged home, the nurse should provide education to the family or primary caregiver about the importance of keeping the patient clean and dry to prevent complications.

### Monitoring Skin Integrity

Patients with neuromuscular disorders often spend extended periods of time in bed or sitting in wheelchairs because they have muscle weakness, making it difficult or impossible to ambulate. These periods of immobility increase their risk of skin breakdown and pressure injuries. A pressure injury is defined as breakdown of skin integrity caused by prolonged internal pressure against a bony prominence or persistent contact with an external surface (e.g., furniture, medical or other devices) often in combination with shear. Pressure injuries commonly occur

on the sacrum, heels, ischial tuberosities, and coccyx and form when a layer of skin tissue gets caught between an external hard surface, such as a bed or chair, and the internal hard surface of a bone. Nursing interventions for the care of a patient with or at risk for pressure injuries include the following:

- assessing and documenting skin status frequently
- applying prophylactic dressings to high-risk areas
- keeping skin free of excessive moisture
- promoting a high-protein diet (if appropriate for patient) and encouraging fluid intake
- repositioning the patient frequently (e.g., every two hours)
- keeping bed linens clean and free from wrinkles

### **Assisting with ADLs**

Muscle weakness often makes it difficult or impossible for patients with neuromuscular disorders to perform ADLs on their own. The nurse should encourage the patient to perform ADLs as independently as possible and participate in prescribed physical therapy. For instance, the nurse should encourage the patient to perform active or passive range of motion exercises as prescribed by the physical therapist or if necessary perform these ADLs for the patient. The nurse should be aware that pain and fear of falling can be major deterrents to a patient's willingness to ambulate or perform physical therapy, so the nurse should educate the patient about appropriately using assistive devices and adhering to other fall precautions. The nurse should encourage rest between activities. For patients who are bedridden, the nurse should elevate the head of the bed to 30 to 45 degrees, unless medically contraindicated, and turn and reposition the patient every two hours. Furthermore, the nurse should perform hourly rounding to check on the patient's needs and prevent falls. In some cases, the use of assistive devices may be used to restore some of the patient's mobility, increasing their ability to participate in performing ADLs. Examples of these devices include canes, walkers, crutches, wheelchairs, mobility scooters, and braces.

### **Emotional Needs**

Patients with neuromuscular disorders often have emotional needs in addition to physical needs. These disorders can be debilitating, which can negatively affect the patient's quality of life and result in depression or anxiety. To improve this, the nurse should provide support for both the patient and their family members and teach effective coping strategies.

### **Provide Patient and Family Support**

Many patients with neuromuscular disorders have family caregivers who are an extension of the healthcare team and constantly work with the patient. It is important for nurses to also assess the caregiver when seeing them with the patient in the home, clinic, hospital, or long-term care setting and provide encouragement. What do caregivers want? Research shows that caregivers want and need the following (Lowey, 2024):

- support, assistance, and practical help (e.g., finding others to assist with grocery shopping, going to the pharmacy, and food preparation)
- honest conversations with the healthcare team
- assurance that their loved one is being honored
- inclusion in decision-making
- desire to be listened to and their concerns heard
- remembrance as a good and compassionate caregiver
- assurance that they did all they possibly could for their loved one

Nurses should assess caregivers' social support network and any needs for further assistance. This assessment includes assessing the caregiver's physical needs, sleep patterns, and ability to perform other responsibilities. Nurses should watch for signs of declining health, clinical depression, or increased use of alcohol and drugs. Listening to their stories and providing presence, active listening, and touch contributes greatly to the caregiver's sense of worth. The nurse should help the patient's caregiver in identifying and using support systems and should refer them to resources and support groups in the community as needed.

### **Teach Coping Strategies**

Interventions to enhance coping can be implemented for patients with neuromuscular disorders as well as for family members. Sample interventions that the nurse should consider implementing include the following:

- Assist the patient in identifying short- and long-term goals.
- Help the patient find available resources to meet the goals.
- Encourage relationships with others who have common interests and goals.
- Help the patient solve problems in a constructive manner.
- Assist the patient in breaking down complex tasks into small, manageable steps.
- Help the patient identify alternative responses to difficult situations.
- Use a calm, reassuring approach.
- Provide an atmosphere of acceptance.
- Help the patient identify information they are most interested in obtaining.
- Provide factual information regarding medical diagnosis, treatment, and prognosis.
- Provide the patient with realistic choices about certain aspects of care.
- Encourage an attitude of realistic hope as a way of dealing with hopelessness.
- Seek to understand the patient's perspective of a stressful situation.
- Discourage decision-making when the patient is under severe stress.
- Acknowledge the patient's cultural and spiritual background and encourage use of spiritual resources, if desired.
- Encourage verbalization of feelings, perceptions, and fears.
- Encourage family involvement, as appropriate.
- Help the patient identify positive strategies to deal with limitations and manage needed lifestyle or role changes.
- Instruct the patient on the use of relaxation techniques.

## PATIENT CONVERSATIONS

---

### Teaching Visualization and Mindfulness as Coping Strategies

**Scenario:** The patient is a 67-year-old male being seen in a multiple sclerosis rehabilitation clinic.

**Nurse:** Hi, my name is Jaxson. I'll be your nurse today. How are you feeling about everything?

**Patient:** I'm actually feeling really overwhelmed. All I can think about is MS and how it's turned my life upside down.

**Nurse:** I understand. It's natural to feel anxious about MS. Before you meet with your occupational therapists, why don't we work on some coping strategies together. Have you ever tried any techniques to manage your anxiety?

**Patient:** Not really. I've just been trying to keep busy, but it's not helping much.

**Nurse:** I see. Let's try something different. One effective technique is visualization. Close your eyes and imagine yourself in a calm and peaceful place. It could be a beach, a forest, or anywhere that makes you feel relaxed. Picture the details—the sights, sounds, and smells.

**Patient:** That sounds nice. I'll give it a try.

**Nurse:** Great. Another technique is mindfulness meditation. It involves focusing on the present moment without judgment. Pay attention to your thoughts, feelings, and sensations without trying to change them.

**Patient:** How do I do that?

**Nurse:** Start by sitting comfortably and bringing your attention to your breath. Notice the sensation of each inhale and exhale. If your mind starts to wander, gently bring it back to your breath.

**Patient:** Okay, I think I can do that.

**Nurse:** Practice these techniques daily for ten to fifteen minutes. They can help you feel more calm and centered. And remember, if you ever need support, I'm here for you.

**Patient:** Thank you so much. I really appreciate it.

**Nurse:** You're welcome. Take care, and remember to be gentle with yourself during this time.

---

### Developmental Needs

Many neuromuscular disorders are diagnosed in early childhood, which emphasizes the need to discuss the patient's developmental needs. These needs will be quite different for children versus adults. Some challenges and considerations related to the developmental needs of children with neuromuscular disorders are described in ([Table 23.7](#)).

Challenge	Pediatric Nursing Considerations
Decreased muscle tone, strength, and coordination	<ul style="list-style-type: none"> <li>Gross and fine motor skill development may be delayed.</li> <li>Specialized therapy (e.g., physical therapy, occupational therapy) may be required to improve motor function, mobility, and independence with ADLs.</li> </ul>
Delayed or impaired cognitive development	<ul style="list-style-type: none"> <li>Potential for condition to cause intellectual disabilities.</li> <li>Children with cognitive impairment may benefit from educational interventions, cognitive-behavioral therapy, and strategies to support learning and academic achievement.</li> </ul>
Mental health challenges	<ul style="list-style-type: none"> <li>Living with a neuromuscular condition can impact social interactions, self-esteem, and emotional well-being.</li> <li>Individuals may experience feelings of frustration, isolation, or anxiety related to their condition.</li> <li>Supportive interventions, such as counseling, peer support groups, and social skills training, can help individuals navigate social challenges and build resilience.</li> </ul>
Decreased independence	<ul style="list-style-type: none"> <li>Neuromuscular conditions may affect an individual's ability to perform self-care tasks independently, such as dressing, feeding, grooming, and toileting.</li> <li>Occupational therapists can provide training and adaptive equipment to promote independence and maximize functional abilities in daily activities.</li> </ul>
Difficulty transitioning to adulthood	<ul style="list-style-type: none"> <li>As individuals with neuromuscular conditions transition to adulthood, they may face additional challenges related to independence, employment, health care, and social integration.</li> <li>Transition planning should address vocational training, job placement, independent living skills, and access to adult healthcare services.</li> </ul>

**TABLE 23.7** Developmental Challenges and Considerations for Children with Neuromuscular Disorders

### Provide Education

Parents of children with newly diagnosed neuromuscular disorders are often scared and anxious about many aspects of their new reality with a sick child. For this reason, it is important that the nurse provides thorough education regarding the diagnosis itself and how to care for the child in the home setting. Additionally, the nurse will need to educate patients and families about typical developmental milestones and how neuromuscular conditions may affect the attainment of these milestones. The nurse should emphasize the importance of early intervention services and explain how these therapies can help promote optimal development, improve functional abilities, and enhance quality of life. The nurse can also provide information about adaptive strategies, assistive devices, and

mobility aids that can support independence and participation in daily activities. Thinking on a bigger scale, the nurse can also educate families and educators about the educational rights and needs of individuals with neuromuscular conditions to promote advocacy.

The nurse must also be prepared to address any other questions the parents or guardians may have. It is important to remember that parents may require repetition of information because often they are anxious, making it difficult for them to process large amounts of information. Most importantly, the nurse should be patient, kind, and nonjudgmental when providing education and interacting with both the child and family.

### **Promote Self-Care Regimens**

Often, young children are unable to participate in a self-care regimen, but as they get older, the nurse should emphasize the importance of allowing children to perform as much of their own self-care as possible. Having a neuromuscular disorder takes away much of a person's independence, so they should be encouraged to perform as much care for themselves as possible in an effort to restore some of that autonomy. In the hospital setting, the nurse should allow the patient to do as much on their own as possible while still remaining in close proximity to be prepared to help if the patient requires assistance.

### **Collaborative Care Considerations**

Caring for patients with neuromuscular disorders requires collaboration between various disciplines to promote optimal outcomes. Some of the members of the interdisciplinary team are discussed in the next section.

#### **Specialty Consults**

Many specialty healthcare personnel may be part of the interdisciplinary team caring for a patient with a neuromuscular disorder. These include dietitians, occupational therapists (OT), physical therapists (PT), psychologists and psychiatrists, respiratory therapists, social workers, and speech therapists.

- **Dietitians:** Dietitians assess, plan, implement, and evaluate interventions including those relating to dietary needs. They also provide dietary education and work with other members of the healthcare team when a client has dietary needs secondary to neuromuscular disorders (e.g., dysphagia).
- **Occupational therapists (OT):** Occupational therapists are licensed healthcare professionals who assess, plan, implement, and evaluate interventions related to independence. This includes activities that facilitate the patient's ability to achieve their highest possible level of independence in their ADLs (e.g., bathing, grooming, eating, dressing).
- **Physical therapists (PT):** Physical therapists are licensed healthcare professionals who assess, plan, implement, and evaluate interventions related to the patient's functional abilities (e.g., strength, mobility, balance, gait, coordination, joint range of motion). They supervise prescribed exercise activities according to a patient's condition and provide and teach patients how to use assistive aids (e.g., walkers, canes) and perform exercise regimens.
- **Psychologists and psychiatrists:** Psychologists and psychiatrists are licensed healthcare professionals who provide mental health and psychiatric services to patients with mental health disorders. They also provide psychological support to family members and significant others as indicated. Patients with neuromuscular disorders are prone to anxiety and depression, so having a mental health professional on the care team offers many benefits.
- **Respiratory therapists:** Respiratory therapists are licensed healthcare professionals who treat respiratory-related conditions in patients. Their specialized respiratory care includes managing oxygen therapy and managing patients on specialized oxygenation devices (e.g., mechanical ventilators), which are used by some patients with severe neuromuscular disorders.
- **Social workers:** Social workers are licensed healthcare professionals who counsel patients and provide psychological support, help set up community resources according to patients' financial needs, and serve as part of the team that ensures continuity of care after the person is discharged.
- **Speech therapists:** Speech therapists are licensed healthcare professionals who assess, diagnose, and treat communication and swallowing disorders. They play a large role in assisting with dysphagia associated with neuromuscular disorders.

### Caregiver Resources

Caregivers of patients with neuromuscular disorders are often the closest family member (e.g., spouse, adult children, siblings, parents). They may provide the bulk of the care for the patient in the home setting. Because of this, these caregivers are prone to burnout and caregiver fatigue. It is important for the nurse to provide caregivers with resources to take good care of the patient but to also take care of themselves. In some cases, this may mean referring the family to a social worker who can assist with finding in-home help or a long-term care center. Social workers can help provide the caregiver with contact information for a community support group to connect with other caregivers. The nurse should openly discuss the needs of the caregiver to determine the most appropriate resources to provide.

### LINK TO LEARNING

---

Nearly every neuromuscular disorder has a dedicated foundation or association that provides resources to patients and families. Most of these organizations also provide resources for caregivers. For example, the [Muscular Dystrophy Association \(MDA\)](https://openstax.org/r/77mda) has published this list of resources (<https://openstax.org/r/77mda>) for caregivers of patients with MD.

---

### Environmental Considerations

The muscle weakness caused by neuromuscular disorders puts these patients at higher risk for falls and other injuries. This risk highlights the importance of maintaining a safe environment. Interventions to ensure a safe environment and prevent falls for patients with neuromuscular disorders include the following:

- removing clutter from walking areas
- reminding the patient to use a call light before getting out of bed
- setting bed alarms before leaving the room
- keeping the bed in the lowest and locked position
- having the patient wear brightly colored “fall-risk” socks or a fall-risk armband to increase team member awareness of the patient’s fall risk

### CLINICAL SAFETY AND PROCEDURES (QSEN)

---

#### QSEN Competency: Safety

**Definition:** Minimizes risk of harm to patients and providers through both system effectiveness and individual performance. The nurse will:

- Value vigilance and monitoring (even of own performance of care activities) by patients, families, and other members of the healthcare team.
  - Communicate observations or concerns related to hazards and errors to patients, families, and the healthcare team.
  - Demonstrate effective use of strategies to reduce risk of harm to self or others.
-

## Summary

### 23.1 Foundations of Neuromuscular Functioning

The neuromuscular system is the combination of the neurological system and the musculoskeletal system working together effectively. The neurological system is composed of the brain, spinal cord, and peripheral nerves. The musculoskeletal system is made up of bones, muscles, and various connective tissues. Signals from the neurological system send messages to the musculoskeletal system to cause responses and reactions to external and internal stimuli to maintain homeostasis and protect the body from injury. The primary functions of the neuromuscular system include essential body movement, posture control, breathing, and maintenance of homeostasis.

### 23.2 Factors Affecting Neuromuscular Functioning

Several diagnostic tests can be used to help diagnose neuromuscular disorders or rule out other conditions that may be causing similar symptoms. These tests include blood tests, electromyography (EMG), radiographic imaging, nerve condition velocity testing, muscle biopsies, and genetic tests. Used in combination, these tests can help narrow down which specific disorder, among the many different types of neuromuscular conditions, the patient is experiencing, all of which have varying clinical manifestations and prognoses. Common disorders that impair the neuromuscular system include Charcot-Marie-Tooth disease, congenital myopathy, muscular dystrophy, amyotrophic lateral sclerosis, multiple sclerosis, cerebral palsy, and spinal cord injuries. Although these disorders are different in many ways, they typically all involve similar symptoms of neuromuscular impairment including loss of balance; muscle weakness, stiffness, and atrophy; pain; and breathing, swallowing, and vision impairment.

### 23.3 Considerations for Care of Neuromuscular Impairment

Nursing considerations for patients with neuromuscular impairment include physical needs such as maintaining respiratory function, promoting mobility, implementing pain management strategies, ensuring optimal nutrition, and monitoring elimination and skin integrity. Beyond the physical needs, it is also important for nurses to consider the emotional needs of the patient because these disorders can negatively impact overall quality of life. Additionally, it is important for nurses to collaborate with other members of the healthcare team to ensure optimal patient outcomes. This typically involves collaboration with specialty consults including dietitians, occupational and physical therapists, social workers, and speech therapists, among others. Environmental considerations for patients with neuromuscular conditions involve maintaining a safe environment because these patients are at higher risk for falls and injury. Some interventions for maintaining a safe environment include removing clutter from the room, ensuring bed alarms are on, and keeping the bed in the lowest and locked position.

## Key Terms

**amyotrophic lateral sclerosis (ALS)** a progressive neurological disorder that affects motor neurons

**anterior horn** gray-matter region of the spinal cord that contains multipolar motor neurons, sometimes referred to as the ventral horn

**appendicular skeleton** consists of the limbs, which are attached to the axial skeleton

**ascending tract** a column of nervous system fibers that carry sensory information up to the brain

**aspiration** the process of food or other foreign particles entering the airway

**autonomic nervous system (ANS)** component of the peripheral nervous system that regulates involuntary physiologic responses and includes the sympathetic and parasympathetic nervous system

**axial skeleton** consists of 80 bones that form the head and trunk of the body

**bone** hard, dense connective tissue that form most of the adult skeleton, the primary support structure of the body

**brain** contained within the cranial cavity of the skull is the central organ of the nervous system responsible for controlling bodily functions, processing sensory information, and enabling cognitive processes such as learning and memory

**brain stem** region of the adult brain that includes the midbrain, pons, and medulla oblongata, which develops from the mesencephalon, metencephalon, and myelencephalon of the embryonic brain

**cardiac muscle** muscle specifically related to cardiac tissue

**cartilage** type of connective tissue that provides structural support and flexibility and helps reduce friction during joint movement

- cauda equina** a bundle of nerve roots located at the end of the spinal cord that resembles a horse's tail
- central nervous system (CNS)** the primary processing center of the body; includes the brain and spinal cord
- cerebellum** an area of the brain largely responsible for comparing information from the cerebrum with sensory feedback from the periphery through the spinal cord
- cerebral cortex** the outer gray matter covering the forebrain, marked by wrinkles and grooves known as gyri and sulci
- cerebral hemisphere** one half of the bilaterally symmetrical cerebrum
- cerebral palsy (CP)** an umbrella term for a group of disorders caused by damage to the brain during pregnancy, childbirth, or in early infancy that affect the ability to move and stay balanced
- cerebrum** the region of the brain responsible for higher neurological functions such as memory, emotion, consciousness, and voluntary muscle movement
- Charcot-Marie-Tooth (CMT) disease** a progressive genetic neuromuscular disorder that affects the peripheral nerves, most often those of the arms, hands, legs, and feet
- congenital myopathy** a genetic muscle deformity that is present from birth resulting in a lack of muscle tone and severe muscle weakness
- connective tissue** cartilage, ligaments, and tendons that connect tissues and organs
- corpus callosum** the large white matter structure that connects the cerebrum to the rest of the nervous system and provides the major pathway for communication between the right and left cerebral hemispheres
- cranial nerve** one of twelve nerves connected to the brain that are responsible for sensory and motor functions of the head and neck
- deep vein thrombosis (DVT)** the formation of a blood clot in the deep veins in the body, usually in the legs
- descending tract** a column of nervous system fibers that carry motor commands from the brain
- diencephalon** the region of the adult brain that retains its name from embryonic development and includes the thalamus and hypothalamus
- diplopia** double vision
- electromyography (EMG)** a diagnostic procedure involving small needles that record electrical activity in the muscles
- excitability** the ability of muscle plasma membranes to change electrical states and send action potentials along the entire length of a membrane to cause contraction
- gray matter** the butterfly-shaped structure consisting of neuronal cell bodies that is subdivided into regions called horns and is involved in processing information in the brain.
- gyri** a wrinkle or fold formed by convolutions in the surface of the cerebral cortex
- hypothalamus** a collection of nuclei that are largely involved in regulating homeostasis
- hypotonia** decreased muscle tone
- incontinence** the involuntary expulsion of urine or feces from the body
- joint** a location where bones come into contact, allowing for movement
- lateral horn** the region of the spinal cord gray matter in the thoracic, upper lumbar, and sacral regions that is the central component of the sympathetic division of the autonomic nervous system
- ligament** tough but flexible fibrous tissue that connects bones or holds joints together
- longitudinal fissure** the separation of tissue in the cerebrum that divides the brain into two distinct halves (cerebral hemispheres)
- medulla** the connection point between the brain stem and spinal cord
- motor neuron** a nerve cell that receive signals from the brain and spinal cord to cause voluntary skeletal muscle movements and breathing
- multiple sclerosis (MS)** a neurological disorder that causes immune system cells to attack myelin; subtypes of MS include relapsing-remitting, secondary-progressive, primary-progressive, and progressive-relapsing
- muscle atrophy** the wasting and breakdown of muscle tissue
- muscular dystrophy** a genetic muscular disorder that results in progressive muscle weakness
- myasthenia gravis** an autoimmune disorder in which antibodies attack the neuromuscular junction of skeletal muscles, resulting in progressive muscle weakness (e.g., arms, hands, fingers, legs, neck) and fatigue
- myelin** the protective coating on nerves
- negative feedback** a mechanism that reverses a deviation from the set point
- nerve conduction velocity (NCV) testing** a diagnostic procedure involving placement of electrodes over nerves to

determine how fast nerve signals are sent to skeletal muscles

**neuromuscular junction (NMJ)** the site where a motor neuron's terminal meets the muscle fiber and responds to motor signals

**paralysis** a complete loss of sensation and mobility

**paraplegia** paralysis of the legs and portions of the trunk but not the arms

**parasympathetic nervous system** the part of the ANS that results in involuntary “rest and digest” types of reactions

**peripheral nervous system (PNS)** the portion of the nervous system located on the periphery of the central nervous system containing peripheral structures including ganglia and nerves

**pons** the connection point between the medulla and the thalamus

**posterior horn** the gray-matter region of the spinal cord in which sensory input arrives

**ptosis** eyelid drooping

**set point** the physiological value around which the normal range fluctuates

**skeletal muscle** muscle that attaches to bone and creates intentional movement as it contracts and relaxes, causing the bones to move

**skeletal system** the bones, joints, and other structures that allow for movement, form the body, make blood cells, and shield organs

**smooth muscle** muscle in the walls of hollow organs such as the urinary bladder, uterus, stomach, and intestines

**somatic nervous system** the part of the peripheral nervous system that controls voluntary movements of skeletal muscle

**spinal cord** a long, thin, tube-shaped bundle of nerves that extends from the base of the brain through the vertebral column; contained within the vertebral cavity of the vertebral column

**spinal cord injury** damage to the spinal cord, often as a result of trauma (e.g., a motor vehicle accident, a fall) or cancer

**spinal nerve** one of thirty-one peripheral nerves connected to the spinal cord; each is named for the level of the spinal cord at which it emerges

**sulci** grooves formed by convolutions in the surface of the cerebral cortex

**sympathetic nervous system** the part of the ANS that causes involuntary reactions in the body to help combat a perceived threat resulting in “fight or flight” types of reactions

**tendon** a tough connective tissue located on each side of a joint that controls joint movement

**tetraplegia** paralysis from the neck down

**thalamus** a collection of nuclei that relay information between the cerebral cortex and the brain stem, spinal cord, and periphery

**tracheostomy** an opening in the trachea into which a tube is placed that allows for mechanical ventilation to be delivered

**white matter** myelinated nerve fibers that facilitate communication between different regions of the brain

## Assessments

### Review Questions

- The nurse is caring for an older adult patient who is concerned about losing their memory. What statement by the nurse best describes what the patient can expect as they age?
  - “There are no changes that occur within the brain that are associated with aging.”
  - “You can expect to see an improvement in your memory as you get older.”
  - “You gain extra brain tissue with age, but this can cause your memory to decrease.”
  - “Neurological messages may be sent more slowly as you age, resulting in decreased reaction times.”
- The student nurse is reviewing the function of the cranial nerves. What nerve does the student nurse recognize as being responsible for movements of the tongue?
  - hypoglossal nerve
  - olfactory nerve
  - spinal accessory nerve
  - trochlear nerve

3. The nurse is caring for a patient who is feeling anxious before a medical procedure. What clinical manifestation would the nurse expect that would be consistent with activation of the patient's sympathetic nervous system?
  - a. decreased heart rate
  - b. pupil dilation
  - c. tightening of airway muscles
  - d. increased digestion
4. What type of connective tissue found within the musculoskeletal system is responsible for limiting movement of joints?
  - a. cartilage
  - b. tendons
  - c. bones
  - d. ligaments
5. What is a major function of the neuromuscular system?
  - a. digestion
  - b. lymph production
  - c. breathing regulation
  - d. cardiovascular control
6. The nurse is caring for a patient undergoing diagnostic testing for multiple sclerosis (MS). The patient asks the nurse what the creatine kinase (CK) test is checking for. What response by the nurse is correct?
  - a. "This test shows us how quickly your blood clots."
  - b. "Creatine kinase is a reflection of how much inflammation there is in your body."
  - c. "This test indicates whether there is muscle damage occurring somewhere in the body."
  - d. "Creatine kinase will determine whether or not you have an infection of some kind."
7. The nurse is caring for a patient who presents with a history of cold hands and feet, weak grips, and difficulty walking. Upon assessing the patient, the nurse notices that the patient has curled toes on both feet. What neuromuscular condition does the nurse suspect the patient may have based on these findings?
  - a. multiple sclerosis
  - b. Charcot-Marie-Tooth disease
  - c. muscular dystrophy
  - d. myasthenia gravis
8. The nurse is caring for a patient with Duchenne muscular dystrophy (DMD). What finding is most consistent with this specific type of muscular dystrophy?
  - a. The patient is female.
  - b. The patient was diagnosed at age 5.
  - c. The patient has enlarged calf muscles.
  - d. The patient has an outward curvature of the spine.
9. The nurse is caring for a patient newly diagnosed with the primary-progressive form of multiple sclerosis. The patient asks the nurse what they should expect with this type of disease. What statement by the nurse is correct?
  - a. "You should expect to have good days and bad days."
  - b. "It is likely that your symptoms will be completely gone for weeks at a time."
  - c. "Expect to have symptoms that get worse over time with frequent symptom attacks."
  - d. "Your symptoms will likely get worse over time without any extra attacks or periods of remission."
10. What mechanism best describes why patients with neuromuscular disorders experience vision problems?
  - a. Eye muscles become weak.

- b. Progressive eye muscle atrophy is occurring.
  - c. High cervical spinal injury damages eyesight.
  - d. Demyelination of nerve cells of the eyes occurs.
- 11.** The nurse is caring for a patient with a neuromuscular disorder. What intervention does the nurse know is the highest priority?
- a. maintaining a patent airway
  - b. removing clutter from the floor
  - c. administering prophylactic heparin
  - d. providing emotional support
- 12.** The nurse is caring for a patient who is bedridden with a neuromuscular disorder. What intervention is most appropriate for preventing complications associated with immobility?
- a. turning the patient every four hours
  - b. removing clutter from the floor
  - c. performing active range of motion exercises
  - d. implementing a fluid restriction
- 13.** What breakfast would be most appropriate for a patient with muscle weakness from a neuromuscular disorder?
- a. bagel and cream cheese
  - b. oatmeal and yogurt
  - c. English muffin, eggs, and cereal
  - d. orange juice and a granola bar
- 14.** What member of the interdisciplinary care team is most likely to assist a patient who has a neuromuscular disorder with washing their face and brushing their teeth?
- a. dietician
  - b. physical therapist
  - c. speech therapist
  - d. occupational therapist
- 15.** The nursing student is preparing to leave the room of a patient who has a neuromuscular disorder. What action by the nursing student would require the nurse to intervene?
- a. The student nurse places the patient's robe and slippers on the bedside table for easy access.
  - b. The student nurse leaves the bed alarm off because the patient agreed to call before getting up.
  - c. The student nurse locks the bed and makes sure it is in the lowest position.
  - d. The student nurse double-checks that the patient is wearing a fall-risk band.

### Check Your Understanding Questions

1. What is the purpose and function of the thalamus and hypothalamus in the neurological system?
2. What is the difference between the sympathetic nervous system and the parasympathetic nervous system?
3. What are the three different types of muscle in the body and their functions?
4. You are caring for a patient who is about to undergo electromyography (EMG) testing. How would you explain the procedure to the patient?
5. What is the difference between electromyography (EMG) and nerve conduction velocity (NCV) testing?
6. What are early symptoms of amyotrophic lateral sclerosis (ALS)? What are late symptoms?
7. Based on your knowledge of immobility seen in patients with neuromuscular disorders, what are some nursing interventions you could implement to prevent associated complications?

8. What are some strategies you could use when teaching coping skills to a patient with a neuromuscular disorder?

### Reflection Questions

1. Reflect on the anatomy of the spinal cord and identify a difference between the adult spinal cord and that of an infant.
2. Reflect on the mutually supportive functions of the different types of connective tissue found in the musculoskeletal system.
3. Imagine you are caring for a pediatric patient who has just been diagnosed with Duchenne muscular dystrophy (DMD). The parents of the child are extremely upset about the diagnosis. How would you manage the situation?
4. Imagine that you are caring for a 94-year-old female whose family is concerned about her memory lapses and difficulty with self-care and movement. Reflect on how aging affects the neuromuscular function for this patient.
5. What kinds of nonpharmacological interventions to address pain and discomfort could you use for a patient with a neuromuscular disorder?

### What Should the Nurse Do?

1. The nurse is caring for a patient who just arrived in the emergency department by ambulance with a left shoulder gunshot wound. Upon initial assessment, the nurse observes that the patient is sitting upright, eyes wide with pupils fully dilated, and breathing rapidly. What should the nurse do next?

The nurse is caring for a patient who presents to the emergency department with double vision, dysphagia, and muscle weakness.

2. What follow-up questions should the nurse ask to obtain subjective data from the patient?
3. What assessments would you perform to obtain objective data?
4. What do you suspect is going on with the patient based on the provided information?
5. The nurse is caring for a patient with a neuromuscular disorder. When assessing pain, the patient reports a 10/10 stabbing pain in their legs. What should the nurse do next?

### Competency-Based Assessments

1. Perform a complete cranial nerve assessment on a peer or draw a diagram depicting cranial nerve placement and function.
2. Create a table comparing and contrasting the pathophysiology, clinical manifestations, and diagnostic tests for three different neuromuscular disorders.
3. Role-play with a peer, family member, or friend to perform a focused skin assessment on a patient who uses a wheelchair or is bedridden due to a neuromuscular disorder.
4. Role-play with a peer, family member, or friend to demonstrate minimizing risk of harm to patients and providers.

## CHAPTER 24

# Skin Integrity

**FIGURE 24.1** This is a surgical wound created upon the removal of a large sebaceous cyst on the back of the neck after having been packed with gauze. (credit: modification of “Woundsm” by Wikimedia Commons, Public Domain)

### CHAPTER OUTLINE

- 24.1 Structures and Function of the Skin
- 24.2 Skin Integrity
- 24.3 Wound Classification
- 24.4 Wound Healing

**INTRODUCTION** The integumentary system is an essential component to every healthcare encounter. The condition of an individual’s skin, hair, and nails provides important information about their physical and emotional health. The structures of the integumentary system play significant functions in the body and reflect dysfunctions from other body systems. For example, someone with inadequate perfusion may have a cyanotic, or blue, appearance to their skin. Thus, when a nurse notes this abnormal skin appearance, appropriate interventions can be identified and implemented to promote optimal outcomes. Therefore, nurses must be competent in the anatomy and physiology of the integumentary system to adequately develop a plan of care, identify potential risks, and implement appropriate nursing interventions. The nurse must also have knowledge of factors affecting skin integrity, wounds, and wound management.

## 24.1 Structures and Function of the Skin

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Review the anatomy and functions of the skin
- Identify functions of skin and mucous membranes
- Recognize how assessment findings may vary in special populations

The integumentary system is the body’s first line of defense, serving as a physical barrier between the external and internal environments. The external environment includes microorganisms, radiation, temperature, or other threats of physical trauma or injury. The internal environment is the body that the integumentary system serves to protect and maintain homeostasis. The integumentary system includes the skin, hair, nails, as well as glands (e.g., sebaceous, sweat, mammary) (Kim & Dao, 2023).

Nurses play a vital role in maintaining skin integrity and promoting wound healing. To effectively protect and preserve a patient's skin, the nurse must understand the anatomy and physiology of the integumentary system, factors affecting skin integrity, and how to appropriately manage wounds.

### Anatomy of the Skin

The skin, which covers the body entirely, is the largest organ of the body. It serves as a protective barrier against heat, light, infection, and injury and performs additional essential functions. The skin varies in thickness, color, and texture across the body. For example, the palms of the hands and soles of the feet are thicker than skin on the abdomen. The skin is made up of three distinctive layers: the epidermis (i.e., the outermost layer of the skin); dermis (i.e., the layer below the epidermis); and hypodermis or subcutaneous tissue (i.e., the deepest layer) (Figure 24.2). Each layer varies in its anatomy and function (Yousef et al., 2022).

**FIGURE 24.2** The skin is composed of the epidermis, dermis, and hypodermis layers. The nurse must be competent in the anatomy of the skin to adequately assess and manage an individual's skin integrity. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

#### Epidermis

The epidermis is the thin outer layer of the skin and consists of epithelial cells. The main function of the epidermis is to protect deeper tissue layers from water, mechanical and chemical trauma, exposure to microorganisms, and damage from ultraviolet (UV) light. The epidermis has four or five layers depending on its location (Figure 24.3). There are five layers over the palms of the hands and soles of the feet while the rest of the body has four layers. Starting from the bottom, the layers are the stratum basale, stratum spinosum, stratum granulosum, stratum lucidum, and stratum corneum.

**FIGURE 24.3** The epidermal layers include the stratum basale, stratum spinosum, stratum granulosum, stratum lucidum, and stratum corneum. The stratum lucidum is only present in the soles of the feet and palms of the hand. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **stratum basale** (i.e., stratum germinativum) is the deepest layer of the epidermis and contains a type of cell known as a **melanocyte**, which produces a pigment called **melanin** and a cell called **keratinocyte** that produces **keratin**. Melanin forms a protective shield to protect the keratinocytes and nerve endings from damage caused by ultraviolet light. Melanin is also responsible for the color of the skin. Keratin is a fibrous, water-repellent protein that gives the epidermis its strong, protective quality. The keratinocytes move upward through the layers as they mature and become dead cells on the outermost layer of the skin (Osseiran et al., 2018). A **Merkel cell** serves as a sensory receptor for light touch. These cells are also found in the stratum basale.

The next layer above the stratum basale is the **stratum spinosum**. This layer is several layers thick and contains cells that arise from the bone marrow and move up to the epidermis. The cells are “irregular, polyhedral cells with cytoplasmic processes and are often called ‘spines’ that extend outward and contact neighboring cells by desmosomes” (Yousef et al., 2022). A cell called a **Langerhans cells** is primarily located in the stratum spinosum. These cells are first-line defenders and are antigen-producing cells that determine the appropriate response to, for example, inflammation, or tolerance of foreign substances.

The next layer, the **stratum granulosum**, is only two to three cell layers thick. This layer contains a glycolipid that slows water loss across the epidermis. A thickening of plasma membranes of a cell, or **keratinization**, begins in this layer. The next layer, the **stratum lucidum**, is only found in the thicker areas of the skin (e.g., palms and soles of feet). It is two to three cell layers thick and is made up of flattened, dead keratinocytes. The outermost layer of the epidermis, the **stratum corneum**, is the thickest layer and makes up about 75 percent of the total thickness. This layer contains dead keratinocytes that secrete **defensin** (i.e., a class of host-defense peptides found in neutrophils that have antimicrobial and/or cytotoxic properties) and is part of the body’s first immune defense.

### Dermis

The second, deeper layer of the skin is the **dermis**, which is connected to the epidermis by dermal papillae. Its main function is regulating temperature and supporting, protecting, and nourishing the epidermis. This layer consists of the **papillary layer** and **reticular layer**. The upper papillary layer is the thinner of the two and is composed of loose connective tissue and contacts the epidermis. It also contains capillaries as well as touch and pain receptors. The deeper layer, the reticular layer, is the thicker of the two. This layer consists of dense connective tissue and collagen bundles and houses most of the sweat glands, sebaceous glands, hair follicles, hair, muscles, blood vessels, and deep sensory neurons (Yousuf et al., 2022).

The **sebaceous gland** is attached to the hair follicles and are present over the body minus the palms of hands and soles of feet. The sebaceous glands secrete sebum, an oily substance that makes the hair and skin waterproof. There are two types of sweat glands: eccrine glands and apocrine glands. The eccrine gland is located over the skin entirely, secretes sweat, and aids in thermoregulation. The apocrine gland correlates with the hair follicles present in the perineum, axillae, and areolae of the breasts. These glands are nonfunctioning and small until puberty has been reached. After the onset of puberty, the glands secrete a milky sweat.

### Hypodermis

The **hypodermis** (i.e., **subcutaneous tissue**) is the subcutaneous fatty layer beneath the dermis that separates the skin from the underlying tissue. The hypodermis also anchors the dermis to the underlying tissues of the body and insulates, protects, and stores fat for the body. This layer is made up of loose connective tissue and stores about half of the body's fat cells. This layer provides a cushion for the body against trauma, stores fat for energy, and insulates the body from heat loss. Some skin appendages (e.g., hair follicles, blood vessels, sensory neurons) are found in the hypodermis. This layer also contains blood and lymph vessels and nerves. The blood vessels supply nutrients to the tissues, and the lymph vessels provide a pathway for the movement of waste products to and from the skin.

### Functions of the Skin

The skin performs essential functions including protection, thermoregulation, sensation, absorption, elimination, and vitamin D production. The skin contributes to the psychosocial aspect of an individual because of its contribution to the external appearance of the person and plays a role in self-esteem. The skin also aids in communication with the brain via the sensory neurons located in the skin.

#### Protection

The skin provides protection because it covers the body entirely and serves as the physical barrier between the internal and external environments. Breaks in the skin trigger an immune response to promote healing and fight off foreign debris that may lead to infection. The many layers of the skin provide protection from injury to underlying tissues and organs. The skin also acts as a shield from microorganisms, damaging ultraviolet rays, and other substances including water. The layers of keratin and glycolipids in the skin serve to protect the body against moisture loss from both the surface and underlying structures.

#### Thermoregulation

Temperature regulation is another function of the skin. The skin is highly vascularized, which allows the body to regulate body temperature through vasoconstriction and vasodilation of blood vessels. When body temperature decreases, blood vessels vasoconstrict to decrease blood flow to the periphery in an effort to conserve core body heat. A muscle called the **arrector pili muscle** triggers hair follicles on the body to flex causing the hair to rise up (i.e., goosebumps), which further prevents heat loss (Figure 24.4). When body temperature increases, blood vessels vasodilate to increase blood flow. Sweat is secreted, which evaporates from the skin contributing to heat loss bringing the body temperature down (Kim & Dao, 2023).

**FIGURE 24.4** The arrector pili muscles pull hair upright in an attempt to prevent heat loss and is also part of the fight-or-flight response of the sympathetic nervous system. (credit: “fresh breeze” by Everjean/Flickr, CC BY 2.0)

## LIFE-STAGE CONTEXT

### Thermoregulation and Newborns

During the first hours of life, newborns experience difficulties regulating their body temperature. The balance of heat production and heat loss is linked to the metabolism and oxygen consumption of the newborn. Newborns can attempt to conserve heat and increase their heat production by increasing peripheral vasoconstriction, metabolic rate, and muscular activity through moving. Newborns may also assume a fetal position to hold in heat and decrease body surface area exposure. Nursing interventions to aid in maintaining body temperature of newborns include the following (Albahrani & Hunt, 2019):

- Dry newborns completely after birth or baths to prevent heat loss through evaporation. (Baths should be performed after newborn is stable, and a radiant heat source should be used.)
- Prewarm blankets and caps to reduce heat loss through conduction.
- Place a cap on a newborn after drying thoroughly.
- Use a warm cover on the scale when weighing a newborn.
- Warm stethoscopes and hands before touching a newborn.
- Avoid placing a newborn near air vents or areas with drafts, and avoid placing cribs near cold outer walls.
- Keep infant transporter fully charged and heated.
- Avoid placing skin temperature probes over brown fat areas (found on the back, neck, and shoulders in babies to help regulate body temperature).
- Encourage parent skin-to-skin contact with stable newborns.
- Use heated and humidified oxygen.

### Sensation

The skin provides sensation for the body and allows a patient to feel temperature, pressure, pain, and touch through the various sensory nerve endings. Each type of sensory receptor sends signals to the brain and spinal cord that allow a patient to respond and adjust to the environment as needed. For example, when a patient touches something that is extremely hot, they typically move their hand away quickly, which is the body’s reflex in response

to the external stimuli in an effort to protect itself from harm.

## PATIENT CONVERSATIONS

---

### Older Adults and Decreased Sensation

**Scenario:** A nurse is assessing an older adult with diabetic neuropathy who is being seen in the clinic for a sore on his right foot.

**Nurse:** Hi. My name is Linda, and I will be your nurse today. Will you tell me your name and date of birth?

**Patient:** Yes. Hi, my name is Joseph Gellar. My date of birth is April 25, 1941.

**Nurse:** Thank you. What brings you in today?

**Patient:** Well, I have this sore on my foot, and I am not sure how I got it.

**Nurse:** Okay, let me take a look. [The nurse assesses the wound.] Let's verify your health history

**Patient:** Well, I have diabetes, high blood pressure, and high cholesterol.

**Nurse:** What medications do you currently take?

**Patient:** I take my insulin, metoprolol, and atorvastatin. But I forgot to check my blood sugar today and take my insulin.

**Nurse:** Okay, have you noticed any changes in sensation? Like being able to feel things that are painful, hot, or cold?

**Patient:** Yeah, I noticed that a few years ago, but I just thought it was normal.

**Nurse:** Diabetic neuropathy is common with uncontrolled blood sugar and high levels of fat that can cause nerve damage. Because of this, it is important to be aware of your surroundings to avoid injury. Check your feet every day for any injuries like cuts, scrapes, or bruises. It is also important to try to manage your blood sugar as much as possible with your diet, exercise, and medications.

**Patient:** Oh, that makes sense. I think my wife and I have a friend who had something similar happen.

**Nurse:** Yes sir. Do you have any questions for me before I give an update to your doctor, so he can come in and see you?

**Patient:** No, that will be it for now.

**Nurse:** Okay, great. I will be in after the doctor sees you to go over any orders or treatments he prescribes for you.

---

### Absorption

The skin is porous and therefore absorbs substances that may be on it. Substances that can be absorbed through the skin will enter the bloodstream. Certain medications may be absorbed by **transdermal administration** (placed on the skin and absorbed either locally or systemically), including scopolamine, estrogen, testosterone, some opioids, nicotine, and some contraceptives. It is important to note that anything on the skin may be absorbed and thus has the potential to cause harm. Certain chemicals and medications require appropriate handling to avoid the risk of harm or injury. For example, when administering fentanyl, it is important to wear gloves to avoid accidental absorption into the bloodstream. This is also why sunscreen or other lotions are not used on babies under 6 months old due to thin skin and increased absorption.

### Elimination

The elimination function of the skin helps the body get rid of excess water and salts through sweat produced by the sweat glands. Sweat, or **perspiration**, may contain electrolytes, water, and nitrogenous wastes like urea, uric acid, and ammonia. In the event other organs become unable to eliminate toxins, the skin will try to push out toxins to aid in removal. In addition to removing wastes, the excretion function of the skin aids in regulating body temperature as previously described.

### Vitamin D Production

The skin initiates the biochemical processes necessary for vitamin D production. Ultraviolet sun exposure leads to the conversion of 7-dehydrocholesterol to cholecalciferol (i.e., vitamin D<sub>3</sub>) in the skin. Cholecalciferol is hydroxylated in the liver and then in the kidneys, which converts it into the active, metabolite form, calcitriol. The chemical process in which a hydroxyl group (-OH) is introduced into an organic compound is called **hydroxylation**. This metabolite leads to enhanced calcium production in the gut and is vital for bone health (Kim & Dao, 2023).

### Assessment Findings for Special Populations

There are distinct considerations for special populations that the nurse must consider when assessing a patient's skin. The assessment findings may vary among different cultures and ethnicities, developmental levels, and age groups. It is essential that the nurse be aware of the variations when performing a skin assessment to avoid stereotypes and to ensure accuracy when developing a plan of care to promote optimal outcomes. For example, darker skinned patients may not show pallor in the same way a lighter skinned patient would. The nurse must assess the mucous membranes, such as their gums or palpebral conjunctiva, of a darker skinned patient to adequately assess for pallor.

## REAL RN STORIES

---

### Identifying Dermal Melanocytosis

**Name:** Bailey, BSN

**Clinical setting:** Pediatric clinic

**Years in practice:** 3

**Facility location:** Rural area of Kansas

Our pediatric clinic is the only one in a 50-mile radius, so we are always swamped. One day, I was working in the well-baby side of our clinic. I was assessing a baby who was here for her 6-month wellness visit. Her mother, Ali, brought her in and introduced her baby girl as Alexis. After taking her medical history, I began the physical assessment. I noticed what appeared to be bruises along Alexis's back similar to those seen in abuse cases ([Figure 24.5](#)). I was concerned and thought that the baby may be experiencing abuse at home. The spots were bluish in color and along the baby's backside, so the areas were not visible to others.

As I began to plan my next steps, Alexis's mother stated, "I am ready for the Mongolian spots to start disappearing!" Then, I recalled learning about these in nursing school. I put my fingers on the skin to blanch the area and was relieved when I observed that the spots were nonblanchable, confirming dermal melanocytosis, formerly known as Mongolian spots. The spots are actually pigmented skin lesions that may be present at birth or develop within the first few weeks of life.

I asked Ali about the first noticeable spot, and she said they showed up when Alexis was about 2 weeks old. We then discussed how Mongolian spots may disappear by childhood. Ali said she understood but would be happy when they were gone. It was the first time I had actually seen Mongolian spots, and I was really relieved that they were bruises from abuse.

**FIGURE 24.5** Dermal melanocytosis presents as skin lesions that may be present at birth or develop within the first few weeks of life. (credit: “6 month old Taiwanese baby girl,” by abby/Flickr, CC BY 2.0)

### Cultural Considerations

While people share a similar number and distribution of eccrine glands over the body, the glands vary in activity depending on patient-specific characteristics and environmental adaptations. For example, those born in tropical areas have more functioning eccrine glands than those who move there later in life. People who acclimate to hot environments do not excrete as much chloride in their sweat as others. People of Asian and American Indian descent have fewer functioning apocrine glands than White and Black people. The amount of sweat and body odor an individual has is genetically determined and is in relation to the functionality of the apocrine glands. Therefore, Asians and American Indians have little to no underarm sweat or body odor. People born farther from the equator usually have fairer skin and are at a greater risk of developing skin cancers due to lower levels of the protective pigment, melanin. Additional factors for fair-skinned individuals include the presence of freckles and an increased susceptibility to sunburn. However, all people with excessive levels of sun exposure are at risk for sun damage to skin and skin cancer and should, therefore, avoid excessive exposure to UV light. Darker skinned patients typically produce more melanin in general (Salminen et al., 2023). The higher levels of melanin are a protective factor and reduce the risk of developing skin cancers. However, darker skinned individuals are more susceptible to certain skin abnormalities (Figure 24.6):

- **post-inflammatory hyperpigmentation** (temporary pigmentation that occurs after an injury or inflammatory skin condition, most commonly seen in patients with darker skin types)
- **dermatosis papulose nigra** (small dark or skin-colored bumps on the face, neck, and upper torso, common in patients with darker skin colors)
- **keloid** (a thick fibrous scar caused by excessive collagen formation in response to trauma or a surgical incision)
- **pityriasis** (any of various skin conditions characterized by dry scaling patches of skin)
- **vitiligo** (chronic autoimmune disorder that causes partial or total loss of skin color in patches)
- hair loss
- dry skin

**FIGURE 24.6** The skin abnormalities are as follows: (a) post-inflammatory hyperpigmentation, (b) dermatosis papulosa nigra, (c) keloids (d) pityriasis, and (e) vitiligo. (credit a: “Post inflammatory hyperpigmentation” by Kylie Aquino/Flick, Public Domain; credit b: “Figure 13” by Wolters Kluwer -- Medknow Publications, CC BY 2.0; credit c: modification of “Figure 1” by BMC Medl Ethics, CC BY; credit d: “Pityriasis rosea 1,” by Mike Blyth/Wikimedia Commons, CC BY 3.0; credit e: modification of “Figure 3” by Stacie J. Becker & Jeffrey E. Cassisi, CC BY 4.0)

### Developmental Considerations of Infants and Children

A person's skin undergoes changes throughout the life span. Sebaceous glands do not function maturely at birth. Sebum production increases in the prepubescent and adolescent years, which makes individuals within these age ranges more prone to acne. The sweat glands of an infant function to some degree and produce sweat in response to heat or emotional stimuli. By the time the child reaches middle child years, the sweat glands are fully functional. Until the glands function fully, temperature regulation is not as efficient as it is with the fully functioning glands of older children and adults.

Infants also have a thinner epidermis than adults. Infants have less subcutaneous tissue, so the blood vessels lie closer to the skin's surface. Therefore, an infant loses more heat through the skin's surface than an older child or adult. In addition, substances absorb more readily through infant skin than adult skin because of the thinness of the skin. Infant skin contains more water than adult skin. The epidermis is loosely bound to the dermis, and that means that friction may easily separate the layers, resulting in blisters or skin breakdown.

Regardless of ethnicity, infant skin is less pigmented, placing the infant at higher risk of skin damage from sun exposure. As the infant ages, the skin becomes tougher and less hydrated, making the infant less susceptible to invasions from microorganisms. When the child reaches teenage years, the skin characteristics and thickness are at the adult level. Infant skin and mucous membranes are more easily injured and susceptible to infection; therefore, the nurse must carefully handle infants to protect them from harm or infection.

### LIFE-STAGE CONTEXT

#### Overheating Infants

Overheating an infant can easily happen if a caregiver fears that the infant is cold. Newborns and infants do not have

a mature thermoregulatory system. This means that they are more vulnerable to overheating. Signs and symptoms of overheating include the infant

- feeling warm to the touch;
- having flushed or red skin;
- developing heat rash;
- sweating or having damp hair;
- developing tachycardia;
- developing tachypnea;
- acting fussy;
- appearing sluggish, confused, or dizzy; or
- becoming unresponsive.

Nurses should be aware of these signs and the interventions needed: administer fluids (e.g., breast milk, water, or formula depending on their age), apply cold compresses, take off any excessive clothing or bedding, and go to a well-ventilated area. If the nurse is educating a caregiver, they should also include the need to call 911 if the child is unresponsive. Interventions to prevent overheating include avoiding the use of excessive clothing and bedding, keeping the room temperature between 68°F and 72°F (20°C and 22°C), ensuring adequate room ventilation, using curtains if needed to block out excessive light and heat, and avoiding the use of heating pads.

---

The nurse must also consider patients with developmental differences, such as cognitive disabilities. Individuals with cognitive dysfunction may not know how to check their own skin for abnormalities or impairments, or they may not recognize any changes in their skin. These patients may also neglect skin care. This can lead to itching, scratching, and picking because of buildup of dead skin and other debris, which can lead to injury or infection. The nurse may need to establish rapport with those who have disabilities to gain their trust. This enables the nurse to perform an assessment and provide coaching to teach them how to perform skin assessments at home. If a patient with a disability has a caregiver, the caregiver should be included in education of skin assessment as well as findings to report.

The nurse must also consider the patient's developmental level when communicating and when describing the steps of assessment. For example, an infant may be examined in the caregiver's lap versus the school-aged child who can sit on the examination table. The nurse should speak with terms that are appropriate for the age or developmental level. The nurse should also speak to the patient regardless of the developmental level, especially school-age children and adolescents, to help them feel included in the plan of care.

### Age-Related Considerations

Much like the infant's skin changes from birth to adulthood, the skin continues to change as a person ages ([Figure 24.7](#)). The thickness of the epidermis in older people decreases, making the skin more delicate and at risk of tears or injury. The subcutaneous (SQ) tissues also become thinner, making thermoregulation more difficult and increasing the risk of pressure ulcers. The degree in which a population of cells proliferates, or **mitotic activity**, decreases leading to delayed wound healing. As the subcutaneous and dermal tissues thin with age, the skin becomes more prone to wrinkles, and pressure and pain sensations are reduced.

**FIGURE 24.7** Aging is a normal part of life and includes skin changes. The skin layers become thinner and less elastic, making the skin more prone to wrinkles and impaired skin integrity. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

As the activity levels of the sebaceous and sweat glands decrease, the skin becomes dryer, and older people may experience **pruritis**, itching. Melanin declines with age leading to unevenly pigmented skin and gray or white hair. Hyperplasia of the melanocytes may lead to small areas of **hyperpigmentation**, darkened patches of skin (liver spots). Decreased melanin in an area can cause **hypopigmentation**, lighter patches of skin (age spots). The elastic fibers degenerate causing the skin to lose its elasticity. There is often a redistribution of adipose tissue leading to cellulite (lumpy skin), increased abdominal fat, sagging of breasts, and reduced **tenting** (when the skin does not snap back when pinched; instead, it maintains a tentlike shape, which may indicate dehydration). Decreased vitamin D production, which is normal with aging, increases the risk of osteomalacia (bone demineralization) and osteoporosis (a decrease in bone mass and density).

## 24.2 Skin Integrity

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify risk factors for impaired skin integrity
- Examine common skin disorders that cause impaired skin integrity
- Describe health promotion behaviors related to skin integrity

Skin integrity refers to the overall health of the skin. Factors that influence healthy skin are patient specific. These factors include age, genetics, and overall health. For example, the skin color of a patient of Asian descent will appear different from that of a patient of Eastern European descent. In addition, skin changes as people age, so the nurse must consider age when assessing a patient's skin. It is crucial that nurses obtain the patient's health history and perform an assessment to identify risk factors for impaired skin integrity to effectively implement nursing interventions and provide education to patients and families. The nurse must be aware of common skin disorders that can lead to impaired skin integrity as well as health promotion behaviors related to skin integrity.

## Risk Factors for Impaired Skin Integrity

When the skin is healthy and unbroken, the skin is able to efficiently carry out its functions. Resistance of the skin and mucous membranes to injury varies among patients and is dependent on factors including age and medical conditions. Patients with adequate nutrition are also more resistant to injury or disease. Adequate perfusion is vital in maintaining cell life. When skin integrity is impaired, cells do not get the nourishment they need and cannot eliminate wastes effectively. To identify risks for impaired skin integrity, the nurse must examine lifestyle and behavioral factors as well as genetic and state of health factors.

### Lifestyle and Behavioral Factors

Lifestyle and behavioral factors that affect skin integrity include a patient's nutrition, activity levels, sexuality, medications used, illicit drug use, body piercings, tattoos, and substances that come in contact with the skin like soaps, detergents, and lotions. Nutrition plays an important role in the health of a patient's skin. Inadequate nutrition may lead to skin breakdown, delayed wound healing, premature aging of the skin, inflammation, dryness, and changes in hair. A patient's exposure to the sun or other UV light may place them at risk of skin cancer as a result of prolonged exposure.

The use of certain types of hygiene products may also place a patient at risk of impaired skin integrity. Certain types of soaps, lotions, and detergents may be too harsh for a person's skin based on their age, health condition, and genetics. Some detergents and soaps increase the pH levels of the stratum corneum, and those products may cause rashes, inflammation, dermatitis, and acne breakouts. Older people who do not use **emollients** (ingredients that soothe dryness) are at risk of impaired skin integrity because their skin is dry and more susceptible to cracking.

### State of Health and Genetic Factors

State of health and genetic factors may affect the skin. Nutrition can adversely or positively affect the health of the skin. Some people experience dehydration and malnourishment caused by an illness versus a lifestyle choice. Dehydration and malnourishment result in a deficiency in fluids, protein, and vitamin C. This causes the skin to lose its elasticity and become more susceptible to breakdown.

Side effects of certain medications may also affect skin. For example, localized pruritis (itching) is common with hydrocodone, and patients may scratch themselves in an attempt to relieve the itching. Corticosteroids cause thinning of the skin making it more susceptible to injury, and certain antibiotics increase sensitivity to sunlight causing an individual to burn easily. Patients who experience incontinence or have issues with diarrhea are at risk of skin breakdown as a result of the excess moisture. Patients with jaundice are at risk of lesions and infections from scratching because of dry, itchy skin. There are also numerous conditions that cause secondary disruptions to the integumentary system. For example, patients undergoing radiation treatment for cancer are at risk of **erythema** (reddening of the skin), pruritus, or loss of skin integrity ([Figure 24.8](#)).

**FIGURE 24.8** Erythema (i.e., reddening of the skin) has multiple causes—in this case, heat rash. (credit: “16850” by Dr. Lester Cordes/CDC, Public Domain)

## Common Skin Disorders

There are various skin disorders that the nurse should be aware of to effectively care for their patients. Common

skin disorder classifications include bacterial infections, viral infections, fungal infections, inflammatory reactions, and skin cancers. It is crucial for the nurse to be able to identify and describe skin disorders as well as their underlying cause and treatment.

### Bacterial Infections

Bacteria naturally reside on the skin. An infection can occur, however, when the skin is not intact allowing bacteria to enter through hair follicles or breaks in the skin (e.g., scrapes, surgical incisions, bites). Some bacterial infections are localized and involve just the skin or the soft tissues under the skin, or they can become systemic involving multiple body systems. Common bacterial infections of the skin include impetigo, folliculitis, carbuncles, and cellulitis ([Table 24.1](#)).

Disorder	Description	Example
Impetigo	Contagious superficial skin infection	 <p>(attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>
Folliculitis	Infection of the hair follicle	 <p>(attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>

**TABLE 24.1** Common Bacterial Skin Disorders

Disorder	Description	Example

**TABLE 24.1** Common Bacterial Skin Disorders

### Impetigo

A highly contagious superficial skin infection called **impetigo** is most commonly found in children. Patients with impetigo can spread it to other areas of their own body as well as to other people they come in contact with. Although it can occur anywhere on the body, it primarily occurs on the arms, legs, and face. Impetigo is either bullous or nonbullous in nature. Caused by *Staphylococcus aureus*, **bullous impetigo** is usually sporadic and develops on intact skin. Flaccid bullae generally grow in size to form larger blisters filled with clear yellow to dark turbid fluid and burst to expose raw skin that becomes covered with a thin brown crust. The most common kind of impetigo, **nonbullous impetigo**, usually occurs after injury to the skin or as a secondary bacterial infection of another skin disorder like atopic dermatitis. Nonbullous impetigo presents as clusters of pustules that rapidly break down and form thick adherent honey-colored crusts on the face and extremities. Other risk factors for impetigo include poor hygiene and a moist environment. Treatment for impetigo may include topical or oral antibiotics.

Often called deep impetigo, **ecthyma** is a skin infection that occurs deep inside the skin characterized by shallow, small ulcers that look punched out and may contain pus. The brown crust that covers the ulcers is thicker than the crust that covers the ulcers of impetigo. Treatment options for impetigo and ecthyma include antibiotic ointments or creams for smaller areas. Larger infected areas or areas that are not responding to the topical antibiotics may require oral antibiotics. The infected areas should be washed gently with soap and water multiple times a day to remove crusts. Individuals who have recurrent infections should have a nasal swab cultured to see if they are a nasal carrier of *Staphylococci* or *Streptococci*. People who are nasal carriers will need a topical antibiotic applied to their nasal passages (Rehmus, 2023).

### Folliculitis

An infection of the hair follicle that often results from occluded hair follicles is called **folliculitis**. It may affect a single hair follicle or multiple hair follicles. Common risk factors for folliculitis include poor hygiene, maceration (i.e.,

occurs when skin is exposed to a moist environment for too long), occlusive emollient products, and contact with contaminated water. Folliculitis often appear as pustules surrounded by erythema where a hair follicle is present. Hair follicles may easily fall out as well. Treatment includes warm compresses after washing with antibacterial soap and water multiple times a day, topical antibiotics, and oral antibiotics.

### **Carbuncle**

Clusters of skin abscesses connected to one another below the surface of the skin, known as **carbuncles**, often form when one or more hair follicles become infected. If left untreated, the abscesses fill with pus and will rupture, discharging a creamy pink or white fluid. If the abscess is too deep, it may not be able to drain on its own. Bacteria can spread from the abscess and infect surrounding tissues and lymph nodes. Infected individuals may also have a fever, chills, and malaise. Carbuncles are likely to leave a scar. Most carbuncles are caused by *Staphylococcus aureus*. Risk factors for the development of carbuncles include poor overall health, friction from shaving or clothing, and poor hygiene. Patients with weakened immune systems are more likely to develop *Staphylococcus* infections that lead to carbuncles. Some skin abscesses may go away on their own with the use of warm compresses. However, some carbuncles may require a provider to open and drain the abscess and then wash out the pocket with a sterile saline solution. Oral antibiotics may also be needed to aid in treating the infection. Individuals with recurrent skin abscesses may be instructed to wash their skin with antiseptic solutions (e.g., iodine) (Rehmus, 2023).

### **Cellulitis**

A localized infection and inflammation of the skin and tissues beneath the skin is called **cellulitis**. It is most often caused by *Streptococcus*, *Staphylococcus*, and methicillin-resistant *Staphylococcus aureus*. The infection usually occurs when the bacteria enter open wounds, skin abscesses, fungal infections, or other skin conditions. Although cellulitis can occur anywhere on the body, it occurs most often on the legs and affects one side of the body. Bilateral cellulitis is rare, and its presence should warrant assessment of other health conditions (Chuang et al., 2022).

The infection generally presents with redness, tenderness, and pain. The skin also often becomes hot and swollen and may look slightly pitted. Fluid-filled **vesicles** (small blisters) or **bullae** (large blisters) may appear on the infected areas. Some patients may experience fever, rapid heart rate, headache, confusion, hypotension, or chills. If the infection spreads to the lymph nodes, the nodes can become tender and swollen, and the vessels can become inflamed. Treatment may include antibiotics, drainage of any abscesses, and treatment of any disorders contributing to the infection (Rehmus, 2023). Compression stockings (i.e., thromboembolic deterrent [TED] hose) may also be effective by reducing **edema** (swelling caused by excessive buildup of fluid in tissue spaces or a body cavity) and increasing blood flow.

### **Viral Infections**

Viral skin infections are the result of a reaction from a systemic virus within the body or an infection of the skin itself. This type of infection encompasses a variety of conditions such as herpes simplex, herpes zoster, verruca, and human papillomavirus (Table 24.2). Viral skin infections are often contagious, and some may be passed by skin-to-skin contact or through the air when the infected individual coughs or sneezes.

Disorder	Description	Example
Herpes simplex	Infection caused by herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2)	 <p data-bbox="889 604 1393 659">(credit: "Herpes labialis - opryszczka wargowa" by Jojo/Wikimedia Commons, Public Domain)</p>
Shingles	Rash associated with varicella-zoster virus	 <p data-bbox="889 1100 1393 1155">(credit: modification of "21506" by K.L. Herrmann/CDC, Public Domain)</p>
Verruca	Growths on the skin caused by human papillomavirus	 <p data-bbox="889 1537 1393 1591">(credit: "Verruca vulgaris" by Abbassyma/Wikimedia Commons, Public Domain)</p>

**TABLE 24.2** Common Viral Skin Disorders

### Herpes Simplex

A viral infection that can cause painful blisters or ulcers is called **herpes simplex** and is categorized into herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2). Most often, HSV-1 spreads by oral contact and causes infections in or around the mouth or lips. This virus presents as ulcers or blisters (cold sores). It can also cause genital herpes if an infected person made contact with another person's genital mucosa. Herpes simplex virus type 1 is commonly spread through kissing, sharing objects that are in or near the mouth, and any other skin-to-skin contact. On the other hand, HSV-2 is spread by sexual contact and causes genital herpes. This virus usually presents as open sores, blisters, or bumps around the anus or genitals. It may also appear in the sacral area. The virus can also be spread

from mother to baby during childbirth if the mother has an active outbreak.

### Herpes Zoster

Chicken pox, or **varicella**, is caused by the varicella-zoster virus. After the initial illness has ended, the virus remains dormant in the dorsal root ganglia and can reactivate later in the person's life causing a painful, maculopapular rash called **herpes zoster** (or shingles). Patients who have received a varicella vaccine are also at risk of developing herpes zoster later. The rash associated with shingles most often appears on the trunk of the body along a thoracic dermatome. The rash primarily stays on one side of the body, follows dermatomes, and does not cross the midline. Although not common, the rash can affect three or more dermatomes and is called **disseminated zoster**. This type of rash occurs in patients with a weakened or suppressed immune system. The symptoms are often painful, tingly, or itchy and may precede the appearance of the rash. Some patients may also experience headache, malaise (overall weakness) in the **prodromal** state (period between the appearance of initial symptoms and the full development of an illness), chills, or photophobia (bright light sensitivity). Vesicles develop into clusters, which continue to form over three to five days and gradually dry and crust over. The rash usually heals in two to four weeks and can leave scarring or pigmentation changes behind. Shingles can be prevented by the recombinant zoster vaccine. This virus can spread to others when it is active and can cause varicella in those who have never had varicella or been vaccinated against it. Antiviral medications, like valacyclovir and acyclovir, may also be used to shorten the length and severity of a shingles breakout.

### Verruca

Warts, or **verruca**, are growths on the skin caused by the viral infection, human papillomavirus (HPV). The warts may appear raised or flat and can have a black dot in the middle. Warts are often not painful; although, some people may complain of pain. Warts may develop at any age but are more commonly found in children. Patients with warts may have as few as one or as many as hundreds. Warts are contagious and can spread from one area of the patient's body to another body part or to another person through prolonged or repeated contact. Only a small break in the skin needs to be present for the virus to spread (Dinulos, 2023c). Genital warts, however, are spread by sexual contact.

Verrucae are classified by their shape and location. A type of wart that grows in clusters is referred to as a **mosaic wart**. Common warts are firm, round, or irregularly shaped growths with a rough surface. They may be brown, yellow, gray-black, or light gray and are generally less than 1 centimeter across. These warts appear on the face, fingers, elbows, and knees. A wart on the soles of the feet, known as a **plantar wart**, is usually flat due to the pressure of standing and walking. Warts that appear on the soles of the feet may cause pain when walking or standing. A wart found on the palms of the hand is called a **palmar wart**. Both palmar and plantar warts tend to be hard and flat with well-defined boundaries and a rough surface. Thick, cauliflower-like growths around the fingers are known as periungual warts. A long, small, narrow growth that appear on the lips, face, or eyelids is called a **filiform wart**. Typically smooth, flat topped, and either yellow-brown, pink, or flesh colored, **flat warts** may appear in areas that are shaved or along stretch marks. A wart (condyloma acuminata, venereal warts) occurring on the vagina, vulva, cervix, and penis is called a **genital wart** and can be either flat, smooth, and irregular or velvety bumpy growths with a cauliflower-like texture (Dinulos, 2023c).

Generally, warts are easily recognizable by appearance. Occasionally, a biopsy may be needed to confirm the diagnosis. Treatment options include applying topical chemicals and burning, cutting, or freezing the wart. A *Candida* yeast antigen may be injected into the warts causing an immune response to fight against the virus (Dinulos, 2023c). Warts may return even after removal. The human papillomavirus (HPV) vaccine may be used to prevent the spread of the virus. Patients with genital warts should have the warts removed to prevent spreading from person to person. They should also be educated on safe sex and the need to inform their partners of the diagnosis.

### Fungal Infections

Fungal skin infections caused by fungus overgrowth most commonly occur in moist areas of the skin, such as between the toes, under the breasts, or in the genital areas. Fungal skin infections are usually caused by yeasts (e.g., *Candida albicans*) or dermatophytes (e.g., *Microsporum*). The fungi live on the stratum corneum and typically do not penetrate deeper into the skin. Patients who experience obesity are more likely to have fungal skin infections related to excessive skinfolds. Patients with diabetes are also at risk of fungal infections (Aaron, 2023). Common fungal skin infections include six types of tinea ([Table 24.3](#)).

Disorder	Description	Example
Tinea pedis	Also known as athlete's foot; a fungal infection characterized by a buildup of scale and may be accompanied by redness and itching	 <p>(credit: "Athletes foot" by Ellington/Wikimedia Commons, Public Domain)</p>
Tinea barbae	Also known as beard ringworm; generally a superficial infection but may occur deeper	 <p>(credit: modification of "4807" by CDC, Public Domain)</p>
Tinea corporis	Also known as body ringworm; a fungal skin infection affecting the face, arms, trunk, and legs	 <p>(credit: modification of "Tinea corporis" by Mohammad3021/Wikimedia Commons, Public Domain)</p>

**TABLE 24.3** Common Fungal Skin Disorders

Disorder	Description	Example
Tinea cruris	Also known as jock itch; a fungal skin infection of the groin	 <p>(credit: modification of “21482” by Dr. Lucille K. Georg/ CDC, Public Domain)</p>
Tinea capitis	Also known as scalp ringworm; a fungal infection of the scalp	 <p>(credit: modification of “Tinea capitis clinical presentation” by Coulibaly O, Kone AK, Niaré-Doumbo S, Goïta S, Gaudart J, Djimé AA, et al., CC BY 4.0)</p>
Tinea unguium	Also known as onychomycosis; a fungal infection of the toenail or fingernail	 <p>(credit: modification of “579” by Dr. Edwin P. Ewing, Jr./CDC, Public Domain)</p>

**TABLE 24.3** Common Fungal Skin Disorders

### Tinea

Known as ringworm, **tinea** may be found on the feet, beard, body, groin, scalp, or toes. Athlete’s foot, or **tinea pedis**, is characterized by a buildup of scale and may be accompanied by redness and itching. This infection is commonly caused by sweat from the feet accumulating between the toes allowing fungi to grow. This infection can spread to others who share showers, bathrooms, or other areas where infected individuals walk barefoot. Patients who wear tight shoes are also at risk of developing this infection. Fluid-filled blisters may also form with this infection. If the scaling is severe, the skin may crack and can lead to bacterial infections. Athlete’s foot may be treated by topical

antifungal ointments or oral antifungals like itraconazole (Sporanox). Prevention measures include wearing sandals or shower shoes in communal bathrooms, wearing breathable shoes, frequently changing socks, minimizing moisture on feet and in footwear, and completely drying feet and in between toes after bathing. Antifungal powders may also be used to aid in keeping the feet dry (Aaron, 2023).

Beard ringworm, or **tinea barbae**, is generally a superficial infection but may occur deeper into the dermis. Tinea barbae is characterized by circular patches or a swollen patch that may ooze pus and can result in scarring or whisker loss. Most beard skin infections are caused by bacteria rather than fungi; however, tinea barbae is a fungal infection. Antifungal medications or corticosteroids are common treatments for beard ringworm (Aaron, 2023).

Body ringworm, or **tinea corporis**, is a fungal skin infection affecting the face, arms, trunk, and legs. This infection is characterized by round, pink-to-red patches with raised, scaly borders that can be itchy. Clearing in the center may also be present. This infection can spread from one area of an infected person's body to another or from person-to-person contact. Antifungal medications may be applied topically or taken orally to treat this infection (Aaron, 2023).

Jock itch, known as **tinea cruris**, is a fungal skin infection of the groin. This is often characterized by a painful, itchy rash with a scaly, pink border. This infection is more common in men and is caused by trapped moisture between the scrotum and thigh. It most often develops in warm weather or when wearing tight or wet clothing. Patients experiencing obesity are at risk as well because of trapped moisture in skinfolds. The infection usually begins in the skinfolds of the genital area and spreads to the upper inner thighs. Antifungal medications may be taken orally or applied topically (Aaron, 2023).

Scalp ringworm, or **tinea capitis**, is a fungal infection of the scalp. This infection is characterized by a scaly, dry patch, a patch of hair loss, or both. The hair shafts may break at the surface (black dot ringworm) or break above the surface (gray patch ringworm). This infection can also cause dandruff-like flaking. A kerion may also be present. A kerion is a large, inflamed, swollen, and sometimes painful patch that can ooze pus. A culture may be needed to assess the type of fungus, or an ultraviolet light may be used to confirm the diagnosis. Treatment of scalp ringworm includes oral antifungals, antifungal creams, selenium sulfide (Selsun Blue) shampoos, or corticosteroids (Aaron, 2023).

A fungal infection of the toenail or fingernail is called **tinea unguium**. This infection is characterized by thickened nails that crumble easily and have white or yellow discoloration. The whole nail may become detached in more severe infections. If left untreated, the patient may have pain, balance issues, or a candidal infection. Treatment options include oral antifungals, topical ciclopirox olamine (Penlac) nail lacquer, and topical antifungals. Prevention is similar to that of preventing athlete's foot.

### Parasitic Infections

An organism that lives in or on an organism of a different species (the host), and depends on the host for nutrients is called a **parasites**. Parasitic skin infections occur when insects or worms burrow into the skin of a patient to lay their eggs or live there. Common parasitic skin infections include scabies and pediculosis (lice) ([Table 24.4](#)). Both infections are spread from person to person through physical contact. The parasites can live on physical objects such as brushes, clothing, furniture, and bedding; therefore, the parasites can spread to another person as well when contact is made with infested objects. Parasitic infections are generally treated by removing the source of the infestation as well as topical and oral medications to aid in killing the parasites and relieve any swelling, itching, or skin damage (Campbell & Soman-Faulkner, 2023).

Disorder	Description	Example
Scabies	Mites	 <p data-bbox="711 606 1325 632">(credit: "ScabiesDo3," by Cixia/Wikimedia Commons, Public Domain)</p>

**TABLE 24.4** Common Parasitic Skin Disorders

### Scabies

Caused by the *Sarcoptes scabiei* mite, **scabies** are accompanied by extreme itching no matter how few mites have burrowed into the skin (Dinulos, 2023a). Initially, the burrows are often visible and can be anywhere on the body, except they are less likely on the face. The burrows appear as a thin line and can have a tiny bump where the mite is located. Darker skinned individuals may only display raised, solid areas. Due to the intense scratching, this infestation can often turn into a bacterial infection. Over time, the areas usually become inflamed, making the burrows less visible. Infestations that turn severe may cause areas of crusted, thickened skin that do not itch. Risk

factors for attracting scabies are crowded conditions like schools, multifamily homes, and shelters. Hygiene is not a factor with scabies.

### **Pediculosis**

A lice infestation is called **pediculosis**. Lice are wingless insects that are not easily seen and may infect the body, head, or pubic area. Each type of lice can cause severe itching and bites that range from red (body and head lice) to grayish blue (pubic lice). An infestation with lice may be diagnosed with the presence of lice, nits (eggs), or both. A fine-toothed comb may be needed to assess the hair for lice, and the nits may be easier to see versus the lice itself. Body lice are often found in the seams of clothing and bedding. Pubic lice may require an ultraviolet light or a microscope to be seen. Pubic lice may leave feces on the patient's skin or underwear, which are characterized by dark brown specks. An infestation with lice will require replacing or thoroughly cleaning and drying linens and clothing. Items that are not able to be laundered can be placed in an airtight bag for two weeks to kill the lice. People who have close contact with an infected patient should also treat themselves, including sexual partners (Dinulos, 2023b).

Body lice (**pediculosis corporis**) live on and lay their eggs on bedding and clothing rather than the skin. The lice will migrate to various areas of the body to feed. Patients who live in crowded areas, have poor hygiene, or are of low socioeconomic status are more at risk of acquiring body lice. The lice spread because of sharing contaminated bedding and clothing. This type of lice can also transmit different types of fevers (Dinulos, 2023b). Treatment includes thoroughly cleaning linens and clothing.

Head lice (**pediculosis capitis**) are found on the hair and scalp. The lice lay eggs that take about one week to hatch and are called nymphs. It takes another seven days for the nymphs to reach their adult stage. The lice require a blood supply to live and will feed off their host several times a day. If the lice are deprived of blood, they will usually die within one to two days. Hygiene and socioeconomic status have no bearing on head lice. Shampoos that contain permethrin (Acticin), piperonyl butoxide (Red Pediculicide), or lindane are effective for treating head lice. Creams that contain malathion (Ovide) or spinosad (Natroba) suspensions may also be effective. Nits need to be removed with a fine-toothed comb. Treatments must be repeated seven to ten days later to kill any potential newly hatched lice. Ivermectin (Stromectol) may also be used if lice are resistant to medicated shampoos or creams (Dinulos, 2023b).

Pubic lice (**pediculosis pubis**), often referred to as crabs, infest the hairs of the anal and genital areas but can also infest the thigh, chest, and facial hair. This type of lice may be spread by sexual contact or close contact or by physical objects like linens and clothing. The same shampoos and creams used for head lice are effective for treating pubic lice. In addition, petroleum jelly, physostigmine ointment, fluorescein eye drops, petrolatum salve, and oral ivermectin (Stromectol) are effective for the lice that have infested a patient's eyelashes (Dinulos, 2023b).

### **Inflammatory Reactions**

Inflammatory skin reactions are either chronic or acute and are the result of a hypersensitivity reaction, an autoimmune disorder, or a genetic predisposition. These skin reactions may also recur when the stress factor or environmental trigger that caused the reaction are present. Inflammatory skin reactions include eczema, seborrheic dermatitis, urticaria, acne vulgaris, psoriasis, and systemic lupus erythematosus (SLE) (Table 24.5). These reactions require obtaining a comprehensive health history including family history, medications, diet, hygiene practices, and environmental conditions as well as a full assessment to identify possible triggers or causes.

Disorder	Description	Example
Eczema	Itchy, chronic inflammation of the skin	 <p>(credit: "Eczema-arms" by Jambula/Wikimedia Commons, Public Domain)</p>
Seborrheic dermatitis	Inflammatory skin reaction primarily on the scalp and face	 <p>(credit: "Seborrhoeic dermatitis2" by Klaus D. Peter/Wikimedia Commons, CC BY 3.0)</p>
Urticaria	Rash characterized by wheals and erythema	 <p>(credit: "Urticaria2" by Hyper84/Wikimedia Commons, Public Domain)</p>

**TABLE 24.5** Common Inflammatory Skin Disorders

Disorder	Description	Example
Acne vulgaris	Inflammatory skin reaction caused by clogged hair follicles	 <p data-bbox="938 552 1357 600">(credit: "Acne papulopustulosa" by Dr. Thomas Brinkmeier, CC BY 4.0)</p>

**TABLE 24.5** Common Inflammatory Skin Disorders

### Eczema

Atopic dermatitis, known as **eczema**, is part of the atopy family. Atopy means there is a genetic tendency to develop allergic conditions like asthma, eczema, and allergic rhinitis, and it is associated with a heightened immune response. This rash is characterized by itchy, chronic inflammation of the outer skin layers. In the acute phase, the rash may be red, oozing, and crusted areas with occasional blisters present. The chronic phase may have dry, thickened areas caused by scratching and rubbing. The rash may occur in one or more areas in adult patients and can spread to several areas on infants. The rash can vary in intensity, color, and location but is always itchy and triggers scratching, which can cause the skin to break and bleed. Stress, irritation, and dry air also make the itching more intense. Environmental triggers include harsh soaps, excessive bathing or handwashing, sweating, rough fabrics (e.g., wool), or *Staphylococcus aureus* present on the skin. Allergens like wheat, dairy, and eggs may also be a trigger. Tears in the skin caused by scratching or rubbing can often lead to bacterial infections.

Prevention includes minimizing triggers and managing stress. Treatments include skin care, ultraviolet light, corticosteroids, and biologic agents. General skin hygiene includes using soap substitutes, applying moisturizers after bathing, using lukewarm water, and patting skin dry. Antihistamines may also be used to relieve itching. Antibiotics may be needed when the reactions escalate to bacterial infections or for patients who are at risk of developing an infection (Ruenger, 2023). This reaction can be disabling and have long-term emotional effects that may require additional assessment and interventions to promote positive coping and body image.

### Seborrheic Dermatitis

An inflammatory skin reaction called **seborrheic dermatitis** affects the scalp and may also be present on the face, around the ears, and occasionally on other areas that have oil glands present. This reaction is more common in infants and adult patients from 30 to 70 years of age. Genetic factors and cold-weather conditions affect the severity and risk of this disorder. The rash is characterized by greasy, yellow scales, pruritis, and dandruff.

### Urticaria

Hives, or **urticaria**, is a type I hypersensitivity reaction resulting from an immunologically mediated antigen-antibody response of mast cells releasing histamine. This reaction is characterized by wheals (or hives) and erythema present after vasodilation and increased vascular permeability. The rash is easily identifiable by raised, swollen, flesh-colored or red bumps or welts on the skin. This reaction often begins rapidly and may be accompanied by swelling of the face, lips, throat, or airways (**angioedema**). The wheals can take several weeks to resolve.

### Acne Vulgaris

Acne is a common inflammatory skin reaction causing pimples, papules, pustules, blackheads, whiteheads, cysts, or abscesses on various areas of the skin. These skin abnormalities vary in size, severity, and deepness into the skin layers. Caused by bacteria, dead skin cells, or dried sebum that clogs hair follicles, **acne vulgaris** prevents sebum from passing up through the pores (Figure 24.9).

**FIGURE 24.9** There are several types of acne. The most common types are whiteheads, blackheads, pustules, papules, cystic acne, and nodules. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Mild acne includes blackheads, whiteheads, pimples, papules, and pustules and generally does not leave scars unless skin injury occurs when popping or squeezing the pimples:

- **blackhead:** flesh-colored, small bumps with a dark center
- **whitehead:** flesh-colored small bumps that do not have a dark center

- **pimple:** a small area of red skin that can be painful or cause discomfort
- **pustule:** similar to pimples but contain white or yellow pus

Severe acne is when patients have several blackheads, whiteheads, pimples, pustules, nodules, or deep acne (i.e., cystic acne). Lesions called **cystic acne** are usually larger, red, painful, and pus-filled nodules that merge under the skin and often leave scars.

Acne generally lessens in severity by the midtwenties but may appear to those in their forties. This type of skin reaction can cause emotional stress and may require counseling. General care for acne includes washing daily with a mild soap, using water-based cosmetics, and eating a balanced diet low in processed carbohydrates.

Inflammatory foods like gluten or dairy may need to be limited because it can cause acne for some individuals.

Blackheads and whiteheads can be removed by **comedone extraction**. This is the use of a comedone extractor by a healthcare professional to incise the pore and then use gentle pressure around the pore opening with a wire loop.

### Psoriasis

A recurring, chronic skin condition called **psoriasis** causes one or more raised areas of red skin patches with silvery scales and a distinct border. Psoriasis is caused by an abnormally high rate of skin cell growth. This skin condition is immune mediated and often occurs because of a genetic predisposition. It can occur anywhere on the body. Various triggers may exacerbate this skin condition, but it is controllable. Flare-ups of psoriasis may be triggered by burns, colds or infections, stress, certain medications, cold weather, obesity, HIV, smoking, and inflammatory foods like gluten. Therapeutic management includes coal tar topical (Balnetar) shampoos, ultraviolet light, topical steroids, mineral oil, topical anti-inflammatories, emollient creams, immunosuppressants (e.g., methotrexate [Trexall]), and other medications (e.g., acitretin [Soriatane], infliximab [Avsola]). Patients who have identifiable triggers may need to engage in lifestyle modifications, such as limiting cold exposure or eliminating inflammatory foods, such as sugar and high fructose syrups (Das, 2023).

### Systemic Lupus Erythematosus

A chronic autoimmune inflammatory disorder called **systemic lupus erythematosus** (SLE) involves connective tissues of the joints, skin, kidneys, mucous membranes, and blood vessel walls. This skin disorder, also known as lupus, can be diagnosed with blood tests or other diagnostic testing. Sudden fever is often the first symptom of this condition. The rash is characterized by round, raised, and reddened areas that can lead to skin loss, scarring, and hair loss. This skin disorder may also include a butterfly-shaped reddened area across the nose and cheeks. Light-exposed areas (e.g., face, scalp) also have clusters of the rash. The rash may be flat or have psoriasis-like characteristics, and those affected may experience painful joints and fatigue. Migraines, mental disorders, epilepsy, and organ dysfunction may also occur. Patients with SLE may experience lung problems (e.g., pleural effusion), heart problems (e.g., pericarditis), enlarged lymph nodes or spleen, kidney failure, decreased blood cells or platelets, gastrointestinal problems (e.g., nausea, pancreatitis), or pregnancy complications (e.g., miscarriage, stillbirth) (Nevaras, 2022). People with SLE often also experience **Raynaud syndrome**, a condition that causes pale or blue fingers with cold exposure. Flare-ups of lupus may be triggered by infection, pregnancy, surgery, or sun exposure. Early detection is optimal for a better prognosis and limiting the risks of kidney and other organ damage.

### Skin Cancer

The most common type of cancer is skin cancer, which has three main types: basal cell carcinoma, squamous cell carcinoma, and malignant melanoma (Figure 24.10). Patients with fair skin and lower melanin production and patients who spend a significant time in the sun are at higher risk of all types of skin cancers. However, patients with darker skin and those who spend minimal time outdoors can still develop skin cancer.

**FIGURE 24.10** The three main types of skin cancer include (a) basal cell carcinoma, (b) squamous cell carcinoma, and (c) melanoma. (credit a: “Basal cell carcinoma” by John Hendrix/Wikimedia Commons, Public Domain; credit b: “skin cancer, squamous cell carcinoma, face” by Kelly Nelson/National Cancer Institute, Public Domain; credit c: “Melanoma” by National Cancer Institute, Public Domain)

### Basal Cell Carcinoma

The most common type of skin cancer, **basal cell carcinoma**, is generally found on the head or neck. This type of skin cancer rarely metastasizes to other parts of the body but does invade and gradually destroy surrounding tissues. Basal cell carcinomas grow slowly and can go unnoticed because of the gradual change. These tumors can grow near the eyes, mouth, nose, or ears. They can be serious but are not usually fatal. Most tumors generally grow into the skin. The lesions are small, shiny bumps that may break open, form a scab, and sometimes bleed or flatten and look like scarring. Although a healthcare provider can easily identify this type of lesion, a biopsy should be performed to confirm the type of cancer. Treatment options include removal of the tumor by curettage and electrodesiccation, cutting it out, or cryosurgery. Topical chemotherapy medications may be applied to the skin. Using lasers and chemicals on the skin, known as **photodynamic therapy**, and radiation therapy are also options. Larger areas of basal cell carcinoma may require the **Mohs procedure**, where layers of the skin are removed and examined for cancer cells until no signs of cancer remain. The healthcare provider (often a dermatologist) may use sutures, skin flaps, or skin grafts to replace the removed skin or refer the patient to a plastic surgeon for closure (Nambudiri, 2024).

### Squamous Cell Carcinoma

The second most common type of skin cancer, **squamous cell carcinoma**, generally develops on sun-exposed areas but can grow where sun exposure is limited. Squamous cell carcinoma is the cancer of squamous cells, keratinocytes, the main epidermal structural cells. This type of skin cancer is more likely with patients who have precancerous growths like actinic keratoses, scarred skin, and chronic mucus membrane or skin sores. This skin cancer generally starts as a red area with a crusted, scaly surface that may turn into a raised, firm, wartlike surface. This lesion can become an open sore and grow into the underlying tissues. Biopsy is also best for diagnosing this type of cancer. The prognosis is generally excellent with early intervention. This type of cancer can metastasize and become fatal if not treated in time. Treatment options are similar to basal cell carcinoma but also include using an immune checkpoint inhibitor (e.g., PD-1 inhibitor [cemiplimab]). For patients who have large lesions that have metastasized or spread to the tissues underneath or cannot have surgery, PD-1 inhibitors help the body’s immune system annihilate the cancer (Nambudiri, 2024).

### Malignant Melanoma

The most dangerous of the skin cancers, **malignant melanoma**, originates in the melanocytes. As sunlight increases melanin production, the risk of skin cancer increases. Melanoma metastasizes to distant parts of the body and can often go undetected, making it fatal. Those with undetected melanoma may not be diagnosed until affected organs of the body start displaying symptoms.

Melanoma may begin as a small, pigmented growth in a sun-exposed area or develop in a preexisting mole but can also occur in the mouth, on the genitals or rectal areas, in the brain, in nail beds, or in or around the eyes. Risk factors for melanoma include those mentioned for other skin cancers but also include those with previous history of skin cancer, large number of moles, weakened immune system, fair skin, freckles, family history of melanoma, advanced age, and large congenital melanocytic nevus.

Melanomas usually are identifiable by an atypical mole with irregular borders and inconsistent colors. Some may be flat, irregular brown patches with small black spots or can be raised brown patches with blue, black, red, or white

spots. Melanoma can also be red, black, gray, and firm. A biopsy is needed for diagnosis. Nurses should understand the ABCDEs of melanoma and help educate patients on these warning signs ([Table 24.6](#)).

Letter	Meaning	Examples
A	Asymmetry = two halves of a mole are not equal	 <p>(credit: "Skin Cancer, Melanoma, Red And Brown Lesion 2" by Laurence Meyer/National Cancer Institute, Public Domain)</p>
B	Borders = borders are irregular and seem to blend in or are not oval or round	 <p>(credit: "Skin Cancer, Melanoma, Brown Lesion" by Laurence Meyer/National Cancer Institute, Public Domain)</p>
C	Color = existing mole changes color or moles that have drastically different colors than other moles present on the body	 <p>(credit: "Skin Cancer, Melanoma, Red And Brown Lesion 1" by Laurence Meyer/National Cancer Institute, Public Domain)</p>

**TABLE 24.6** The ABCDEs of Melanoma

Letter	Meaning	Examples
D	Diameter = more than ¼ inch (0.6 cm) wide	 <p>(credit: "Skin Cancer, Melanoma, Foot" by Kelly Nelson/National Cancer Institute, Public Domain)</p>
E	Evolution = mole that changes (bleeds, enlarges, becomes tender, itches) or development of a new mole after the age of 30 years	 <p>(credit a: "Common Mole" by National Cancer Institute, Public Domain; credit b: "Melanoma" by National Cancer Institute, Public Domain)</p>

**TABLE 24.6** The ABCDEs of Melanoma

Everyone should be screened regularly for skin cancer by a healthcare provider or dermatologist. Nurses should take any opportunity to educate people about sun exposure and ways to help prevent skin cancer. Key points to educate patients include how to observe changes or unusual skin markings that they should report to their healthcare provider. Additionally, nurses should educate patients about avoiding the sun or seeking shaded areas, especially when the sun's rays are the strongest (between 10 a.m. and 4 p.m.), wearing sunscreen with a sun protection factor (SPF) of at least thirty or greater, wearing protective clothing (e.g., hats, sunglasses, long sleeves), and avoiding the use of tanning beds (Nambudiri, 2024).

## PATIENT CONVERSATIONS

### Tanning Beds and Cancer Risks

**Scenario:** A nurse is performing an annual checkup on a patient who subsequently states they have been an avid tanning bed user for more than thirty years.

**Nurse:** Hi. My name is Susie, and I will be your nurse today. May I have your name and date of birth?

**Patient:** Yes. Hi, my name is Tiffany Ball, date of birth is May 12, 1975.

**Nurse:** What medications are you currently taking?

**Patient:** None.

**Nurse:** Any known medication allergies?

**Patient:** No.

**Nurse:** The last time we saw you, your surgical history included a cesarean section. Is that correct? Any other surgeries?

**Patient:** Nope. Just that one so far.

**Nurse:** Thank you. Have you noticed any new spots on your skin or anything that may concern you?

**Patient:** I have not noticed anything.

**Nurse:** Okay, well if you are ready, I will let the provider know you are ready for the skin check.

[The provider comes in and, while performing the annual examination, notices a suspicious mole on the patient's upper back. The provider removes it with the patient's permission and sends it off to pathology for a biopsy. The provider leaves the room.]

**Patient:** Wow. So, what causes skin cancer? I hardly go outside.

**Nurse:** Do you have a family history of skin cancer? Do you use tanning beds?

**Patient:** I think my dad had a spot removed a few years ago. I have been tanning in a tanning bed since high school, so maybe thirty years or so. I was told a tanning bed was safer.

**Nurse:** Tanning beds do increase your risk of developing skin cancer due to the ultraviolet (UV) rays (e.g., UV-A, UV-B) that may be used.

**Patient:** Oh, so since I already have a spot anyway, I can still tan, right?

**Nurse:** Your results will come back from the laboratory, and then we can confirm whether or not it is cancerous. It is best to minimize your risks for skin cancer. Just because you have one potential spot does not mean you could not have another. The risks for skin cancer include family history and sun exposure especially between 10 a.m. and 4 p.m. If you are going to be in the sun, use sunscreen with an SPF of at least thirty, find shade often, and wear protective clothing like long sleeves, pants, and wide-brimmed hats.

**Patient:** So, what are you saying about using tanning beds?

**Nurse:** Tanning beds do not offer a safe alternative to sunlight. Unfortunately, they also increase the risk for skin cancers, including melanoma, the deadliest form of skin cancer.

---

## Health Promotion and Behavioral Considerations

Health promotion as it relates to skin integrity includes lifestyle choices and behaviors that promote healthy skin. Those with impaired skin integrity should be careful with their hygiene practices and behaviors to avoid further aggravating their skin conditions. Some behaviors that help protect the skin include the following:

- using pH-balanced or mild soaps when bathing
- patting dry versus rubbing, which makes skin more prone to friction tears or other skin damage
- using emollients that moisturize and soften the skin
- avoiding the use of detergents that contain fragrance
- avoiding the use of deodorant soaps
- eliminating triggers

Any possible infectious skin lesions should be observed for signs of improvement or worsening. Drainage is a possibility from skin lesions; therefore, nurses should follow standard and transmission-based precautions when assessing the skin or changing dressings. Standard precautions may include wearing gloves, gowns, masks, or face shields as needed and disposing of them properly after use. Any contaminated dressings should also be disposed of according to organizational policies. Patients who have lesions may need to be educated on proper at-home wound care.

Nurses should educate patients and families on adequate hygiene and proper skin care for prevention of impaired skin integrity. Other behaviors that promote adequate skin integrity should also include understanding the importance of routine skin checks, minimizing sun exposure during the time of day when the ultraviolet rays are the strongest, wearing protective clothing while in the sun, and using sunscreen. Age-related and cultural considerations should be taken into consideration when providing education on health promotion behaviors for impaired skin integrity.

### Age-Related Considerations

Newborns have thinner skin that is more sensitive and susceptible to rashes (e.g., contact dermatitis), newborn acne, and seborrheic dermatitis. Newborns cannot care for themselves; therefore, caregivers should be educated on the need to keep the newborn and caregiver nails trimmed to avoid scratching the baby. They should also be educated on signs and symptoms of common skin irritations as well as prevention actions and treatment options.

Toddlers and preschoolers are more prone to accidents because of their high activity levels and difficulties with mobility. They may fall or run into inanimate objects that may lead to lacerations, burns, or other abrasions. Caregivers should be educated to implement safety precautions to prevent injuries. For example, padding sharp corners may prevent accidents.

Head lice, impetigo, scabies, and rashes are more common in school-age children and adolescents. Acne vulgaris generally starts during adolescence and can lead to an impaired body image, which may require counseling. This age group typically wants to be more independent, so education may be needed to ensure proper skin care.

Skin changes as people age (see [24.1 Structures and Function of the Skin](#)). Older adults should focus on adequate nutrition and hydration, especially ensuring adequate protein intake to promote wound healing. Older adults may have impaired mobility, making adequate hygiene difficult or impossible for this age group to perform. Therefore, it is important that the nurse or caregiver promote appropriate skin care, prevention, and intervention with impaired skin integrity. Some skin changes are benign, such as cherry angiomas, seborrheic keratoses, spider angiomas, wrinkles, dryness (**xerosis**), neurodermatitis, liver spots, melasma, **telangiectasia** (red marks on the skin caused by widening of shallow blood vessels), and hair loss.

### Culturally Related Considerations

Nurses should remember that cultural considerations regarding skin conditions are common but may be different among various cultures and ethnic groups (see [24.1 Structures and Function of the Skin](#)). Patients with fair skin produce less melanin and are more at risk of skin cancers than darker skinned individuals. However, patients with darker skin are more susceptible to post-inflammatory hyperpigmentation, dermatosis papulose nigra, keloids, hair loss, pityriasis, vitiligo, and dry skin. Other considerations include cultures that may not believe in medical interventions. For example, people who follow the Amish religion may not believe in accepting outside medical care or interventions. The nurse should not make assumptions but should assess beliefs and preferences as well as provide education to the patient and their family members regarding the skin disorder, treatment options, and risks of not being treated. The patient should be allowed to decide what interventions they do or do not want to receive without bias from the nurse. The nurse should also analyze a patient's cultural preferences when developing a plan of care to promote healing and improve skin integrity.

## 24.3 Wound Classification

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the different classifications of wounds
- Recognize the risk factors for pressure injury development
- Describe the staging process for pressure injuries

A **wound** is defined as an injury that causes a disruption of normal skin or tissue integrity. Wounds can be typed as an **incision, contusion, abrasion, laceration, puncture, penetration, avulsion, burn, and ulcer** ([Table 24.7](#)). In order to effectively manage wounds, nurses must first recognize the various wound classifications. They must also identify individuals at risk of pressure injury development and describe the technique for staging pressure injuries.

Wound Type	Description
Incision	A surgical cut made in skin or flesh
Contusion	A region of injured tissue or skin in which blood capillaries have been ruptured (bruise)

**TABLE 24.7** Types of Wounds

Wound Type	Description
Abrasion	An area of skin or tissue damaged by scraping
Laceration	A deep cut or tear in the skin or flesh or underlying tissue
Puncture	A wound made by a pointed object
Penetration	A wound caused by an object that pierces the skin and lacerates or damages adjacent tissue
Avulsion	A forcible tearing off of skin or another part of the body
Burn	An injury to the skin caused by thermal, electrical, chemical, or electromagnetic energy
Ulcer	An open sore caused by poor blood flow

**TABLE 24.7** Types of Wounds

### Different Types of Wound Classification

Wounds are classified in several ways and include intentional or unintentional wounds, open or closed wounds, acute or chronic wounds, pressure injuries, and friction and shear. Wounds also may be described according to how they were acquired, how long the wound has been present, or how deeply the wound affects the skin or tissues ([Table 24.8](#)).

Classification	Description	Example
Intentional wound	<ul style="list-style-type: none"> <li>• An example is a planned incision (wound) as the result of a treatment or therapy.</li> <li>• They serve a therapeutic purpose.</li> <li>• Wounds are clean with approximated edges and are performed under aseptic or sterile procedures.</li> <li>• Typically, the bleeding is well controlled, and surgical incisions are closed immediately after the procedure.</li> <li>• Examples include surgical incisions, venipunctures, and lumbar punctures.</li> </ul>	 <p>(credit: "Hip replacement, surgical staples", by Wikimedia Commons, CC BY 3.0)</p>
Unintentional wound	<ul style="list-style-type: none"> <li>• These wounds are from unexpected trauma and can result in multiple injuries.</li> <li>• The wounds are not acquired under sterile or aseptic conditions.</li> <li>• Wound edges are irregular and not clean like those of intentional wounds.</li> <li>• Bleeding is not controlled in this setting.</li> <li>• Examples include a broken bone or laceration from bicycle or automobile accidents, burns, work-related injuries, and penetrating wounds from a bullet or metal fragments.</li> </ul>	 <p>(credit: modification of "Injury showing open finger dislocation," by National Library of Medicine, CC BY 3.0)</p>
Open wound	<ul style="list-style-type: none"> <li>• This is a break in the skin or mucous membranes caused either intentionally or unintentionally.</li> <li>• It creates an entry for microorganisms, which combined with tissue damage and bleeding increases the risk of a prolonged healing time and infection.</li> <li>• Examples include incisions, abrasions, punctures, lacerations, penetrating wounds, and avulsions.</li> </ul>	 <p>(credit: "Screwdriver penetrating the chest" by P. A. Dieng et al, CC BY 3.0)</p>
Closed wound	<ul style="list-style-type: none"> <li>• This results from a force or blow, such as from a fall, being hit by an object, or in a collision with a person or inanimate object.</li> <li>• Examples include contusions and hematomas.</li> </ul>	 <p>(credit: "Plateletpheresis hematoma 2016" by Wikimedia Commons, CC0)</p>

TABLE 24.8 Wound Classifications

Classification	Description	Example
Acute wound	<ul style="list-style-type: none"> <li>• It will generally heal within days to weeks.</li> <li>• Progress through the normal stages of healing without disruption.</li> <li>• Examples include traumatic injuries, burns, and surgical incisions.</li> </ul>	 <p data-bbox="938 583 1365 632">(credit: "Longitudinal mini-incision" by National Library of Medicine, CC BY 2.0)</p>
Chronic wound	<ul style="list-style-type: none"> <li>• Typically, this type of wound has jagged edges, a higher risk of infection, and a delayed healing time of more than thirty days.</li> <li>• The patient does not progress through the normal stages of healing and usually experiences an interruption in the healing process.</li> <li>• Generally, the wound stays in the inflammatory stage of healing.</li> <li>• Examples include pressure injuries, diabetic ulcers, or ulcers from vascular insufficiency.</li> </ul>	 <p data-bbox="938 1052 1406 1100">(credit: "Bedsore ulcer" by Wikimedia Commons, CC BY 4.0)</p>

**TABLE 24.8** Wound Classifications

Classification	Description	Example
Pressure injury	<ul style="list-style-type: none"> <li>• This is a localized ischemic lesion of the skin and underlying tissue caused by external pressure that impairs blood and lymph flow.</li> <li>• Lack of blood supply, oxygen, and nutrients to the tissues results in necrosis and eventual ulceration. This ischemia also leads to inflammation and edema.</li> <li>• Pressure injuries may also be called decubitus ulcers, bed sores, and pressure sores.</li> <li>• This type of wound can occur in as little as one hour and may be acute or chronic.</li> <li>• Pressure injuries often arise when the soft tissues are compressed between an external surface and a bony prominence or from friction or shearing forces that injure blood vessels and abrade the epidermis.</li> <li>• Examples include bony prominences, including the heels, sacrum, coccyx, and greater trochanter.</li> </ul>	 <p data-bbox="938 604 1333 653">(credit: modification of "Escarre Stade 4" by Wikimedia Commons, CC BY 4.0)</p>

**TABLE 24.8** Wound Classifications

Classification	Description	Example
Friction injury	<ul style="list-style-type: none"> <li>Occurs when two surfaces rub together, which generates heat and can remove the top layer of the skin, damage superficial blood vessels, and may look like an abrasion.</li> <li>Examples include when a patient attempts to push themselves up in bed using their heels, arms, or hands or when personnel pull patients up in bed by a draw sheet or when transferring patients to a stretcher using a transfer or draw sheet.</li> </ul>	 <p>(credit: "Self-captured photograph of a rope burn (friction burn)" by Jesusjonez, Public Domain)</p>
Shear injury	<ul style="list-style-type: none"> <li>This occurs when one tissue layer slides over the other.</li> <li>The shearing force separates the skin from its underlying tissues. Blood vessels stretch and bend or tear causing injury, thrombosis, and impaired circulation to the tissue cells.</li> <li>Examples include when patients are pulled when being moved up in bed or transferred from bed to stretcher or chair, when a patient slides down when sitting in a chair, or their torso slides down when sitting in bed and the head of the bed is elevated.</li> </ul>	 <p>(credit: modification of "Blister on toe" by Wikipedia, CC BY 2.0)</p>

**TABLE 24.8** Wound Classifications

### Intentional and Unintentional Wounds

Intentional and unintentional wounds are described according to their acquisition. A planned or **intentional wound** is the result of a treatment or therapy. Surgical incisions, venipunctures, and lumbar punctures are examples of intentional wounds that are necessary for a specific treatment. The wounds are made in sterile conditions, and any bleeding is controlled, which promotes adequate healing time and reduces the risk of infection. For example, surgical incisions are made deliberately with careful techniques and in aseptic conditions, then closed immediately after the procedure.

A wound from unexpected traumas (e.g., a broken bone or laceration from bicycle or automobile accidents, burns, work-related injuries, penetrating wounds from a bullet or metal fragments) is known as an **unintentional wound**. These types of injury can result in multiple areas of trauma and involve tissue loss. The wounds are not acquired under sterile or aseptic conditions. Wound edges are irregular and not clean like those of intentional wounds. Bleeding is not controlled in this setting. Individuals who require medical attention may experience a delay getting emergency help depending on location, availability to call for help or other resources, and if anyone nearby is able to help control blood loss. These conditions create the potential for a longer healing process and an increased risk of

infection.

### Open and Closed Wounds

A break in the skin or mucous membranes is called an **open wound** and is caused either intentionally or unintentionally. Open wounds create an entry for microorganisms. This combined with tissue damage and bleeding increase the risk of a prolonged healing time and infection. Examples of open wounds include incisions, abrasions, punctures, lacerations, penetrating wounds, and avulsions. Furthermore, the term *open wound* is sometimes used to convey that the wound is not covered or dressed with bandages. It may even be left open to air as part of the treatment process.

A wound that does not have a break in the skin and occurs under the skin's surface is called a **closed wound**. Nevertheless, there may be bleeding, tissue damage, and internal injury under the skin's surface. Closed wounds may result from a force or blow like from a fall, being hit by an object, or a collision with a person or inanimate object. Examples of closed wounds include contusions and hematomas. Sometimes the term *closed wound* may relate to how wound edges are brought together. An example is when nurses say the wound is closed with sutures or staples.

### Acute and Chronic Wounds

Another way to classify wounds is by acute versus chronic. A wound that occurs suddenly and progresses through expected stages of healing is called an **acute wound**. These wounds should be assessed based on the way they occurred and the anatomical damage (Nagle et al., 2023). Often the full extent of acute wounds is unknown until several days after an injury. Initial issues such as swelling may mask the true extent and even depth of the wound.

In contrast to acute wounds, a **chronic wound** is a wound in which little to no healing occurs for at least three months (Bowers & Franco, 2020). There are a variety of ways and reasons that wounds become chronic (Table 24.9). For caregivers, these are complex to manage and may never heal completely. The goals of care for chronic wounds are to determine why the wound is not healing and identify strategies to overcome those reasons and allow the wound to heal (Nagle et al., 2023).

Cause	Explanation
Arterial insufficiency (such as scleroderma or Raynaud disease)	Insufficient arterial blood flow to the extremities impacts the transportation of oxygen and even antibiotics to diseased tissues.
Venous insufficiency	Insufficient return of blood from the extremities causes increased pressure and fluid in intravascular spaces, decreasing the body's ability to heal effectively.
Infection	Infections in tissues and bones (cellulitis and osteomyelitis, respectively) prevent the healing process. Expect to culture for biological, viral, and fungal agents.
Pressure	Constant or frequent pressure against healing tissues impacts the ability to heal and/or tears healing tissues back open.
Radiation therapy	This may cause occlusion or damage to blood vessels, impacting the healing of localized tissues.
Systemic diseases	Diseases such as diabetes and immunodeficiencies may impact the body's ability to heal naturally.
Nutrition	Protein malnutrition and elevated glucose levels can impact healing. For example, protein requirements to heal a chronic wound could rise as high as 250 percent normal requirements.

**TABLE 24.9** Causes of Chronic Wounds (Source: Nagle et al., 2023.)

Cause	Explanation
Age and hormones	While older age may lengthen the time it takes for an acute wound to heal, it does not cause chronic wounds. However, differences in androgens and estrogen may impact healing.
Medications	Several medications can slow down healing, including hydroxyurea, chemotherapeutic agents, and steroids.
Genetic issues	There is a genetic predisposition to issues such as keloid scarring and other skin conditions that may negatively impact wound healing.

**TABLE 24.9** Causes of Chronic Wounds (Source: Nagle et al., 2023.)

### Pressure Injury

A localized ischemic lesion of the skin and underlying tissue, known as a **pressure injury**, is caused by external pressure that impairs blood and lymph flow. The lack of blood supply, oxygen, and nutrients to the tissues results in necrosis and eventual ulceration. This ischemia also leads to inflammation and edema. Pressure injuries may also be called decubitus ulcers, bed sores, and pressure sores. This type of wound can occur in as little as one hour and may be acute or chronic. Healthy people who have full control of their limbs make changes in their position constantly. However, when someone remains in the same position for an extended period of time, an injury occurs. The portion of the skin where the patients' weight and force are applied is injured. Pressure injuries often arise when the soft tissues are compressed between an external surface, such as a bed or chair, and a bony prominence or from friction or shearing forces that injure blood vessels and abrade the epidermis. Examples of bony prominences include the heels, sacrum, coccyx, and greater trochanter. Pressure injuries may occur in home settings, hospitals, and long-term care facilities. Pressure injuries require aggressive intervention and treatment to decrease unwarranted pain or discomfort, inhibit further tissue damage, accelerate wound healing, decrease length of stays, and decrease healthcare costs.

### Friction and Shear

Friction and shear are mechanical forces that tear and injure blood vessels and can contribute to the development of pressure injuries. When two surfaces rub together and generate heat, friction is produced and can remove the top layer of the skin, may damage superficial blood vessels, and may look like an abrasion. Friction injuries may occur when a patient attempts to push themselves up in bed using their heels, arms, or hands. This can also happen when patients are pulled up in bed by a draw sheet or transferred to a stretcher using a transfer or draw sheet.

When one tissue layer slides over the other, **shear** occurs. The shearing force separates the skin from its underlying tissues. Blood vessels stretch and bend or tear causing injury, thrombosis, and impaired circulation to the tissue cells. Shear injuries may occur when patients are pulled when being moved up in bed or transferred from bed to stretcher or chair. Shear injuries may also occur if a patient slides down when sitting in a chair or their torso slides down when sitting in bed and the head of the bed is elevated.

## LIFE-STAGE CONTEXT

### Life Span Considerations for Older Adults

Part of the aging process occurs when changes in skin collagen makes skin less elastic. The subcutaneous and dermal tissues are thinner, and the patient often has reduced sensations of pressure and pain. This makes older adults more susceptible to friction and shear injuries. Careful considerations for the older adult include checking skin frequently to monitor for breakdown or tears, ensuring bedding and linens are dry and wrinkle free, padding bony prominences, and ensuring proper lifting technique when moving patients in bed or transferring out of bed.

### Risks for Pressure Injury Development

Pressure injuries may result from pressure and friction and shearing forces but may also be caused by other factors.

The risk factors for pressure injury development include moisture exposure, nutrition and hydration, mobility, and level of cognition. Other factors that may contribute to pressure injuries include the following:

- advanced age
- poor skin hygiene
- loss of sensation
- fractures
- immunosuppression
- diabetes
- history of corticosteroid use
- multiple organ dysfunction
- history of previous pressure injuries
- increased body temperature
- higher weight
- significantly lower weight
- terminal illnesses
- end-of-life processes
- microvascular dysfunction

### Moisture Exposure

Exposure to excessive moisture can cause skin **maceration** where the tissues are softened by prolonged wetting or soaking. Macerated tissue makes the skin less resistant to trauma or pathogens and more susceptible to injury. Moisture from incontinence of feces or urine or gastric tube drainage promote **excoriation**, the loss of the superficial layers of the skin, and is also known as denuded area. The accumulation of excretions or secretions overhydrates the skin and makes it more alkaline. The moisture exposure irritates the skin, harbors microorganisms, and makes the skin more susceptible to breakdown and infection. In fact, any substance that is excessively applied might overmoisten the skin and can lead to skin damage. People who experience incontinence should be monitored for skin breakdown. Absorbent pads may be used to aid in protecting the linens from getting soiled. The patient should be cleansed as quickly as possible after each soiling; skin barriers may be used to protect intact skin (Shi et al., 2020).

### Nutrition and Hydration

Nutrition and hydration play a major role in skin health. Cells that do not get adequate nutrition are more easily damaged. Malnutrition can lead to weight loss, muscle atrophy, and a decrease in adipose tissue resulting in the reduction of padding between the skin and bony prominences. Low protein in the blood, or **hypoproteinemia**, leads to a negative nitrogen balance, insufficient calorie intake, edema, and electrolyte imbalances, which predispose the skin to injury. Protein is vital for wound healing as it serves multiple critical functions in the reparative process. It acts as the primary building blocks for collagen synthesis, facilitating the formation of new connective tissue essential for wound closure and tissue regeneration. Additionally, protein supports the proliferation and migration of cells involved in wound repair, such as fibroblasts and keratinocytes, enabling the formation of new tissue and closure of the wound. Moreover, protein plays a crucial role in maintaining immune function, supporting the inflammatory response necessary for clearing debris and combating pathogens at the wound site. Protein is made up of nitrogen. Negative nitrogen balance means that the body is excreting more nitrogen than is being ingested. This will delay wound healing. Deficiencies in vitamin C may lead to frail capillaries and result in inadequate circulation contributing to the development of pressure injuries. Edema and dehydration can also interfere with perfusion.

### Mobility Status

Impaired mobility is a significant factor in pressure injury formation. People who have problems with mobility or are bedridden are unable to adjust themselves and may remain in one position for a prolonged period of time. People who have adequate mobility are able to move independently when they experience discomfort on an area of the body caused by pressure and also move freely in bed. People who are unconscious, have extreme weakness or pain, or have any other cause of decreased activity are unable to change positions and relieve the pressure even if their bodies sense the need to change position. Patients who require assistance in moving in bed or transferring are at risk of friction and shear injuries that may lead to pressure injuries if they are not properly lifted in the process.

### Cognition Status

Cognition consists of the mental processes that take place in the brain, such as thinking, language, learning, memory, perception, and attention. Patients who have an altered mental status or have decreased awareness (e.g., unconsciousness, sedation, dementia) are at risk because they are less likely to recognize and respond to the discomfort from pressure. This means that medication or therapy that decreases a patient's mental status can increase their risk for pressure injuries. People who are more alert are more likely to respond to increased pressure, protect their own skin integrity, and perform adequate hygiene to prevent the development of pressure injuries.

### Braden Scale

A wound assessment risk can be used to evaluate a patient's risk for developing wounds or to monitor healing. Different strategies can be employed depending on the risks various patients experience. For wounds that are more difficult to heal, providers must have reliable assessment methods to ensure appropriate and accurate communication among team members and allow for accurate assessment of changes between visits (Bates-Jenson et al., 2019).

The **Braden scale** is the most used pressure injury risk assessment tool in the United States and is used across many healthcare settings, including critical and acute care, long-term care, rehabilitation, and even by home-based nurses (Kennerly et al., 2022). It evaluates the relative risk of a patient developing skin breakdown and pressure injuries. The scores can be used to tailor pressure injury prevention interventions to at-risk patients (Kennerly et al., 2022).

### LINK TO LEARNING

The **Braden scale** (<https://openstax.org/r/77brandenscl>) is a helpful tool to establish the relative risk of a patient experiencing issues with skin breakdown.

The Braden scale uses six subscales: mobility, activity, sensory perception, nutrition, friction/shear, moisture (Kennerly et al., 2022). Each of these six factors is scored on a scale from one to four, depending on the factor. After each item is decided, the ratings are added together for a possible score between six and twenty-three. The lower the score, the greater is the risk for development of a pressure injury. All patients scoring eighteen and below should be reassessed regularly, on a schedule dictated by facility and healthcare setting. Patients scoring above eighteen should be reassessed when they experience condition-related changes. The Braden scale is a tool used by nurses to identify a patient's risk of developing pressure injuries and is typically completed on admission to a hospital or other healthcare facility as well as once per shift ([Table 24.10](#)).

Category	1 (most severe)	2	3	4
Sensory perception	Completely limited, unresponsive	Very limited, only responds to painful stimuli	Responds to verbal commands but limited communication	No impairment, responds and communicates
Moisture	Constant moisture	Frequent moisture/linen changes	Occasional moisture/extra linen change	Usually dry/routine linen change
Activity	Bedbound	Chairbound, limited walking	Short distance walking	Frequent walking
Mobility	Immobile	Very limited	Slight limitations	No limitations

**TABLE 24.10** The Braden Scale

Category	1 (most severe)	2	3	4
Nutrition	Very poor	Likely inadequate	Adequate	Excellent
Friction, shear	Constant friction, requires assistance	Movement with minimal assistance	Independent movement	N/A

TABLE 24.10 The Braden Scale

## Staging Pressure Injuries

Depending on the extent of damage, pressure injuries are assessed and classified as stages one through four or as deep tissue or unstageable. Stage one is the least severe of the stages. It is essential for nurses to adequately stage pressure injuries to implement appropriate interventions and assess for improvement or worsening damage.

Blanching is a part of the assessment process and can aid in identifying those at risk of pressure injury development. Normal **blanching** is temporary whitening or lightening of the skin around the wound site upon applying pressure. When the pressure is relieved, normal blood flow should return promptly to the area, and the skin should return to its normal color.

Prolonged pressure to an area makes it more difficult for adequate blood flow to return, thus resulting in pressure injuries. Patients who have been sitting or lying in a prolonged (e.g., two hours or more) position who are then repositioned may take sixty to ninety minutes for hyperemia (reddening of the skin) and warmth of the skin to resolve.

### Stage I

A stage I pressure injury is characterized by localized nonblanchable erythema of intact skin ([Figure 24.11](#)). Darker pigmented skin may not have apparent blanching, but the color of the skin may differ from the adjacent skin. Purple or maroon skin discoloration may be indicative of deep-tissue pressure injuries and not a stage I pressure injury. The area may also be painful, soft or firm, or warmer or cooler than its neighboring tissues.

FIGURE 24.11 (a) In darkly pigmented skin, the area of concern is a different shade than the surrounding tissue. (b) In a light-skinned individual, an area of pink and red erythema may be seen. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Stage II

Stage II pressure injuries are characterized by partial-thickness skin loss involving the epidermis or dermis. The wound bed is viable, moist, red or pink, and may appear as an abrasion, shallow crater, or blister ([Figure 24.12](#)). The adipose and deeper tissues are not visible at this stage, nor is **slough** (yellow, gray, green, tan, or brown dead tissue), **eschar** (hardened, black, tan, or brown necrotic tissue), or **granulation tissue** (delicate new reddish connective tissue) or tiny blood vessels that bleed easily but provide the framework for scar tissue development.

**FIGURE 24.12** A stage II pressure injury is a partial-thickness loss of skin with exposed dermis. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Stage III

Stage III pressure injuries are characterized by full-thickness skin loss where the adipose, granulation, and deeper tissues are visible and may have a presence of slough or eschar (Figure 24.13). The depth of this tissue damage will vary depending on its location on the body and amount of adipose tissue present. The ulcer presents as a deep crater with or without tunneling and undermining; however, fascia, tendon, ligament, muscle, cartilage, and bone are not exposed at this stage. Rolled or curled-under wound edges called **epibole** slow or stop the wound healing process and may occur at this stage.

**FIGURE 24.13** A stage III pressure injury has necrotic tissue and epibole. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Stage IV

Stage IV pressure injuries show full-thickness skin loss with extensive destruction; necrosis; and exposed or palpable fascia, tendon, ligament, muscle, cartilage, and bone (Figure 24.14). Slough and eschar are often visible along with epibole, undermining, and/or tunneling. The depth of this tissue damage will vary depending on its location on the body and the amount of adipose tissue.

**FIGURE 24.14** A stage IV pressure injury extends to the bone, with necrotic tissue and epibole. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Deep Tissue or Unstageable

Deep-tissue pressure injuries are classified as persistent, nonblanchable areas of the skin that have maroon, deep red, or purple discoloration (Figure 24.15). The affected areas of the skin may be intact or nonintact. There is a break in the epidermis that reveals a dark wound bed or blood-filled blister. With this type of injury, changes in the color of the skin are preceded by pain and temperature changes. Skin discoloration may appear differently in individuals with darker skin. For example, a bruise that may appear bluish in a lighter-skin-toned patient, may appear black in a patient with darker skin. Deep-tissue injuries are often the result of prolonged or intense pressure and shear forces at the bone-muscle interface. This wound may resolve without tissue loss or progress rapidly to expose the magnitude of tissue injury. Deep-tissue pressure injuries should not be used to describe traumatic, neuropathic, dermatologic, or vascular skin conditions.

**FIGURE 24.15** The presence of both eschar and slough occludes the true depth of the injury and causes it to be unstageable. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Pressure injuries are classified as unstageable if they have full-thickness skin or tissue loss and have excessive slough or eschar that obscures the extent of the damage. If slough or eschar is removed, a stage III or IV ulcer may be revealed. Stable eschar on the ischemic limb or heels should not be removed or softened. Eschar that is adherent, dry, and intact without **fluctuance** (tense area of skin with a wavelike or boggy feeling on palpation) and erythema is called **stable eschar**.

### UNFOLDING CASE STUDY

#### Unfolding Case Study #4: Part 5

Refer to [Chapter 19 Oxygenation and Perfusion](#) and [Chapter 22 Activity](#) for Unfolding Case Study Parts 1–4 to review the patient data. Mrs. Jenson, a 72-year-old female, presents to the emergency room with worsening shortness of breath, fatigue, and swelling in her lower extremities over the last week. She reports increasing difficulty performing activities of daily living due to weakness and increased dyspnea. She has been admitted to the telemetry unit.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, heart failure (class III), osteoarthritis</p> <p><b>Family history:</b> No significant family history reported.</p> <p><b>Social history:</b> Widowed ten years ago, currently living in an assisted care facility. No children.</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Lisinopril 20 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Metoprolol 50 mg PO once daily</li> <li>• Aspirin 81 mg PO once daily</li> <li>• Furosemide 40 mg PO once daily</li> <li>• Losartan 25 mg PO once daily</li> <li>• Ibuprofen 400 mg PO Q6 hours PRN mild arthritic pain</li> </ul>
Nursing Notes	<p><b>1500:</b></p> <p>Patient reports experiencing persistent joint pain, particularly in the shoulders and wrists, rated at 6/10 on the numerical pain scale. Patient states that pain interferes with daily activities, such as getting dressed and cooking. Patient also reports stiffness in affected joints, especially in the morning or after prolonged periods of rest, which improves with movement throughout the day. Occupational therapy referral sent per provider's orders. Acetaminophen administered at 1415. Patient reports improvement in pain level, which she now rates as a 2/10 on the numerical scale.</p>
Nursing Notes	<p><b>1530:</b></p> <p>During shift assessment, nonblanchable redness was noted on the patient's sacrum. When asked about it, patient reports tenderness in the area that gets worse with prolonged sitting. Patient describes the sensation as a mild "stinging" feeling.</p>

1. Recognize cues: What cues are most important for the nurse to recognize?
2. Analyze cues: What other information would the nurse want to obtain from the patient at this time related to the recognized cues in the previous question?
3. Prioritize hypotheses: What factors does the nurse hypothesize are contributing to the development of the patient's pressure injury?

## 24.4 Wound Healing

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine the phases involved in wound healing
- Identify complications to wound healing
- Educate patients and caregivers on self-care of wounds at home

Wound management encompasses many nursing interventions that are essential for promoting healing and regeneration of tissues. Different techniques are used to treat wounds, such as applying dressings or leaving the wound open to air. The technique or intervention used is dependent on the type of wound present. To effectively manage wounds, nurses must understand the phases of wound healing, factors affecting wound healing, psychological effects of wounds, complications affecting wound healing, and the nurse's role in wound care management.

There are three types of wound healing: primary, secondary, and tertiary intention healing. When wound edges have been approximated with little to no tissue loss and show formation of nominal granulation tissue and scarring, this is known as **primary intention healing**. For example, a surgical incision closed after surgery using sutures or a liquid adhesive is primary intention healing. These wounds are easily closed in a line formation. The healing process of extensive wounds that have significant tissue loss making approximating edges difficult or not a good option is

called **secondary intention healing**. Pressure injuries are examples of secondary intention healing. Secondary intention healing takes longer, has more scarring, and is more susceptible to infection. Delayed primary intention, or **tertiary intention healing**, occurs in wounds that are intentionally left open for three to five days to allow edema or infection to resolve or to let any exudate to drain. After that period of time, the wounds are closed with sutures, adhesive closures, or staples.

### Phases of Wound Healing

Wound healing can be broken down into the following phases: hemostasis, inflammatory phase, proliferation phase, and maturation phase (Figure 24.16). There are three phases of wound healing: inflammatory, proliferation, and maturation; in this case, hemostasis is included as part of the inflammatory phase. After an injury, the body automatically undergoes these phases, which methodically lead to tissue repair.

**FIGURE 24.16** The phases of wound healing are inflammation, proliferation, and maturation. This process begins immediately after an injury and varies in length. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

#### Hemostasis

Immediately after an injury, hemostasis (cessation of bleeding) occurs through vasoconstriction of blood vessels in the area, deposition of fibrin, and formation of blood clots through blood platelets. The blood clots provide a matrix of fibrin that becomes the framework for cell repair. After vasoconstriction, exudate is formed when the blood vessels expand, increasing capillary permeability, which allows plasma and blood components to leak out into the injured area. Pain and swelling may occur as a result of the buildup of exudate. Heat and erythema are the outcome of increased perfusion. Scabs form on the wound surface to protect the injury when blood clots lose their fluid. Epithelial cells migrate under the scab to provide a barrier between the body and the environment and to prevent the entrance of microorganisms.

#### Inflammatory Phase

Following hemostasis, the inflammatory phase begins and lasts about two to three days. During this phase, when leukocytes and macrophages move into the interstitial space to ingest bacteria and cellular debris, **phagocytosis** occurs. The macrophages also release angiogenesis factor that stimulates the formation of epithelial buds at the ends of injured blood vessels. The growth factor attracts fibroblasts that help fill in the wound. This phase may be depicted by pain, redness, heat, and swelling at the injury site. The patient may have a general body response like a slightly elevated temperature, elevated number of white blood cells, and general discomfort.

#### Proliferation Phase

The proliferation phase is also known as the reconstructive, fibroblastic, regenerative, or connective tissue phase. This phase begins around day three or four and may last up to several weeks. Fibroblasts that migrated to the wound begin to synthesize **collagen**, a whitish protein substance that adds flexible strength to the wound. Collagen

synthesis peaks in five to seven days, although the collagen deposits may persist for several weeks or years depending on the size of the wound. The fibroblasts also produce specialized growth factors that prompt blood vessel formation and proliferate the amount and migration of endothelial cells. Capillaries grow across the wound increasing the blood supply and oxygen needed through a process called **angiogenesis**.

Fibroblasts move from the bloodstream into the wound to deposit fibrin. As the capillary network develops, the tissue becomes a translucent red, granulation tissue that is delicate and bleeds easily. This granulation tissue provides the framework for scar tissue development. Wounds that heal by first intention have epidermal cells that seal the wound within twenty-four to forty-eight hours making granulation tissue not evident. Wounds that were not sutured need the injury site to be filled in with granulation tissue. After maturation of the granulation tissue, marginal epithelial cells migrate to the site, proliferating over this connective tissue base to fill in the wound.

The majority of white blood cells have left the wound area making the wound lighter in appearance by the end of the second week after the injury. The generalized symptoms the patient had generally disappear by this point. Adequate nutrition and oxygenation are essential patient care considerations for this phase. Any wound closed with sutures or other types of closures should be prevented from experiencing any type of strain, for example, picking up something heavy or pulling the patient in a way that adversely affects the injury site.

### Maturation Phase

The maturation phase is the final phase of wound healing and begins around day twenty-one and can last up to months or years. Fibroblasts continue to synthesize collagen during this phase. The collagen fibers are reorganized into an orderly structure in this phase and promote a stronger wound. The collagen also aids in making the wound more like its neighboring tissues. When new collagen continues to synthesize, the blood vessels in the healing wound compress so that the scar does not sweat, tan in sunlight, or grow hair. The scar becomes a flat, narrow line and is not as elastic as uninjured tissue. The scar becomes stronger, but the tissue in the repaired area is never as strong as normal tissue. Wounds healed by secondary intention may take longer to remodel and form a scar. When scars form over a joint or adhere to body structures, **arthrofibrosis** occurs, which may limit mobility or cause a disability. For example, arthrofibrosis occurs when scar tissue forms around the knee joint after knee surgery, which limits the range of motion.

### Circumstances Affecting Wound Healing

There are several factors that influence the speed of wound healing. Localized factors are those factors that occur directly in the wound or directly influence the wound's characteristics. On the other hand, systemic factors occur throughout the body due to a disease state or overall health of the individual and their body's ability to promote healing. Some factors may be related, and systemic factors act through the local effects that can impact wound healing (Monika et al., 2022).

#### Localized Factors

Desiccation, maceration, trauma, pressure, excessive bleeding and edema, or infection are all **localized wound healing factors** that directly affect the wound and may delay the process of healing. Meticulous care is necessary with wound management to prevent or limit these factors that can impede wound healing. It is important for nurses to understand these factors to promote optimal outcomes, improve wound care, improve the patient's quality of life, and prevent significant healthcare costs.

#### Desiccation

Unintentional wound or tissue dehydration, known as **desiccation**, occurs when cells do not get adequate moisture, so they dry up and die. This cell death leads to a crust that forms over the wound site, which impedes healing. This can occur naturally as part of the wound healing process or as a result of external factors such as exposure to air, inadequate wound dressing, or excessive use of wound irrigation solutions. While a certain level of desiccation is normal and may promote wound healing by facilitating the formation of a protective scab, excessive desiccation can impede the healing process. Prolonged drying of the wound bed can lead to tissue dehydration, delayed epithelialization, and increased risk of infection. Additionally, desiccation can cause discomfort and pain for the patient as well as impair the migration of cells involved in wound repair.

#### Maceration

Just like a wound can get too little moisture, there can also be an excess of moisture. Maceration is softening and

breakdown of the skin due to overhydration. A common cause of maceration is urinary and fecal incontinence. This type of moisture also causes changes in the pH level of the skin, destroys skin from friction on moist skin, and causes overgrowth of bacteria or infection of the skin that in combination leads to maceration and impaired skin integrity.

### Infection

Infection is often caused by bacteria or other microorganisms in the wound. Infection puts a strain on the affected person's body because of the increase in demand for energy by the immune system to combat microorganisms. This strain leaves little or no energy for the body to promote the process of repair and healing. Bacteria also produces toxins and releases them when they die, which further affects wound healing and leads to cell death.

### Systemic Factors

Healing factors that are not related to the wound itself, called **systemic wound healing factors**, take place throughout the body and include age, venous insufficiency, poor oxygenation, obesity, diabetes, medications, and smoking or alcohol use. In addition, wound etiology directly affects the process of wound healing. Wounds that are the result of a systemic issue may recur like a venous ulcer. Nutritional status plays a significant role in wound healing as adequate carbohydrates, proteins, fats, minerals, fluids, and vitamins are needed to rebuild cells and tissues, promote epithelization and collagen synthesis, and support optimal cell function. Patient adherence to the treatment plan is also a crucial element of wound healing. Patients who are noncompliant can experience negative effects on wound healing. Protein supplements may be necessary to meet wound healing needs in patients who are unable to adequately intake the proper nutrition needed.

### Age

Skin changes are a normal part of aging. However, these changes can adversely affect an older adult's wound healing. Vascular changes (e.g., atherosclerosis, capillary atrophy) can impede blood flow. Collagen is less elastic, which increases the risk of injury or damage by pressure, friction, and shearing. Immune system changes can decrease antibody and monocyte formation, which is needed for wound healing processes to occur. Older adults may also be deficient in nutrients and fluids needed or have chronic conditions that impair oxygen delivery to wounds (e.g., chronic lung disease). Cell renewal is slower in older adults and results in prolonged healing.

### Venous Insufficiency

Venous ulcers caused by **venous insufficiency** can lead to an increase in pressure and buildup of fluid in the lower legs. This generally is the result of high blood pressure, long periods of sitting or standing, lack of exercise, smoking, deep vein thrombosis, obesity, tissue trauma, and phlebitis. This combination leads to cell death, tissue damage, or wounds because of a lack of nutrients and oxygen. Blood flow is needed to not only deliver nutrients and oxygen but also to remove bacteria, toxins, and other debris. Therefore, wounds caused by venous insufficiency or another source are at risk of delayed wound healing.

### Poor Oxygenation

Oxygen is essential for the biological processes that take place within the phases of wound healing like angiogenesis and collagen synthesis. Poor oxygenation may be due to systemic factors like diabetes or advanced age. It may also result from any factors that impair vascular flow to the tissues. A lack of oxygen prolongs healing and can lead to cell death. Oxygen also has antimicrobial effects and plays a vital role in the inflammatory response. People with poor oxygenation are more susceptible to infection, which further complicates wound healing.

### Diabetes

Diabetes negatively affects wounds. Diabetes impairs circulation needed to deliver oxygen and nutrients. Uncontrolled blood sugar can damage the nerves and cause numbing sensations known as **diabetic neuropathy**. This reduced sensation means that the affected person may not be aware of the wound resulting in the lack of or delayed intervention. Uncontrolled blood sugar levels also impair white blood cell function needed to fight bacteria and close wounds in the inflammatory response.

### Medication

Some medications may have an adverse effect on wound healing. Steroids affect the inflammatory phase and decrease its response. Radiation results in decreased leukocytes and increases the chance of infection because of depressed bone marrow function. Chemotherapeutic agents may impair or stop the growth of new cells needed for

wound healing. Patients who have prolonged antibiotic use are at risk of secondary infection or **superinfection** (e.g., *Clostridioides difficile*). This means that the infection is unrelated to the original infection and results from opportunistic colonization following immunosuppression. Medications used to treat skin disorders inadvertently cause thinning of the outermost layer of the skin, increasing susceptibility to breaks in the surface.

### Wound Complications

There are several events that can interfere with wound healing and may cause complications. Infection, hemorrhage, dehiscence and evisceration, and fistulas can increase the risk of death or generalized illness, increase healthcare costs, and prolong the need for healthcare interventions. These complications can also exacerbate the emotional stressors associated with wounds.

### Infection

Wound infections are common. Wounds are by their nature “dirty” and contain bacteria. However, not all wounds are infected. When the immune system fails to limit microbial growth, wound infection occurs ([Figure 24.17](#)). The invasion of microorganisms can occur at the time of the injury, during surgery or postoperatively, or any time after the injury. People with suppressed immune systems or who are undergoing myelosuppressive cancer treatment are more susceptible to infection. [Table 24.11](#) provides signs and symptoms of wound infections that should be routinely monitored (Bishop, 2021).

**FIGURE 24.17** To be considered infected, a wound must include pain, redness, swelling, and purulence (Nagle et al., 2023). (credit: “MRSA Staph Infection” by Cayobo/Flickr, CC BY 2.0)

Sign/Symptom	Examples
Wound bed	Bright red, fragile granulation tissue with pockets
Exudate	Increased exudate, cloudy, yellow, green, pus, smelly, leaking around wound closures
Periwound area	Redness, inflammation, streaks leading out from wound
Swelling	Unusual swelling near the wound and nearby swollen lymph nodes

**TABLE 24.11** Signs and Symptoms of Infections in Wounds (Source: Bishop, 2021.)

Sign/Symptom	Examples
Fever	Typically seen in combination with other symptoms
Pain	Increasing in intensity, new, or changed from previous pain

**TABLE 24.11** Signs and Symptoms of Infections in Wounds (Source: Bishop, 2021.)

### Hemorrhage

Some wound bleeding is normal. Massive bleeding (or hemorrhaging) is abnormal and may be caused by a dislodged clot, slipped stitch, or erosion of a blood vessel by a foreign body. If possible, any dressings should be checked frequently during the first forty-eight hours after the injury and at least every eight hours thereafter. In the event of excessive bleeding, interventions may include packing or applying a pressure dressing, surgical intervention, fluid replacement, and monitoring vital signs. Internal bleeding may result in a **hematoma**, a localized collection of blood under the skin that may appear reddish blue and swollen. A large hematoma can be hazardous because it places pressure on blood vessels and causes tissue ischemia.

### Dehiscence and Evisceration

The most serious wound complications include dehiscence and evisceration (Figure 24.18). Smoking, obesity, malnourishment, anticoagulant therapy, excessive coughing, vomiting, infected wounds, or straining increases the risk of dehiscence and evisceration. The partial or total rupturing of a sutured wound is called dehiscence and is caused by excessive stress on unhealed wounds. Dehiscence may be preceded by the presence of serosanguineous fluid from the wound days postoperatively. It is common for the patient to say, “it feels like something has given way.” The dehisced wound is managed like an open wound. The protrusion of the viscera through the incision when the wound completely separates is called evisceration and most commonly occurs with abdominal incisions.

**FIGURE 24.18** Dehiscence and evisceration are serious complications. Dehiscence may occur from strenuous activity like coughing or vomiting and can lead to evisceration. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

These complications should be treated like a medical emergency. The patient should be placed in the low Fowler position, and the area should be covered with a sterile towel soaked with sterile 0.9 percent sodium chloride. Placing the patient in the low Fowler position and slightly bending their knees will lower intra-abdominal pressure on the wound. This will prevent more wound damage until the physician arrives. The provider should be notified immediately because surgical intervention is required. Other nursing interventions include remaining with the patient, providing reassurance, administering intravenous pain medications as needed, and ensuring that the patient remains **NPO** (nothing by mouth).

### Fistula

A **fistula** is an abnormal passage from one internal organ or vessel to another or an internal organ or vessel to the outside of the body. Fistulas may be created on purpose, such as an arteriovenous fistula to provide access for

kidney dialysis. However, with wound complications, infection can lead to the development of a fistula from an abscess. The collection of undrained infected fluid applies pressure on the surrounding tissue creating the abnormal passage. Fistulas increase the risk of prolonged healing, skin breakdown, additional infection, and fluid and electrolyte imbalances.

### Psychological Effects on Wound Healing

Wounds can be debilitating and have a significant effect on a person's self-identity and emotional well-being. The skin plays a role in communicating with other organs in the body through its sensory functions and affects a person's self-image. Patients can experience anxiety, post-traumatic stress disorder, and depression from how the wound is created based on it being a traumatic injury, either intentional or nonintentional, and emotions contribute to the patient's overall well-being in the outcome. Wounds and pressure injuries cause stress and emotional factors related to pain, fear, disruption to activities of daily living, and an altered body image. These stressors are interconnected and can impact not only the patient but also their caregiver or loved ones.

#### Pain

Any type of trauma can cause pain no matter the size of the injury. Pain is a physical complication but has a substantial psychological element. Wound pain may be caused by coughing, moving in bed, dressing changes, ambulating, or other activities that require movement. Pain attributed to these activities may result in the patient hesitating or avoiding them altogether. It can be debilitating to the affected persons. Pain can often lead to depression, further contribute to stress, cause fear and anxiety, and disrupt overall activities of daily living. Pain can also cause altered vital signs like tachycardia, tachypnea, and elevated blood pressure. Nursing interventions to reduce pain can reduce discomfort and emotional stress. For example, administering pain medication before performing wound care may reduce the amount of pain during the process.

#### Fear

Fear is a common response to wounds. The pain and disruption to activities of daily living can contribute to anxiety and fear. Patients are often concerned about the wound healing process and complications that may arise such as wound dehiscence (partial or complete opening of a wound) and infection. They may also be worried about other people's response to the wound appearance or smell as well as how much their privacy will be invaded when undergoing wound care. The fear of rejection may lead to social isolation. Nursing interventions should include therapeutic conversation encouraging expression of feelings, answering questions honestly and accurately, exhibiting empathy and acceptance, and preventing excessive exposure of body parts during care.

#### Altered Body Image

A negative body image can damage a person's self-esteem. The skin is part of what gives someone their identity; therefore, any wound or trauma requires adaptation of the concept of self. This may make a person self-conscious when scars or wounds are visible to others. Scars on the face or ones that take up a large margin of skin may result in diminished self-worth or feelings of unattractiveness. This type of negative self-image can lead to social isolation, further exacerbating the other stressors associated with wound management. Nursing interventions are similar to that of fear and include therapeutic conversations encouraging expression of feelings, answering questions honestly and accurately, exhibiting empathy and acceptance, and referring patients and their caregivers to support groups or counselors who can aid in coping skills and acceptance.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Recognize and Analyze Cues

Before recognizing cues, nurses must make sure they have enough information about a patient's situation before interpreting the information and developing a plan of care. For example, patients experiencing fear related to their wound may have anxious feelings about wound care, pain, rejection from others, or how this wound will affect their life. The nurse should assess the patient's feelings and gather information about activities of daily living, how much support or help the patient has at home, and any other aspects affecting the patient's self-identity and mental well-being. The nurse should also be aware of nonverbal cues during care (e.g., looking away, grimacing) to assess discomfort or unease.

## Nursing Interventions Used in Wound Management

Wound care requires an interdisciplinary approach and may require a number of nurses and other healthcare providers to work together. It is essential that nurses understand their role in wound care management to effectively implement interventions within their scope of practice. The nursing role includes assessment and documentation, positioning, dressing care, drain care, suture and staple care, cleaning, debridement, administering growth factors, heat and cold therapy, wound care education and health promotion, and teaching the patient to perform self-care at home. Other therapies that the nurse may be required to assist with include hyperbaric oxygen therapy and surgery. It is important to note that wound care is not 100 percent dictated on the bedside nurse, it can vary based on specialty background and acute care area. If nurses truly desire to become experts in wound care, they can achieve additional certification and become a certified wound care nurse (CWCN) and ostomy care nurse (CWCON), and they would be a bigger member of the interdisciplinary team.

### Assessment and Documentation

Wound assessment is an ongoing process that requires thorough evaluation and clear, concise documentation for adequate tracking of the healing progression. This allows for continuity of care, adequate care evaluation, and proper interventions or changes in wound care. All photos should be taken with a measuring device (e.g., ruler) placed by the wound to indicate proportions and should be documented and dated for an accurate timeline. In addition to the assessment findings, documentation should include wound care or therapies provided during the encounter, how well the patient tolerated it, any medications administered and the patient response, any communication to the provider of abnormal findings and whether new orders were received, and any education or supplies given to the patient or family members as well as their understanding of the teaching.

### Positioning Devices

Patients who have pressure injuries or have been identified as at risk may benefit from positioning devices to aid in preventing pressure injuries or promote healing. Examples of positioning devices include gel interfaces, foam wedges, or pressure-reducing boots that can be positioned to keep pressure and body weight off bony prominences. If possible, avoid using pillows or other surfaces that collapse under the patient's body weight. These do not cause adequate support. Ring cushions (i.e., donuts) should not be used because they can cause increased venous pressure in the surrounding areas.

### Dressings

Wounds may be left open to air or covered with a protective dressing. Wounds may be left open to air per provider order if closing the wound makes infection more likely. Wounds left open to air develop dried eschar or a scab leading to slower healing. The scab may be inadvertently removed if the area rubs or hits the wound, causing reinjury. Dressings used to cover wounds provide a moist environment that promotes healing. This moist environment aids in rapid epithelial cell migration, maximizing the healing process. Dressings should also be absorbent, provide a barrier from bacteria, limit pain at the wound site, provide thermal insulation, and permit pain-free removal. Covered wounds help patients cope with the change in their body image.

Binders are designed for a specific part of the body like abdominal binders, shoulder slings, or chest binders. T-binders are used to secure rectum or perineum dressings. A double T binder is used for males, and a single T binder is used for females. The belt should be passed around the waist, and then the tails should pass between the legs prior to fastening. Typically, the binders are made of cloth or elasticized material that can be fastened with Velcro.

**Montgomery straps** are ties that attach to an adhesive backing that holds a dressing in place. They are useful in preventing skin irritation or tissue damage when retaping is necessary for repetitive dressing changes. The patient's skin should be protected with a skin barrier or hydrocolloid dressing before applying the Montgomery straps. The adhesive backing is applied to the adjacent skin with the ties extending over the wound area. The straps should be untied and turned back during wound changes and retied after the new dressing has been applied.

## UNFOLDING CASE STUDY

### Unfolding Case Study #4: Part 6

Refer to [Unfolding Case Study #4: Part 5](#) for a review of the patient data.

Nursing Notes	<p><b>1600:</b>          Focused skin assessment performed. Open wound noted on bottom of left foot. Patient reports stepping on broken glass about a month ago but states, "I assumed my foot was fully healed because it doesn't hurt at all." Upon assessment, the wound is red with purulent drainage and surrounded by edematous tissue. Prophylactic dressing applied to sacral area. Provider notified.</p>
Provider's Orders	<p><b>1700:</b></p> <ul style="list-style-type: none"> <li>• Consultation with wound care team</li> <li>• Consultation with diabetes educator</li> <li>• Apply nonadherent gauze dressing on foot</li> </ul>

---

4. Generate solutions: What are the rationales for the provider's orders?
5. Take action: What are the priority actions by the nurse at this time?
6. Evaluate outcomes: The wound care team assesses the patient and orders an antibacterial cream and dressing changes every other day. What findings would indicate that these interventions were successful?

### Drains

Drains are often used with wounds that are expected to have an accumulation of fluid that would impede wound healing ([Table 24.12](#)). Drains may be placed during surgery to prevent fluid collection underneath the incision site. Drains, tubes, or catheters may be used in or near the wound site. These are commonly used after surgical procedures in which the surgeon places one end of a drain or tube near or in the area to be drained and passes the opposite end through the skin, through either the incision or a different opening (i.e., stab wound). Drains are either closed or open systems.

Type	Examples	Image
<p>Closed drainage systems have a tube connected to a portable reservoir that provides continual low suction. These are typically sutured to the skin and require emptying to reestablish suction when needed.</p>	<p>Jackson-Pratt bulb drain Hemovac</p>	 <p>(credit: modification of "Surgical drain – waste container" by Wikimedia Commons, Public Domain)</p>
<p>Negative pressure wound therapy is a type of closed drainage system that uses a special sponge that works with a semioclusive barrier that connects to a drainage system.</p>	<p>Vacuum-assisted wound closure</p>	 <p>(credit: "KCI Wound Vac01" by Noles1984/ Wikimedia Commons, Public Domain)</p>  <p>(credit: "KCI Wound Vac02" by Noles1984/ Wikimedia Commons, Public Domain)</p>

**TABLE 24.12** Different Types of Drains

Type	Examples	Image
<p>Open drainage systems do not have a collection device. The drainage empties from the wound or surgical site into absorbent dressings. These are typically sutured in place. The provider may order reducing the length of the drain inside the wound each day. This may be done by clamping the end of the drain with sterile forceps, then pulling it out a small distance using a twisting motion, and then cutting off the end with sterile scissors. A new sterile pin should be placed at the base as close to the skin as possible.</p>	<p>Penrose drain</p>	 <p>(credit: "Compartment syndrome in the hand Intraoperative image of the dorsal region of the right hand" by Belzunequi T, Louis CJ, Torrededia L, Oteiza J - Scand J Trauma Resusc Emerg Med/Wikimedia Commons, Public Domain)</p>

**TABLE 24.12** Different Types of Drains

### Sutures and Staples

Sutures and staples are placed by the surgeon or provider to close the wound edges but may be removed by the nurse as ordered. They may be removed after the wound is strong enough to hold its edges together. The length of time needed to develop tensile strength varies among individuals and depends on wound location, age, and nutrition level of the patient. Silk sutures are generally removed after six to eight days to avoid marks; however, the collagen formation and remodeling can take up to three weeks. This may lead to stretching or widening of the scar after the sutures are removed.

### Cleaning

Wound cleaning is essential to help remove microorganisms or debris and protect healthy granulation tissue. Normal saline solution (0.9 percent sodium chloride) is the typical cleaning agent used in wound care. However, there are other products available like cleaning antiseptic or surfactant sprays that may be used with infection, debris, or increased amounts of bacterial colonization. Wounds are cleaned after the old dressings have been removed and before applying new dressings.

### Growth Factors

Growth factors are naturally occurring polypeptides involved in essential cellular processes needed for tissue regeneration. Growth factors bind to their corresponding receptors on the cell surface to induce signaling pathways to initiate signaling molecules that can stimulate cytoplasmic proteins or prompt the transcription of new proteins (Park et al., 2017). The only exogenic growth factor that has shown to be efficient in treating chronic wounds is the recombinant platelet-derived growth factor. This growth factor is synthesized outside the human body and stimulates the immune cells and fibroblasts to prompt the development of the extracellular matrix. Growth factors may be applied topically to the wound by the nurse with an order from the provider.

### Hyperbaric Oxygen Therapy

A more advanced wound care therapy is hyperbaric oxygen therapy (HBOT). This technology expedites repair of compromised healing wounds. Patients undergoing this therapy are placed in a pressurized, hyperbaric chamber for generally one to two hours where they breathe 100 percent oxygen. This amount of oxygen enhances the amount of oxygen dissolved in the plasma and also promotes cell proliferation and healing. A highly concentrated oxygen environment boosts wound metabolism, enhances the response to growth factor, activates angiogenesis, and provides antioxidant and antibacterial effects to enhance immune function. Nurses work under the supervising provider to administer this therapy to patients. Patients should be supervised throughout the entire treatment and monitored for adverse effects like oxygen toxicity, claustrophobia, middle ear injuries, or pneumothorax. Fragranced hygiene products, medical devices like glasses or hearing aids, jewelry, flammable objects, and electronics should be avoided while inside the chamber (Alemayehu et al., 2019).

## LINK TO LEARNING

Patients may be unsure about hyperbaric oxygen therapy and may ask for a reference to review at home. The Food and Drug Administration provides [an overview of hyperbaric oxygen therapy \(https://openstax.org/r/77hyperbaric\)](https://openstax.org/r/77hyperbaric) for consumers to review.

### Debridement

The removal of slough or necrotic tissue and foreign material by various methods is **debridement**. Along with removal of dead tissue and bacteria, this process stimulates growth factor to promote wound healing. In **autolytic debridement**, occlusive dressings are used to enhance the body's own defense mechanisms to liquefy or soften necrotic tissue. Applying commercially prepared enzymes that accelerate the body's autolytic process is **enzymatic debridement**. In **mechanical debridement**, external physical force is applied to remove debris or necrotic tissue. This method may be accomplished through wound irrigation with pulsed pressure lavage, ultrasound, laser therapy, surgical debridement, or whirlpool therapy.

Wet-to-dry dressings may still be ordered with debridement, although there are concerns that this method interrupts angiogenesis. If this method is ordered, it is important that the nurse ensure that the product being used supports moisture balance and that there is no dry gauze in the wound.

### Wound Care Education and Health Promotion

Education is a vital component of a nurse's care of patients, particularly when the nurse is preparing the patient for discharge. Education should include the patient and their family members. Continuity of care, whether it is the patient going home or being transferred to another facility or unit, is essential to promote healing and prevent infection or worsening complications. Education may also be taught during home care. Education may include at-home wound care and pressure injury prevention.

Patients and their families should be taught about risk factors for pressure injuries, how and where these injuries may arise, and prevention strategies. Any instructions or illustrations provided should be written at a level the patient can understand and in their preferred language. Other education should include proper hand hygiene before and after care as well as the signs and symptoms of infection.

Education and health promotion should include adequate nutrition and hydration to promote wound healing. The nurse should assess for any deficiencies and make recommendations as needed. Regular visits with the provider should also be encouraged, which allows the provider to oversee the progression and quality of wound healing. This also allows the provider to make changes to the healing and wound care processes, as needed. If the patient complains of pain associated with wound care, the nurse should educate the patient on using pain medication thirty to sixty minutes before wound care is provided.

## PATIENT CONVERSATIONS

### Nutrition Education to Support Wound Healing

**Scenario:** A nurse is providing discharge education to a patient with a stage III pressure injury that will be transitioning to the outpatient wound clinic. During the education, the nurse realizes that the patient does not currently intake enough protein.

**Nurse:** All right. So, we have covered everything in your discharge plan. I would like to go more in depth with you about nutrition to ensure we are promoting your healing process. Is that okay?

**Patient:** Sure. I guess I just don't understand why it matters.

**Nurse:** Nutrition is vital in the healing process. When your body does not have adequate nutrition, it struggles to promote the adequate healing process. Things like protein, vitamin C, and fluids are important to intake in adequate amounts. If you have any deficiencies, it may lead to further skin breakdown, electrolyte imbalances, inadequate circulation, and swelling. All of those either slow healing or inhibit it all together. Does that make sense?

**Patient:** It does. I drink about 100 ounces of water a day, and I take a daily vitamin. How do I know if I am getting enough protein in?

**Nurse:** That is a great question. This actually varies from person to person. Studies have shown that wound healing requires 1.5 grams of protein per kilogram each day (Saghaleini et al., 2018). So, I see here that you weigh 155 pounds and that would equate to 106 grams of protein a day. You can either write down what you eat or track it in an app on your mobile phone to ensure you meet that daily goal.

**Patient:** Oh, like that MyFitness Pal my daughter put on my phone?

**Nurse:** Yes sir. Have you used it before?

**Patient:** Well, I played with it when she first installed it. It seems pretty easy. I just stopped using it when I was in the hospital.

**Nurse:** Okay. Do you need help using it at all?

**Scenario follow-up:** The patient got his phone out and opened the app. The patient was able to input various food items with little assistance. This return demonstration allowed the nurse to assess that the patient was able to perform this task.

**Nurse:** I am glad you are able to use the app. If you do not want to use an app, you can always keep a handwritten food journal. What kind of protein do you usually enjoy eating?

**Patient:** Steak or any kind of beef, cheese, and pork.

**Nurse:** Okay, do you enjoy chicken, eggs, or any dairy products?

**Patient:** Yeah, I do, and I do eat those.

**Nurse:** Great. Those are also great sources of protein as well as nuts, seeds, nut butters, beans, lentils, and edamame.

**Patient:** Oh, I do enjoy a lot of those as well. Sometimes I only eat breakfast and dinner, so I do not think I get 106 grams of protein in a day. I just have not been hungry lately.

**Nurse:** You can supplement your diet with things like protein shakes or drinks to aid boosting your protein intake. I have a list here that I am going to send you home with. It includes protein and other food groups that support wound healing.

**Patient:** That will be great. My wife would like that.

**Nurse:** Of course.

---

Any education provided to the patient and their family should be evaluated. The patient and family should verbalize understanding or give a return demonstration. The patient or family should be encouraged to participate in wound care, so that the nurse has a chance to reinforce or confirm proper care techniques.

### Teaching Self-Care at Home

Teaching self-care at home should cover supplies, infection prevention, and wound healing. Supplies should be easily attainable so the patient can perform care at home. The nurse should consider cost and ease of use when making recommendations on how the patient can obtain supplies. Most supplies are available from a medical supply store, discount store, drugstore, or pharmacy. The patient may have preferences in regard to the location of the store to their home. Insurance companies may reimburse or provide financing for supplies, so the nurse should encourage the patient to follow up with their insurance provider.

Infection prevention is paramount with wound healing because infection can slow wound healing or cause further complications. The nurse should provide education on proper hand hygiene, glove usage, and wound care steps. The patient and family should be educated on signs and symptoms of infection and when to notify the provider. Signs and symptoms include fever, flu-like symptoms, increased pain, thick drainage with a foul odor that may be yellow tinged, and red or separated wound edges. The education should also include instructions on proper disposal of old dressings (e.g., putting old dressings in a plastic bag and placing it in the trash bin).

Wound healing self-care should focus on promoting optimal healing. The education should cover balanced nutrition high in protein and vitamins as well as drinking at least forty-eight to sixty-four ounces of hydrating fluids. Rest periods should be encouraged during the day to avoid overexertion or injury. The patient may also need modifications surrounding their activities of daily living until the healing is complete. The provider may have restrictions or recommendations to follow, which should be taught to the patient. The family should be educated as well to be able to help the patient and ensure compliance. Patients who struggle with an altered body image or difficulty coping with the wound and activity restrictions may benefit from counseling in a group setting or with a one-on-one therapist.

## Summary

### 24.1 Structures and Function of the Skin

The epidermis, dermis, and hypodermis are the three distinct layers of the skin. The epidermis is the outermost portion and is made up of stratified epithelial cells. The dermis is the second layer of skin that consists of elastic connective tissue made up of collagen. The bottom layer, the hypodermis or subcutaneous tissue, anchors the skin to the underlying tissues. The functions of the skin include protection, thermoregulation, sensation, absorption, elimination, and vitamin D production. These functions each play a major role in maintaining health and homeostasis of a person. The skin has psychosocial effects and serves to aid in identification. Assessment findings may vary among cultures and ethnicities, developmental levels, and age groups.

### 24.2 Skin Integrity

Normal healthy skin is based on the age, ethnicity, genetics, and health condition of the patient. Patients are at risk of impaired skin integrity if they have risky lifestyle and behavioral factors (e.g., poor nutrition, activity levels, sexuality, illicit drug use, body piercings, tattoos). State of health (e.g., illnesses, medications, mobility status) and genetic (e.g., vitiligo, acne, melanoma, psoriasis, eczema) factors may also pose a risk. Common skin disorders include bacterial infections, viral infections, fungal infections, inflammatory reactions, and skin cancers. Common bacterial infections of the skin include impetigo, folliculitis, carbuncles, and cellulitis. Viral skin infections include herpes simplex, herpes zoster, and verruca. Common fungal skin infections include tinea that affects the feet and toes, beard, body, groin, and scalp. Parasitic skin infections include pediculosis that affects the body, scalp, and groin, and scabies. Inflammatory skin reactions include eczema, seborrheic dermatitis, urticaria, acne vulgaris, psoriasis, and SLE. Skin cancer has three main types: basal cell carcinoma, squamous cell carcinoma, and malignant melanoma. People with impaired skin integrity may need to make lifestyle modifications to promote healing. Nurses must take age-related and cultural factors into consideration when developing a plan of care and educating patients, their family members, or their caregivers to promote skin health.

### 24.3 Wound Classification

Wounds are classified in several ways and include intentional or unintentional wounds (treatment and therapy or accidental), open or closed wounds (break in the skin or under the skin layers), acute or chronic wounds (follow normal healing process or healing is delayed and does not follow normal healing process), pressure injuries, and friction and shear. Pressure injuries are localized ischemic lesions of the skin and underlying tissue caused by external pressure that impairs blood and lymph flow. Friction and shear are mechanical forces that tear and injure blood vessels and can contribute to the development of pressure injuries.

Risk factors for pressure injury development include exposure to excessive moisture, malnutrition and dehydration, lack of mobility, and cognitive factors. Moisture weakens the skin integrity and makes it more susceptible to breakdown and infection. Malnourishment leads to cell damage, inadequate perfusion, and lack of padding for bony prominences. People who have mobility issues or are bedridden are unable to adjust themselves in response to pressure and are often in one position for a prolonged period of time. Those with altered mental status and who have decreased awareness (e.g., unconsciousness, sedation, dementia) are at risk because they are less likely to recognize and respond to the discomfort from pressure.

Depending on the extent of damage, pressure injuries are assessed and classified as stages one through four and as deep tissue or unstageable. A stage I pressure injury is characterized by localized nonblanchable erythema of intact skin. Stage II pressure injuries are characterized by partial-thickness skin loss involving the epidermis or dermis. Stage III pressure injuries are characterized by full-thickness skin loss in which the adipose, granulation, and deeper tissues are visible and may have a presence of slough or eschar. Stage IV pressure injuries are characterized by full-thickness skin loss with extensive destruction, necrosis, and exposed or palpable fascia, tendon, ligament, muscle, cartilage, and bone. Slough and eschar are often visible along with epibole, undermining, and/or tunneling. Deep-tissue pressure injuries are characterized by persistent, nonblanchable areas of intact skin that have maroon, deep red, or purple discoloration. Pressure injuries are classified as unstageable if they have full-thickness skin or tissue loss with excessive slough or eschar that obscures the extent of the damage.

## 24.4 Wound Healing

Wound management encompasses many nursing interventions that are essential for promoting healing and tissue regeneration. To effectively manage wounds, nurses must understand the phases of wound healing, factors affecting wound healing, psychological effects of wounds, complications affecting wound healing, and the nurse's role in wound care management. Wounds are healed by primary, secondary, or tertiary intention. Wound healing can be broken down into the following phases: hemostasis, inflammatory phase, proliferation phase, and maturation. Several factors may influence the speed of wound healing and may be localized or systemic. Localized factors are those factors that occur directly in the wound (i.e., desiccation, maceration, trauma, edema, infection). Systemic factors are not related to the wound itself. These factors take place throughout the body (i.e., age, venous insufficiency, poor oxygenation, obesity, diabetes, medications, smoking and alcohol use). Wounds and pressure injuries cause stress and emotional challenges caused by pain, fear, disruption to activities of daily living, and an altered body image that can have a significant effect on an affected person's self-identity and mental well-being. There are several events that can interfere with wound healing and cause complications. Infection, hemorrhage, dehiscence and evisceration, and fistulas can increase the risk of death or generalized illness, increase healthcare costs, and prolong the need for healthcare interventions. The nursing role includes assessment and documentation, positioning, dressing care, drain care, suture and staple care, cleaning, debridement, administering growth factors, heat and cold therapy, wound care education and health promotion, and teaching the patient to perform self-care at home. Other therapies that the nurse may be required to assist with include hyperbaric oxygen therapy and surgery. It is essential that nurses understand their role in wound care management to effectively implement interventions within their scope of practice.

### Key Terms

**abrasion** an area damaged by scraping

**acne vulgaris** a common inflammatory skin reaction caused by bacteria, dead skin cells, or dried sebum that clogs hair follicles and prevents sebum from passing up through the pores

**acute wound** a wound that occurs suddenly and progresses through expected stages of healing

**angioedema** swelling of the face, lips, throat, or airways

**angiogenesis** process where capillaries grow across the wound increasing blood supply and oxygen

**apocrine gland** correlates with the hair follicles present in the perineum, axillae, and areolae of the breasts

**arrector pili muscle** triggers hair follicles on the body to flex causing the hair to rise up

**arthrofibrosis** scar tissue formed around a joint during the healing process, which limits range of motion

**autolytic debridement** using occlusive dressings to enhance the body's own defense mechanisms to liquefy or soften necrotic tissue

**avulsion** a forcible tearing off of skin or another part of the body

**basal cell carcinoma** the most common skin cancer that is generally found on the head or neck; it may be serious but is not usually fatal

**blackhead** flesh-colored, small bump with a dark center

**blanching** temporary whitening or lightening of the skin around the wound site upon applying pressure

**Braden scale** pressure injury risk assessment tool used across healthcare settings to evaluate the relative risk of a patient developing skin breakdown and pressure injuries

**bullae** large blisters

**bullous impetigo** type of impetigo that has large, flaccid bullae on the skin that rupture and leave a thin brown crust

**burn** injury to the skin caused by thermal, electrical, chemical, or electromagnetic energy

**carbuncle** cluster of skin abscesses connected to one another below the surface of the skin; often form when one or more hair follicles are infected

**cellulitis** localized infection and inflammation of the skin and tissues that are immediately beneath the skin

**chronic wound** no healing occurs for at least three months

**closed wound** does not have a break in the skin and occurs under the skin's surface

**collagen** whitish protein substance that adds flexible strength to the wound

**comedone extraction** use of a comedone extractor by a healthcare professional to remove blackheads and whiteheads by incising the pore and then using gentle pressure around the pore opening with a wire loop

**contusion** a region of injured tissue or skin in which blood capillaries have been ruptured

- cystic acne** lesions that are usually large, red, painful, and pus-filled nodules that merge under the skin and often leave scars
- debridement** removing slough or necrotic tissue and foreign material by various methods
- defensin** has antimicrobial and/or cytotoxic properties and is part of the body's first immune defense
- dehiscence** partial or total rupturing of a sutured wound
- dermatosis papulose nigra** small dark or skin-colored bumps on the face, neck, and upper torso; common in people with darker skin colors
- dermis** the layer of skin below the epidermis connected to the epidermis by dermal papillae
- desiccation** unintentional wound or tissue dehydration
- diabetic neuropathy** nerve damage that causes numbing sensations
- disseminated zoster** herpes zoster rash that affects three or more dermatomes
- eccrine gland** located over the skin entirely, secrete sweat, and aid in thermoregulation
- ecthyma (also, deep impetigo)** a skin infection that occurs deep inside the skin characterized by shallow, small ulcers that look punched out and may contain pus
- eczema (also, atopic dermatitis)** rash characterized by itchy, chronic inflammation of the upper skin layers; associated with a heightened immune response
- edema** swelling caused by excessive buildup of fluid in tissue spaces or a body cavity
- emollients** ingredients that soothe skin dryness
- enzymatic debridement** applying commercially prepared enzymes that accelerate the body's autolytic process (cell breakdown by enzymes contained in the affected tissue)
- epibole** rolled or curled-under wound edges that slow or stop the wound healing process
- epidermis** the outermost layer of the skin consisting of epithelial cells
- erythema** reddening of the skin
- eschar** dead tissue that forms over healthy skin and then, over time, falls off or sheds
- evisceration** protrusion of the viscera through the incision when the wound completely separates
- excoriation** loss of the superficial layers of the skin, also known as a denuded area
- filiform wart** long, small, narrow growth that appears on the lips, face, or eyelid
- fistula** an abnormal passage from one internal organ or vessel to another or an internal organ or vessel to the outside of the body
- flat wart** may appear in an area that is shaved or along a stretch mark
- fluctuance** tense area of skin with a wavelike or boggy feeling on palpation
- folliculitis** an infection of the skin follicle
- friction** two surfaces rubbing against each other
- genital wart (also, condyloma acuminata, venereal wart)** occurs on the vagina, vulva, cervix, and penis
- granulation tissue** delicate, new reddish connective tissue and tiny blood vessels that bleed easily but provide the framework for scar tissue development
- hematoma** localized collection of blood under the skin that may appear reddish blue with swelling
- hemostasis** cessation of bleeding
- herpes simplex** viral infection that can cause painful blisters or ulcers
- herpes zoster (also, shingles)** maculopapular rash associated with shingles; most often appears on the trunk of the body along a thoracic dermatome
- hydroxylation** the chemical process in which a hydroxyl group (-OH) is introduced into an organic compound
- hyperpigmentation** darkened patches of skin (liver spots)
- hypodermis** the subcutaneous fatty layer beneath the dermis that anchors the dermis to the underlying tissues of the body
- hypopigmentation** lighter patches of skin (age spots)
- hypoproteinemia** abnormally low amounts of serum protein from the diet
- impetigo** highly contagious bacterial skin infection that forms pustules and yellow crusty sores
- incision** a surgical cut made in skin or flesh
- intentional wound** a planned wound; the result of a treatment or therapy
- keloid** a thick fibrous scar caused by excessive collagen formation in response to trauma or a surgical incision
- keratin** fibrous water-repellant protein gives the epidermis its strong, protective quality
- keratinization** a thickening of plasma membranes of a cell

- keratinocyte** cell that produces keratin
- laceration** deep cut or tear in the skin or flesh
- Langerhans cell** antigen-processing cell that determines the appropriate response to, for example, inflammation, or tolerance of a foreign substance
- localized wound healing factors** affects wound healing directly (desiccation, maceration, trauma, pressure, excessive bleeding and edema, infection)
- maceration** softening of tissues caused by prolonged wetting or soaking
- malignant melanoma** the most dangerous type of skin cancer that originates in the melanocytes
- mechanical debridement** applies external physical force to remove debris or necrotic tissue
- melanin** dark brown to black pigment protects the keratinocytes and nerve endings from ultraviolet light damage that appears in the skin and hair
- melanocyte** cell that produces melanin and keratinocyte
- Merkel cell** found in the stratum basale and serves as a sensory receptor for light touch
- mitotic activity** the degree in which a population of cells proliferates
- Mohs procedure** layers of the skin are removed and examined for cancer cells until no signs of cancer remain
- Montgomery straps** ties that attach to an adhesive backing that holds a dressing in place
- mosaic wart** wart that grows in a cluster
- nonbullous impetigo** type of impetigo that has pustules that rapidly break down and form thick adherent honey-colored crusts on the face and extremities
- NPO** nothing by mouth
- open wound** a break in the skin or mucous membranes caused either intentionally or unintentionally
- palmar wart** wart on the palm of the hand
- papillary layer** thin, dermal layer of the dermis composed of loose connective tissue, which contacts the epidermis
- parasite** an organism that lives in or on an organism of a different species and depends on the host for nutrients
- pediculosis** lice infestation
- pediculosis capitis** lice infestation of the scalp
- pediculosis corporis** lice infestation of the body
- pediculosis pubis** lice infestation of the hairs of the anal and genital areas but can also infest the thigh, chest, and facial hair
- penetration** wound caused by an object that pierces the skin and lacerates or damages adjacent tissue
- perspiration** (sweat) excess water and salts that are eliminated from the body via sweat glands
- phagocytosis** occurs as leukocytes and macrophages move into the interstitial space to ingest bacteria and cellular debris
- photodynamic therapy** using lasers and chemicals on the skin
- pimple** has a small area of red skin and can be painful or cause discomfort
- pityriasis** any of various skin conditions characterized by dry scaling patches of skin
- plantar wart** wart on the sole of the foot
- post-inflammatory hyperpigmentation** temporary pigmentation that occurs after an injury or inflammatory skin condition, most commonly seen in people with darker skin types
- pressure injury** a localized ischemic lesion of the skin and underlying tissue caused by external pressure that impairs blood and lymph flow
- primary intention healing** type of healing in which the wound edges have been approximated with little to no tissue loss and show formation of nominal granulation tissue and scarring
- prodromal state** period between the appearance of initial symptoms and the full development of an illness causing headache, malaise, chills, or photophobia
- pruritis** itching
- psoriasis** a recurring, chronic skin condition that causes one or more raised areas of red skin patches with silvery scales and a distinct border
- puncture** wound made by a pointed object
- pustule** similar to a pimple but contains white or yellow pus
- Raynaud syndrome** a condition that causes pale or blue fingers with cold exposure
- reticular layer** thick, dermal layer of the dermis that consists of dense connective tissue and collagen bundles and

houses most of the sweat glands, sebaceous glands, hair follicles, hair, muscles, blood vessels, and deep sensory neurons

**scabies** contagious skin infestations caused by a burrowing mite

**sebaceous gland** secretes sebum, an oily substance that makes the hair and skin waterproof

**seborrheic dermatitis** inflammatory skin reaction primarily on the scalp and face

**secondary intention healing** healing process of extensive wounds that have significant tissue loss making approximating edges difficult or not a good option

**shear** when one tissue layer slides over the other

**slough** a nonviable layer of dead tissue that is stringy, moist, and yellow, tan, gray, green, or brown in color

**squamous cell carcinoma** the second most common type of skin cancer that generally develops on sun-exposed areas but can grow where sun exposure is limited

**stable eschar** area of eschar on the skin that is adherent, dry, and intact without fluctuance

**stratum basale** (stratum germinativum) deepest layer of the epidermis that contains melanocytes and keratinocytes

**stratum corneum** thickest and outermost layer of the epidermis that secretes defensins as part of the body's first immune defense

**stratum granulosum** layer above the stratum spinosum that contains a glycolipid, which slows water loss across the epidermis

**stratum lucidum** layer of skin only found in thick areas like the soles of the feet and palms of hands

**stratum spinosum** layer above the stratum basale; contains cytoplasmic processes (spines) that extend outward and contact neighboring cells

**subcutaneous tissue** the subcutaneous fatty layer (hypodermis) beneath the dermis that separates the skin from the underlying tissue

**superinfection** secondary infection that is unrelated to the original infection and results from opportunistic colonization after immunosuppression

**systemic lupus erythematosus (SLE)** a chronic autoimmune inflammatory disorder involving connective tissues of the joints, skin, kidneys, mucous membranes, and blood vessel walls

**systemic wound healing factors** occurs throughout the body and is not related to the wound itself (e.g., age, venous insufficiency, poor oxygenation, obesity, diabetes, medications, smoking or alcohol use)

**telangiectasia** red mark on the skin caused by the widening of shallow blood vessels

**tenting** the skin does not snap back when pinched; instead, it maintains a tentlike shape, which may indicate dehydration

**tertiary intention healing** delayed primary intention where the wound is left open for three to five days to allow edema or infection to resolve or to let any exudate to drain

**tinea (also, ringworm)** may be found on the feet, beard, body, groin, scalp, or toes

**tinea barbae (also, beard ringworm)** fungal infection of the beard

**tinea capitis** fungal infection of the scalp

**tinea corporis** fungal skin infection of the arms, trunk, legs, and face

**tinea cruris** fungal infection of the groin

**tinea pedis (also, athlete's foot)** fungal infection of the feet

**tinea unguium (also, onychomycosis)** fungal infection of the toenail or fingernail

**transdermal administration** placed on the skin and absorbed either locally or systemically

**ulcer** open sore caused by poor blood flow

**unintentional wound** a wound from an unexpected trauma

**urticaria (also, hives)** rash of raised, swollen, flesh-colored or red bumps or welts on the skin

**varicella (also, chickenpox)** caused by the varicella-zoster virus

**venous insufficiency** failure of the veins to adequately circulate the blood, especially from the lower extremities

**verruca (also, warts)** raised or flat growths caused by the viral infection human papillomavirus

**vesicles** small blisters

**vitiligo** chronic autoimmune disorder that causes partial or total loss of skin color in patches

**whitehead** flesh-colored small bump that does not have a dark center

**wound** an injury that causes a disruption of normal skin or tissue integrity

**xerosis** skin dryness

## Assessments

### Review Questions

1. What term would the nurse document when describing the depth of a laceration through the second layer of skin?
  - a. Langerhans
  - b. keloid
  - c. keratin
  - d. dermis
2. Which layer of the epidermis is only present in the soles of the feet?
  - a. stratum basale
  - b. stratum granulosum
  - c. stratum lucidum
  - d. stratum spinosum
3. What is the primary function of the skin?
  - a. protection
  - b. store and release fat
  - c. vitamin B production
  - d. digestive enzyme production
4. The nurse is educating a patient on how their skin helps with temperature regulation. The nurse explains to the patient that when the body temperature decreases, the blood vessels do what?
  - a. vasoconstrict to increase blood flow
  - b. vasoconstrict to decrease blood flow
  - c. vasodilate to increase blood flow
  - d. vasodilate to decrease blood flow
5. The nurse caring for a dark-skinned patient knows that the patient is more susceptible to which of the following?
  - a. freckles
  - b. keloids
  - c. skin cancer
  - d. sunburns
6. The pediatric nurse is educating a new mother on risk factors that may contribute to her young infant's risk for hypothermia. What statement from the mother would suggest that she understood the teaching?
  - a. "My child is at risk for hypothermia because he has a lesser amount of subcutaneous tissue, meaning his blood vessels are farther away from the surface."
  - b. "My child is at risk for hypothermia because he has more subcutaneous tissue, meaning his blood vessels are farther away from the surface."
  - c. "My child is at risk for hypothermia because he has more subcutaneous tissue, meaning his blood vessels are closer to the surface."
  - d. "My child is at risk for hypothermia because he has a lesser amount of subcutaneous tissue, meaning his blood vessels are closer to the surface."
7. What is an example of a lifestyle choice that is a behavioral risk factor for impaired skin integrity?
  - a. diabetes
  - b. illicit drug use
  - c. medication use for congenital heart disease
  - d. impaired mobility

8. A 67-year-old patient presents to the clinic with redness, edema, and fluid-filled vesicles on the right leg that is hot to the touch. The patient also complains of pain and tenderness. The patient's heart rate is 110 and temperature is 100.8°F (38.2°C). The nurse should suspect what skin abnormality?
- folliculitis
  - carbuncles
  - impetigo
  - cellulitis
9. The nurse is caring for an adult who has just been diagnosed with shingles. What statement from the patient would suggest that she understood the teaching?
- "Varicella lies dormant after having the vaccination or chickenpox. It can reactivate later in life and present as shingles."
  - "Shingles can only occur if you have had the varicella vaccine."
  - "I had chickenpox as a kid, so I should not be getting this virus."
  - "Shingles only affect women."
10. You are educating a patient on preventing skin cancer. What statement from the patient would suggest that she understood the teaching?
- "I will only go to the tanning salon twice a week."
  - "I will avoid the sun from 9 a.m. to 1 p.m. when the ultraviolet rays are the strongest."
  - "I will wear protective clothing like long sleeves, hats, and sunglasses, and use sunscreen at the lake this weekend."
  - "I will use a sunscreen that has an SPF factor of five or greater."
11. What is *not* a benign skin change found in older adults?
- cherry angiomas
  - wrinkles
  - carbuncle
  - melasma
12. Identify an example of an intentional wound.
- bullet
  - stab wound
  - surgical incision
  - fracture
13. The nurse recognizes that what factor does not put a patient at risk for pressure injury development?
- altered mental status
  - loss of appetite
  - advanced age
  - weightlifting
14. Maceration can be defined as:
- loss of superficial layers of the skin
  - tissue softened by prolonged wetting or soaking
  - tissue hardened by pressure
  - tissue that has development of slough
15. The nurse is assessing a patient with a deep red area of intact skin that does not blanch. At what stage of pressure injury is this classified?
- stage I injury
  - deep-tissue injury
  - unstageable injury

- d. stage II injury
- 16.** The nurse is educating a new graduate nurse on pressure injuries. What statement from the student would suggest that she understood the teaching?
- “The difference in stage III and IV pressure injuries is the visibility of fascia, tendon, ligament, muscle, cartilage, and bone.”
  - “Slough and eschar are present at every stage.”
  - “If the area blanches, it is stage I.”
  - “A diabetic ulcer is also called a deep-tissue pressure injury.”
- 17.** During which phase of the healing process do leukocytes move into the interstitial space to ingest bacteria and cellular debris?
- hemostasis
  - inflammatory phase
  - proliferation phase
  - maturation phase
- 18.** The nurse is explaining complications associated with wound healing to a new patient at the clinic. How should the nurse describe maceration?
- occurs when hydration leads to cell death
  - occurs when there is trauma the wound
  - occurs when there is swelling that interrupts blood flow
  - occurs where the cells are overhydrated, leading to skin softening and breakdown
- 19.** What nursing intervention is appropriate when performing a dressing change?
- administering pain medication prior to wound care when the patient states that wound care is painful
  - telling the patient that they just need to look at the wound
  - explaining to the patient that the smell from the wound is not that bad
  - encouraging the patient that they do not have to make any changes in their activities of daily living
- 20.** What type of debridement promotes the body’s own defense mechanisms?
- enzymatic debridement
  - mechanical debridement
  - autolytic debridement
  - wet-to-dry debridement

### Check Your Understanding Questions

- Describe the layers of the skin, including name, location, and primary function.
- Describe the layers of the epidermis.
- Which skin condition is shown in the picture?

(credit: “Basal Cell Carcinoma” by National Cancer Institute, Public Domain)

- basal cell carcinoma
- pustule
- tinea corporis
- verruca

4. Describe intentional and unintentional wounds.
5. Describe closed and open wounds.

### Reflection Questions

1. What information should a nurse include when educating a caregiver about administering transdermal medications to their loved one at home?
2. Describe how the skin provides protection.
3. What information might you consider when assessing whether a patient is at risk of developing a pressure injury?
4. What information should you consider when preparing education for self-care at home?

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #4: Part 5](#).  
How would you perform a Braden scale assessment on the patient?
2. Refer to [Unfolding Case Study #4: Part 6](#).  
What is the purpose of using a nonadherent gauze dressing as opposed to another type?

### What Should the Nurse Do?

1. The nurse is caring for a patient with malignant melanoma that has metastasized to the brain, spine, lungs, and liver. The patient states they do not want any medical treatment or interventions. What should the nurse do?

The nurse on an intensive care unit is caring for an 83-year-old female admitted for a urinary tract infection and sepsis. The patient has been in a nursing home following a cerebrovascular accident resulting in right-sided weakness and paresthesia. The patient appears to be malnourished with sunken skin over bony prominences. During the shift assessment, the nurse notes a reddened area of intact nonblanchable skin on the sacral areas. The head of the bed is elevated because the patient is at risk of aspiration with feedings.

2. How would the nurse assess the skin?
3. What factors increase this patient's risk of skin breakdown?
4. What things can the nurse do to prevent further damage and promote healing?

### Competency-Based Assessments

1. Prepare a fifteen-minute presentation on the anatomy of the skin.
2. Prepare a fifteen-minute presentation on the functions of the skin.
3. Develop an infographic comparing bacterial infections of the skin.
4. Prepare a script for teaching a patient with a dark skin tone about the types of skin conditions more prevalent in people with darker skin.
5. Describe key points the nurse would teach the patient about wound management at home.

## CHAPTER 25

# Hygiene

**FIGURE 25.1** Patient hygiene is of paramount importance in all healthcare settings and has significant implications for both patient well-being and infection control. Maintaining proper hygiene practices for patients helps prevent the spread of infections, enhances patient comfort, and contributes to overall health. (credit: modification of “U.S. Navy Sailors perform medical care at Billings Clinic Hospital 211113-A-PE084-003” by Navy Medicine/Flickr, Public Domain)

### CHAPTER OUTLINE

25.1 Hygienic Practices

25.2 Factors Affecting Hygienic Practices

25.3 The Nurse’s Role in Hygiene

**INTRODUCTION** You are a nurse assessing an 87-year-old patient in a care facility who has very limited mobility. Your patient welcomes you in while ambulating with a walker and slowly removes some items from a chair, signaling for you to sit. As you strike up a casual conversation to build rapport, you begin to observe their disheveled appearance. You notice their unkempt hair, soiled clothing, rough skin, and dirt under some of their fingernails. Your sense of smell detects body odor, indicating a lack of bathing and oral care. Evaluating patient hygiene is important to determine how well a patient can care for themselves or how well someone is caring for them. Good hygiene is necessary for health, comfort, personal well-being, and safety.

## 25.1 Hygienic Practices

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the importance of good hygiene practices
- Describe hygiene-related diseases
- Recognize the impact good hygiene has on mental health

The term **hygiene** is defined as the measures or practices conducive to preserving health and preventing disease

through cleanliness. The self-care measures one would perform to preserve their own health are called **personal hygiene**. Examples of personal hygiene include handwashing, bathing, brushing and flossing teeth, as well as washing and combing hair. These measures may seem like basic tasks; however, they are essential procedures that aid in preserving one's health. Hygiene practices promote **medical asepsis**, also known as the clean technique, inhibiting the growth and spread of disease-producing microorganisms. Hygiene practices may vary among individuals and cultures. Allowing patients to perform self-care tasks as independently as they can for the purposes of preserving the patients' quality of life, self-worth, and autonomy is crucial to maintaining the individual's self-esteem and independence (both present and future). Performing self-care tasks also allows the nurse to determine the patient's ability to perform activities of daily living (ADLs) during recovery while the patient is working toward discharge. Patients may often need assistance, so the nurse's responsibility is to oversee the patient's privacy as well as their ability to adequately perform the various hygiene tasks. For instance, some circumstances may be presented when the patient is fully dependent on the nurse to aid in necessary bathing, elimination, bed making, oral care, or any other tasks. Nurses aiding patients with hygiene have an obligation to respect individual patient preferences while providing the care that the patient should not or is not able to provide for themselves. In addition, nurses should take into consideration the patient's physical and emotional well-being.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Patient-Centered Care

**Definition:** Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs.

The nurse will:

- Examine common barriers to active involvement of patients in their own healthcare process.
- Describe strategies to empower patients or families in all aspects of the healthcare process.
- Respect patient preferences for degree of active engagement in care process.
- Integrate understanding of multiple dimensions of patient-centered care: patient/family/community preferences and values, coordination and integration of care, physical comfort and emotional support, involvement of family and friends, and transition and continuity.

---

## Benefits of Good Hygiene Practices

Good hygiene practices include not only personal hygiene but also those measures that may require a nurse's or an aid's full or partial assistance. Hygiene practices promote medical asepsis and prohibit the growth of pathogenic microorganisms, which leads to decreased chances and/or incidence of infection. Good hygiene can not only protect an individual from becoming ill but can also prevent individuals from spreading diseases to others. Good hygiene also promotes self-esteem and can boost a patient's mood, resulting in improved mental health.

### Skin

The skin is the largest organ and the body's first line of defense. This organ provides a barrier to protect the body from invasion of bacteria or other potential environmental hazards. The skin houses various functional body structures, such as the capillaries, vessels, and glands. For example, the dermis layer of the skin contains sebaceous glands. These glands release **sebum**, an oily secretion that hydrates and protects the skin. It is important to note this glandular function, as inadequate hygiene may lead to excess sebum and skin breakouts. Proper hygiene practices can help promote and maintain skin integrity. Regular exfoliation and cleansing can promote smoother, softer, and more even-toned skin, slower aging, and boost circulation. In turn, these measures allow the skin to properly perform the functions of protection, sensation, heat regulation, excretion, secretion, and absorption. Each function plays a pivotal role in maintaining homeostasis and preserving the individual's health. For example, when the skin integrity is intact, the skin is able to prohibit the entry of pathogens, prevent water loss, and reduce the absorption of harmful chemicals or substances (World Health Organization, 2020). In addition, the regular practice of skin hygiene allows for early detection and intervention of abnormal skin growths that may appear.

The **skin breakdown** refers to damage or injury to the skin and underlying tissue due to prolonged pressure, friction, shear, or moisture. Examples of skin breakdown include burns, scrapes, cuts, blisters, and pressure injuries. Factors

associated with skin breakdown include immobility, certain medications, incontinence, altered mental status, loss of sensation, or inadequate nutrition. Therefore, the crucial maintenance of proper skin hygiene in the healthcare setting must be ensured. Any skin breakdown that develops after a patient is admitted to a facility becomes the healthcare facility's responsibility, including the financial burden for the treatment and recovery of the skin injury. Preventing skin breakdown through good skin hygiene can result in optimal healing of a patient's skin and prevent an increase in healthcare costs, length of stay, and patient discomfort.

### Hair

The hair is also part of the integumentary system and is found all over the body, except the palms of the hands and soles of the feet. Hair is a large part of the integumentary system and has several functions. First, hair has a protective function. By trapping bacteria, debris, and harmful particles, the hair does not allow these offensive agents to enter the skin. Hair also blocks sunlight from the scalp, protecting against excess exposure to ultraviolet radiation. Hair provides warmth by trapping air close to the skin. Hair grows from the skin and when the skin produces sebum, it can build up on the hair shaft. An overabundance of sebum can build up if the hair or body is not regularly washed. A common skin condition is folliculitis, which happens when hair follicles become inflamed; it can occur when the hair follicles become infected due to the buildup of sebum. When the scalp of the head is not regularly washed, dead skin, product residue, sweat, and dirt may also build, which results in an increased risk for infection, unpleasant odor, and greasy hair. In addition, prolonged periods of not washing the hair on the head can damage hair and impede its ability to grow. When the body is not regularly washed, the overproduction of sebum found on the skin can lead to oily skin or acne. Proper hair hygiene supports reducing those risks and aids in reducing bacterial and fungal growth. Bacteria and fungus can cause conditions such as ringworm, which is a common fungal infection of the skin, hair, or nails.

### Nails

The nails are also part of the integumentary system. Proper nail hygiene prevents the spread of infection through bacteria hidden under the fingernails. Additional benefits of nail hygiene include preventing fungal infections under the nails, reduced risk of ingrown nails, and promoting proper nail growth. Therefore, proper cleaning under the fingernails and keeping the nails trimmed using clean tools are essential practices. Another benefit of properly trimmed nails is the minimized risk of lacerations that can result from a patient using unkept nails to scratch themselves or others.

### Oral Cavity

Good oral hygiene aids in maintaining the mouth, gums, lips, and teeth. Regular teeth brushing removes plaque, bacteria, and food particles to prevent tooth decay. These measures also massage the gums, help break up tissue or bacteria, increase blood flow, and relieve discomfort caused by unpleasant odors and tastes. Proper oral hygiene promotes digestion and gum health, and it can affect one's overall health status. For instance, bacteria found in gum disease from poor oral practices can travel through the body, triggering infection and inflammation in heart valves. Good oral hygiene can also provide a patient with a sense of well-being and positive self-esteem, resulting in improved mental health. A condition expressed by foul-smelling breath, **halitosis**, can be considered embarrassing and impede someone's desire to speak or smile. Without adequate oral care, patients who are taking nothing by mouth (NPO) can experience negative outcomes that include aspiration pneumonia. Those patients who are NPO or on ventilators need frequent oral care to prevent ventilator-associated pneumonia. Oral hygiene can stimulate an appetite by increasing salivary flow, which supports proper chewing to break down food. Proper oral hygiene also prevents diseases such as gingivitis or periodontitis, which will be discussed later in this chapter.

## LIFE-STAGE CONTEXT

---

### Life Span Considerations for Older Adults

As the body ages, there is a decrease in saliva production, which can lead to dry mouth, tooth decay, a sore throat, and difficulty swallowing. Saliva contributes to the overall oral health by washing bacteria and food particles from the mouth. Maintaining oral hygiene as a patient ages is especially important and may require more frequent brushing at home. For example, the caretaker or older adult may want to add oral care after meals in addition to morning and night cleanings. Good oral hygiene practices promote the preservation of the older adult's ability to eat

by promoting the production of saliva to stimulate the appetite. In addition, proper oral hygiene maintains oral health and dentition to be able to chew and digest food. Because the saliva contributes to overall oral health by washing food particles and bacteria from the mouth, proper oral hygiene promotes dental health and maintains dentition. The better oral health patients have throughout their life, the greater the probability that these individuals will have functioning teeth with aging. To promote good dental hygiene practices, it is important to educate and encourage patients in establishing dental care routines. These practices include proper denture hygiene, such as cleaning dentures with a denture brush daily followed by placing the dentures in a cleansing soak overnight.

---

### Perineum

Perineal care includes the genital and rectal areas of the body. Because the perineal area is warm, dark, and moist, these areas become an optimal breeding ground for bacteria. Good perineal hygiene prevents infections such as urinary tract infections, removes discharges, eliminates bad odor, promotes comfort, alleviates itching, and reduces the risk of chafing and skin rashes. Perineal hygiene is of particular importance during menstruation, after bowel movements, postpartum, and when hemorrhoids are present.

### LINK TO LEARNING

---

The Centers for Disease Control and Prevention (CDC) has a [quick reference for hygiene and personal hygiene facts, tips, and other resources \(https://openstax.org/r/77HygieResource\)](https://openstax.org/r/77HygieResource) and is a great source to share with patients to aid with patient education and self-care.

---

### Hygiene-Related Diseases

Poor hygiene can include infrequent bathing or washing of hair, inadequate oral care, wearing soiled clothing, and untrimmed or dirty nails. Poor hygiene can result in infections as well as various hygiene-related diseases, such as tooth decay, scabies, pinworm infection, ringworm, trachoma, otitis externa (swimmer's ear), urinary tract infection (UTI), sepsis, gingivitis, and periodontitis.

Many diseases and conditions of the body systems can be prevented or controlled through regular hygiene practices. These practices include brushing teeth and routinely washing parts of the body and hair with soap and water. Implementing and encouraging regular body washing and oral care can prevent the spread of hygiene-related diseases outlined in [Table 25.1](#).

Body System	Hygiene-Related Disease or Condition	Image

**TABLE 25.1** Common Diseases Caused by Poor Hygiene

Body System	Hygiene-Related Disease or Condition	Image
Sensory	Swimmer's ear, <b>otitis externa</b> , is an infection of the outer ear canal that runs from the eardrum to the outside of the head and is often caused by water remaining in the ear after swimming.	 <p>(credit: "Otitis externa" by Klaus D. Peter/Wikimedia Commons, CC BY 3.0)</p>
	Bacterial infection of the eyes is called <b>trachoma</b> .	 <p>(credit: modification of work by Tim Kubacki/Flickr, CC BY 2.0)</p>
Urinary	A <b>urinary tract infection (UTI)</b> is an infection of any part of the urinary system: urethra, bladder, or kidneys.	 <p>(credit: "Pus in urine in a severe urinary tract infection" by John Campbell/Flickr, Public Domain)</p>

**TABLE 25.1** Common Diseases Caused by Poor Hygiene

Many hygiene-related diseases can continue to progress if left untreated. For example, gingivitis can be treated and resolved. However, untreated gingivitis can lead to periodontitis, which is a severe stage of gum disease. As periodontitis worsens, holes form around the teeth, forming pockets. The infection and pockets can deepen as the jaw deteriorates until teeth become loose and fall out. This type of infectious process can even lead to an earache. However, with proper oral hygiene and dental care, both gingivitis and periodontitis can be prevented or resolved.

### Hygiene's Impact on Mental Health

Poor hygiene can be a sign of self-neglect and is often accompanied by depression or other mental disorders. Those with obsessive-compulsive disorder may overindulge in hygiene practices, which can take up much of their time as well as lead to skin breakdown or pain, depending on their compulsions. As previously discussed, poor oral hygiene can lead to tooth decay or bad breath. This can have a negative impact on self-esteem as one may be embarrassed

to smile or socialize with others.

Good hygiene and self-care practices can improve mood, decrease stress levels, provide a sense of well-being, and prevent or limit anxiety. These measures can also boost an individual's self-esteem and confidence. Good hygiene also supports a positive impact on relationships as hygiene impacts attraction and physical intimacy.

## REAL RN STORIES

---

### Assisting with Hygiene

**Nurse:** Stephanie, RN

**Clinical setting:** Acute care hospital

**Years of experience:** 5

**Facility location:** Texas

One day, I walked in to perform a shift assessment on a patient. I noticed that the patient appeared gloomy or worried. I asked her if she would like to discuss what seemed to be worrying her. She stated that her daughter was coming to visit her for the first time since admission, and that her daughter had never seen her ill before, and that she was worried about her appearance. I asked what time her daughter was arriving and if she would like to have a bath before the daughter arrived. The patient appeared excited and stated that a bath would be great. The patient suggested a time for bathing, as well as what preferences she had in assistance with the bath. I returned with towels, soap, shampoo, lotion, a comb, a toothbrush, and toothpaste. The patient required minor assistance, so I helped her with the bath, washing the areas she couldn't reach, and styling her hair. Upon completion, the patient was smiling and even making jokes. She told me she felt better after the bath and was now looking forward to, instead of dreading, the visit from her daughter.

---

## 25.2 Factors Affecting Hygienic Practices

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe population differences contributing to personal hygiene practices
- Identify physical factors impacting personal hygiene practices
- Identify psychological factors impacting personal hygiene practices

Hygiene measures and practices can promote health and prevent disease. These measures and practices may differ among various groups and people. It is important to remain culturally sensitive when encountering preferences that may differ from your own. The term cultural sensitivity is defined as recognizing and acknowledging that cultural differences exist among people and showing respect and appreciation of others' beliefs, values, practices, and perspectives. Respecting patient differences and preferences in hygiene practices while remaining unbiased is essential to the nursing practice. Nurses must also remember to provide care and education to patients in a nonjudgmental manner.

### Population Differences in Hygiene Practices

Cultural practices or behaviors, socioeconomic status, developmental level, and personal preferences are factors that influence an individual's hygiene practices. These factors may differ greatly from one individual to the next. Understanding these differences and factors that impact how an individual practices personal hygiene is important as a nurse. Nurses may need to modify care and education to meet the needs of the individual patient.

#### Cultural Preferences

Cultural factors can strongly influence hygiene practices and patient preferences. Identifying those variations and their impact on a patient's personal hygiene is crucial. Nurses can identify cultural variations by asking the patient about their normal hygiene routines. The nurse should also explain that the reason for asking is not to be offensive, but rather to understand their practices, reminding the patient about the impact hygiene can have on an individual's physical and mental health. The nurse may need to ask specific questions such as, "How do you clean and take care of your body?" or "Tell me about your oral hygiene routines."

Cultural preferences may impact hygiene practices in terms of frequency and the type of products used. For example, people in some cultures place a high emphasis on daily bathing; otherwise they feel unclean. There are other cultures in which people may bathe only once a week. In addition, there are some cultures that also consider the use of products to mask body odor essential, while other cultures may deem those products as unsafe and view body odor as pleasant rather than unpleasant. Learned behaviors, such as touch, are also culturally significant. Some cultures may find touch offensive, which is important for the nurse to remember. Asking for permission before touching a patient when helping with hygiene practices is crucial to remember as well. The nurse should keep in mind that some cultures practice communal versus private bathing. Some cultures may prefer the same sex nurse assist with hygiene. Nurses are not to stereotype hygiene preferences based upon one's culture; rather, nursing personnel should ask the patient about their preferences and beliefs to provide care that aligns with the patient as an individual.

## CULTURAL CONTEXT

---

### Cultural Considerations and Personal Hygiene

Personal hygiene is especially important to East Indian Hindu culture. To many individuals from this culture, a daily bath is a religious duty. Some Hindus believe that bathing after a meal will result in an injury. Some Hindus also believe water that is too hot will injure their eyes. When preparing a bath, these persons may also believe that hot water can be added to cold water but not vice versa. Once the individual has completed the bath, they must carefully and thoroughly dry the body. Personal hygiene practices can differ among individuals and communities, even within the same religious group. Additionally, modern lifestyles and urbanization may influence personal hygiene habits that differ from the traditional cultural habits. For instance, cultural diffusion is the spreading out and merging of pieces from various cultures. This type of cultural shift is a common practice in today's ever-evolving society. Cultural appropriation, which is the exploitation of another culture's religion and/or cultural traditions, can be found offensive by some and should be avoided by the nurse. Understanding and respecting these cultural and religious practices is essential for providing culturally sensitive care and fostering positive interactions with people from the East Indian Hindu culture.

---

### Socioeconomic Status

A person's socioeconomic status and financial resources often influence the type or extent to which hygiene is practiced. An individual's socioeconomic status and finances often impact the resources available. Financial limitations may impact the ability to obtain clean clothing or toiletries but could also influence water usage or access. Sometimes a person may have to make a choice between buying food to feed their family and purchasing personal hygiene products. Another example of financial limitations is homelessness. An individual may only be able to access a public bathroom, which limits choices to the type of soap and water that is available. Oftentimes, a public bathroom has only a sink with no shower or privacy. Therefore, the person experiencing homelessness is limited to how much of their body can be cleaned at one time.

### Developmental Level

Hygiene practices are behaviors that most people learn as children from family members or others surrounding them. Those behaviors may include frequency and/or time of day in addition to feelings of modesty and nudity. Infants are dependent upon others for hygiene needs, but as children grow into adolescents, they may become more concerned with personal appearance while adopting individual practices. For example, adolescents may become aware of their body odor and develop preferences for using deodorants or body sprays. The teen may even acknowledge the need to bathe more frequently and make an autonomous choice to practice such a regimen. Adolescents also tend to prefer privacy, performing independent hygiene rather than in the presence of others. Therefore, hygiene education may be impacted when a parent is present. The nurse may need to ask the parent to step out of the room in order to offer privacy for the young adult, properly identify preferences, and provide any needed education.

A person's developmental level can negatively impact hygiene practices if the ability to understand proper hygiene practices is impaired or limited. A child who wants to be independent may want to perform their own hygiene but may not be able to effectively apply the proper measures to achieve this goal. Older adults may experience mobility

limitations that impact the frequency of bathing or ability to reach all areas of the body.

### Personal Preference

Personal preference is a significant factor in a person's hygiene practices. Considering a person's preferences when scheduling or aiding with hygiene is important. Some preferences may include bathing in a bathtub versus using a shower, morning bathing versus evening bathing, and the types of soaps, shampoos, conditioners, toothbrushes, toothpastes, cloths, or loofahs used to facilitate the individual's body cleaning. A person's sexuality and self-concept may also impact their hygiene practices. For example, sexually active women may use a variety of feminine hygiene products after intercourse to promote cleanliness.

Frequency of hygiene practices are influenced by a patient's personal preferences, possibly stemming from cultural influences, social practices, or hygiene education. Some people prefer to bathe daily, wash their hair every other day, and perform oral care twice a day. Still others may prefer a different frequency schedule. Hair and nail care frequency preferences may depend on nail length or appearance, which a person may use to gauge when they feel that care is warranted. For example, a person who prefers their nails a certain length may use nail length as their cue to perform nail hygiene. Hair preferences may also vary among individuals. Some people prefer the hair a certain length and will use hair length as a cue to get a haircut. Some individuals may prefer their hair to be free of oils and will use the level of oil in the hair as a cue to wash their hair. Also, some people prefer to have a clean-shaven face and will shave or trim the facial hair to keep it at the desired length.

The timing of hygiene practices is also influenced by a patient's personal preferences. Some patients prefer bathing at the beginning of the day to perk themselves up while others prefer the end of the day, finding bathing to be relaxing instead. Oral care timing preferences may include upon waking, prior to sleeping, or even after meals. For example, a person with braces may perform oral care after every meal to decrease food build up and odors. In the hospital setting, the timing may also be impacted by any tests or procedures scheduled for the patient. This timing could be due to the required prewashing with or without specialized products prior to certain diagnostics.

## PATIENT CONVERSATIONS

---

### What If You Think Your Patient Is Refusing a Bath?

**Scenario:** A medical-surgical nurse was completing rounds to assess patients' hygiene needs. The nurse notices their 62-year-old patient had an odor, food stains on his face and gown, and soiled hair.

**Nurse:** Hi, Mr. Thomas. I hope you enjoyed your breakfast. Would you like to schedule a bath this morning?

**Patient:** Well, no. I only like to bathe at night. I like to be clean before I get into bed. My mom always told me when you go to bed without a shower, you're taking your whole day to your sheets.

**Nurse:** Okay, Mr. Thomas. I understand. I will make a note of your request, so that the night shift staff can assist you with your bath.

**Scenario follow-up:** The nurse pulls up the patient's chart in the patient room to document the patient's request and noticed that for the last three days, the patient had refused a daytime bath. There was no documentation of the patient's request for a nighttime bath, so the nurse wondered if the patient was refusing a bath overall.

**Nurse:** Mr. Thomas, have you told any of the other nurses that you prefer a nighttime bath?

**Patient:** Well, the first day I just told them no, but I did tell them on the second day I was here that I like nighttime baths. The night nurse never asked me about it though. I just assumed they were too busy.

**Nurse:** I am sorry about that. I just put in your request for a nighttime bath in the computer and will also make a note on the bath schedule at the charge nurse's desk. We can always do a bath this morning to get you caught up if you'd like.

**Patient:** No, dear. I can wait until tonight. I wouldn't mind just washing my face for now though.

**Nurse:** We can absolutely do that. Would you like a new gown in the meantime as well?

**Patient:** Sure. I would like that in case anyone comes to see me today.

**Nurse:** Okay, great. Is there anything else you would like to do this morning for hygiene?

**Patient:** No. I already brushed my teeth this morning.

**Nurse:** Okay. I will get your bath set up for you tonight. Is there anything you need before I leave the room?

**Patient:** No, I think I am good.

**Nurse:** Okay, well I will send in Suzie (unlicensed assistive personnel, UAP) to come help you with washing your face and getting you a new gown. Let me put your call light within reach, and you can always call us if you need us while we aren't in here.

**Patient:** Thanks a million.

**Scenario follow-up:** The dayshift nurse made a note on the bath schedule at the nurse's station and in the patient's chart. The UAP helped the patient get set up to wash his face and provided the patient with a new gown. At shift change, the nurse also informed the night shift nurse of the patient request. The patient received his bath that night and his linens were also changed. The charge nurse was also aware of the situation and provided education to all nurses to ensure they are marking patient preferences in the chart and on the bathing schedule as well as communicating any special requests to the appropriate shift nurses to ensure patient requests are being met.

---

## Physical Factors Affecting Personal Hygiene

A person's physical condition will greatly impact personal hygiene. Mobility status and health state are important for a nurse to identify when caring for a patient and planning the individual's hygiene care.

### Mobility Impairment

People with mobility impairment have limited hygiene measures and options. For instance, paralyzed patient may require a bed bath performed by another person. Identifying the best practices for this patient and a hygiene schedule to protect their skin, increase comfort, and control odor is important. Providing a bath every day ensures a comprehensive skin assessment can be conducted, and taking extra steps to reposition more frequently will promote circulation as well as improve skin integrity.

### Health Status

The status of a person's health plays an important role in any plan of care. Injury, surgery, or disease can diminish an individual's capability or the desire to perform hygiene. With hygiene, a patient in the late stages of an illness may lack the energy or dexterity to perform their own personal hygiene. Some diseases may incapacitate or exhaust a patient, thus warranting the need for the caregiver to perform all aspects of this practice. For example, a person with serious pulmonary conditions may not be able to tolerate activities and may require a great deal of assistance.

## Psychological Factors Affecting Personal Hygiene

Psychological factors that may affect personal hygiene include cognitive diseases as well as an individual's mental health status. The psychological factors will impact a person's ability to perform hygiene as well as the patient's motivation for or memory of these practices. It is imperative the nurse assess for any psychological factors that might inhibit a person's personal hygiene habits.

### Cognitive Diseases

Some cognitive diseases or disorders that may affect personal hygiene include Alzheimer disease, attention deficit disorder, autism, intellectual disabilities, substance use disorder (SUD), and multiple sclerosis. Careful consideration by the nurse is necessary when planning hygiene for persons with any type of cognitive diseases or disorders due to the impact on a person's memory, focus, visual perception, abstract reasoning, and ability to learn or perform hygiene practices. For example, a person with a developmental disorder may struggle to learn the importance of self-care as well as how to perform the task. Patients with Alzheimer disease may lose the ability to remember to perform hygiene, struggle with emotions, and become agitated.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Recognize and Analyze Cues

Before recognizing cues, nurses must make sure enough information about a patient's situation has been gathered and assessed before interpreting the information and developing a plan of care. For example, an individual with Alzheimer disease may struggle to perform hygienic activities. This person may also struggle to regulate emotions, becoming upset or embarrassed about being undressed in front of someone else. The patient may feel rushed or confused when being coached in performing various hygiene measures. The nurse must observe the patient and recognize the individual's Alzheimer disease stage of progression. In addition, the nurse must analyze the person's cues and assess the patient's ability to perform hygiene. A person's readiness to receive assistance in order to develop the patient's individual plan of care must also be considered.

### Mental Illness: Depression

Hygiene can be greatly impacted by depression. People with depression may struggle with self-esteem and the motivation to perform hygiene measures. Depression may cause fatigue and cognitive effects such as negative thought patterns, memory problems, and brain fog. Individuals with depression may also struggle with executive dysfunction that impacts their ability to maintain hygiene and carry out the practices.

### Body Image

Body image can also impact hygiene. People with depression often have a negative body image or do not care about their image. Those individuals with a negative body image may possess this image due to body shape, body size, or feelings of being ugly. A negative self-image can lead to stress regarding the undressing involved in the process of bathing. Often, patients experiencing this situation will avoid normal hygiene practices. The person with a negative body image may notice an improvement in self-esteem after performing hygiene or may lack the desire to perform hygiene. Those people with a positive body image may have the drive to establish and commit to a good hygiene routine in order to maintain the image of themselves in their mind.

## 25.3 The Nurse's Role in Hygiene

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the steps for assisting with patient hygiene
- Analyze differences related to hygiene in the older adult
- Recognize how nurses can use education to promote healthy hygiene habits

The nurse must assess the patient's preferences, physical limitations, and cognitive status in order to analyze, develop, and promote a hygiene and health plan of care. Patients who are completely independent, require some assistance, or are fully dependent on the nurse or nurse's assistant to complete hygiene practices are all factors needing consideration. A nurse's priority when scheduling hygiene is to ensure the patient's safety. This section will focus on the steps for assisting patients with hygiene, the differences related to hygiene in older adults, and how nurses can promote healthy hygiene habits through education.

### Steps for Assisting with Patient Hygiene

When assisting the patient with hygiene, the nurse must integrate the individual's preferences into the plan of care. Determining the patient's normal practices through inquiry are variables that influence hygienic practices. Those variables may include the person's health status, physical limitations, mental health state, cultural beliefs, and personal preferences. The nurse must also assess the appropriateness of these practices to conclude whether the patient has the attitude, skills, resources, and knowledge to carry out the measures independently or if assistance is required for this purpose. The nurse performs a physical assessment to determine the adequacy of the patient's hygiene practices. For the recognized practices to be deemed inadequate, a distinct health threat must exist. For example, upon examining the oral cavity, if gingivitis or periodontitis is visible, the patient may be at a higher risk for conditions such as heart disease, stroke, arthritis, and diabetes if left untreated.

For patients with intravenous (IV) access, the bag of IV fluids and IV tubing may be threaded through the sleeve of

the gown to keep the system intact. There are covers available to keep the site dry during bathing. Dressing changes for the IV must follow facility protocols. Finally, the nurse must try to preserve the patient's privacy throughout the bathing process. To accomplish such privacy, a nurse should reveal only the areas about to be cleaned and keep the rest of the body covered, ensuring the door and/or curtains remain closed. The nurse needs to encourage the individual to perform all tasks as independently as appropriate. Using the bath or various hygienic procedures is an excellent opportunity for the nurse to assess the person's skin, cognition, and mobility status. These simple tasks can reveal subtle changes in the patients' status and allow for early intervention.

In addition, whether the individual is conscious or not, the nurse or UAP must introduce themselves and always inform the patient of what is about to happen and why. This will hopefully prevent any surprises, obtain consent, and complement the nurse's professional demeanor. Research suggests that unconscious patients may hear what others are saying. Nurses who continue to introduce themselves and explain procedures before proceeding will decrease the stress on the individual through their journey to consciousness in a strange and foreign environment.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Patient-Centered Care

**Definition:** Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs.

The nurse will:

- Integrate understanding of multiple dimensions of patient-centered care: information, communication, and education; involvement of family and friends; patient/family/community preferences and values; coordination and integration of care; physical comfort and emotional support; and transition and continuity.
  - Assess own level of communication skill in encounters with other members of the healthcare team as well as patients and families.
  - Communicate patient values, preferences, and expressed needs to other members of the healthcare team.
  - Communicate care needed and provided at each transition in care.
  - Value continuous improvement of own conflict resolution and communication skills.
  - Describe strategies to empower patients or families in all aspects of the healthcare process.
  - Respect patient preferences for degree of active engagement in care process.
- 

### Delegation Considerations

The execution of hygiene practices may be delegated to a nurse's assistant, UAP, or a licensed vocational nurse. The term delegation in nursing is shifting the responsibility of tasks to another person while remaining accountable for the outcome. For example, the nurse may delegate a stable patient's bath to a UAP if and only if the bath is meant for cleanliness and not for assessment of skin or patient condition. Safe and proper delegation allows the registered nurse to attend to more complex patient care needs, such as medication administration or head-to-toe assessments, helps control cost for the organization and advances the skills of nursing assistive personnel. The patient's needs and health status plus the qualifications of the person the task is being delegated to must all be carefully evaluated. The nurse must have the proper qualifications prior to delegating: skills, experience, competency, and education. The person the nurse is delegating the tasks to must also have adequate education, skills, training, experience, and evidence of competency. [Table 25.2](#) summarizes the National Council of State Boards of Nursing (2016) Five Rights of Delegation.

Right	Definition	Example
Right task	The activity coincides with the person's job description or is part of the written policies and procedures of the practice setting.	The nurse can ask a UAP to brush a patient's teeth but not to give medication.
Right circumstance	Appropriate patient setting, available resources, and other relevant factors are considered.	The nurse may ask the UAP to provide a bed bath for a stable patient. The nurse should ask for the UAP to not provide a bed bath when the patient is in severe physical distress, as the nurse should perform the patient's hygiene themselves.
Right person	Delegating the right task to the right person to be executed on the right person	The nurse may ask a unit secretary to call for supplies needed for the bath, such as special surgical wipes, but not ask the unit secretary to bathe the patient.
Right directions and communication	Clear, concise description of the task, including its objective, limits, and expectations	The nurse asking to be notified if the blood pressure is "abnormal" following the patient's bath is not appropriate. The nurse should ask the UAP to notify them if patients' blood pressure is above 130/80 or below 100/60 after the bath, in order to give clear expectations.
Right supervision and evaluation	Apt monitoring, evaluation, intervention, when necessary, and feedback	The nurse may ask the UAP to chart a patient's response to hygiene care if the patient is alert, awake, and oriented because the outcome is expected. The nurse may not ask the UAP to evaluate a patient's response to hygiene care if the patient is confused and unstable because the outcome is unexpected, and this type of evaluation is out of their scope of practice.

**TABLE 25.2** The Five Rights of Delegation

### Oral Care

Care of the oral cavity, **oral hygiene**, helps preserve a healthy state of the lips, gums, teeth, and mouth. Brushing the teeth removes plaque, food particles, and bacteria as well as massages the gums and alleviates any discomfort that may be caused from tastes or unpleasant odors. Patients should be encouraged to brush their own teeth when possible. Independent individuals should be offered supplies to also carry out personal hygiene needs as appropriate. If the patient is unable to do so independently, the nurse or appropriate delegate (i.e., the person who is delegated a responsibility by the nurse) will need to assist with or perform the oral care for this individual.

Patients who are unable to perform their own oral care may require care every one to two hours, if and as necessary. Individuals who are either unable to breathe through the nose or are mouth breathers will need more frequent oral care. More frequent care will ensure that the integrity of the oral mucous is maintained. The nurse must ensure that available suction equipment is available to prevent aspiration, raise the head of the bed to 30–45 degrees, use suction to remove excess fluid/secretions, routinely moisten the mouth, and apply lip balm to prevent lips from cracking.

Teeth should be brushed twice a day and the mouth should be rinsed with water after meals. The toothbrush should be soft-bristled and reach all the teeth. Automatic toothbrushes may be adequate substitutes for patients with arthritis or other conditions that impair their ability to brush adequately. Because the toothbrush cannot reach the areas between the teeth, flossing is recommended once a day to remove food particles and plaque. Water picks, pressured water spray units, and cone-shaped brushes may be used when patients are unable to use floss or perform their own oral hygiene. Toothpastes and other powders aid in the brushing process. Mouthwashes may also be used to reduce bacteria, plaque, tartar, and gingivitis. Many mouthwashes also freshen breath and can protect tooth enamel.

### Denture Care

Artificial teeth not permanently implanted, called **dentures**, are the patient's personal property and must be handled with care. Dentures should soak in a labeled, enclosed cup to be stored when not being worn. Many patients do not wear dentures when sleeping, and dentures must be removed for surgeries or other diagnostic procedures. Many patients also prefer to wear dentures as soon as waking or coming out of a procedure to avoid embarrassment due to feeling self-conscious without them. If the patient goes long periods of time without wearing the dentures, the gum line may change and affect the fit of the dentures. It is also recommended that dentures not be worn twenty-four hours a day, seven days a week. Patients are usually familiar with the necessary care of dentures to prevent infection and irritation, and prefer to perform denture care according to standard practice at home.

### Eyes, Ears, and Nose

Special attention is given to care of the eyes, ears, and nose due to the sensitivity of these areas, and taking exceptional care to avoid injury is important. The nurse should ask the patient about any specific care the patient normally performs in relationship to the eyes, ears, and nose. For example, some people prefer using cotton swabs to clean the outer parts of the ears. The nurse should also be aware of any use of hearing or visual aids, such as eyeglasses, hearing aids, or contacts. The nurse should also ask the patient about any history or treatments of eye, ear, or nose problems.

The circular areas around the eyes are usually cleaned during the bath with the use of a clean washcloth, moistened with warm water. Soap may cause burning or irritation, so avoiding soap around the eyes is advisable. The eye should be cleaned from the inner to outer canthus. A separate section of the rag should be used each time to avoid the risk of spreading infection. If the patient has dried exudate (dried or crusty fluid) that is not easily loosened, try placing a damp gauze or cotton ball on the lid margins to loosen secretions. Avoid applying direct pressure over the eyeball as this may cause injury. Remove any exudate from the eyes carefully and as often as needed to keep the eye clean. Unconscious patients may require more frequent eye care due to the buildup of secretions from the absence of the blink reflex.

The ears are also cleansed during a shower or bed bath. The ear canal should be cleaned with a gentle rotation using a moistened washcloth. A cotton swab is useful for cleaning the pinna or outer aspects of the external ear. Educating patients to never use toothpicks, cotton swabs, or any other device to clean the internal auditory canal is important, as the tympanic membrane can easily be damaged through this action.

Care of the nose includes clearing secretions. Most patients are able to gently blow into a disposable paper tissue. The individual should avoid harsh blowing as this can cause pressure capable of injuring the nasal mucosa, sensitive eye structures, and the tympanic membrane. The patient should blow with both nostrils open to avoid forcing debris into the eustachian tubes. If the external nares are crusted, a warm, moist compress may be used to help soften and remove any exudate. A moist washcloth or cotton swab may be used to clean the opening of the nares but should never exceed past the nares to avoid injury.

## Contacts and Glasses

Eyeglasses are often expensive and are the patient's personal property. Therefore, eyeglasses should be stored in a case or bedside drawer when not in use to prevent damage or loss. Eyeglasses may require special cleaning with the use of cloths made of soft microfiber, cleansing solutions, or lens wipes. Washcloths, paper towels, and tissue paper should be avoided because they can scratch the lenses.

Various types of contact lenses are available, ranging from daily, weekly, or even monthly use. Some patients may sleep in contact lenses, while others cannot or prefer not to leave these lenses in the eyes overnight. The nurse must assess the type of contacts the person wears and any preferred special care measures. Several products are available for lens care, such as saline solutions and hydrogen peroxide solutions. Most patients will prefer to care for their own lenses but should not wear these contacts if unable to independently insert and remove the lenses. Contacts should remain clean and sterile. Reusable lenses should soak in a solution of the owner's choosing when not in use to keep the lens from drying out. Hand hygiene when inserting or removing contacts is essential to prevent infection. A towel may be placed in the sink to prevent a dropped contact from accidentally falling into the drain.

## Hearing Aids

Hearing loss is a common health problem. The ability to hear impacts a person's ability to communicate and react appropriately to things in their environment, and many patients have hearing aids (Figure 25.2). The care of hearing aids includes battery care, proper insertion, and routine cleanings. The nurse should determine the patient's normal method of cleaning the hearing aids. In addition, the nurse should assess the quality of the patient's hearing with the use of the devices to ensure effectiveness and functionality. The hearing aids should not be used when water exposure is a risk to avoid damage to the devices. When hearing aids are not in use, the devices should be labeled and stored in a case or a safe place to avoid damage or loss. The battery should also be removed or turned off when not in use to preserve the battery life. The hearing aids may be cleaned with a dry, soft cloth.

**Styles of Hearing Aids**

**FIGURE 25.2** Hearing aids come in various styles. These supplemental devices work by using parts to amplify sound in an individual's environment and channel it into their ear. The parts include a microphone to detect the sound, an amplifier to make the sound stronger, a speaker to send the sound into the ear, and a battery to provide power to the electric parts. (Credit: modification of work "HearingAidTypes" by Wikimedia Commons, Public Domain)

## Hair

Hair care will depend greatly on the patient's preferences, culture, and physical and cognitive limitations. Hair should be shampooed as often as necessary or per individual preference. The brush and comb should be washed each time the hair is washed, or as appropriate. Prior to shampooing the hair, brush or comb the hair to stimulate the scalp and untangle hair. Whenever possible, encourage the patient to brush and wash their own hair. In the event regular shampooing is contraindicated for various conditions, bedside products such as foams, dry powders, or concentrates that do not require rinsing may be used. Shampoo caps are also available and should be warmed in the microwave if they are not stored in a warmer. Once the cap is on the patient's head, massage the hair and scalp to lather the shampoo per manufacturer's directions, and discard after use. Towel dry the hair after each type of cleansing, followed by combing and styling to the patient's preference. If the person requests, an electric razor can be provided. If a hair dryer is not appropriate or available, the hair should be covered with a towel until dry to minimize the individual becoming chilled. Some healthcare facilities, such as a skilled nursing facility, may have beauticians or barbers to assist with hair care but this does not dismiss the nurse of obligation.

Hair type should also be considered with hair care. For tightly curled hair, a wide-toothed comb is best to untangle the hair, working from the neckline to the forehead. This hair type may also prefer small braids that do not need to be undone for shampooing. Application of a lubricant oil should be applied to the braids to prevent hair breakage. Those individuals with alopecia and/or baldness should still cleanse and moisturize the scalp to prevent dryness. Dandruff may also be present and is not considered contagious or infectious. Dandruff and hair loss may be embarrassing for a patient, so the nurse must remain professional and preserve the person's dignity.

### Nails

Nails may harbor bacteria, so maintaining nail care to prevent the risk of infection or injury from scratching is crucial. Nurses must follow the agency's policy related to nail care, as some facilities do not allow nail trimming by clippers. If allowed, nails should be trimmed straight across then rounded at the tips in a gentle curve. The nails should not be trimmed too short as the skin and cuticles may become injured. Hangnails, which are broken pieces of cuticle, should be cut off with cuticle scissors and not torn or ripped off. Cuticles should be gently pushed back, after softening by washing with warm water, using a terry cloth or blunt instrument. A moisturizer or emollient may be applied to the nails and cuticle to prevent hangnails. The underside of the nails should be cleaned with a blunt instrument or nail brush. Damaging the area where the underlying tissue and nail are attached by being forceful is discouraged. Once the care is completed, a massage to the hands using lotion may increase blood flow and provide comfort.

### Feet

Feet also require special attention to prevent odors, injury, and infection. Poor care of the feet may result in conditions such as calluses, neuropathy, pain, ingrown toenails, or deformities (such as hammertoe). Feet may be cleaned in the shower or using a basin with tepid water and mild soap for bedside baths. The feet should not be soaked. Feet should be dried immediately after being washed. Lotion may be applied and massaged on the feet to promote circulation and provide comfort. In the presence of athlete's foot, an antifungal foot powder should be ordered and used for treatment. Toenails should also be kept short to minimize bacteria underneath the nail. Care of the toenails is very similar to the care of fingernails. In some facilities, only the registered nurse may be allowed to trim the toenails of patients with diabetes, using a nail file to reduce the risk of trauma or injury. The patient with diabetes may have reduced sensation in their feet and must be taught how to examine and care for the feet daily. Some patients may need to see a podiatrist for treatment of corns, calluses, or bunions. The nurse should also educate the individual or ensure the use of cotton socks for warmth and perspiration absorption, as well as the importance of properly fitting footwear to avoid complications.

## LINK TO LEARNING

The ADA provides a [reference for daily foot care tips \(https://openstax.org/r/77FootCareTips\)](https://openstax.org/r/77FootCareTips) as diabetes can alter a person's ability to feel pain, heat, or cold in their feet. This leaves an individual susceptible to injury or infection. Therefore, it is essential that the nurse educates the patient on proper foot care.

### Perineal and Vaginal Care

Care of the genitalia, called perineal care, is part of a complete shower or bath. Patients who are able to perform hygiene independently may prefer to cleanse on their own. Those persons not able to perform this practice independently may request someone of the same gender to assist with perineal care or a bath in general. This request must be communicated and followed as best as possible. Patients who require help may include those who have physical or cognitive limitations. Individuals who are postpartum, recovering from rectal or genital surgery, or have an indwelling catheter require meticulous care to avoid infection. Other instances that may also cause vaginal or perineal problems include douching, some sexually transmitted infection (STI), diabetes mellitus, and urinary or fecal incontinence. Maintaining a professional attitude, preserving the patient's dignity, ensuring privacy, and gaining permission to touch the patient is important when aiding in perineal care regardless of consciousness. The nurse needs to remember to always clean from the least contaminated areas to the most contaminated areas to prevent infection.

Sitz baths may also be used after childbirth, rectal surgery, or vaginal surgery. This treatment may also be used to relieve discomfort from a fissure or hemorrhoids. A sitz bath is most often performed on the toilet with a tub lining

the bowl. The tub is filled with three to four inches of warm, not hot, water. The patient will submerge the pelvic area for twenty to thirty minutes to aid in reducing inflammation. Other options for cleansing the perineal and vaginal areas of a patient who is postpartum include either a shower or sitting on a stool using a perineal irrigation bottle.

### Catheter Care

Catheters come in many forms, such as internal (indwelling and Foley catheters) and external (wick and condom catheters). For patients with an indwelling catheter, powders and lotions should be avoided after cleaning. Betadine, antibiotic, or other microbial cleaners should be avoided at the urethral meatus. Catheter care is usually performed after perineal care and is usually ordered twice daily. Nurses should pay close attention to how long the catheter has been inserted and request confirmation from the provider to remove the catheter as soon as possible if it needs removal. Prompt removal and precise cleaning can help to avoid an associated infection. According to the CDC, catheter-associated urinary tract infection (UTI) have been cited as the number one healthcare-associated infection (HAIs) (Werneburg, 2022). Patients with fecal incontinence may require more frequent cleanings. Nurses wear clean gloves and perform hand hygiene before and after caring for the patient. The catheter should always be cleansed gently from the meatus outward using mild soap and running water. Each stroke should use a clean portion of the washcloth or disposable wipe.

## LIFE-STAGE CONTEXT

---

### Menstrual Hygiene

Patients who experience menstrual cycles will need proper menstrual hygiene. There are various products available such as pads, tampons, cups, sponges, and padded underwear or briefs. Some cultures practice free bleeding. Assessing the patient's preferences for the type of products normally used for these purposes is important. Sanitary pads and briefs should be changed every few hours or more frequently depending on the menstrual flow. Tampons should be changed every four to eight hours or more frequently with heavier flows. Menstrual cups should be cleaned daily after use and can be sanitized by rinsing thoroughly and boiling in water for one to two minutes or per manufacturer guidelines. Period underwear should be washed per manufacturer instructions. The risks associated with improper menstrual hygiene can lead to yeast infection, toxic shock syndrome, rash, irritation, and impaired skin integrity. The nurse must assess the patient's knowledge and preferences, as well as provide education about menstrual hygiene.

Additionally, addressing period poverty is vital. Period poverty refers to the lack of access to affordable and adequate menstrual hygiene products, facilities, and education. Those affected by period poverty may experience significant discomfort and health issues due to inadequate menstrual management. This can include severe menstrual cramps, which can be exacerbated by improper use of menstrual products, and increased risk of infections such as bacterial vaginosis or urinary tract infections, often due to the use of unhygienic or makeshift menstrual products. Poor menstrual hygiene can also lead to skin irritation, rashes, and fungal infections, as well as toxic shock syndrome from the misuse of tampons. Beyond physical health problems, period poverty can hinder participation in daily activities and education due to embarrassment, stigma, or the inability to manage menstrual flow effectively. Supporting menstrual health equity involves advocating for better access to menstrual products, providing educational resources, and promoting policies that address these disparities. Integrating awareness of period poverty into patient care ensures that all individuals have the necessary resources for effective menstrual management, helping to prevent health issues and supporting broader public health outcomes (Jaafar et al., 2023).

---

### Special Focus on the Older Adult

Life span considerations for the older adult include age-related changes that require special focus and nursing strategies. Age-related changes include impaired physical mobility, impaired oral mucous membranes, and an increased risk for impaired skin integrity. Older adults are also more likely to become chilled when left uncovered during bathing. The room should be maintained at a warmer temperature, and drapes should be used during care to provide modesty and avert chilling. Older adults also may experience neurologic changes or impaired circulation that impede the ability to sense temperature changes in water. Using caution to prevent burns or injury to the skin is also important to remember. In addition, frequent bathing and use of soaps may have harmful effects on the skin.

### Age-Related Changes

Impaired physical mobility related to aging includes decreased dexterity and muscle strength, chronic conditions that compromise functional mobility, and decreased range of motion. Some examples of chronic conditions that compromise functional ability include heart disease, diabetes mellitus, rheumatoid arthritis (RA), coronary heart disease, chronic obstructive pulmonary disease (COPD), and osteoarthritis. Patients with deficits after a stroke, Parkinson disease, or other neurologic disorders may also experience physical limitations.

Part of the aging process also includes a loss of elasticity, reduced blood supply to connective tissue, and degeneration of epithelial cells that lead to impaired mucous membranes. Older patients are also likely to have impaired oral mucous membrane due to the decreased production of saliva and medications that cause dry mouth. For example, decongestants, antidepressants, antihistamines, blood pressure medications, Alzheimer disease medications, analgesics, and diuretics may cause dry mouth.

Older adults are also at risk for impaired skin integrity due to the loss of elasticity, thinning of the epidermis and subcutaneous fat, and dryness caused by decreased activity of oil and sweat glands. The older adult's nails may become opaque, brittle, scaly, tough, or hypertrophied. These skin-related changes may also be visible in the feet. Older adults are at an increased risk of friction shear and pressure ulcers due to age-related skin changes and impaired mobility.

### Nursing Strategies

Nursing strategies for patients with impaired physical mobility include ensuring patient safety. For example, grab bars, adequate lighting, and nonslip mats in the bathrooms should be available to reduce the chances of falling or injury. Providing frequent rest periods, and scheduling hygiene sessions after periods of rest can ensure the patient does not become overly exhausted. Older adults may benefit from adaptive hygiene devices such as a long-handled body sponge, shower chair, large or extended handled toothbrushes, and grab bars (Figure 25.3). Physical therapy, or exercise, and occupational therapy may also be needed to aid in activities of daily living and help patients retain their independence by improving their mobility and functionality.

**FIGURE 25.3** Grab bars are a great way to prevent falling in older adults who have balance issues. (credit: Untitled by Unknown/Flicker, CC BY 2.0)

Good oral hygiene measures may aid in the preservation of the older person's ability to eat and can also reduce the alteration in taste common with aging. Patients should be encouraged to have dental exams every six months and should avoid spicy, acidic, coarse, and sugary foods that may cause dental caries. Mouthwashes that contain alcohol should also be avoided. Nurses should also encourage or aid with brushing teeth with fluoride toothpaste twice a day. Dentures should be brushed twice daily and rinsed with cool water. Other strategies include rinsing the mouth after meals, examining the mouth daily to check for inflammation and lesions, and applying lubricant to lips.

Patients may have sugar-free gum or candies and salivary substitutes, such as mouth sprays, gel, swabs, dissolving tablets, or an oral rinse.

Maintaining skin integrity is essential to ensure the integumentary system is able to properly perform its functions of protection, sensation, heat regulation, excretion, secretion, and absorption. For example, the nurse can incorporate strategies for how hygiene can be tailored to keep the patient warm, such as keeping a blanket over the patient while exposing one body part at a time for personal care. The nurse can also perform bathing as quickly as possible and place a warm blanket on the exposed individual immediately after the bath. Because older adults are more susceptible to friction shear and other injuries, the bedding should be wrinkle free, clean, and dry. Draw sheets should be used when repositioning or moving patients to avoid skin injury as well. Water temperature for bathing should be monitored to ensure the temperature is tepid and not hot. Older patients who are able should use showers and avoid bathtubs as this method can dry out the skin. The skin should be rehydrated with lotions or emollients daily while avoiding excessive amounts. Any excessive amounts of lotions or emollients should be wiped off to avoid skin breakdown. Older adults should also be encouraged to drink hydrating fluids to aid in hydrating the skin. Because frequent bathing and the use of detergent soaps can be harmful to the skin, bathing should be regular but not every day and pH-balanced skin cleansers should be used.

### Promoting Health through Education

One of the most essential roles nurses have in disease prevention and health promotion is through education. The nurse should assess a patient's knowledge about hygiene as well as individual cultural and personal preferences. The nurse should educate people on the importance of good hygiene practices. For example, promoting medical asepsis prohibits the growth of pathogenic microorganisms, which leads to decreased chances of infections. In addition, good hygiene can aid in preventing the spread of diseases to others, promote self-esteem, and boost mood. Once the nurse assesses the patient's knowledge and ensures understanding, the nurse should educate the person on the steps needed to perform hygiene to avoid infection or injury. The nurse should also assess a patient's ability to perform care independently via performing a head-to-toe assessment. The nurse should reinforce proper steps as needed while educating and giving instructions on the importance of diet and nutrition to promote healthy skin and mobility.

## PATIENT CONVERSATIONS

---

### What If Your Patient Does Not Have Adequate Knowledge about Oral Hygiene?

**Scenario:** Nurse walks into the newly admitted patient's room to determine hygiene needs. The patient is a college student that has not seen a dentist in a few years and has red, inflamed gums.

**Nurse:** Hi, my name is Marie, and I am going to be your nurse today. Do you mind verifying your name and date of birth?

**Patient:** My name is Sarah Milton, date of birth December 4, 2003.

**Nurse:** Thank you. I am going to ask you a few questions about your personal hygiene. Is that okay?

**Patient:** What is personal hygiene? Like how I do my private care? I'm confused.

**Nurse:** Personal hygiene is the self-care measures you would perform such as bathing, brushing and flossing your teeth, hair care, and nail care.

**Patient:** Well, I let my roommate do my nails, since she is in cosmetology school. I shower almost daily and wash my hair every other day. I brush my teeth a few times a week and never floss.

**Nurse:** Okay, when was the last time you saw a dentist?

**Patient:** I don't know, maybe two or three years ago. I was still in high school, and my mom made me go.

**Nurse:** Have you ever had cavities, gingivitis, or any other dental issues?

**Patient:** I do not know what gingivitis is. My gums bleed when I brush them, which is why I do not brush as much. I

remember the dentist made me use a special mouthwash once. I had several cavities as a kid. I think I had to get fillings at almost every visit.

**Nurse:** Gingivitis is inflammation of the gums. If left untreated, it can lead to periodontal disease that can ultimately lead to loss of teeth due to infection and deterioration of the gums. If infection entered the bloodstream, it could also increase the chances of stroke, heart attack, or other serious events. Signs of gingivitis include swollen gums, reddened gums, gums that bleed easily with brushing or flossing, bad breath, and tender gums. I know you said your gums bleed easily. Do you experience any of the other symptoms?

**Patient:** Yeah, my gums are pretty tender. I have never looked for the other things though.

**Nurse:** Okay, do you mind if I examine your mouth?

**Patient:** Sure.

**Scenario follow-up:** Upon examination, the nurse noted a foul odor, visible food particles in the patient's mouth, and reddened, swollen gums.

**Nurse:** You do have reddened, swollen gums with food particles present. Food left in between teeth can cause irritation and inflammation. Flossing will aid in the removal of food particles, plaque, and tartar. Seeing a dentist for examination and professional cleaning to remove plaque, tartar, and bacteria regularly will aid in the prevention of dental issues as well. I will go over oral care with you and demonstrate the steps to perform twice a day as well as rinsing your mouth after meals. I will also provide you with a mouthwash to use while you are here.

**Patient:** Okay, great. Thank you. My parents did not tell me any of this. I do not want my teeth to fall out.

---

## Summary

### 25.1 Hygienic Practices

Hygiene measures can support health and prevent disease. Hygiene practices include but are not limited to the care of the skin, hair, nails, oral cavity, and perineal areas. The lack of adequate hygiene practices may lead to various hygiene-related diseases or infections such as lice (body, hair, and pubic), tooth decay, scabies, pinworm infection, ringworm, trachoma, swimmer's ear, urinary tract infection (UTI), gingivitis, and periodontitis. There are many benefits to adequate hygiene, such as preventing infection while preserving mental and physical health. Good hygiene and self-care practices may enhance mood, reduce stress levels, promote a sense of well-being, prevent or limit anxiety, boost an individual's self-esteem, and positively impact relationships.

### 25.2 Factors Affecting Hygienic Practices

There are various factors that impact a person's personal hygiene. Cultural practices, socioeconomic status, developmental level, and personal preferences greatly influence an individual's hygiene. These factors may differ from person to person. For instance, cultural preferences can greatly impact how a person performs hygiene in terms of products used, frequency, and touch. Socioeconomic status greatly impacts how hygiene is performed by an individual due to financial limitations, product availability, and access to bathrooms or water. Developmental level can impact personal hygiene throughout the life span. Children through older adults will experience changes in their bodies that may impact the skin, mobility, and effectiveness of performing personal hygiene. Personal preferences play a large role in someone's hygiene practices. Preferences may include timing, frequency, type of products used, use of bathtubs versus showers, nail length, hair length, and hair oiliness. Physical factors, such as a person's mobility status and health state, can potentially interfere with personal hygiene practices throughout one's life. Psychological factors, such as confusion, depression, mental health crises, or even stress from a negative self-image can also influence personal hygiene or prevent an individual from taking care of their body. Remembering to remain nonjudgmental when speaking with patients about personal hygiene practices and preferences is important for nurses. Keep in mind that hygiene or lack of hygiene can be indicative of a person's mental state.

### 25.3 The Nurse's Role in Hygiene

Prior to assisting with hygiene and health promotion, the nurse must analyze the patient's preferences, ability to perform or if and how much assistance is needed, and physical and cognitive status. The nurse must also consider the Five Rights of Delegation prior to delegating tasks: right task, right circumstance, right person, right directions and communication, and right supervision and evaluation. Hygiene practices should always include a baseline assessment to check for lesions, infections, secretions, or other impairments or abnormalities. The patient's privacy and dignity should also be maintained. The patient's dignity can be preserved by a professional, matter-of-fact attitude. Oral care may include flossing teeth and brushing teeth, gums, tongue, cheeks, and roof of mouth. It may also include denture care and mouth rinses. Careful cleaning is necessary for the eyes, ears, and nose to preserve their sensory functionality. Care may also be needed for contact lenses, eyeglasses, or hearing aids. Hair care will depend greatly on the patient's preferences and hair type. Nail and foot care should be carefully provided to avoid injury, and nails should be trimmed short to prevent injury or infection. Perineal and vaginal care must be carefully provided to avoid infection or other vaginal and perineal problems. Life span considerations for the older adult include age-related changes that require special focus and nursing strategies. Age-related changes include impaired physical mobility, impaired oral mucous membrane, and the risk for impaired skin integrity. Nurses can promote health through education by ensuring or reinforcing a patient's knowledge, ability, and skills to carry out hygiene tasks.

## Key Terms

**dentures** artificial teeth not permanently implanted

**gingivitis** inflammation of the gums or gingivae

**halitosis** persistent foul-smelling or bad breath

**hygiene** the measures or practices conducive to preserving health and preventing disease, particularly through cleanliness

**medical asepsis** techniques and procedures used to decrease the potential for the spread of microorganisms and infection

**oral hygiene** care of the oral cavity

**otitis externa** an infection or inflammation of the external ear canal, usually caused by water exposure or bacterial/fungal infections

**pediculosis** lice infestation

**periodontitis** marked inflammation of the gums that also involves degeneration of the dental bone and tissues

**personal hygiene** self-care measures one performs to preserve their own health

**pinworm** an intestinal worm that usually spreads when an infected individual scratches the anal area

**ringworm** a fungal infection of the skin or scalp

**scabies** a contagious skin infestation caused by a burrowing mite accompanied by extreme itching

**sebum** an oily secretion of the sebaceous gland

**skin breakdown** the damage or injury that occurs to the skin and underlying tissue due to prolonged pressure, friction, shear, or moisture

**tooth decay** visible cavities or holes in the outer surface of a tooth or enamel

**trachoma** a bacterial infection of the eyes

**urinary tract infection (UTI)** a bacterial infection affecting any part of the urinary system

## Assessments

### Review Questions

1. A nurse caring for patients in a long-term living facility knows that providing good oral hygiene is an essential part of nursing care. What is the benefit of providing oral hygiene?
  - a. It eliminates the need for flossing.
  - b. It compensates for poor nutrition.
  - c. It promotes a sense of well-being.
  - d. It decreases oropharyngeal secretions.
2. A nurse is scheduling hygiene for patients on the medical-surgical unit. What should be the nurse's priority consideration when arranging a patient's personal hygiene?
  - a. where the hygiene fits in with the nurse's schedule
  - b. the best time for the patient care technician to aid with the patient's hygiene needs
  - c. the patient's personal hygiene practices and preferences
  - d. the outside temperature
3. A patient presents to the primary care office with complaints of constant itching of scalp and hair. The patient states that they recently noticed insects in their hair after spending the day volunteering at a shelter. What does the nurse know the patient is more than likely experiencing?
  - a. pediculosis
  - b. dry scalp
  - c. folliculitis
  - d. gingivitis
4. What is true about older adults' saliva?
  - a. Older adults have a decreased production of saliva.
  - b. Older adults have an increased production of saliva.
  - c. Older adults have no change in saliva production.
  - d. Older adults have a change in the color of their saliva.
5. What is another term for the clean technique?
  - a. personal hygiene
  - b. surgical asepsis
  - c. medical asepsis
  - d. sepsis
6. What is *not* an example of hygiene personal preferences?

- a. time of day
  - b. frequency
  - c. shampoo brand
  - d. financial status
7. What can being aware that cultural differences and similarities between people exist without assigning them value be defined as?
- a. cultural sensitivity
  - b. cultural insensitivity
  - c. cultural diffusion
  - d. cultural appropriation
8. A 72-year-old patient with Alzheimer disease is a new admission to a long-term facility. The patient presents with an odor, soiled clothing, and greasy hair. What does the nurse need to consider prior to scheduling a bath for this patient?
- a. the last time the patient told the nurse they had a bath
  - b. where the patient is in their disease progression
  - c. the temperature outside
  - d. the patient's financial status
9. When aiding a patient who is paralyzed and bedridden, what does a nurse need to recognize that the hygiene will not do?
- a. decrease comfort
  - b. increase comfort
  - c. control odor
  - d. protect the skin
10. What is the top priority with nursing strategies and hygiene?
- a. patient ethnicity
  - b. safety
  - c. patient-to-staff ratios
  - d. when the patient will discharge
11. A 77-year-old patient with Alzheimer disease is a new admission to a long-term facility. The patient appears under distress during bathing. What guidelines should the nurse consider?
- a. the last time the patient said they had a bath
  - b. demanding the patient take a bath
  - c. playing calming music and reassuring the patient
  - d. scrub hard and fast
12. What should the nurse do prior to providing patient education about health promotion?
- a. Gather information online about the patient's ethnicity.
  - b. Assess the patient's current knowledge.
  - c. Tell the patient the nurse's personal preferences.
  - d. Tell the patient they have to perform hygiene a certain way.
13. When the nurse is performing perineal care on an uncircumcised male patient, what is not a step in the process?
- a. Gently grasp the shaft and retract the foreskin.
  - b. Wash the tip in a circular motion.
  - c. Replace the foreskin.
  - d. Leave the foreskin alone.

## Check Your Understanding Questions

1. Describe the benefits of good skin hygiene.
2. Describe hygiene-related diseases.
3. Describe how a person's socioeconomic status can impact personal hygiene.
4. Compare and contrast the physical and psychological factors that affect hygiene.
5. Describe the Five Rights of Delegation.
6. Describe age-related changes and nursing strategies related to impaired mucous membranes.

## Reflection Questions

1. What information might you need to include when educating a patient about the importance of hygiene?
2. What information might you include when educating a new nurse about cultural preferences?
3. What information might you include when educating a recently admitted teenager who just started her first menstrual cycle?

## What Should the Nurse Do?

1. A nurse is assessing a patient with oily hair and noticeable debris on their face and arms. The nurse also notices that the patient's gown is soiled. The nurse asks the patient when they last showered and if the patient would like to shower that morning or afternoon. The patient refuses to perform hygiene practices. What should the nurse do?
2. A 58-year-old patient has recently been admitted to the medical-surgical unit. The patient appears uncomfortable when the nurse asked if the patient would like to have a bath that day. What should the nurse do?

You are a home health nurse visiting a new patient. The patient is an 80-year-old male with diabetes who has impaired mobility after a stroke. The patient ambulates with a walker and was able to greet you at their door. The patient lives alone as his wife died last year. Upon entering the home, you notice clutter in various areas: a table covered in books, newspapers, dishes, and pictures; couches and chairs have clothing and miscellaneous medical equipment on them; and there are cords spread across walkways. The patient makes space for you to sit at the kitchen table and tells you it is ok to push anything aside that is in your way. While establishing rapport, you notice the patient has various body odors; soiled clothing; dry, flaky skin; and food particles visible in his teeth.

3. How would you address the patient's hygiene habits?
4. How would you address the clutter in the patient's home?
5. What would you educate the patient about regarding hygiene?
6. How would you respond if the patient tells you he prefers baths?
7. You are ready to develop a plan of care for this patient. What are three hygiene goals you can make?

## Competency-Based Assessments

1. Develop a ten-minute presentation defining hygiene and explaining its benefits.
2. Develop a five-minute presentation on promoting healthy hygiene habits through patient education.

## CHAPTER 26

# Urinary Elimination

**FIGURE 26.1** A urinalysis provides valuable information about the function of the urinary system. (credit: Department of Defense, Public Domain)

### CHAPTER OUTLINE

- 26.1 Urinary System
- 26.2 Functions of the Urinary System
- 26.3 Factors Affecting Urinary Elimination
- 26.4 The Nurse's Role in Urinary Elimination

**INTRODUCTION** The urinary system, a remarkable and intricate physiological network, is an indispensable component of the human body's regulatory mechanisms. Operating quietly behind the scenes, it diligently filters waste, regulates fluid levels, and maintains electrolyte equilibrium, playing a vital part in sustaining the body's overall balance and functionality. This chapter delves into the multifaceted dimensions of the urinary system, exploring its fundamental functions, examining the various factors that impact urinary elimination, and highlighting the integral role nurses play in ensuring optimal urinary health for their patients.

Recognizing the urinary system's intricacies is not merely a professional nuance for nurses; it is a cornerstone in delivering comprehensive patient care. Armed with this knowledge, nurses become adept at spotting early signs of potential issues, intervening promptly, and averting complications. Nurses also serve as educators, empowering patients to actively engage in their urinary health. The comprehension of the urinary system contributes to accurate diagnosis, guiding care plans and shaping interventions tailored to each patient's unique needs.

## 26.1 Urinary System

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize the anatomy of the urinary system
- Describe the process of urine formation
- Explain the physiological act of urination

A comprehensive understanding of the urinary system, urine formation, and the physiological act of urination is fundamental to appreciating the intricate mechanisms that contribute to maintaining the body's internal balance. The anatomy of the urinary system, composed of the kidneys, ureters, bladder, and urethra, serves as the foundation for the elaborate processes involved. Exploring the process of urine formation unravels the intricate series of filtration, reabsorption, and secretion orchestrated by the kidneys. Meanwhile, understanding the physiological act of urination, from the micturition reflex to the stages of voiding, sheds light on the controlled release of urine. This knowledge is pivotal not only for comprehending the complexities of human physiology but also for recognizing the significance of these processes in sustaining overall health and homeostasis.

### Anatomy of the Urinary System

The **urinary system**, a vital component of the human anatomy, is a sophisticated network of organs responsible for producing, storing, and eliminating urine from the body. Comprising the kidneys, ureters, bladder, and urethra, this intricately designed system orchestrates the filtration of blood, the formation of urine, and the controlled expulsion of waste from the body (Cleveland Clinic, 2023; Johns Hopkins, n.d.). The kidneys, positioned on either side of the spine, act as intricate filters, extracting excess fluids and waste products from the bloodstream. Nephrons, the microscopic functional units within the kidneys, play a central role in this process. The ureters transport the produced urine from the kidneys to the bladder, a muscular reservoir situated in the pelvic cavity. The urethra then serves as the exit pathway for urine, allowing for regulated voiding (Cleveland Clinic, 2023; Johns Hopkins, n.d.). This part of the chapter takes a closer look at each of these components.

#### Kidneys

A **kidney** is a bean-shaped organ located on either side of the spine, just below the rib cage, in the human body. Kidneys are essential components of the urinary system and play a critical role in maintaining overall health. The primary functions of the kidneys include filtering waste and excess substances from the blood to form urine, regulating fluid and electrolyte balance, managing acid-base equilibrium, contributing to **erythropoiesis** (the production of red blood cells), participating in detoxification by filtering drugs and toxins, aiding in the activation of vitamin D for calcium and phosphorus metabolism, and regulating blood pressure through the renin-angiotensin-aldosterone system (RAAS) (Cleveland Clinic, 2023; Johns Hopkins, n.d.). The kidneys are vital for maintaining physiological balance and supporting various bodily functions that contribute to overall well-being.

The size of the kidneys can vary among individuals, but on average, a typical adult human kidney is approximately 10 to 12 cm (about 4 to 5 in) in length and weighs about one-third of a pound (Preminger, 2022). The kidneys are encapsulated by a protective layer known as the **renal capsule**. Structurally, each kidney comprises an outer layer called the **renal cortex** and an inner region known as the **renal medulla**. A microscopic unit within the kidneys, called a **nephron**, is the functional units responsible for blood filtration and urine formation (Preminger, 2022). With approximately one million nephrons in each kidney, these structures play a pivotal role in maintaining the body's fluid balance and regulating electrolytes (Preminger, 2022).

Blood is supplied to the kidneys through the renal artery, while the deoxygenated blood exits via the renal vein. As blood circulates through the nephrons, excess fluids, electrolytes, and waste, called **urea**, are meticulously filtered. The body generates urea during the breakdown of protein-containing foods. Subsequently, urea is transported through the bloodstream to the kidneys, where it, along with water and other waste products, is eliminated in the form of urine (Johns Hopkins, n.d.; Preminger, 2022). The resulting urine accumulates in the **renal pelvis**, a funnel-shaped structure that directs the urine into the ureter. The ureter, in turn, conveys the urine to the bladder for storage (Preminger, 2022). The location and anatomy of the kidneys are depicted in [Figure 26.2](#).

**FIGURE 26.2** The kidneys are situated bilaterally on either side of the spine, below the rib cage and within the retroperitoneal space. These bean-shaped organs are essential components of the body's urinary system. (credit: "Blausen 0592 KidneyAnatomy 01.png" by BruceBlaus/Wikimedia Commons, CC BY 3.0)

### Ureters

Within the human body, there are two ureters, one connected to each kidney. Each **ureter** is a muscular tube that serves as a conduit for transporting urine from its kidney to the urinary bladder. The ureters' primary function is to facilitate the unidirectional flow of urine, preventing backflow and ensuring the efficient drainage of urine from the renal pelvis to the bladder (Lescay et al., 2024). The unique structure and function of the ureters ensure the efficient and regulated transport of urine, safeguarding the urinary system from complications such as reflux (backflow) and obstruction (blockage).

Originating from the renal pelvis of each kidney, the ureters extend downward along the posterior abdominal wall before entering the pelvic cavity. Composed of smooth muscle and lined with specialized mucosa, the ureters exhibit rhythmic muscular movements called peristaltic contractions, which propel urine in a unidirectional flow toward the bladder. The ureters traverse the pelvic brim, passing behind the bladder before entering its posterior wall. This anatomical arrangement prevents the backflow of urine into the kidneys during bladder contraction (Lescay et al., 2024).

### Bladder

The **bladder**, an essential component of the urinary system, acts as a storage reservoir for urine prior to its regulated expulsion from the body (Figure 26.3). Positioned within the pelvic cavity, this hollow and muscular organ possesses a flexible structure, enabling it to expand as it accumulates urine (Shermadou et al., 2023). In females, the bladder lies posterior to the pubic bone and anterior to the uterus and rectum. During late pregnancy, its capacity is reduced due to compression by the enlarging uterus, resulting in increased frequency of urination. In males, the anatomy is similar, minus the uterus and with the addition of the prostate inferior to the bladder.

**FIGURE 26.3** The bladder's triangular shape is characterized by three openings: two for the ureters and one for the urethra. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

As the bladder gradually fills, stretch receptors in its walls send signals to the central nervous system, indicating the need for voiding. The **detrusor muscle**, a layer of smooth muscle within the bladder wall, contracts under nervous system control, while the external urethral sphincter relaxes, facilitating the expulsion of urine through the urethra. The bladder's triangular shape is characterized by three openings: two for the ureters and one for the urethra. The **trigone**, a triangular area between these openings, acts as a physiological valve, preventing reflux of urine into the ureters. The neck of the bladder connects to the urethra, through which urine exits the body during voiding (Shermadou et al., 2023). The bladder's intricate anatomy and functional mechanisms enable it to store urine efficiently and facilitate controlled release, contributing to the overall regulation of the body's fluid and waste balance.

### Urethra

The **urethra**, the final component of the urinary system, serves as the conduit for the expulsion of urine from the body. The urethra is a tubular structure extending from the neck of the bladder to the external urethral orifice. The length of the urethra varies between males and females, with males typically having a longer urethra that also functions as a passageway for semen during ejaculation. The female urethra is shorter and solely dedicated to the elimination of urine. The urethra is lined with mucous membrane and surrounded by muscle, contributing to its role in the voluntary control of urine release. The **external urethral sphincter**, a ringlike muscle, aids in the regulation of urine flow (Cleveland Clinic, 2022).

### Process of Urine Formation

The process of urine formation, a sophisticated series of physiological events coordinated by the kidneys, is essential for maintaining the body's internal balance and eliminating waste products (Figure 26.4). This intricate journey begins with glomerular filtration, where blood entering the kidneys is meticulously filtered in the glomerulus to form an initial filtrate. Following filtration, tubular reabsorption occurs along the renal tubules, selectively reclaiming vital substances such as water, glucose, and ions from the filtrate back into the bloodstream. Simultaneously, tubular secretion involves the active transport of certain substances from the bloodstream into the renal tubules for further elimination. This complex interplay between glomerular filtration, tubular reabsorption, and tubular secretion culminates in the production of urine, a dynamic and essential function for sustaining internal homeostasis and overall bodily health.

**FIGURE 26.4** The complex interplay between glomerular filtration, tubular reabsorption, and tubular secretion culminates in the production of urine. These processes also ensure the fine-tuning of the urine's composition, regulating electrolyte levels, fluid balance, and the removal of metabolic waste. (credit: "Anatomy and physiology of animals Summary of the processes involved in the formation of urine.jpg" by Ruth Lawson/Wikipedia, CC BY 3.0)

### Glomerular Filtration

The initial and crucial step in the process of urine formation is **glomerular filtration**. It takes place within the **glomerulus**, the intricate network of tiny blood vessels in the kidneys. As blood flows into the glomerulus through the afferent arteriole, the high pressure in this network forces water, electrolytes, and small molecules, including waste products, out of the blood and into the renal tubules. This resulting **glomerular filtrate** consists of essential substances required by the body and waste materials slated for elimination. It is noteworthy that the selective permeability of the glomerular membrane retains larger molecules like proteins and blood cells in the bloodstream. The rate at which glomerular filtration occurs is quantified as the **glomerular filtration rate (GFR)**, a critical indicator of kidney function. The normal GFR ranges between 120 and 125 mL/min. Glomerular filtration establishes the foundation for subsequent phases in urine formation, setting the groundwork for reabsorption and secretion processes that ultimately lead to the production of urine (Ogobuiro & Tuma, 2023).

### Tubular Reabsorption

Following glomerular filtration, the pivotal phase of **tubular reabsorption** occurs within the renal tubules of the kidneys. The glomerular filtrate, which initially contains water, electrolytes, and essential substances, moves through the proximal convoluted tubule, loop of Henle, distal convoluted tubule, and collecting duct. Along this journey, the renal tubules selectively reabsorb critical components back into the bloodstream, ensuring the retention of substances vital for maintaining the body's balance. This includes the reabsorption of water, glucose, ions, and other necessary molecules, effectively reclaiming them from the filtrate. This reabsorption process is highly regulated, responding to the body's needs and adjusting the composition of the filtrate accordingly. Tubular reabsorption significantly concentrates the urine, conserving valuable water resources and aiding in the maintenance of electrolyte and solute balance within the body (Ogobuiro & Tuma, 2023).

### Tubular Secretion

The final crucial phase in the process of urine formation, **tubular secretion**, occurs in the renal tubules of the kidneys following glomerular filtration and tubular reabsorption. This selective mechanism involves actively transporting certain substances, including excess ions, drugs, and metabolic by-products, from the peritubular

capillaries surrounding the tubules into the renal tubules. These substances, not effectively filtered during glomerular filtration or requiring further elimination, are crucial for maintaining the body's acid-base balance and controlling specific ion concentrations. For instance, the secretion of hydrogen ions actively regulates blood pH. Tubular secretion ensures the elimination of substances not initially cleared from the bloodstream, actively contributing to the final composition of urine (Ogobuiro & Tuma, 2023).

## Act of Urination

The act of **urination** (also referred to as voiding or micturition) is a fundamental physiological process that reflects the intricate coordination between the nervous and muscular systems to eliminate urine from the bladder through the urethra. Centered within the urinary system, this multifaceted mechanism involves distinct stages (Flores et al., 2023). Understanding the act of urination delves into the anatomical and physiological intricacies that underlie the body's ability to store, process, and eliminate urine. This exploration not only reveals the complexity of micturition but also underscores its critical role in maintaining the body's internal equilibrium and overall well-being.

## LIFE-STAGE CONTEXT

---

### Age-Related Changes with Urination

As individuals age, various physiological adjustments occur in the urinary system, influencing the act of urination. One notable change is a decrease in bladder capacity, leading to a more frequent urge to urinate and a reduced tolerance for larger fluid volumes. Additionally, the pelvic floor muscles, crucial for maintaining bladder control, tend to weaken with age, contributing to instances of urinary incontinence, particularly during activities that increase intra-abdominal pressure. Nocturnal urination, or nocturia, becomes more prevalent in older adults, disrupting sleep patterns and impacting overall sleep quality. The micturition reflex, responsible for coordinating the voiding of urine, may slow down, resulting in delays in initiating urination and potential issues with urgency. For males, an enlarged prostate (benign prostatic hyperplasia) can further complicate the act of urination by causing difficulties in initiating and maintaining a steady urine stream. Awareness of these age-related changes is crucial for healthcare providers to tailor interventions and support for older individuals, ensuring optimal bladder function and overall well-being.

### Micturition Reflex

The act of micturition involves a complex physiological process governed by the **micturition reflex**. This reflex is generated by the nervous system, primarily the autonomic nervous system and the spinal cord. As the bladder fills with urine, stretch receptors in the bladder wall are activated, sending signals to the spinal cord. The parasympathetic nervous system is then stimulated, causing the detrusor muscle in the bladder wall to contract while simultaneously relaxing the internal urethral sphincter. The sensation of a full bladder is conveyed to the brain, and when an individual voluntarily decides to empty the bladder, the external urethral sphincter, under conscious control, relaxes. This coordinated relaxation of the sphincters and contraction of the detrusor muscle result in the expulsion of urine through the urethra. The micturition reflex is a finely tuned mechanism that ensures controlled and voluntary release of urine while preventing involuntary leakage. Dysfunction in this reflex can lead to issues such as **urinary retention** (the inability to empty the bladder fully) or **urinary incontinence** (involuntary loss of bladder control, leading to the unintentional release of urine) (Flores et al., 2023).

### Stages of Micturition

The stages of micturition encompass a series of precisely coordinated events within the urinary system. From the resting and filling stages, in which the bladder gradually accommodates accumulating urine, to the pivotal voiding stage, in which conscious and involuntary mechanisms converge to facilitate controlled urination, each stage plays a crucial role in maintaining continence and ensuring efficient waste elimination. Understanding these stages not only unveils the physiological intricacies of the micturition process but also sheds light on the intricate coordination between nervous system responses and voluntary muscle actions. This exploration into the stages of micturition is essential for comprehending the dynamic interplay of factors that contribute to the regulated release of urine, a fundamental aspect of the body's homeostatic mechanisms.

### Resting and Filling Stages

During the resting stage, the bladder is in a relatively inactive state. As urine accumulates, stretch receptors in the

bladder wall are activated, generally sending signals when there is at least 50 to 100 mL, signaling to the nervous system that the bladder is filling and prompting urination. The parasympathetic nervous system is gradually activated, leading to a mild contraction of the detrusor muscle while maintaining closure of the internal and external urethral sphincters. This allows the bladder to gradually expand to accommodate the increasing volume of urine without initiating the urge to void (Flores et al., 2023).

During this filling stage, the bladder continues to receive urine. The stretch receptors continue to send signals to the spinal cord and brain, providing information about the increasing volume of urine. Despite ongoing contractions of the detrusor muscle, the urethral sphincters remain contracted, preventing the involuntary release of urine. The individual typically remains unaware of the filling process during this stage, as the bladder's main function is to store urine without generating a strong urge to void (Flores et al., 2023).

These early stages are essential for maintaining **continence** (the ability to control and maintain bladder functions) and preventing the constant need for urination. The transition to the next stage, the voiding or emptying stage, is initiated when the bladder reaches a certain level of distension, triggering the micturition reflex and the conscious sensation of needing to urinate.

### Voiding Stage

The **voiding stage**, also known as the emptying stage, is a crucial phase in the micturition process. It follows the resting and filling stages and involves a coordinated series of events controlled by the micturition reflex and culminating in the release of urine stored in the bladder. The parasympathetic nervous system becomes more active, causing the detrusor muscle in the bladder wall to contract more forcefully. Simultaneously, the internal urethral sphincter relaxes involuntarily, allowing urine to flow from the bladder into the urethra. The conscious component of this stage involves the individual's decision to voluntarily relax the external urethral sphincter, allowing urine to exit the body. This conscious control is crucial for maintaining continence and preventing involuntary urine release (Flores et al., 2023).

The voiding stage is a dynamic process, and the coordination between involuntary and voluntary muscle actions ensures efficient and controlled urination. Dysfunction in this stage can lead to issues such as urinary retention or incontinence. Overall, the voiding stage represents the culmination of the micturition process, facilitating the expulsion of urine from the body while maintaining voluntary control over the process.

## 26.2 Functions of the Urinary System

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify how the urinary system removes waste products from the body
- Recognize how the urinary system maintains balance of the body's fluids and electrolytes
- Explain the urinary system's role in regulating blood pressure
- Describe how the urinary system controls production of red blood cells

The urinary system serves multifaceted roles, extending beyond the excretion of waste products. This section explores the intricate mechanisms by which the urinary system actively removes waste products and maintains several delicate balances within the body. Furthermore, it explores the urinary system's pivotal role in regulating blood pressure, highlighting its involvement in broader physiological processes. Additionally, the section clarifies how the urinary system, through the secretion of hormones such as erythropoietin, contributes to the control and coordination of red blood cell (RBC) production. Together, these aspects underscore the comprehensive and dynamic functions of the urinary system in sustaining overall health and internal equilibrium.

### Removal of Waste Products from the Body

The removal of urea, creatinine, and uric acid in urine constitutes a crucial physiological process central to the body's waste elimination mechanism. These nitrogenous waste products are metabolic by-products resulting from the breakdown of proteins and nucleic acids during various cellular processes. The kidneys play a pivotal role in filtering the bloodstream to selectively excrete these waste substances. The intricate kidney filtration and excretion processes contribute significantly to maintaining the body's internal balance and preventing the accumulation of potentially harmful waste products. Understanding how the urinary system efficiently manages the removal of urea,

creatinine, and uric acid is fundamental to appreciating the kidneys' vital role in overall homeostasis.

### Urea

As you learned in the previous section, urea is a nitrogenous waste product that forms in the liver during the breakdown of proteins and amino acids. It is a key component of urine and is excreted from the body through the kidneys. Urea is crucial for maintaining the body's nitrogen balance, preventing the accumulation of toxic ammonia. The liver converts ammonia into urea, which is less toxic and more water soluble, making it easier for the kidneys to filter and eliminate from the body (Mayo Clinic, 2023). Monitoring urea levels in the blood and urine is essential in assessing kidney function and overall metabolic health. The normal urea level in the blood typically ranges between 7 and 20 mg/dL (milligrams per deciliter). However, it is important to note that reference ranges may vary slightly depending on the specific laboratory and the units of measurement used. Additionally, factors such as age, gender, and underlying health conditions can influence urea levels.

### Creatinine

Another waste product, **creatinine**, results from the breakdown of creatine phosphate, which is used as an energy source in muscle cells. Like urea, creatinine is filtered by the kidneys and excreted in urine, and creatinine levels in the blood and urine serve as important indicators of kidney function. Elevated creatinine levels may suggest impaired kidney function, as the kidneys may be struggling to effectively filter and eliminate this waste product. Regular monitoring of creatinine levels is common in assessing kidney health and identifying potential kidney disorders (National Kidney Foundation, n.d.). Normal creatinine levels in the blood can vary based on several factors, including age, gender, muscle mass, and ethnicity. In adult males, typical reference ranges for serum creatinine levels are approximately 0.6 to 1.2 mg/dL, while in females, the range is typically 0.5 to 1.1 mg/dL. It is important to note that these reference ranges may slightly differ between laboratories.

### Uric Acid

A chemical compound, **uric acid** is generated as a by-product during the breakdown of a compound called a **purine**, which is a naturally occurring substance found in the body's cells and in specific foods, such as organ meats, seafood, and certain vegetables. Following the breakdown of purines, uric acid is typically filtered by the kidneys and expelled from the body through urine. However, if there is an excessive production of uric acid or if the kidneys struggle to efficiently eliminate it, elevated uric acid levels in the bloodstream may occur. This heightened concentration can lead to the formation of urate crystals. A **urate crystal** is a solid structure that has the potential to accumulate in joints and other tissues, giving rise to conditions such as **gout**, a type of arthritis characterized by intense pain, swelling, and tenderness in the joints, often affecting the big toe (El Ridi & Tallima, 2017). It is crucial to monitor and effectively manage uric acid levels to prevent complications associated with conditions like gout. The normal uric acid levels in the blood typically range between 3.4 and 7.0 mg/dL for males and 2.4 to 6.0 mg/dL for females. However, reference ranges may vary slightly between laboratories, and factors such as age, gender, diet, and underlying health conditions can influence uric acid levels.

### Maintenance of Balance

The urinary system contributes significantly to overall physiological stability as a pivotal regulator of the body's fluid, electrolyte, and acid-base balance. The kidneys act as refined filters, meticulously processing blood through mechanisms such as glomerular filtration, tubular reabsorption, and tubular secretion. These processes collectively determine the composition of urine, allowing for the precise regulation of electrolyte levels and fluid volume and the removal of metabolic waste. The efficient transport of urine from the kidneys to the bladder through the ureters, its storage within the bladder, and its controlled release via the urethra all contribute to fluid balance.

Moreover, the urinary system plays a vital role in maintaining acid-base equilibrium. Through selective processes in the renal tubules, acidic hydrogen ions and alkaline bicarbonate ions are regulated to help control the body's pH. The elimination of excess acids or bases in urine ensures that the blood remains within a narrow pH range, preventing deviations that could disrupt cellular function. The dynamic interplay between the urinary system's filtration and excretion processes ensures that the body's fluid and electrolyte balance, as well as its acid-base equilibrium, are finely tuned for optimal physiological function and overall well-being.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Ensuring Fluid and Electrolyte Homeostasis through Urinary System Regulation

The Quality and Safety Education for Nurses (QSEN) framework underscores the critical importance of understanding how the urinary system actively maintains the body's fluid balance. This pivotal role aligns seamlessly with QSEN principles, emphasizing the utmost significance of clinical safety and procedures within nursing practice.

Key aspects of QSEN pertaining to fluid and electrolyte homeostasis through urinary system regulation include the following:

- **Patient-centered care:** A comprehensive understanding of the urinary system's role in fluid and electrolyte balance ensures patient-centered care by addressing individualized needs related to kidney function. The tailoring of interventions to support patients with conditions affecting the urinary system contributes to personalized and effective care.
- **Teamwork and collaboration:** Collaborative efforts among healthcare professionals are crucial in managing patients with kidney issues, emphasizing the need for interdisciplinary teamwork. Effective communication and collaboration between nurses, providers, and other team members enhance the overall care provided to patients.
- **Evidence-based practice:** The knowledge of how the urinary system maintains fluid and electrolyte balance is rooted in evidence-based practices. Nurses relying on evidence-based information can make informed decisions in the assessment and management of patients with kidney conditions, contributing to better outcomes.
- **Quality improvement:** Recognizing the urinary system's role in fluid balance is integral to quality improvement initiatives in health care. Continuous evaluation and improvement of protocols related to kidney care contribute to enhanced patient outcomes and overall quality of care.
- **Patient safety:** Ensuring the balance of fluids and electrolytes through the urinary system aligns with patient safety goals. Nurses, through their understanding of urinary system regulation, can actively contribute to preventing complications related to imbalances and promoting a safe patient environment.

By integrating these QSEN principles into nursing practice, healthcare professionals can uphold the highest standards of patient care, ensuring safety, quality, and optimal outcomes in managing fluid and electrolyte balance through urinary system regulation.

---

### Fluid and Electrolyte Balance

Fluid and electrolyte balance in urine is a dynamic and finely regulated process crucial for maintaining the body's internal homeostasis. At the forefront of this regulatory mechanism are the kidneys, which act as the primary orchestrators in filtering and excreting substances to uphold an optimal internal environment. The glomerular filtration process serves as the initial step by which water and electrolytes are meticulously filtered from the bloodstream into the renal tubules. In subsequent tubular reabsorption, the kidneys selectively reclaim crucial substances, including sodium, potassium, and water, redirecting them back into the bloodstream to prevent excessive loss (Preminger, 2022).

Concurrently, tubular secretion actively eliminates excess ions and substances that were not adequately filtered during the earlier glomerular filtration phase. This intricate coordination between filtration, reabsorption, and secretion is fundamental in refining the composition of urine. Importantly, this dynamic interplay contributes significantly to the body's ability to regulate key physiological parameters such as blood volume, blood pressure, and electrolyte concentrations (Preminger, 2022). By fine-tuning these factors, the kidneys ensure the body's internal equilibrium, supporting overall physiological balance and health.

### Acid-Base Balance

Acid-base balance in urine is a crucial aspect of maintaining the body's overall pH equilibrium. The kidneys play a pivotal role in regulating acid-base balance by selectively excreting hydrogen ions ( $H^+$ ) and reabsorbing bicarbonate ions ( $HCO_3^-$ ) in the renal tubules. This process occurs in response to variations in the body's acid-base status,

helping to eliminate excess acids or bases.

The process of reabsorption of bicarbonate helps to maintain the blood's pH balance by acting as a buffer against acidosis. Additionally, the excretion of hydrogen ions assists in preventing alkalosis by regulating the blood's acidity levels. The kidneys' ability to finely tune the excretion and reabsorption of these ions ensures that the urinary system actively participates in maintaining the delicate balance of pH in bodily fluids (Merck Manual, n.d.). This intricate mechanism is essential for overall homeostasis and the prevention of disruptions in acid-base equilibrium that could adversely affect cellular function and physiological processes.

## Release of Hormones to Regulate Blood Pressure

The regulation of blood pressure is a critical aspect of maintaining overall health and homeostasis within the body. Hormones play a pivotal role in this regulation by exerting control over various physiological processes that influence blood pressure. Through the release of specific hormones into the bloodstream (e.g., renin, angiotensin, aldosterone, epinephrine, norepinephrine), the body can effectively adjust blood pressure levels in response to changing conditions and demands. The renal system is also involved in regulating blood pressure; however, it does not do so by directly regulating hormones within the bloodstream. Instead, the kidneys, as part of the endocrine system, play a crucial role in blood pressure regulation by releasing hormones that influence various physiological processes. The RAAS is a key pathway involved in this regulation. When the kidneys detect reduced blood flow or low blood pressure, they release the enzyme renin. Renin then initiates a series of events leading to the production of angiotensin II, a potent vasoconstrictor.

### Renin

An enzyme synthesized and discharged by specialized juxtaglomerular cells in the kidneys, **renin** is a key player in the intricate regulatory system known as the **renin-angiotensin-aldosterone system (RAAS)**. RAAS is a complex hormonal cascade that plays a crucial role in regulating blood pressure, electrolyte balance, and fluid volume within the body. The release of renin into the bloodstream is prompted by conditions like decreased blood flow to the kidneys or a decline in blood pressure (Fountain et al., 2023).

Once released, renin acts on angiotensinogen, a protein originating from the liver and circulating in the bloodstream. Renin hydrolyzes **angiotensinogen** to produce **angiotensin I** (a peptide hormone); further conversion of angiotensin I to **angiotensin II** occurs primarily in the lungs through the action of angiotensin-converting enzyme (ACE). Notably, angiotensin II exerts a potent vasoconstrictor effect, causing the narrowing of blood vessels, thereby elevating blood pressure (Fountain et al., 2023).

Additionally, angiotensin II stimulates the adrenal glands to release **aldosterone**, which, in its role as a hormonal facilitator, enhances the reabsorption of sodium and water in the kidneys (Fountain et al., 2023). This process contributes to an augmentation in blood volume and, consequently, an increase in blood pressure. Individuals experiencing kidney failure may encounter challenges in effectively regulating blood pressure, often resulting in elevated blood pressure levels (Preminger, 2022).

## Production of Red Blood Cells

The urinary system controls the production of RBCs indirectly through the release of erythropoietin, a hormone produced by the kidneys. (Red blood cells are also known as erythrocytes.) When the kidneys detect low oxygen levels in the blood, often due to factors like decreased RBC count or insufficient oxygen availability, they respond by releasing erythropoietin into the bloodstream. Erythropoietin then travels to the bone marrow, where RBCs are formed, and stimulates an increase in the production of RBCs. This regulatory mechanism, known as erythropoiesis, is vital for maintaining the oxygen-carrying capacity of the blood and ensuring homeostasis within the circulatory system.

### Erythropoietin

A glycoprotein hormone, **erythropoietin (EPO)** plays a crucial role in the regulation of RBC production. Produced primarily by the kidneys, EPO is released in response to low oxygen levels in the blood, a condition known as hypoxia. The hormone's primary function is to stimulate the bone marrow to produce and release more RBCs into the bloodstream (Cleveland Clinic, 2022; Preminger, 2022).

High levels of erythropoietin (EPO) are typically triggered by low oxygen levels in the body, such as in response to

conditions like anemia or hypoxia. EPO, in turn, stimulates the proliferation and differentiation of erythrocyte precursor cells in the bone marrow, leading to an increased production of RBCs (Cleveland Clinic, 2022). This process enhances the blood's oxygen-carrying capacity, helping to alleviate hypoxia and maintain the body's overall oxygen balance.

On the other hand, low levels of EPO can occur when there is sufficient oxygen in the blood or when the kidneys are not functioning properly. Conditions such as chronic kidney disease can lead to decreased EPO production. The treatment approach for low EPO depends on the underlying cause. In cases where low EPO is associated with chronic kidney disease, healthcare providers may consider EPO replacement therapy to stimulate RBC formation. This synthetic EPO can help compensate for the reduced natural EPO production in the kidneys. Additionally, addressing the root cause of low EPO is essential. Managing conditions like chronic kidney disease through medications, lifestyle adjustments, or advanced interventions like dialysis or kidney transplant can contribute to improved EPO levels (Cleveland Clinic, 2022).

## 26.3 Factors Affecting Urinary Elimination

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify considerations for impaired urinary elimination
- Recognize the effect of medications on urinary elimination
- Describe pathological factors affecting urinary elimination

This section explores the many factors influencing urinary elimination, ranging from developmental and sociocultural considerations to medication and pathological issues. These insights contribute to a holistic understanding of urinary elimination challenges, enabling nurses to navigate and address the complexities involved. The chapter's overall goal is to foster comprehension of urinary elimination factors, laying the foundation for informed decision-making and effective management in healthcare contexts.

### Considerations for Impaired Urinary Elimination

Impaired urinary elimination refers to a disruption in the normal process of expelling urine from the body, leading to difficulties or abnormalities in urination. Causes of impaired urinary elimination can vary widely and include conditions such as urinary tract infections, bladder dysfunction, kidney stones, neurological disorders, and prostate enlargement, among others. Complications of impaired urinary elimination can lead to more severe conditions, including urinary retention, kidney damage, and urinary incontinence (Srakocic, 2023). Prompt identification and management are crucial to prevent complications and improve overall urinary function.

Impaired urinary elimination encompasses a spectrum of challenges that disrupt the normal processes of urine excretion:

- A condition marked by the absence of urine output is **anuria**, and it is frequently encountered in cases of kidney failure. It presents as less than 50 mL of urine within a twenty-four-hour period.
- Painful or difficult urination is **dysuria**.
- Reduced urine output is **oliguria**. It may indicate potential issues such as dehydration, fluid retention, or diminishing kidney function.
- The urge to urinate multiple times throughout the day or night (nocturia) is **urinary frequency**. It is often accompanied by a compelling sense of urgency, introducing another layer of concern.
- The sensation of an urgent need to void is **urinary urgency**, and this may lead to urge incontinence if prompt access to a restroom is not possible.
- Regular nighttime urination, **nocturia**, can significantly impact an individual's quality of life due to resulting sleep disturbances.
- Excessive urine output, surpassing 2.5 L over twenty-four hours is **polyuria**. It serves as a potential indicator of various medical conditions.

Impaired urinary elimination poses multifaceted challenges that necessitate a comprehensive understanding of various considerations. Developmental considerations, sociocultural factors, and psychological elements play crucial roles in shaping individuals' experiences with impaired urinary elimination. Fluid and food intake, as well as muscle tone and activity, further contribute to the complexity of managing urinary issues. Recognizing these diverse

aspects is fundamental for nurses in providing holistic care, tailoring interventions, and fostering effective communication with individuals facing impaired urinary elimination. A comprehensive approach that considers the interplay of these factors is essential for promoting optimal urinary health and addressing the unique needs of individuals with urinary elimination challenges.

### Developmental Considerations

Developmental considerations for impaired urinary elimination can vary across the life span. Understanding how urinary elimination may be affected at different stages of development is crucial for providing effective nursing care. Developmental considerations for impaired urinary elimination may be categorized by age group:

- Infants and toddlers: Immature neuromuscular control and limited verbal communication skills can contribute to difficulties in bladder control and expressing the need to void. Reliance on diapers may delay toilet training, potentially causing challenges later (Figueroa & DeCotiis, 2023).
- Preschoolers: Incomplete or delayed toilet training may contribute to occasional accidents. Anxiety related to separation from caregivers may affect the ability to use restrooms away from home (Figueroa & DeCotiis, 2023).
- School-age children: Growing independence in self-care may improve toileting habits. Social factors such as peer pressure may impact bathroom habits both positively and negatively.
- Adolescents: Adolescents may be more conscious of body image, affecting restroom use in public places. Busy schedules and peer influences may lead to irregular fluid intake patterns.
- Young adults: Work, academic demands, and social activities may influence voiding patterns and contribute to urinary issues.
- Middle-aged adults: Childbearing experiences may contribute to pelvic floor issues. Sedentary jobs or professions with limited restroom access may impact elimination.
- Older adults: Age-related muscle weakening may lead to incontinence or incomplete emptying. Increased medication use may affect bladder function and contribute to urinary issues. Reduced mobility may pose challenges in reaching the bathroom in time.
- Geriatric population: Dementia or cognitive decline can impact awareness of the need to void. Diminished sensory perception may lead to delayed recognition of a full bladder. Chronic conditions and comorbidities may exacerbate urinary problems.
- End-of-life care: Reliance on others for toileting needs may impact dignity and autonomy. Palliative care may focus on maintaining comfort and addressing urinary symptoms.

Nurses must consider these developmental factors when assessing and providing care for individuals with impaired urinary elimination. Tailoring interventions based on age-specific needs and addressing psychological aspects can contribute to more effective and patient-centered care.

### Sociocultural Considerations

Impaired urinary elimination can be significantly influenced by sociocultural factors, as cultural beliefs, social norms, and access to healthcare services play a pivotal role in shaping individuals' attitudes and behaviors related to urinary health. Sociocultural considerations may impact how people perceive and discuss issues related to urinary function as well as whether they seek medical assistance and adhere to prescribed treatments for issues. Cultural taboos or stigmas surrounding discussions of bodily functions may contribute to delayed or inadequate healthcare-seeking behavior. Additionally, disparities in access to healthcare resources and education within different sociocultural contexts can affect the timely identification and management of urinary issues (Brown & Simon, 2021). A culturally sensitive and inclusive approach to healthcare delivery is essential to address sociocultural considerations related to impaired urinary elimination and ensure that individuals receive comprehensive and equitable care tailored to their specific cultural backgrounds and social contexts.

## CULTURAL CONTEXT

---

### Cultural Sensitivity in Addressing Urinary Health: Navigating Diverse Perspectives

Discussing or seeking help for urinary issues may be perceived differently across cultures. Nurses should approach these situations with cultural competence, recognizing diverse beliefs and practices related to health and illness. By

integrating cultural awareness into nursing care, healthcare professionals can foster trust, enhance communication, and deliver patient-centered solutions tailored to individual cultural contexts. Nurses should keep in mind the following cultural considerations related to impaired urinary retention:

- **Communication styles:** In some cultures, discussing personal health matters openly may be considered taboo. Nurses should be aware of cultural communication norms and adopt a respectful and nonintrusive approach when addressing urinary issues.
- **Modesty and privacy:** Cultural attitudes toward modesty and privacy can influence how patients respond to physical examinations or procedures related to urinary elimination. Healthcare providers should prioritize preserving the patient's dignity and comfort.
- **Gender sensitivity:** Certain cultures may prefer healthcare providers of a specific gender. Nurses should be sensitive to these preferences and, when possible, accommodate requests to ensure the patient feels respected and at ease during examinations or discussions.
- **Alternative medicine practices:** Some cultures may rely on traditional or alternative medicine for health concerns. Nurses should inquire about any cultural practices or remedies related to urinary issues and collaborate with patients to integrate culturally acceptable approaches into their care plans.
- **Family involvement:** Within some cultures, family plays a significant role in decision-making. Nurses should be open to involving family members in discussions about urinary issues, ensuring that cultural norms regarding family dynamics are respected.
- **Dietary and lifestyle practices:** Cultural dietary habits and lifestyle practices can impact urinary health. Nurses should explore and consider these cultural factors when providing advice on dietary modifications or lifestyle changes to manage urinary retention.
- **Beliefs about illness and treatment:** Cultural beliefs regarding the causes of illness and preferred methods of treatment may vary. Nurses should engage in culturally sensitive conversations to understand these beliefs and collaborate with patients to develop care plans that align with their cultural perspectives.
- **Language and health literacy:** Language barriers and health literacy levels can affect understanding and adherence to care plans. Providing information in the patient's preferred language and using culturally appropriate educational materials can enhance communication and comprehension.

By recognizing and respecting these cultural considerations, nurses can ensure that their care is inclusive, patient-centered, and aligned with the diverse needs and preferences of individuals with impaired urinary retention.

---

### Fluid and Food Intake Considerations

Impaired urinary elimination can be influenced by fluid and food intake considerations, highlighting the intricate relationship between diet and urinary health. Adequate hydration based on individual needs and environmental factors is crucial for maintaining optimal urinary function. In cases of reduced fluid intake, urine may become concentrated, potentially leading to discomfort, increased risk of urinary tract infections, and altered urinary patterns. On the other hand, excessive fluid intake, especially of diuretic substances like caffeine or alcohol, may contribute to frequent urination and potential dehydration. Moderation in the consumption of caffeinated and alcoholic beverages is advised, especially for individuals prone to urinary urgency (Whelan, 2023). Distributing fluid intake evenly throughout the day can help maintain consistent urine production and reduce the likelihood of dehydration or overhydration. Individuals who wake up at night to urinate should refrain from drinking a few hours before going to sleep (Mayo Clinic, 2023). Paying attention to fluid intake patterns and adjusting them based on individual preferences and needs supports overall urinary health.

Additionally, certain foods can impact urinary health. [Table 26.1](#) provides examples of food that can impact urinary health, along with recommendations for practice.

Food	Impact	Recommendations
Sodium	A diet high in sodium can contribute to water retention, affecting overall fluid balance and potentially leading to edema or increased stress on the urinary system.	Maintaining a balanced sodium intake by avoiding excessive salt in the diet supports overall kidney health and urinary balance.
Fruits and vegetables	A diet high in fruits and vegetables provides essential nutrients and antioxidants that support urinary health. Some fruits, like watermelon and cucumber, have high water content, contributing to overall hydration.	Inclusion of a variety of fruits and vegetables in the diet ensures a range of beneficial compounds that positively impact urinary function.
Spicy foods	Spicy foods may irritate the bladder in some individuals, potentially leading to increased urinary frequency or discomfort.	Monitoring individual responses to spicy foods and adjusting the diet based on personal tolerance can help manage potential irritants.
Citrus fruits	Citrus fruits contain citric acid, which in moderate amounts is generally tolerated well. However, excessive consumption may contribute to conditions like kidney stones in susceptible individuals.	Balanced intake of citrus fruits as part of a diverse diet is generally healthy, but those with specific conditions may need to monitor their consumption.

**TABLE 26.1** Foods that Impact Urinary Elimination (Source: Whelan, 2023.)

Individual responses to fluid and food intake can vary, and personalized approaches—considering factors such as age, health status, and specific medical conditions—are essential. Maintaining a well-balanced diet, staying adequately hydrated, and being mindful of individual sensitivities contribute to optimal urinary elimination.

### Psychological Factors

Psychological factors play a significant role in impaired urinary elimination, contributing to conditions such as urinary incontinence or retention. Emotional stress, anxiety, and mental health disorders can influence the nervous system's regulation of the micturition reflex, leading to disruptions in bladder control (Gao & Rodriguez, 2022). Individuals experiencing high levels of stress may encounter involuntary contractions of the detrusor muscle or heightened sensitivity to bladder signals, resulting in urgency or incontinence. Conversely, psychological factors can contribute to urinary retention: emotional distress may lead to a subconscious inhibition of the micturition reflex, making it challenging to void urine. Additionally, conditions like depression or cognitive impairment can impact an individual's ability to recognize or respond to signals of a full bladder.

## CULTURAL CONTEXT

### Cultural Perspectives on Urinary Health: Navigating Psychological Factors, Stigmas, and Gender Roles

Psychological factors affecting urinary elimination need to be viewed through a cultural lens, acknowledging the influence of cultural considerations on these aspects. Cultural intricacies play a crucial role in shaping beliefs, attitudes, and behaviors concerning urinary health. Recognizing how culture affects psychological factors is imperative for developing interventions that are culturally sensitive and delivering comprehensive care to individuals facing challenges in urinary elimination.

- Cultural stigmas and taboos: Cultural beliefs and practices surrounding bodily functions can impact an individual's psychological well-being and, consequently, their urinary habits. Societal stigmas or taboos related to discussing or seeking help for urinary issues may contribute to psychological distress.
- Cultural perceptions of aging: Cultural perspectives on aging may influence how individuals perceive and cope

with age-related changes in urinary function. Acceptance of or resistance to seeking medical or psychological help can vary across cultures.

- Gender roles: Cultural expectations and gender roles may affect how individuals cope with urinary issues. For instance, societal expectations around masculinity or femininity could influence how males and females express or address psychological factors related to urinary elimination.

Considering cultural factors is crucial in tailoring interventions for individuals experiencing impaired urinary elimination. Healthcare providers should adopt culturally sensitive approaches and acknowledge the diverse cultural backgrounds and beliefs of patients, promoting a more comprehensive and personalized approach to urinary health.

---

Here are some other psychological factors that can contribute to impaired urinary elimination:

- Trauma and post-traumatic stress disorder: Individuals who have experienced trauma may exhibit altered urinary patterns due to the impact of psychological distress on the nervous system.
- Fear and phobias: Specific fears or phobias related to toileting, using public restrooms, or surviving experiences such as sexual assault can contribute to urinary difficulties.
- Psychosomatic factors: Some individuals may manifest physical symptoms, including urinary issues, as a result of psychological distress, without a clear underlying medical cause.
- Coping mechanisms: Unhealthy coping mechanisms, such as substance misuse, may also indirectly affect urinary function.

Addressing these psychological factors is essential in comprehensive treatment. An interdisciplinary approach involving healthcare professionals, psychologists, and counselors is often beneficial. Treatment strategies may include the following:

- Counseling and psychotherapy: Addressing underlying psychological issues through therapy can help individuals manage stress, anxiety, trauma, or phobias that contribute to urinary problems.
- Stress management techniques: Teaching stress-reduction techniques, such as mindfulness, deep breathing exercises, or progressive muscle relaxation, can positively impact bladder function.
- Behavioral therapy: Specifically for conditions like urinary incontinence, behavioral therapy can involve bladder training, scheduled voiding, and habit retraining.
- Medication: In some cases, medications may be prescribed to address anxiety, depression, or other mental health issues that impact urinary function.
- Support groups: Participating in support groups can provide individuals with a sense of community and understanding, helping them cope with psychological aspects of their urinary issues.

Recognizing and addressing psychological factors in the management of impaired urinary elimination is crucial for a holistic approach to health care. Combining medical interventions with psychological support can improve outcomes and enhance the overall well-being of individuals experiencing urinary difficulties.

### Muscle Tone and Activity

Muscle tone and activity are critical considerations in impaired urinary elimination, influencing the proper functioning of the urinary system. The muscles surrounding the bladder, urethra, and pelvic floor play a pivotal role in maintaining continence and facilitating effective voiding. Impaired muscle tone, often associated with factors such as aging, neurological conditions, or pelvic floor dysfunction, can lead to difficulties in controlling the release of urine. Age-related hormonal changes, as seen in menopausal transitions, contribute to a decrease in pelvic floor muscle tone. Pelvic floor dysfunction is also associated with childbirth or trauma, which may weaken the muscles that support urinary function. Furthermore, neurological conditions such as multiple sclerosis or spinal cord injuries can disrupt the communication between the brain and the muscles involved in urinary control.

Impaired muscle tone can lead to challenges in controlling the release of urine. Weakened pelvic floor muscles may result in stress incontinence, as activities like coughing or sneezing induce involuntary urine leakage due to increased pressure on the bladder. Decreased muscle activity can contribute to incomplete bladder emptying, raising the risk of urinary tract infections and other complications. Moreover, altered muscle tone can impact the neuromuscular coordination required for timely and controlled voiding, leading to difficulties in effective bladder emptying. Understanding the impact of muscle tone and activity on urinary function is essential for developing

tailored interventions to address and manage impaired urinary elimination in individuals experiencing these challenges.

## LIFE-STAGE CONTEXT

---

### Age-Related Muscle Tone Changes in Urinary Health

As people navigate the journey of aging, the impact on muscle tone becomes particularly significant in the context of urinary health. Alterations in the pelvic floor muscles, neuromuscular coordination, and joints and connective tissue manifest as integral components accompanying the aging process.

- Pelvic floor changes:
  - Menopausal transitions: Age-related hormonal changes, especially during menopause in those assigned female at birth, can contribute to a decrease in muscle tone in the pelvic floor. Weakening of these muscles may lead to challenges in maintaining urinary continence.
  - Effects of aging on muscles: The natural aging process can result in the gradual loss of muscle mass and tone throughout the body, including the pelvic region. Diminished muscle tone can impact the ability to effectively control the release of urine.
- Neuromuscular coordination:
  - Decline in nervous system function: Aging can affect the nervous system's ability to coordinate muscle contractions, including those involved in the micturition reflex. This decline may contribute to difficulties in timely and controlled voiding.
  - Sarcopenia and general muscle atrophy: Sarcopenia, the age-related loss of skeletal muscle mass, can extend to the muscles involved in urinary elimination. General muscle atrophy can affect the coordination required for proper bladder function.
- Changes to joints and connective tissue:
  - Impact on pelvic support structures: Aging can lead to changes in joint flexibility and connective tissue integrity, affecting the support structures around the bladder and urethra. This may contribute to issues such as stress urinary incontinence.

Understanding the impact of aging on muscle tone is crucial for addressing age-related urinary challenges. Tailored interventions, including targeted exercises and lifestyle modifications, can help mitigate the effects of muscle tone changes on urinary elimination in different stages of life.

Addressing impaired muscle tone and activity involves a multidimensional approach. Behavioral therapy, including bladder training and habit retraining, can assist in managing incontinence and improving bladder control by optimizing muscle function. Lifestyle modifications, such as maintaining hydration and adopting a healthy diet, contribute to overall muscle health and support urinary function. Understanding the psychological factors influencing muscle tone is also crucial, as stress and anxiety can further exacerbate urinary problems. Medications may be prescribed to manage underlying conditions affecting muscle function, and physical therapy—specifically pelvic floor exercises—can improve muscle tone and coordination. Surgical interventions may be recommended for structural abnormalities hindering proper muscle function. Lifestyle modifications, including regular exercise and a balanced diet, play a crucial role in supporting overall muscle health.

### Medication Considerations

The administration of medications is a critical aspect of medical care, and various drugs can have significant effects on urinary elimination. Understanding the impact of medications on urinary function is essential for healthcare providers to make informed decisions and ensure patient well-being. Medications can influence urine production, frequency, and composition, either by impairing or enhancing the process. Factors such as drug interactions, side effects, and individual patient characteristics must be carefully considered when prescribing and administering medications. Common medications that may affect urinary elimination can be found in [Table 26.2](#) (Arianayagam, n.d.).

Drug Class	Examples	Impact
Alpha blockers and Beta blockers	tamsulosin, propranolol	Alpha blockers may relax smooth muscle in the prostate and bladder neck, improving urinary flow. Beta blockers, on the other hand, may cause urinary retention in some individuals.
Anticholinergics	oxybutynin, tolterodine	Anticholinergic drugs block acetylcholine receptors, leading to relaxation of smooth muscle. While they are used to treat overactive bladder and urinary incontinence, they may also cause urinary retention in some individuals.
Antidepressants	amitriptyline, duloxetine	Some antidepressants can affect nerve signals and muscle tone, potentially leading to urinary retention or incontinence.
Antipsychotics	olanzapine, risperidone	Some antipsychotics may cause urinary retention or other urinary disturbances as a side effect.
Calcium channel blockers	nifedipine, verapamil	These medications may affect bladder contractility and can contribute to urinary retention in some individuals.
Diuretics	furosemide, hydrochlorothiazide	Diuretics increase urine production and can lead to frequent urination. They are commonly used to manage conditions like hypertension and edema.
Nonsteroidal anti-inflammatory drugs (NSAIDs)	ibuprofen, naproxen	NSAIDs can sometimes cause fluid retention and edema, leading to changes in urinary habits.
Opioid analgesics	morphine, oxycodone	Opioids can cause constipation, which may indirectly affect urinary elimination by putting pressure on the bladder. Constipation can lead to difficulties in voiding.
Sedatives and hypnotics	benzodiazepines (e.g., diazepam, lorazepam)	Sedative medications can affect the central nervous system, potentially leading to impaired bladder control and urinary retention.

**TABLE 26.2** Medications that Affect Urinary Elimination

### Medications that Impair Urinary Elimination

Certain medications can significantly impact urinary elimination, introducing a range of effects that may lead to challenges in this physiological process. Anticholinergic medications, commonly prescribed for overactive bladder, can disrupt nerve signals and contribute to urinary retention, particularly in older individuals. Opioid analgesics may induce constipation, complicating voiding and promoting urinary retention. Antidepressants can affect both nerve signals and muscle tone in the bladder, potentially resulting in urinary retention or incontinence (Arianayagam, n.d.). Additionally, medications with antispasmodic properties can influence muscle tone in the urinary tract, potentially causing hesitancy or difficulty in initiating urine flow.

Nurses must be vigilant in assessing the potential side effects of medications to anticipate and manage any adverse impacts on urinary elimination, ensuring comprehensive and individualized care for patients. Addressing these medication-induced challenges to urinary elimination requires tailored interventions. Healthcare providers may consider adjusting medication dosages, switching to alternatives with fewer urinary side effects, or incorporating additional medications to counteract adverse effects. For instance, prescribing medications to mitigate constipation

alongside opioids may alleviate the impact on urinary function. Furthermore, lifestyle modifications, such as increasing fluid intake and maintaining regular physical activity, can play a supportive role in managing medication-induced urinary complications.

Close monitoring of individuals on these medications is crucial, especially in older adults or those with preexisting urinary conditions. Collaboration between healthcare providers, pharmacists, and patients is essential to balance the therapeutic benefits of medications with their potential adverse effects on urinary elimination. The aim is to optimize overall health while minimizing the impact on urinary function, ensuring a holistic and individualized approach to patient care.

### Medications that Increase Urinary Elimination

Certain medications are designed to increase urinary elimination and are commonly prescribed to address various medical conditions. Diuretics are commonly prescribed to manage conditions like hypertension and edema. These medications enhance urine production by promoting the excretion of excess fluids and electrolytes from the body. While diuretics can be beneficial in addressing fluid retention, they may lead to increased frequency of urination and potential electrolyte imbalances (Arianayagam, n.d.). One significant concern is the wasting of potassium ions, a condition known as hypokalemia, which can result from the use of certain diuretics. Potassium is crucial for maintaining proper cardiac function, and its depletion can lead to serious cardiac issues such as arrhythmias, muscle weakness, and severe complications like ventricular tachycardia or fibrillation. Interventions for individuals on diuretics may involve close monitoring of electrolyte levels, dietary adjustments to include potassium-rich foods, and, in some cases, dosage modifications or the use of potassium-sparing diuretics to maintain electrolyte balance and ensure cardiac health.

In addition to diuretics, medications classified as anticholinergic drugs are often prescribed to treat overactive bladder. By blocking acetylcholine receptors, anticholinergics reduce bladder contractions and increase bladder capacity. These medications may result in increased urine volume and decreased urgency (Arianayagam, n.d.). Interventions may include careful titration of dosage to balance therapeutic effects with potential side effects such as dry mouth or constipation.

Individuals taking alpha blockers, commonly prescribed for benign prostatic hyperplasia (BPH), may experience improved urinary flow due to relaxation of smooth muscle in the prostate and bladder neck (Arianayagam, n.d.). Interventions may involve monitoring for potential side effects like dizziness or orthostatic hypotension.

Understanding the impact of medications that increase urinary elimination is essential for healthcare providers to make informed decisions about prescribing and managing potential side effects. Regular monitoring, individualized adjustments, and patient education are crucial components of ensuring the optimal therapeutic benefits of these medications while minimizing any associated risks or complications.

### Pathological Factors

Pathological factors influencing urinary elimination encompass a spectrum of conditions that can disrupt the normal functioning of the urinary system. These factors extend beyond the typical physiological processes and may involve disorders or dysfunctions affecting various components of the urinary system. Pathological factors can impede the intricate coordination required for fluid balance, waste elimination, and overall homeostasis maintained by the urinary system. These disruptions may result from diseases affecting the kidneys, urinary tract, or neurological pathways involved in micturition. Understanding these pathological factors is essential in comprehending the diverse challenges individuals may face in achieving and maintaining optimal urinary function. It also underscores the importance of a comprehensive approach to health care that considers both physiological and pathological aspects to effectively address urinary elimination issues.

### Endocrine Disorders

Endocrine disorders can profoundly impact urinary elimination by disrupting the finely tuned hormonal balance that regulates kidney function and fluid balance. Hormones play a pivotal role in orchestrating various aspects of the urinary system, including blood pressure regulation, fluid and electrolyte balance, and the production of RBCs. [Table 26.3](#) displays endocrine disorders that commonly affect urinary elimination.

Endocrine Disorder	How It Affects Urinary Elimination	Interventions
Cushing syndrome	Excess cortisol, as seen in Cushing syndrome, can lead to increased water retention and electrolyte imbalance, affecting urinary output. It may contribute to conditions such as hyperaldosteronism, leading to fluid and electrolyte disturbances.	Treating the underlying cause, often related to cortisol-producing tumors, involves surgery or medication. Managing fluid and electrolyte imbalances is crucial.
Diabetes mellitus	Uncontrolled diabetes can lead to elevated blood glucose levels, causing damage to the nerves (diabetic neuropathy) and blood vessels in the urinary system. This can result in bladder dysfunction, affecting the ability to sense when the bladder is full or causing incomplete emptying. Additionally, diabetes may contribute to polyuria, an increased production of urine, as the kidneys attempt to eliminate excess glucose from the bloodstream.	Proper management of diabetes through medication, lifestyle modifications, and regular monitoring of blood glucose levels is essential. Addressing urinary symptoms may involve medications to improve bladder function and control.
Hyperparathyroidism	Elevated levels of parathyroid hormone can lead to increased calcium in the blood (hypercalcemia), which may contribute to kidney stones. Kidney stones can obstruct urinary flow and lead to issues such as painful urination and urinary retention.	Treatment focuses on addressing the underlying cause through surgical removal of parathyroid tumors or medications to regulate calcium levels.
Hypothyroidism	Hypothyroidism can lead to reduced metabolism and decreased kidney blood flow, impacting the kidneys' ability to filter and eliminate waste products. This may result in decreased urine production.	Thyroid hormone replacement therapy is the primary treatment for hypothyroidism, restoring normal thyroid function and improving kidney function.
Polycystic ovary syndrome (PCOS)	PCOS, characterized by hormonal imbalances in women, may contribute to conditions such as insulin resistance and obesity, which can impact urinary health. Obesity, in particular, is linked to an increased risk of urinary incontinence.	Lifestyle modifications, weight management, and hormonal therapies may be part of the management approach for PCOS.

**TABLE 26.3** Endocrine Disorders that Affect Urinary Elimination

Endocrine disorders pose intricate challenges to urinary elimination by affecting the hormonal control mechanisms that govern kidney function and fluid dynamics. Understanding these pathological factors is crucial for healthcare professionals to develop effective management strategies and optimize patient outcomes. Managing urinary elimination issues in the context of endocrine disorders involves an interdisciplinary approach, including endocrinologists, urologists, and other healthcare professionals. Treatment strategies aim to address the underlying endocrine disorder and manage associated urinary symptoms to improve overall quality of life.

### Kidney Disorders

Kidney disorders encompass a spectrum of pathological factors that can significantly impact urinary elimination by

compromising the structure and function of the kidneys. Conditions such as chronic kidney disease (CKD), nephrotic syndrome, urinary tract infections (UTIs), kidney calculi (kidney stones), acute kidney injuries (AKI), and polycystic kidney disease (PKD) contribute to disturbances in the normal processes of urine formation, filtration, and excretion.

Characterized by gradual and irreversible loss of kidney function over time, **chronic kidney disease (CKD)** is a major contributor to impaired urinary elimination. As the kidneys become damaged, their ability to effectively filter and excrete waste products diminishes. This often leads to reduced urine output, alterations in electrolyte balance, and the accumulation of toxins in the bloodstream. Treatment focuses on managing underlying causes, such as hypertension or diabetes, to slow the progression of CKD. In advanced stages, a medical procedure that mechanically filters and purifies the blood in individuals with kidney failure called **dialysis** (Figure 26.5) or **kidney transplantation** (a surgical procedure in which a healthy kidney from a living or deceased donor is transplanted into a recipient with end-stage kidney disease to restore kidney function) may be considered.

**FIGURE 26.5** Blood is filtered externally in the process of dialysis. Blood is taken from a patient, run through a filtration machine, and then returned. (credit: "Blausen 0313 Dialysis.png" by BruceBlaus/Wikimedia Commons, CC BY 3.0)

## PATIENT CONVERSATIONS

### Navigating Dialysis and Its Impact on Urinary Elimination

**Nurse:** Good morning, Ms. Johnson. How have you been feeling lately?

**Patient:** Good morning. Well, you know, the usual. Managing, I guess.

**Nurse:** I can sense that managing it all might be challenging. I'm here to support you, both physically and emotionally. Your well-being is important to us. I wanted to talk to you about your experiences with dialysis and how it's been affecting your urinary elimination. Could you share a bit about any changes you've noticed?

**Patient:** Oh, sure. Since I started dialysis, I've noticed that I don't have to go as often as before. Sometimes, I don't go at all. It's a bit strange.

**Nurse:** That's insightful. Changes in frequency and volume are common with dialysis. Dialysis takes over the primary function of the kidneys, filtering waste and excess fluids from the blood directly, thus reducing the need for urine production. How about any challenges or discomfort during the procedure?

**Patient:** Well, there are days when I feel a bit tired afterward.

**Nurse:** It's completely normal to feel a bit fatigued, especially after the procedure. Dialysis can be demanding on

your body, and it's important to allow yourself some rest.

**Patient:** Yeah, that makes sense. I've been trying to stay hydrated, but not too hydrated, following the fluid restrictions you all gave me. And I've adjusted my schedule a bit to allow for some rest after the sessions. It seems to help.

**Nurse:** That's excellent. It's great that you've found a routine that works for you. Remember, if you ever experience any discomfort or notice significant changes, it's essential to let us know. We're here to support you and make any necessary adjustments to ensure your well-being.

**Patient:** I appreciate that. It's been a learning curve, but I'm getting the hang of it. Just taking it one day at a time.

**Nurse:** Absolutely, Ms. Johnson. Dialysis can be an adjustment, and you're doing remarkably well. If you ever have questions or need further guidance, we're here for you. Let's work together to make this journey as comfortable as possible.

**Patient:** Thank you. I appreciate your support and understanding.

**Scenario follow-up:** This conversation emphasizes the nurse's acknowledgment of the patient's experiences, provides context on the physiological aspects of dialysis, and reinforces the importance of the patient's well-being. The nurse encourages open communication and collaboration to navigate the challenges of dialysis and its impact on urinary elimination.

---

Another kidney disorder that disrupts urinary elimination is **nephrotic syndrome**. In this condition, damage to the glomeruli, the filtering units of the kidneys, results in increased permeability, allowing essential proteins like albumin to leak into the urine, a condition called **proteinuria**. This protein loss contributes to fluid imbalance, causing edema (fluid retention) and altering the composition of urine. Management includes medications to control proteinuria, diuretics to manage edema, and addressing underlying causes such as infections or autoimmune disorders.

A **urinary tract infection (UTI)** is a bacterial infection affecting any part of the urinary system; a UTI that affects the kidneys is called **pyelonephritis**. A UTI can lead to inflammation and secondary infections, causing pain, urgency, and changes in urinary habits. Antibiotics are commonly prescribed to treat bacterial infections. Drinking plenty of fluids and maintaining good hygiene can help prevent recurrent UTIs.

A kidney stone, or kidney calculus, is a solid, crystalline structure formed in the kidneys that can obstruct the normal flow of urine ([Figure 26.6](#)). Solid masses of these stones form from crystals that accumulate in the urinary tract, leading to pain, inflammation, and potential blockages. The presence of kidney stones can cause discomfort during urination and impact the volume and composition of urine. Treatment may involve pain management, increased fluid intake to facilitate stone passage, and in some cases, surgical intervention or shock wave lithotripsy, a medical procedure used to break up kidney stones into smaller pieces, allowing them to pass more easily through the urinary tract and be excreted from the body.

**FIGURE 26.6** Kidney stones form in the kidney and may grow large enough to block the ureter. (credit: “Blausen 0595 KidneyStones.png” by BruceBlaus/Wikimedia Commons, CC BY 3.0)

A sudden and often reversible loss of kidney function called **acute kidney injury (AKI)** leads to decreased urine output and impaired filtration. An AKI can be classified into three different stages based on the underlying cause: prerenal, intrarenal (or intrinsic), and postrenal. Prerenal AKI occurs due to reduced blood flow to the kidneys, impairing their ability to filter waste from the blood. It is the most common type of AKI and is often reversible if the underlying cause is promptly addressed. Common causes include hypovolemia from dehydration, excessive bleeding, or severe burns; heart failure leading to reduced cardiac output and decreased kidney perfusion; sepsis causing widespread inflammation and decreased blood flow to the kidneys; and medications such as NSAIDs and ACE inhibitors that reduce kidney blood flow.

Intrarenal (intrinsic) AKI is due to direct damage to the kidney tissues, affecting their ability to filter and reabsorb substances properly. Causes include acute tubular necrosis, often caused by prolonged ischemia or exposure to nephrotoxic agents like certain antibiotics, radiographic contrast dyes, or heavy metals; glomerulonephritis, which is inflammation of the glomeruli potentially caused by autoimmune diseases or infections; interstitial nephritis, which is inflammation of the kidney’s interstitial tissue triggered by allergic reactions to medications or infections; and vascular issues such as vasculitis or malignant hypertension that damage the blood vessels within the kidneys.

Postrenal AKI results from obstruction of the urinary tract, preventing urine from being expelled from the body, causing a buildup of pressure and subsequent kidney damage. Causes include ureteral obstruction due to kidney stones, tumors, or strictures; bladder outlet obstruction often caused by BPH in men; and urethral obstruction due to strictures or congenital abnormalities leading to blocked urine flow. Identifying and addressing the underlying cause, such as dehydration or medication toxicity, is crucial for effective treatment. Supportive measures, including fluid resuscitation and dialysis, may be necessary to manage the symptoms and prevent further complications.

An inherited disease characterized by the formation of fluid-filled cysts in the kidneys called **polycystic kidney disease (PKD)** leads to an enlargement of the organs ([Figure 26.7](#)). This can cause compression of surrounding structures and affect urinary elimination. Management involves controlling blood pressure, pain management, and in severe cases, considering surgical interventions such as cyst drainage or kidney transplantation.

**FIGURE 26.7** In polycystic kidney disease, the kidneys are injured by the formation of multiple cysts, which may grow to be quite large. (credit: “Polycystic kidneys, gross pathology CDC PHIL.png” by Dr. Edwin P. Ewing, Jr./CDC, Public Domain)

Kidney disorders represent a diverse range of pathological factors affecting urinary elimination by impairing the kidneys’ ability to filter, regulate fluid balance, and excrete waste. Managing these conditions through targeted interventions requires a comprehensive understanding of their impact on urinary function.

#### Impaired Parasympathetic Impulses

Impaired parasympathetic impulses can significantly affect urinary elimination by disrupting the intricate coordination required for proper bladder function. The parasympathetic nervous system plays a crucial role in the micturition reflex, the process that signals the bladder to contract and the urethral sphincters to relax, facilitating the expulsion of urine. When these impulses are impaired, it can lead to difficulties in initiating or completing the micturition reflex. These difficulties may manifest as urinary retention, in which the bladder does not empty fully, or conversely, urinary incontinence, in which there is a lack of control over urine release. In some cases, there may be an inability to sense the fullness of the bladder, resulting in a lack of awareness of the need to urinate.

Several conditions can contribute to impaired parasympathetic impulses, disrupting the normal regulation of the micturition reflex. Neurological disorders such as multiple sclerosis, spinal cord injuries, or peripheral neuropathy can damage or interfere with the parasympathetic nerves involved in bladder control. Additionally, conditions like diabetic neuropathy, in which prolonged high blood sugar levels lead to nerve damage, can impact the parasympathetic signals responsible for coordinating the micturition process. Aging itself can also play a role, as the natural degeneration of nerves and muscles may affect the efficiency of parasympathetic impulses in the urinary system.

The consequence of impaired parasympathetic impulses is a disruption in the finely tuned balance required for controlled and voluntary micturition. Patients experiencing these issues may face challenges in managing their urinary elimination, necessitating a comprehensive, multifaceted approach that addresses the underlying neurological factors to optimize bladder function. For example, the following may be considered:

- Medications targeting nerve function or stimulating the parasympathetic nervous system may be prescribed, aiming to enhance signals that facilitate proper bladder emptying.
- Physical therapy, particularly pelvic floor exercises, can help improve muscle tone and coordination, optimizing the response to parasympathetic impulses.
- Biofeedback techniques offer a way for individuals to regain bladder control by providing real-time feedback on muscle activity.
- Behavioral therapy, including bladder training and habit retraining, helps establish more predictable voiding patterns.

Regardless of the specific approaches, collaborative efforts among healthcare professionals, including urologists

and neurologists, are essential to developing a comprehensive care plan. Through a combination of pharmacological, therapeutic, and lifestyle interventions, the goal is to mitigate the impact of impaired parasympathetic impulses, fostering improved urinary elimination and enhancing overall quality of life for individuals facing these challenges. Patient education and ongoing support are crucial elements in managing the condition, ensuring that interventions are tailored to the individual's specific needs and contributing factors.

## 26.4 The Nurse's Role in Urinary Elimination

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify how the nurse assesses for cues for impaired urinary elimination
- Articulate how the nurse manages patients with impaired urinary elimination
- Describe nursing procedures to promote urinary elimination

In the realm of nursing care, the assessment, management, and promotion of urinary elimination are critical to ensuring optimal physiological functioning and overall well-being for patients. The nurse's role in identifying cues for impaired urinary elimination involves a comprehensive and systematic approach, considering various factors that may influence urinary health. Through keen observation, thorough assessments, and effective communication with patients, nurses can discern signs of urinary issues. The nurse then assumes a crucial role in managing patients with impaired urinary elimination, implementing tailored interventions and collaborating with healthcare teams to address underlying causes. Furthermore, understanding nursing procedures that promote urinary elimination is essential for fostering patient comfort and preventing complications.

This section explores how nurses navigate the assessment process, manage patients facing urinary challenges, and employ procedures to enhance urinary elimination, contributing to a holistic and patient-centered approach in nursing practice.

### Assessing and Recognizing Cues for Impaired Urinary Elimination

Assessing and recognizing cues for impaired urinary elimination are fundamental aspects of health care that involve systematic evaluation of various factors influencing urinary function. This comprehensive process aims to identify signs, symptoms, and potential underlying causes associated with impaired urinary elimination, encompassing conditions such as urinary retention, incontinence, and enuresis. Healthcare providers employ a multifaceted approach, considering medical history, physical examinations, diagnostic tests, and patient-reported cues to gain insights into the complexities of urinary issues. Patient assessments may extend across the life span, considering developmental, sociocultural, and psychological factors that contribute to impaired urinary function. By understanding and recognizing these cues, healthcare professionals can tailor interventions, implement targeted management strategies, and provide patient-centered care to enhance urinary health and overall well-being. This proactive approach is vital in ensuring early detection, accurate diagnosis, and effective interventions for individuals facing challenges related to impaired urinary elimination.

#### Analyzing Characteristics of a Urine Sample

Analyzing the characteristics of a urine sample is a crucial aspect of assessing and recognizing cues for impaired urinary elimination. A diagnostic examination of a urine sample to assess various aspects of a person's health is called **urinalysis**. This routine medical test provides valuable information about kidney function, hydration status, and the presence of underlying health conditions. The examination encompasses various aspects, including the physical properties of urine, such as color, clarity, and odor, as well as chemical and microscopic elements such as pH levels, specific gravity, and the presence of proteins, glucose, blood cells, and crystals. The procedure begins with the collection of a urine sample; skilled laboratory professionals then utilize a range of techniques, from chemical dipsticks to microscopic examination, to perform the analysis.

Normal urine should be clear, pale to light yellow in color, and not foul smelling. Alterations in urine color, such as darkening or unusual hues, can signal issues like dehydration, **hematuria** (visible or microscopic blood in urine), or liver dysfunction. Clarity of urine aids in identifying conditions like UTIs, while an abnormal odor may suggest infections or metabolic disorders. Specific gravity serves as an indicator of urine concentration and kidney function. Moreover, normal urinalysis results generally reveal the absence of abnormal elements like blood, glucose, and protein. Microscopic examination confirms the absence of unusual cells, crystals, or bacteria. Normal urine

characteristics can be found in [Table 26.4](#).

Characteristic	Normal Values	Abnormal Interpretation
Color	Pale yellow to deep amber	Abnormal urine color, such as red or pink, dark yellow or amber, orange, green or blue, cloudy or murky, or foamy urine, can indicate various health conditions ranging from urinary tract infections and kidney stones to liver disease or medication side effects.
Odor	Not foul smelling	Foul-smelling urine may indicate the presence of infection or metabolic disorders.
Volume	750–2,000 mL/24 hours	Abnormal urine volume may indicate dehydration, overhydration, kidney disease, diabetes mellitus, or hormonal imbalances.
pH	4.5–8.0	Abnormal pH levels can indicate various conditions such as urinary tract infections, kidney stones, respiratory alkalosis or acidosis, metabolic acidosis or alkalosis, or certain dietary factors.
Specific gravity	1.003–1.032	Abnormal specific gravity levels may suggest dehydration, kidney disease, diabetes insipidus, or syndrome of inappropriate antidiuretic hormone secretion.
Osmolarity	40–1,350 mOsmol/kg	Abnormal osmolarity levels can indicate disorders affecting the kidneys' ability to concentrate urine, such as diabetes insipidus, or conditions causing excessive water loss, such as diabetes mellitus or hypernatremia.
Urobilinogen	0.2–1.0 mg/100 mL	Abnormal urobilinogen levels may indicate liver disease, bile duct obstruction, hemolytic disorders, or certain medications affecting bilirubin metabolism.
White blood cells	0–2 white blood cells per high-power field of microscope	Elevated levels may indicate inflammation or infection in the urinary tract.
Leukocyte esterase	None	Presence may indicate inflammation or infection in the urinary tract.
Protein	None or trace	Elevated levels may indicate kidney damage or disease.
Bilirubin	Less than 0.3 mg/100 mL	Elevated levels may indicate liver disease or obstruction of the bile ducts.
Ketones	None	Presence may indicate metabolic disorders such as diabetes or fasting.
Nitrites	None	Presence may indicate bacterial infection, particularly urinary tract infection (UTI).

**TABLE 26.4** Normal Urine Characteristics

Characteristic	Normal Values	Abnormal Interpretation
Blood	None	Presence may indicate kidney stones, infection, or other urinary tract disorders.
Glucose	None	Presence may indicate diabetes or other metabolic disorders.

**TABLE 26.4** Normal Urine Characteristics

Examining urine sediment to detect crystals or casts is an additional step in pinpointing particular kidney disorders. Conditions that frequently indicate infections include hematuria and **pyuria**, signified by the detection of at least ten white blood cells per cubic millimeter in a urine sample. In severe cases, this may even involve the potential visualization of pus. These aspects hold significant importance in the diagnostic process.

Monitoring urine volume is essential for assessing hydration status and potential issues with fluid balance. Urine volume varies considerably. The normal range is 1 to 2 L per day. The kidneys must produce a minimum urine volume of about 500 mL/day to rid the body of wastes. Output below this level may be caused by severe dehydration or kidney disease and is termed oliguria. The virtual absence of urine production is termed anuria, which may be due to conditions such as kidney failure or shock. Excessive urine production is polyuria, which may be due to diabetes mellitus or diabetes insipidus. [Table 26.5](#) identifies the urine volumes associated with these conditions.

Volume Condition	Volume	Possible Causes
Normal	1–2 L/day	N/A
Polyuria	Greater than 2.5 L/day	Diabetes mellitus; diabetes insipidus; excess caffeine or alcohol; kidney disease; certain drugs, such as diuretics; sickle cell anemia; excessive water intake
Oliguria	300–500 mL/day	Dehydration, blood loss, diarrhea, cardiogenic shock, kidney disease, enlarged prostate
Anuria	Less than 50 mL/day	Kidney failure; obstruction, such as kidney stone or tumor; enlarged prostate

**TABLE 26.5** Urine Volumes and Associated Conditions

Nurses play a crucial role in recognizing subtle changes in these urine characteristics that can serve as early indicators of impaired urinary elimination or underlying health issues. Regular and thorough urinalysis, along with a keen understanding of the significance of various parameters, allows healthcare professionals to promptly address and manage potential urinary concerns, contributing to overall patient well-being.

### Urinary Retention

Assessing and recognizing cues for impaired urinary elimination, specifically urinary retention, are critical aspects of healthcare evaluation. Urinary retention refers to the inability to empty the bladder completely, leading to the accumulation of urine. The condition can be acute (e.g., the inability to urinate after receiving anesthesia during surgery) or chronic (e.g., a gradual inability to completely empty the bladder due to enlargement of the prostate gland in males). Urinary retention following anesthesia during surgery can occur due to the inhibitory effects of anesthesia on the reflexes that control bladder function, leading to temporary dysfunction in bladder muscle contraction and relaxation. Additionally, certain medications used during surgery, such as opioid analgesics and muscle relaxants, can further contribute to urinary retention by causing relaxation of the bladder muscles or interfering with the sensation of bladder fullness. In the case of prostate enlargement, urinary retention may occur

because of a blockage that partially or fully prevents the flow of urine (Figure 26.8) or because the bladder is unable to create a strong enough force to expel all the urine. In addition to causing discomfort, urinary retention increases the patient's risk for developing a UTI.

**FIGURE 26.8** An enlarged prostate gland can block the flow of urine from the bladder into the urethra, causing urinary retention. (credit: modification of work from National Cancer Institute. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Clinically, urinary retention can present with symptoms such as a distended bladder, lower abdominal discomfort, and the inability to initiate or sustain a urine stream. Other times, the patient may have no symptoms at all. Healthcare providers rely on a patient's medical history, findings from a physical examination, and diagnostic tests to identify the underlying cause of urinary retention. When assessing a patient for urinary retention, healthcare providers may inquire about the frequency and volume of urination, the presence of straining during voiding, and any associated pain or discomfort.

Physical examination techniques, such as palpation of the lower abdomen for a palpable and distended bladder, and percussion to assess for dullness, can aid in diagnosing urinary retention. Additionally, ultrasound, bladder scans, or straight catheterization may be employed to determine **postvoid residual urine volume**, a measurement of urine left in the bladder after a patient has voided. The identification of urinary retention is crucial as it can result from various causes, including structural issues, neurological disorders, or medications. Normal PVR volume is typically between 50 and 100 mL. Prompt recognition allows healthcare professionals to implement appropriate interventions, such as catheterization or medications, and to address the underlying cause, preventing potential complications associated with prolonged urinary retention, such as UTIs or kidney damage. Alpha blockers, such as tamsulosin (Flomax), are used to treat urinary retention caused by an enlarged prostate. A surgery called transurethral resection of the prostate (TURP) may be performed to treat urinary retention caused by an enlarged prostate that is not responsive to medication. A TURP is performed by inserting a resectoscope through the urethra to remove excess prostate tissue causing the urinary obstruction. The procedure aims to relieve symptoms of BPH, such as difficulty urinating, frequent urination, and incomplete bladder emptying. The hopeful outcome of TURP is improved urinary flow and symptom relief.

### UNFOLDING CASE STUDY

#### Unfolding Case Study #4: Part 7

Refer to [Chapter 19 Oxygenation and Perfusion](#), [Chapter 22 Activity](#), and [Chapter 24 Skin Integrity](#) for [Unfolding Case Study #4: Part 1](#), [Unfolding Case Study #4: Part 2](#), [Unfolding Case Study #4: Part 3](#), [Unfolding Case Study #4: Part 4](#), [Unfolding Case Study #4: Part 5](#), and [Unfolding Case Study #4: Part 6](#) to review the patient data. Mrs. Jensen, a 72-year-old female, presents to the emergency room with worsening shortness of breath, fatigue, and

swelling in her lower extremities over the last week. She reports increasing difficulty performing activities of daily living due to weakness and increased dyspnea. She has been admitted to the telemetry unit.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, heart failure (class III), osteoarthritis</p> <p><b>Family history:</b> No significant family history reported.</p> <p><b>Social history:</b> Widowed ten years ago, currently living in an assisted care facility. No children.</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Lisinopril 20 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Metoprolol 50 mg PO once daily</li> <li>• Aspirin 81 mg PO once daily</li> <li>• Furosemide 40 mg PO once daily</li> <li>• Losartan 25 mg PO once daily</li> <li>• Ibuprofen 400 mg PO Q6 hours PRN mild arthritic pain</li> </ul>
Provider's Orders	<p><b>1145:</b></p> <ul style="list-style-type: none"> <li>• Admit to telemetry unit</li> <li>• Twelve-lead electrocardiogram</li> <li>• Oxygen therapy to maintain oxygen saturation at greater than 92 percent</li> <li>• 20 mg Furosemide IV STAT</li> </ul>
Nursing Notes	<p><b>1200:</b></p> <p>Twelve-lead ECG completed; results show sinus tachycardia. 2 L oxygen via nasal cannula applied, patient reports improvement in dyspnea. IV placed in right AC, 20 mg Furosemide IV administered. Patient instructed to call before getting up to use bathroom. Patient has not voided since admission. Patient admitted to room on cardiac unit, and handoff given to telemetry nurse.</p>
Nursing Notes	<p><b>1800:</b></p> <p>Patient pressed call light to request to use the bathroom. Ambulated with ×1 assist from nurse due to unsteady gait. Patient was unable to void.</p>

1. Recognize cues: What cues are most important for the nurse to recognize?
2. Analyze cues: What is the significance of the recognized cue in the previous question?
3. Prioritize hypotheses: What other findings should the nurse assess for that would be consistent with a diagnosis of urinary retention?
4. Generate solutions: What are the priority actions by the nurse?
5. Take action: The nurse performs a bladder scan and determines that the patient has 500 mL of urine in the bladder. What order does the nurse anticipate receiving from the provider after relaying this information?
6. Evaluate outcomes: What findings would indicate that the nurse's actions were effective?

### Measuring Residual Urine

Measuring residual urine is a diagnostic procedure used to assess the amount of urine left in the bladder after a person has emptied it. This measurement is crucial in identifying conditions such as urinary retention, which can contribute to various urinary issues and may indicate an underlying problem. Several methods are commonly employed to measure residual urine:

- **Bladder scan/ultrasound:** This is a noninvasive and commonly used method that involves using a portable ultrasound device, known as a bladder scanner. This device uses sound waves to create an image of the bladder and measure the amount of urine present. It is a quick and painless way to assess postvoid residual volume.
- **Straight catheterization:** This is a more invasive method. A thin, flexible tube (catheter) is inserted into the bladder to drain any remaining urine. The volume of urine collected provides information about the residual urine.
- **Catheterization with a Foley catheter:** Like a straight catheter, a Foley catheter is inserted into the bladder, and the amount of urine drained is measured. However, the Foley catheter is often left in place to continuously drain urine, providing ongoing monitoring.

The choice of method depends on the clinical situation, patient factors, availability of equipment, and the provider's orders. Noninvasive methods like ultrasound are generally preferred when appropriate; however, catheterization may be necessary in certain situations, especially when a more accurate measurement is required or when immediate relief is needed in cases of significant urinary retention. The results of residual urine measurements guide healthcare professionals in developing appropriate treatment plans and interventions to address the underlying causes of impaired urinary elimination.

## REAL RN STORIES

---

### Navigating Urinary Challenges: A Nurse's Journey with Bladder Scanning and Straight Catheterization

**Nurse:** Tim, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 3

**Facility location:** The inner city of a large metropolitan area in Massachusetts

I encountered a situation where a bladder scan played a crucial role in assessing a patient's urinary elimination. The patient, a 65-year-old female recovering from a hysterectomy surgery, was experiencing difficulty voiding after the procedure. On recognizing the cues for potential urinary retention, I decided to use a bladder scan to measure the residual urine in the patient's bladder. The noninvasive nature of the scan made it an ideal choice, considering the patient's postoperative state.

The bladder scan revealed a significant amount of residual urine (over 400 mL), indicating a potential issue with complete emptying of the bladder. This information guided our care plan, and we implemented interventions promptly to address the urinary retention. In collaboration with the healthcare team, we initiated measures such as repositioning, encouraging ambulating, turning on the water faucet, and closely monitoring the patient's voiding patterns.

After another hour of no voiding, the patient started complaining of abdominal distension, which was causing pain to her surgical site. I scanned the patient's bladder again, and she had over 500 mL of urine in her bladder. The provider ordered a straight catheterization (sometimes referred to as an "in and out cath") to remove the patient's urine from her bladder. As soon as the catheter reached her bladder, the patient verbalized immediate relief of the abdominal pressure. Knowing the bladder scan had indicated there were at least 500 mL of urine in her bladder, I knew approximately how much urine to expect from the straight catheterization, ensuring her bladder was completely empty before removing the catheter. Thankfully, the patient was able to regain voiding functioning after this instance and did not need to be catheterized again.

---

### Urinary Incontinence

Urinary incontinence is the involuntary loss of urine. Although abnormal, it is a common symptom that can seriously affect the physical, psychological, and social well-being of affected individuals of all ages. It has been estimated that one in five women develop urinary incontinence, but many are too embarrassed to discuss the condition with their healthcare providers. Some believe it is a normal part of aging that they have to live with. Incontinence can lead to isolation and depression as people, embarrassed by the condition, limit their activities and social

interactions. Nurses can greatly improve the quality of life for these patients by assessing for incontinence in a sensitive manner and then providing patient education about methods to prevent or manage symptoms.

Assessing and recognizing cues for urinary incontinence involve a comprehensive evaluation of factors contributing to involuntary urine leakage. The assessment process encompasses a detailed medical history, including the onset, frequency, and severity of incontinence episodes, as well as any potential triggers or exacerbating factors. Physical examinations, such as pelvic floor assessments, may be conducted to evaluate muscle tone and function. It is also essential to assess fluid intake, voiding patterns, and the presence of other contributing factors, such as neurological conditions or medications.

## PATIENT CONVERSATIONS

---

### How to Initiate a Patient Conversation about Urinary Incontinence

Urinary incontinence is a common health concern that significantly impacts the lives of many individuals. Engaging in open and empathetic conversations with patients about urinary incontinence is crucial for providing patient-centered care that addresses their unique needs.

**Nurse:** Good afternoon, Mr. Rodriguez. How are you feeling today?

**Patient:** Hello, Nurse Suzie. I'm feeling okay; however, I've been better. Lately, I've noticed that I'm having trouble controlling my urine, and it's been quite embarrassing.

**Nurse:** I appreciate you sharing that with me, Mr. Rodriguez. It's important for us to discuss any concerns you have. Can you tell me more about when this started and any patterns you've noticed?

**Patient:** It's been happening for a few weeks now, especially when I laugh or cough. It's frustrating.

**Nurse:** It's not uncommon, and we can work together to address this. Have you experienced any pain or discomfort while urinating?

**Patient:** No, it doesn't hurt, but it's just inconvenient.

**Nurse:** I see. Thank you for sharing that. We'll explore some strategies to manage this, and I'll also assess if there are any factors that may be causing these symptoms. In the meantime, if there's anything specific you've noticed that triggers it, let me know.

**Patient:** Thank you, Nurse Suzie. I appreciate your help.

**Scenario follow-up:** Initiating patient conversations about urinary incontinence in a sensitive and informative manner promotes patient engagement, empowerment, and collaborative decision-making for effective management of this common condition.

---

Analyzing characteristics of urine samples can also provide valuable insights into the nature of urinary incontinence. Understanding the specific type of urinary incontinence, whether **functional incontinence**, **mixed urinary incontinence**, **overflow incontinence**, **stress urinary incontinence**, or **urge urinary incontinence**, is crucial for tailoring appropriate interventions ([Table 26.6](#)).

Type of Incontinence	Description
Functional incontinence	<ul style="list-style-type: none"> <li>Occurs in older adults who have normal bladder control but struggle to get to the toilet in time to void because of arthritis or other disorders that make it hard to move quickly or manipulate zippers or buttons</li> <li>Increased risk for functional incontinence in patients with dementia</li> </ul>
Mixed urinary incontinence	<ul style="list-style-type: none"> <li>A combination of urinary frequency, urgency, and stress incontinence (Tso, 2018)</li> </ul>
Overflow incontinence	<ul style="list-style-type: none"> <li>The leakage of small amounts of urine from a bladder that is always full</li> <li>Tends to occur in males with enlarged prostates that prevent the complete emptying of the bladder (National Institute of Aging, 2022)</li> </ul>
Stress urinary incontinence	<ul style="list-style-type: none"> <li>The involuntary loss of urine with intra-abdominal pressure (e.g., laughing and coughing) or physical exertion (e.g., jumping)</li> <li>Caused by weak pelvic floor muscles, which often result from pregnancy and vaginal delivery, menopause, or vaginal hysterectomy (Tso, 2018)</li> </ul>
Urge urinary incontinence (also referred to as “overactive bladder”)	<ul style="list-style-type: none"> <li>Urine leakage accompanied by the sensation of a strong desire to void (urgency)</li> <li>Caused by increased sensitivity to stimulation by the detrusor muscle in the bladder or decreased inhibitory control of the central nervous system (Tso, 2018)</li> </ul>

**TABLE 26.6** Types of Urinary Incontinence

Assessment begins with screening questions during a health history, including questions such as, “Do you have any problems with the leakage or dribbling of urine? “Do you ever have problems making it to the bathroom in time?” If a patient responds “Yes” to either of these questions, it is helpful to encourage them to start a voiding diary to record their urination habits and activities. The voiding diary should include the following:

- when and how much the patient urinates
- urinary leakage and what the patient was doing when it happened (e.g., running, biking, laughing)
- sudden urges to urinate
- how often the patient wakes at night to use the bathroom
- type and volume of food and beverages and the time of intake
- use of medication, such as diuretics, and the timing of administration
- any pain or problems experienced before, during, or after urinating (e.g., sudden urges, difficulty urinating, dribbling urine, weak urine flow, feeling as if the bladder is never empty) (Tso, 2018)

The provider should review the voiding diary, perform a physical assessment, and likely order diagnostic testing, such as a urine dip to check for a UTIs. Urodynamic diagnostic testing involves a variety of tests of bladder function, including filling, urine storage, and emptying (Tso, 2018). Individualized treatment will be based on the results of these assessments as well as any tests assessing for structural abnormalities in the patient’s urinary system.

Nurses should use therapeutic communication with patients experiencing urinary incontinence to help them feel comfortable in expressing their fears, worries, and embarrassment about incontinence and work toward improving their quality of life. Let them know they are not alone and that urinary incontinence is not something they have to live with. Provide education about pelvic floor muscle training exercises, timed voiding, lifestyle modification, and incontinence products. Encourage them to learn more about their condition so they can optimally manage it and improve their quality of life (Tso, 2018).

Nurses play an important role in educating patients about bladder control training to prevent incontinence. Bladder control training includes several of these techniques:

- Pelvic muscle exercises (also known as Kegel exercises) work the muscles used to stop urination, which can help prevent stress incontinence. Learn more about pelvic floor exercises in the [Link to Learning](#) that follows.
- Timed voiding can be used to help a patient regain control of their bladder by urinating on a set schedule (e.g., every hour) whether they feel the urge to urinate or not. The time between bathroom trips is gradually extended, with the general goal of achieving four hours between voiding. Timed voiding helps to control urge and overflow incontinence by training the brain to be less sensitive to the sensation of the bladder walls expanding as they fill (National Institute of Aging, 2022).
- Lifestyle changes can help with incontinence. Losing weight, drinking less caffeine (found in coffee, tea, and many sodas), preventing constipation, and avoiding lifting heavy objects may help with incontinence. Limiting fluid intake before bedtime and scheduling prescribed diuretic medication in the morning or early afternoon are also helpful strategies (National Institute of Aging, 2022).
- Protective products may be needed to protect the skin from breakdown and prevent leakage onto clothing. Incontinence underwear has a waterproof liner and built-in cloth pad to absorb large amounts of urine, thereby protecting skin from moisture and controlling odor. It is available in daytime styles and nighttime styles, which are designed to hold more urine. A product resembling a tampon is another option for females. It is made of absorbent fibers that support the urethra and prevent accidental leaks without inhibiting urination; it also will not move or fall out during bowel movements (National Institute of Aging, 2022).

## LINK TO LEARNING

Watch this video from Michigan Medicine to [learn more about Kegel exercises \(https://openstax.org/r/77kegel\)](https://openstax.org/r/77kegel) and why they work.

Additionally, patient education regarding other treatment options may be provided:

- Biofeedback uses sensors to help a patient become more aware of signals from the body to regain control over the muscles in their bladder and urethra (National Institute of Aging, 2022).
- Mechanical devices, such as pessaries, support the urethra and can support vaginal prolapse to prevent or reduce urinary leakage. They come in various sizes and are professionally fitted by trained healthcare providers. They should be removed, cleaned, and reinserted regularly to prevent infection. Some of the devices, such as ring pessaries, can be removed and reinserted by the patient. They are similar to a diaphragm and can be removed or left in place for sexual intercourse (National Institute of Aging, 2022).
- Anticholinergic medications, such as oxybutynin, may be prescribed to treat urge urinary incontinence and mixed urinary incontinence. They block the action of acetylcholine and provide an antispasmodic effect on smooth muscle to relieve symptoms. However, side effects include dry mouth, constipation, dizziness, and drowsiness, which can increase fall risk in older adults.
- If bladder training and medications are not effective, surgery may be performed, such as a sling procedure or a bladder neck suspension (National Institute of Aging, 2022).

## Enuresis

Commonly referred to as bedwetting or nocturnal enuresis, **enuresis** can be a challenging condition that impacts both children and adults. Assessing and recognizing cues for enuresis involve thorough evaluation of involuntary nighttime bedwetting, particularly in children beyond the age of expected bladder control. The assessment process typically includes a comprehensive medical history that focuses on the frequency and patterns of bedwetting episodes, any associated daytime symptoms, and relevant psychosocial factors.

In pediatric cases, the evaluation may extend to developmental considerations, assessing the child's level of bladder control and emotional well-being. For adults, the assessment may encompass medical, psychological, and lifestyle factors that could contribute to enuresis. It is crucial to rule out potential underlying causes, such as UTIs, diabetes, or neurological issues, through appropriate diagnostic tests.

Understanding the nature of enuresis, whether primary (never achieved continence) or secondary (recurrence after

a period of dryness), is essential for tailoring intervention strategies. Behavioral approaches, moisture alarms, and medications are common components of a comprehensive management plan; it is also important to address any psychosocial factors contributing to stress or anxiety.

The nuanced assessment of enuresis cues enables healthcare providers to implement targeted interventions, providing support and guidance to individuals experiencing bedwetting. Recognizing the various factors influencing enuresis is fundamental in developing effective strategies to manage and improve the overall quality of life for those affected by this condition.

## PATIENT CONVERSATIONS

---

### Assessing Enuresis with a Patient-Centered Approach

**Nurse:** Good morning, Mrs. Li. I hope you're feeling well today. My name is Nurse Martinez. I understand that you've been dealing with some concerns related to bedwetting. Can you share a bit more about what you've been experiencing?

**Patient:** Good morning, Nurse Martinez. Yes, it's been quite embarrassing, but I've been wetting the bed at night, and it's been happening more frequently lately.

**Nurse:** Thank you for sharing that with me. I appreciate your openness. I'd like to ask you a few questions to better understand your situation. First, how often would you say you experience bedwetting, and has there been any change in the frequency over time?

**Patient:** It happens a few times a week now, but it didn't use to be this often. Maybe once a month before.

**Nurse:** I see. And have you noticed any patterns or triggers associated with the bedwetting episodes? For example, does it happen more on certain nights or after specific events or activities?

**Patient:** Well, I haven't really noticed any patterns, but it does seem to happen more when I'm feeling stressed or anxious.

**Nurse:** That's valuable information. Stress can certainly play a role. Now, regarding your overall health, have you experienced any recent illnesses or changes in your urinary habits during the day?

**Patient:** No, nothing unusual during the day. Just the bedwetting at night.

**Nurse:** Okay. Your provider will be here in a few minutes to conduct a physical assessment and check for any signs that might be contributing to the bedwetting. This will include a general examination and possibly some diagnostic tests to rule out any underlying issues.

**Patient:** I just want to figure out why this is happening.

**Nurse:** I understand, Mrs. Li. We will work together to figure out what is going on. Then, we can discuss possible interventions and strategies to help manage or alleviate the bedwetting. If you have any questions or concerns along the way, please feel free to let me know.

**Scenario follow-up:** This conversation is a starting point for the nurse to gather information, establish rapport, and plan further assessments and interventions tailored to the patient's needs.

---

### Managing Patients with Impaired Urinary Elimination

Managing patients with impaired urinary elimination requires an interdisciplinary and patient-centered approach to address the diverse challenges individuals may face in maintaining optimal urinary function. Urinary elimination is a fundamental aspect of physiological well-being, and disruptions in this process can significantly impact a patient's quality of life. Nurses play a crucial role in assessing, recognizing cues, and implementing targeted interventions to manage impaired urinary elimination effectively. This comprehensive care involves understanding the underlying causes of urinary issues, tailoring interventions to the patient's unique needs, and continuously evaluating the effectiveness of implemented measures. From providing meticulous skin care to implementing bladder training and repositioning techniques, nurses strive to enhance patient comfort, prevent complications, and promote the

restoration or maintenance of optimal urinary function. By integrating evidence-based practices and maintaining open communication with patients, nurses caring for those with impaired urinary elimination aim to address both the physiological and psychosocial aspects of this essential bodily function.

### Providing Skin Care

Managing patients with impaired urinary elimination necessitates a multifaceted approach, and providing effective skin care is a crucial aspect of this endeavor. Individuals experiencing urinary incontinence or retention are at an increased risk of skin-related complications, such as irritation, inflammation, pressure ulcers, and potential infections. The nurse's role in this context involves diligent monitoring of the perineal area and surrounding skin, identifying early signs of skin breakdown.

Regular cleansing and gentle drying of the skin are paramount to prevent **moisture-related dermatitis**. Moisture-related dermatitis, often referred to as moisture-associated skin damage, is a skin condition characterized by inflammation and irritation resulting from prolonged exposure to moisture. This type of dermatitis is particularly common in areas of the body where the skin is subjected to moisture, friction, and occlusion, creating an environment conducive to skin breakdown. Application of moisture barriers, protective creams, or ointments helps create a barrier against the corrosive effects of urine and promotes skin integrity. Beyond these direct interventions, nurses should collaborate with interdisciplinary teams to formulate individualized care plans. These plans not only address immediate skin care needs but also target the root causes of impaired urinary elimination.

Patient education is a cornerstone of nursing care in this context. Through ongoing assessment and education initiatives, nurses empower patients to actively engage in their own skin care routines. This collaborative approach not only aids in managing the complexities associated with impaired urinary elimination but also promotes a sense of autonomy for patients to actively participate in decisions regarding their health care and to take actions to improve their own health outcomes.

### Repositioning

Repositioning is a crucial aspect of managing patients with impaired urinary elimination. Particularly for individuals experiencing mobility challenges or those susceptible to urinary retention, extended periods of immobility can lead to discomfort, skin breakdown, and potential urinary complications. Regular and purposeful repositioning not only helps alleviate pressure on vulnerable areas, such as the sacral region, reducing the risk of pressure ulcers, but it also facilitates optimal bladder function.

Repositioning strategies aim to enhance patient comfort, maintain skin integrity, and support overall urinary health. Nurses play a vital role in assessing the individualized needs of patients, implementing appropriate repositioning schedules and ensuring a holistic approach to care that addresses both mobility concerns and urinary elimination challenges. This proactive approach to repositioning contributes to the overall well-being of patients with impaired urinary elimination, promoting comfort and minimizing the risk of complications associated with prolonged immobility.

### Bladder Training

A therapeutic approach, **bladder training**, is employed by healthcare professionals to manage patients with impaired urinary elimination, particularly those experiencing issues such as urinary urgency, frequency, or incontinence. This structured program aims to enhance bladder control and improve voiding habits through behavioral interventions. The process involves creating a voiding schedule, gradually extending the time between bathroom visits, and implementing strategies to suppress the urge to urinate. Additionally, patients are encouraged to practice pelvic floor exercises to strengthen the muscles responsible for bladder function. Bladder training is tailored to individual needs and may include counseling to address psychological factors contributing to urinary issues. This holistic approach empowers patients to regain control over their urinary function, promoting improved continence and overall quality of life. Regular monitoring and adjustment of the bladder training plan are essential to ensure its effectiveness and make necessary modifications based on the patient's progress.

### Evaluating Interventions for Urinary Elimination

Evaluating the restoration or maintenance of urinary elimination is a crucial aspect of nursing care for patients facing impaired urinary function. After implementing interventions such as skin care, repositioning, and bladder training, it is essential for the nurse to assess the effectiveness of these measures in promoting optimal urinary elimination.

This evaluation involves a comprehensive review of the patient's urinary patterns, noting changes in frequency, urgency, and the ability to initiate and complete voiding. The nurse should also monitor the volume and characteristics of the urine, looking for signs of improvement or persistence of issues. Additionally, assessing the patient's comfort level, any reported discomfort or pain during urination, and the impact on overall well-being provides valuable information for evaluating the success of interventions. Regular communication with the patient to gather subjective feedback and address any concerns is integral to this evaluative process. The nurse collaborates with the healthcare team to make necessary adjustments to the care plan based on the assessment findings, ensuring a patient-centered approach that prioritizes the restoration and maintenance of optimal urinary elimination.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Prioritize a Hypothesis: Determining Restoration of Urinary Elimination

A patient who recently underwent bladder training and received meticulous skin care for urinary incontinence reports a decrease in urgency, improved voiding habits, and overall satisfaction with the interventions. The nurse gathers data on the patient's reported symptoms, including changes in urgency and voiding habits; reviews the patient's urinary patterns, characteristics of urine, and comfort level; and utilizes assessment tools, such as voiding diaries and patient interviews, to collect comprehensive data. From the assessment findings, the nurse recognizes improvements in urgency, voiding habits, and patient satisfaction as positive cues. The nurse prioritizes the hypothesis that urinary elimination has been restored based on the positive cues identified and evaluates the consistency and significance of improvements to confirm the effectiveness of implemented interventions. Applying the clinical judgment measurement model to this scenario involves a systematic and data-driven approach, allowing nurses to prioritize and validate the hypothesis of restored urinary elimination based on positive cues and patient feedback. This process contributes to effective clinical judgment and decision-making for enhanced patient outcomes.

### Nursing Procedures to Promote Urinary Elimination

Nursing procedures aimed at promoting urinary elimination address a range of conditions that may compromise this essential physiological function. These procedures encompass a variety of interventions designed to assess, manage, and support individuals experiencing impaired urinary elimination. From the meticulous analysis of urine characteristics to the implementation of catheterization techniques and other interventions, nurses play a vital role in ensuring the well-being and comfort of patients with urinary challenges. The emphasis on maintaining optimal urinary function underscores the importance of these nursing procedures in preventing complications, managing symptoms, and ultimately enhancing the overall quality of patient care.

#### Urinary Catheterization

A nursing procedure, **urinary catheterization** is employed to promote urinary elimination in situations where a patient is unable to void voluntarily or when continuous drainage of urine is necessary. This procedure involves the insertion of a flexible tube, or catheter, through the urethra into the bladder. The catheter can be either removed after the bladder is emptied or connected to a drainage bag to allow the continuous collection of urine. Indications for urinary catheterization include urinary retention, surgical procedures, the need to monitor urine output in critically ill patients, the facilitation of healing in certain medical conditions, and to monitor the effectiveness of treatments provided to the patient to measure expected improved patient outcomes. While urinary catheterization is an effective intervention, it poses potential risks, such as the risk of infection (referred to as a **catheter-associated urinary tract infection**) or trauma to the urinary tract. Therefore, it is crucial for healthcare professionals to adhere to strict aseptic techniques during the insertion and maintenance of urinary catheters and to assess the patient regularly for signs of complication, such as fever, new onset of pain, and UTIs. This nursing procedure requires skill and precision to ensure patient comfort, prevent complications, and maintain optimal urinary function.

#### Performing Irrigations

A **urinary irrigation** is a nursing procedure designed to facilitate and maintain optimal urinary elimination by ensuring the cleanliness and patency of catheters. This technique involves the introduction of a sterile solution into

the bladder through the catheter, with the primary goals of preventing blockages, promoting urine flow, and minimizing the risk of infection. Irrigations are commonly ordered when there is evidence of catheter obstruction due to sediment or blood clots, and they play a crucial role in enhancing the overall effectiveness of urinary catheterization.

To perform bladder irrigation, a catheter is gently inserted into the bladder through the urethra. The sterile solution is then allowed to flow into the bladder, filling it to a predetermined volume. After a brief time, the solution is drained out, carrying away contaminants. This process may be repeated until the irrigating fluid returns clear, indicating successful cleansing, or it may be ordered as continuous bladder irrigation for postsurgical procedures or patients with hematuria (blood in the urine). Throughout the procedure, close monitoring of the patient's response, vital signs, and any signs of discomfort or complications is essential. Healthcare providers adhere to strict aseptic techniques to minimize the risk of infection during the procedure. After irrigation, the catheter is secured, and the patient is closely observed for any adverse reactions.

One notable concern is the risk of infection, as the procedure itself may introduce bacteria into the urinary tract, potentially leading to UTIs. The insertion and manipulation of catheters during irrigation pose a risk of trauma or injury to the urethra, bladder, or surrounding structures, resulting in bleeding, pain, or other complications. Additionally, there is the potential for fluid and electrolyte imbalances, especially if excessive irrigation or absorption of irrigating solutions occurs. Allergic reactions to the solutions used in irrigation, ranging from mild skin reactions to severe respiratory distress, can also occur. In rare instances, aggressive or improperly performed irrigation may lead to **bladder perforation**, a rupture or tear in the wall of the urinary bladder; this is a serious complication that requires immediate attention. Moreover, urinary irrigation, often involving catheters, may increase the overall risk of catheter-associated complications, including infections and catheter-related trauma.

## Summary

### 26.1 Urinary System

The urinary system, composed of the kidneys, ureters, bladder, and urethra, is a vital component of the human anatomy, responsible for maintaining internal balance and waste elimination. The kidneys act as intricate filters, extracting excess fluids and waste products, with nephrons playing a central role. Ureters transport urine to the bladder, a muscular reservoir, while the urethra serves as the exit pathway.

The process of urine formation is orchestrated by the kidneys and involves glomerular filtration, tubular reabsorption, and tubular secretion. Glomerular filtration initiates in the glomerulus, where blood is filtered to form an initial filtrate. Tubular reabsorption selectively reclaims vital substances from this filtrate, and tubular secretion actively eliminates specific substances into the renal tubules. These processes fine-tune urine composition, regulating fluid balance and waste removal.

The act of urination, governed by the micturition reflex, involves a complex interplay between the nervous and muscular systems. The stages, including resting, filling, and voiding, ensure controlled and voluntary release of urine. Dysfunction in this process can lead to issues such as incontinence or retention.

### 26.2 Functions of the Urinary System

The urinary system orchestrates the elimination of crucial waste products, including urea, creatinine, and uric acid, processes that are vital to maintaining the body's internal balance. These nitrogenous by-products are meticulously filtered by the kidneys. Urea, formed in the liver during protein breakdown, undergoes kidney filtration, preventing its accumulation and supporting the body's chemical composition. Creatinine, a product of muscle metabolism, is consistently filtered by the kidneys, with elevated levels indicating potential kidney issues. Uric acid, arising from purine breakdown, undergoes kidney filtration to prevent elevated blood levels, averting conditions like gout.

Fluid and electrolyte balance are also finely regulated by the urinary system. The kidneys, acting as precise filters, undergo glomerular filtration, tubular reabsorption, and tubular secretion to regulate electrolytes, fluid volume, and metabolic waste. These processes contribute to blood volume, pressure regulation, and electrolyte concentrations, sustaining overall physiological balance. The urinary system also actively participates in maintaining acid-base equilibrium by selectively excreting hydrogen ions and reabsorbing bicarbonate ions, ensuring optimal pH levels in bodily fluids.

The kidney system releases hormones to regulate blood pressure through the RAAS. Renin, produced by the kidneys, initiates a cascade leading to the production of angiotensin II, a vasoconstrictor influencing blood pressure. Additionally, the urinary system controls RBC production through erythropoietin (EPO) release. Synthesized by the kidneys in response to low oxygen levels, EPO stimulates bone marrow to produce RBCs, ensuring oxygen transport and contributing to homeostasis.

### 26.3 Factors Affecting Urinary Elimination

Impaired urinary elimination presents a multifaceted challenge, demanding a comprehensive understanding of various considerations. Developmental, sociocultural, psychological, and physiological factors collectively shape an individual's experience with impaired urinary elimination. Developmental considerations vary across the life span, impacting bladder control and toileting habits differently in infants, children, adolescents, adults, and older adults. Sociocultural factors, including cultural beliefs and access to health care, significantly influence attitudes toward urinary health. Adequate fluid and food intake, along with muscle tone, are essential considerations, as they affect urine concentration and the muscles involved in voiding.

Psychological factors, such as stress and mental health, have a crucial impact on the nervous system's regulation of the micturition reflex. Muscle tone and activity are critical, with weakened pelvic floor muscles leading to issues like stress incontinence. Medications can either impair or enhance urinary elimination, requiring careful consideration of their effects. Pathological factors, including endocrine and kidney disorders, as well as impaired parasympathetic impulses, contribute to disruptions in the urinary system's normal functioning. Understanding these factors is vital for healthcare professionals to provide individualized care that promotes optimal urinary health.

## 26.4 The Nurse's Role in Urinary Elimination

The comprehensive assessment and recognition of cues for impaired urinary elimination form a fundamental aspect of health care, requiring a systematic evaluation of various factors influencing urinary function. Healthcare professionals employ a multifaceted approach, considering medical history, physical examinations, diagnostic tests, and patient-reported cues to identify signs, symptoms, and potential underlying causes associated with impaired urinary elimination. By understanding and recognizing these cues, nurses can tailor interventions, implement targeted management strategies, and provide patient-centered care to enhance urinary health and overall well-being.

Analyzing the characteristics of a urine sample is a crucial component of assessing and recognizing cues for impaired urinary elimination. A comprehensive urinalysis, considering parameters like color, clarity, odor, volume, and specific gravity, provides valuable insights into kidney and overall health. Nurses play a crucial role in recognizing subtle changes in these urine characteristics, which serve as early indicators of impaired urinary elimination or underlying health issues. Regular and thorough urinalysis, along with a keen understanding of the significance of various parameters, allows healthcare professionals to promptly address and manage potential urinary concerns.

Assessing urinary retention involves a critical evaluation of a patient's ability to empty the bladder completely. This condition can result from various causes, and healthcare providers employ techniques such as palpation, percussion, and ultrasound to diagnose and measure postvoid residual urine volume. Measuring residual urine is a diagnostic procedure crucial for identifying conditions like urinary retention. Various methods, including bladder scans, straight catheterization, and catheterization with a Foley catheter, provide information about the volume of urine left in the bladder after voiding.

Assessing urinary incontinence involves a comprehensive evaluation of factors contributing to involuntary urine leakage. Recognizing the multifaceted nature of urinary incontinence and addressing underlying causes are fundamental in promoting effective management and improving the overall well-being of individuals experiencing this condition. Assessing enuresis involves a thorough evaluation of involuntary nighttime bedwetting. Understanding the nature of enuresis is essential for tailoring intervention strategies, including behavioral approaches, moisture alarms, medications, and efforts to address psychosocial factors.

Managing patients with impaired urinary elimination requires a multifaceted and patient-centered approach. Providing skin care is crucial for preventing complications such as irritation, inflammation, and pressure ulcers. Repositioning is essential to alleviate pressure on vulnerable areas and facilitate optimal bladder function. Bladder training, a structured program, aims to enhance bladder control and improve voiding habits through behavioral interventions. Evaluating the restoration or maintenance of urinary elimination involves a comprehensive review of urinary patterns and patient comfort, guiding adjustments to the care plan.

Nursing procedures to promote urinary elimination include urinary catheterization, a procedure to facilitate drainage in situations where voluntary voiding is not possible. Performing irrigations is essential for maintaining cleanliness and patency of catheters, preventing blockages, and minimizing infection risks. These procedures require precision, adherence to aseptic techniques, and regular patient monitoring to ensure optimal urinary function.

### Key Terms

**acute kidney injury (AKI)** a sudden and often reversible loss of kidney function

**aldosterone** a hormone that promotes the reabsorption of sodium and water in the kidneys, contributing to an increase in blood volume and blood pressure

**angiotensin I** a peptide hormone

**angiotensin II** a potent vasoconstrictor

**angiotensinogen** a protein produced by the liver that is cleaved by renin to form angiotensin I

**anuria** a condition marked by the absence of urine output, presenting as less than 50 mL of urine within a twenty-four-hour period

**bladder** the storage reservoir for urine prior to its regulated expulsion from the body

**bladder perforation** a rupture or tear in the wall of the urinary bladder

**bladder training** a structured program aiming to improve bladder control and reduce urinary frequency or urgency

**catheter-associated urinary tract infection** urinary tract infection that occurs in patients who have indwelling urinary catheters

**chronic kidney disease (CKD)** a condition characterized by gradual and irreversible loss of kidney function over time

**continence** the ability to control and maintain bladder functions

**creatinine** a waste product that results from the breakdown of creatine phosphate in muscles

**detrusor muscle** the layer of smooth muscle within the bladder wall

**dialysis** a medical procedure that mechanically filters and purifies the blood in individuals with kidney failure

**dysuria** painful or difficult urination

**enuresis** urination during sleep

**erythropoiesis** the production of red blood cells

**erythropoietin (EPO)** a glycoprotein hormone that plays a crucial role in the regulation of red blood cell production

**external urethral sphincter** a ringlike muscle that aids in the regulation of urine flow

**functional incontinence** occurs in older adults who have normal bladder control but struggle to get to the toilet in time to void

**glomerular filtrate** fluid that results from the filtration process in the glomerulus, containing essential substances needed by the body, such as water and electrolytes, as well as waste materials that need to be eliminated through urine

**glomerular filtration** the initial step in the process of urine formation

**glomerular filtration rate (GFR)** a measure of the rate at which glomerular filtration occurs; quantifies the volume of filtrate formed by the kidneys per unit of time

**glomerulus** the network of tiny blood vessels in the kidneys

**gout** a form of arthritis characterized by sudden and severe pain, swelling, and redness in the joints, primarily the big toe, due to the deposition of urate crystals

**hematuria** visible or microscopic blood in urine

**kidney** a bean-shaped organ located on either side of the spine, just below the ribcage

**kidney calculus** solid, crystalline structures formed in the kidneys that can obstruct the normal flow of urine

**kidney transplantation** a surgical procedure in which a healthy kidney from a living or deceased donor is transplanted into a recipient with end-stage kidney disease to restore kidney function

**micturition reflex** an involuntary physiological response that initiates the contraction of the bladder's detrusor muscle and relaxation of the internal urethral sphincter, facilitating the expulsion of urine from the body

**mixed urinary incontinence** a combination of urinary frequency, urgency, and stress incontinence

**moisture-related dermatitis** a skin condition characterized by inflammation and irritation resulting from prolonged exposure to moisture

**nephron** a microscopic unit within the kidneys; a functional unit responsible for blood filtration and urine formation

**nephrotic syndrome** a kidney disorder characterized by excessive protein loss in the urine

**nocturia** regular nighttime urination

**oliguria** reduced urine output

**overflow incontinence** the leakage of small amounts of urine from a bladder that is always full

**polycystic kidney disease (PKD)** an inherited disease characterized by the formation of fluid-filled cysts in the kidneys

**polyuria** excessive urine output, surpassing 2.5 L over twenty-four hours

**postvoid residual urine volume** a measurement of urine left in the bladder after a patient has voided; obtained using ultrasound, a bladder scanner, or straight catheterization

**proteinuria** a medical condition characterized by the presence of abnormal amounts of protein in the urine

**purine** organic compound present in various foods that produces uric acid when it is broken down

**pyelonephritis** a bacterial infection affecting the kidneys

**pyuria** the presence of at least ten white blood cells per cubic millimeter in a urine sample

**renal capsule** the protective layer encapsulating the kidneys

**renal cortex** the outer layer of the kidneys

**renal medulla** the inner region of the kidneys

**renal pelvis** a funnel-shaped structure that directs urine into the ureter

**renin** an enzyme synthesized and discharged by specialized cells in the kidneys

**renin-angiotensin-aldosterone system (RAAS)** a complex hormonal cascade that plays a crucial role in regulating blood pressure, electrolyte balance, and fluid volume within the body

**stress urinary incontinence** involuntary loss of urine with intra-abdominal pressure

**trigone** the triangular area in the bladder that acts as a physiological valve, preventing reflux of urine into the ureters

**tubular reabsorption** the physiological process in the kidneys by which essential substances, including water, glucose, ions, and other necessary molecules, are selectively reclaimed from the filtrate in the renal tubules and returned to the bloodstream

**tubular secretion** the active transport process in the kidneys by which certain substances, including excess ions, drugs, and metabolic by-products, are selectively moved from the peritubular capillaries into the renal tubules during urine formation

**urate crystal** solid structure formed when elevated uric acid levels in the blood lead to the accumulation of crystals in joints

**urea** liquid waste produced by the kidneys during the breakdown of protein-containing foods

**ureter** one of two muscular tubes that serve as conduits for transporting urine from the kidneys to the urinary bladder

**urethra** a tubular structure that serves as the conduit for the expulsion of urine from the body

**urge urinary incontinence** urine leakage accompanied by the sensation of a strong desire to void (urgency)

**uric acid** a chemical compound formed during the breakdown of purines and excreted by the kidneys

**urinalysis** a diagnostic examination of a urine sample to assess various aspects of a person's health

**urinary catheterization** a nursing procedure to promote urinary elimination in situations when a patient is unable to void voluntarily or when continuous drainage of urine is necessary

**urinary frequency** the urge to urinate multiple times throughout the day or night, often accompanied by a compelling sense of urgency

**urinary incontinence** the involuntary loss of bladder control, leading to the unintentional release of urine

**urinary irrigation** a procedure that involves introducing a solution into the urinary tract to cleanse, flush, or treat the bladder and associated structures

**urinary retention** the inability to fully empty the bladder

**urinary system** a sophisticated network of organs responsible for producing, storing, and eliminating urine from the body

**urinary tract infection (UTI)** a bacterial infection affecting any part of the urinary system

**urinary urgency** the sensation of an urgent need to void

**urination** the physiological process of eliminating urine from the bladder through the urethra

**voiding stage** the final phase of the urinary process in which urine is expelled from the bladder through the urethra and out of the body

## Assessments

### Review Questions

1. What is the primary function of the kidneys in the urinary system?
  - a. storage of urine
  - b. filtration of blood
  - c. muscular contractions
  - d. urethra expansion
2. What anatomical structure prevents reflux of urine into the ureters?
  - a. trigone
  - b. renal capsule
  - c. nephron
  - d. urethral sphincter
3. What is the primary function of glomerular filtration in the process of urine formation?
  - a. reabsorbing essential substances

- b. selectively transporting ions
  - c. filtering blood to form an initial filtrate
  - d. regulating blood pH
4. What is the role of tubular secretion in urine formation?
- a. reabsorbing water
  - b. actively transporting substances into renal tubules
  - c. filtrating blood
  - d. controlling blood pressure
5. What is the primary role of the detrusor muscle during the resting stage of micturition?
- a. initiating urination
  - b. relaxing the internal urethral sphincter
  - c. contraction to accommodate urine
  - d. involuntary control
6. Why is regular monitoring of urea levels essential for assessing kidney function?
- a. to detect liver disorders
  - b. to assess metabolic health
  - c. to identify urea deficiencies
  - d. to evaluate kidney health
7. In the glomerular filtration process, what substances are meticulously filtered from the bloodstream into the renal tubules?
- a. oxygen and carbon dioxide
  - b. water and electrolytes
  - c. proteins and carbohydrates
  - d. red and white blood cells
8. What triggers the release of erythropoietin (EPO) by the kidneys?
- a. high oxygen levels in the blood
  - b. low oxygen levels in the blood
  - c. elevated red blood cell count
  - d. increased carbon dioxide levels in the blood
9. The preceptor is reviewing functions of the urinary system with the nursing student. What statement made by the nursing student would demonstrate correct understanding of functions of the urinary system?
- a. "Erythropoietin (EPO) is a glycoprotein hormone that plays a crucial role in the regulation of white blood cell production."
  - b. "The release of renin into the bloodstream is prompted by conditions like increased blood flow to the kidneys or an increase in blood pressure."
  - c. "Low creatinine levels may suggest impaired kidney function."
  - d. "Urea is a nitrogenous waste product that forms in the liver during the breakdown of proteins and amino acids."
10. A newly graduated nurse is reviewing with their preceptor how the urinary system maintains balance of the body's fluids. What statement would warrant further education by the preceptor?
- a. "The glomerular filtration process serves as the initial step, in which water and electrolytes are meticulously filtered from the bloodstream into the renal tubules."
  - b. "The kidneys reclaim sodium, potassium, and water, redirecting them back into the bloodstream to prevent excessive loss during tubular reabsorption."
  - c. "The kidneys play a pivotal role in regulating acid-base balance by selectively excreting bicarbonate ions ( $\text{HCO}_3^-$ ) and reabsorbing hydrogen ions ( $\text{H}^+$ ) in the renal tubules."

- d. “Excess ions and substances that were not adequately filtered during the glomerular filtration phase are eliminated during tubular secretion.”
- 11.** What age group may experience challenges related to the impact of peer influences and busy schedules on voiding patterns?
- infants and toddlers
  - adolescents
  - middle-aged adults
  - older adults
- 12.** The student nurse is reviewing drugs that affect urinary elimination with the clinical preceptor. What statement made by the nurse would warrant further education by the clinical preceptor?
- “Diuretics increase urine production and can lead to frequent urination.”
  - “Anticholinergic drugs are used to treat overactive bladder and urinary incontinence.”
  - “Calcium channel blockers may affect bladder contractility and can contribute to increased urinary elimination in some individuals.”
  - “Alpha blockers relax smooth muscle in the prostate, improving urinary flow.”
- 13.** What statement by a nursing student demonstrates a correct understanding of how pathological factors affect urinary elimination?
- “Elevated levels of parathyroid hormone can contribute to kidney stones.”
  - “Hypothyroidism can lead to increased metabolism and increased kidney blood flow.”
  - “Nephrotic syndrome pulls proteins like albumin out of the urine.”
  - “Acute kidney injury often leads to temporary increased urine output.”
- 14.** What role does the parasympathetic nervous system play in urinary elimination?
- regulating blood pressure
  - initiating the fight-or-flight response
  - enhancing voluntary muscle control
  - promoting relaxation and facilitating bladder emptying
- 15.** The nurse is evaluating a patient for urinary retention. What clinical presentation would the nurse expect to find if the patient is experiencing urinary retention?
- increased urinary frequency
  - distended bladder and lower abdominal discomfort
  - clear urine with a normal odor
  - rapid initiation of the urine stream
- 16.** The nurse preceptor asks the newly graduated nurse why it is essential for providers to employ a multifaceted approach when assessing and recognizing cues for impaired urinary elimination. What statement made by the newly graduated nurse demonstrates an accurate understanding of impaired urinary elimination?
- “Assessing and recognizing cues for impaired urinary elimination simplify the diagnostic process.”
  - “Assessing and recognizing cues for impaired urinary elimination focus solely on the patient’s medical history.”
  - “Assessing and recognizing cues for impaired urinary elimination are important for streamlining patient care.”
  - “Assessing and recognizing cues for impaired urinary elimination assist in gaining comprehensive insights for tailored interventions and effective management.”
- 17.** The nurse is preparing a patient for bladder training. What is the primary focus of bladder training for patients with impaired urinary elimination?
- enhancing fluid balance
  - administering catheterization

- c. strengthening pelvic floor muscles
  - d. conducting urodynamic testing
- 18.** A nurse is assessing a patient who underwent urinary catheterization and irrigations. What is a potential complication associated with these procedures?
- a. development of kidney stones
  - b. increased risk of urinary urgency
  - c. development of nocturia
  - d. trauma to the urinary tract and infection
- 19.** The nurse notes an adult patient had a urinary output of 350 mL in one day. What term would the nurse use to describe this urinary volume?
- a. anuria
  - b. normal
  - c. oliguria
  - d. polyuria

### Check Your Understanding Questions

1. Explain the significance of glomerular filtration rate (GFR) in assessing kidney function.
2. Explain how peristaltic contractions in the ureters contribute to the transport of urine.
3. What is the purpose of the resting and filling stages in the micturition process?
4. How does creatinine serve as an indicator of kidney function, and why is regular monitoring necessary?
5. Describe the role of renin in the initiation of the renin-angiotensin-aldosterone system (RAAS).
6. Provide two examples of foods that impact urinary elimination.
7. How do diuretics affect the process of urinary elimination?
8. Explain the primary goal of measuring residual urine.
9. Describe the purpose of repositioning strategies in the context of managing impaired urinary elimination.

### Reflection Questions

1. Consider the challenges that can arise if the micturition reflex is disrupted. How might this impact an individual's daily life?
2. Consider the role of the kidneys as primary orchestrators in fluid and electrolyte balance. How might disruptions in this balance impact overall health?
3. How might disruptions in the RAAS contribute to imbalances in fluid and electrolyte regulation?
4. Consider the impact of cultural stigmas on an individual's willingness to seek help for urinary issues. How can healthcare professionals address this challenge?
5. Consider the role of nurses in empowering patients to actively participate in their skin care routines. How does patient education foster a collaborative approach to care?
6. Consider the potential risks associated with urinary catheterization. How can healthcare professionals balance the benefits and risks to ensure patient safety?

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #4: Part 7](#). Why do you think the provider would choose to order straight catheterization instead of an indwelling Foley catheter?

## What Should the Nurse Do?

1. A patient with kidney failure is experiencing difficulties in blood pressure regulation. How would you educate them about the role of the RAAS and its impact on their condition?
2. A patient with nocturia seeks advice on reducing nighttime urination. What lifestyle modifications and behavioral strategies should the nurse recommend?
3. A patient voids 300 mL of urine. After the patient empties their bladder, a bladder scan is performed, noting 600 mL of postvoid residual. What immediate actions should the nurse take in response to these findings, and how would you further assess and manage the situation to ensure optimal patient care and safety?

## Competency-Based Assessments

1. Outline the process of urine formation.
2. A teenager with a history of trauma exhibits altered urinary patterns. Outline a collaborative care plan involving healthcare professionals and counselors to address psychological factors that may be contributing to impaired urinary elimination.
3. Identify a potential adverse effect associated with bladder irrigation. Describe the signs or symptoms that may indicate this adverse effect, and outline the immediate actions a nurse should take to address the situation and ensure patient safety.
4. Determine if each of the following urine sample results is normal or abnormal. What might these results indicate?
  - Color: Dark yellow
  - Clarity: Cloudy
  - pH: 6.0
  - Protein: Positive
  - Glucose: Negative
  - Ketones: Negative
  - Nitrites: Positive
  - Leukocytes: Positive
  - Blood: Positive

### CHAPTER OUTLINE

- 27.1 Gastrointestinal Tract Structures and Functions
- 27.2 Factors Affecting Bowel Elimination
- 27.3 Diagnostic Evaluation
- 27.4 Common Conditions Affecting Bowel Elimination

**INTRODUCTION** The gastrointestinal (GI) system, a remarkable and intricate physiological network, is an indispensable component of the human body’s regulatory mechanisms. Operating quietly behind the scenes, it diligently processes food, absorbs nutrients, and eliminates waste, playing a vital part in sustaining the body’s overall balance and functionality. This chapter delves into the multifaceted dimensions of the GI system, exploring its fundamental functions, examining the various factors that affect bowel elimination, and highlighting the integral role nurses play in ensuring optimal GI health for their patients.

Recognizing the GI system’s intricacies is not merely a professional concern for nurses, it is a cornerstone in delivering comprehensive patient care. Armed with this knowledge, nurses become adept at spotting early signs of potential issues, intervening promptly, and averting complications. Nurses also serve as educators, empowering patients to actively engage in their GI health. Fully understanding the GI system contributes to making accurate diagnoses, informing the development of care plans, and shaping interventions tailored to each patient’s unique needs.

## 27.1 Gastrointestinal Tract Structures and Functions

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the organs of the gastrointestinal tract used in bowel elimination
- Recognize the role the nervous system plays in the elimination process
- Explain the functions of the gastrointestinal tract

Understanding the process of bowel elimination involves a comprehensive exploration of the organs constituting the gastrointestinal (GI) system, each pivotal in orchestrating this fundamental physiological function. From the initial ingestion of food to the final expulsion of waste, the GI system performs a symphony of digestive processes essential for maintaining bodily health and balance. Key players in this intricate system include the mouth, pharynx, stomach, small intestine, large intestine, rectum, and anus, each contributing uniquely to the process, from food breakdown to nutrient absorption and waste expulsion. Additionally, the nervous system, intricately intertwined with the GI tract, regulates and coordinates the elimination process through a complex network of nerves, influencing muscle contractions and facilitating the movement of food and waste through the digestive tract. By gaining a comprehensive understanding of these concepts, we can appreciate the complexity of bowel elimination and the intricate interplay between anatomy, physiology, and neural regulation within the GI system.

### Gastrointestinal Organs Used in Bowel Elimination

The **gastrointestinal (GI) system** is a complex network of organs within the human body responsible for the digestion and absorption of nutrients as well as the elimination of waste. The GI system is made up of the GI tract (mouth, pharynx, esophagus, stomach, small intestine, large intestine, anus) and accessory organs (teeth, tongue, glandular organs). The glandular organs include the salivary glands, liver, gallbladder, and pancreas ([Figure 27.2](#)). The GI system plays a vital role in the process of bowel elimination by aiding in the digestion of food, absorption of nutrients, and elimination of waste from the body. Understanding the functions of these organs is essential for comprehending the intricate process of bowel elimination. In this section, we explore the anatomy and functions of the mouth, pharynx, esophagus, stomach, small intestine, and large intestine, highlighting their respective contributions to the process of digestion and elimination.

**FIGURE 27.2** The gastrointestinal (GI) system is composed of the mouth, pharynx, esophagus, stomach, small intestine, large intestine, anus, and accessory organs. (credit: modification of “Blausen 0316 DigestiveSystem” by BruceBlaus/Wikimedia Commons, CC BY 3.0)

#### Mouth

The **mouth** is the beginning of the GI tract. It is the orifice into which food is introduced into the GI system. The mouth consists of the lips, tongue, palates (soft and hard), gums, and three of the accessory organs of the GI system: teeth, tongue, and salivary glands. The tongue is a large muscle attached to the floor of the mouth by the

frenulum linguae.

### Pharynx

The **pharynx** is a funnel-shaped organ; its upper end is wider, and its lower end is narrower. This muscular organ begins in the head behind the nasal cavity, runs below the oral cavity, and then merges with the larynx and esophagus. The walls of the pharynx are made of both circular and longitudinal muscles. The pharynx is considered part of both the GI and respiratory systems. In regard to the GI system, constriction of the circular muscles of the pharynx helps push food to the esophagus and at the same time prevent air from being swallowed. The longitudinal muscle fibers lift the walls of the pharynx during swallowing.

### Esophagus

The **esophagus** is a muscular tube situated behind the trachea and in front of the spine. It begins at the pharynx and goes through the diaphragm to the stomach. Both ends of the esophagus are closed off by sphincters. The sphincters open to allow food to pass through and then close to prevent regurgitation. Peristalsis (contraction of the muscular esophageal walls) moves the food down the esophagus.

### Stomach

The **stomach**, a muscular organ located in the upper abdomen just below the rib cage, plays a pivotal role in the digestive process. Shaped like a hollow pouch, the stomach can vary in size and capacity depending on factors such as age, diet, and individual anatomy. On average, the adult human stomach can hold approximately 1 quart (946 mL) of food when fully distended (Frothingham, 2018).

Anatomically, the stomach is divided into four main regions: cardia, fundus, body, and pylorus. The **cardia** is the uppermost part of the stomach closest to the esophagus, where food enters. The **fundus** is the rounded portion of the stomach that expands as the stomach fills with food. The **stomach body** is the central region of the stomach where most of the digestion occurs; the **pylorus** is the lower portion of the stomach that connects to the small intestine (National Institute of Diabetes and Digestive and Kidney Diseases [NIDDK], 2017).

The stomach's muscular walls are lined with several layers of smooth muscle tissue that contract and relax in coordinated rhythmic, wavelike movements known as **peristalsis**. This muscular activity serves to mix food with gastric juices, promoting thorough digestion. Gastric glands located in the stomach lining secrete gastric juices containing hydrochloric acid and enzymes, including pepsinogen that is converted to pepsin in the acidic environment of the stomach. Pepsin plays a crucial role in breaking down proteins into smaller peptides, initiating the process of protein digestion (NIDDK, 2017).

As food is partially digested in the stomach, it forms a semiliquid mixture of partially digested food, water, and digestive juices called **chyme**. The stomach's role in bowel elimination involves both mechanical and chemical digestion, as well as the regulation of chyme passage into the small intestine. The **pyloric sphincter**, located at the junction between the stomach and the duodenum (the first part of the small intestine), is a muscular valve that controls the release of chyme into the small intestine (NIDDK, 2017). This regulated release ensures that the small intestine can efficiently digest and absorb nutrients while allowing the remainder of undigested food to progress through the digestive tract for eventual elimination as feces. Thus, the stomach's intricate anatomy and physiological functions are essential for effective digestion and bowel elimination.

### Small Intestine

The **small intestine** is a convoluted tube that stretches from the stomach to the large intestine. Despite its name, it is anything but small, measuring around 22 ft (6.7 m) long (Cleveland Clinic, 2021). In fact, the small intestine is longer than the large intestine but gets its name due to its smaller diameter compared to the large intestine. The small intestine consists of three segments: the duodenum, the jejunum, and the ileum.

The first and shortest segment of the small intestine is the **duodenum**. Positioned in the upper abdomen just below the stomach, the duodenum begins at the pyloric sphincter, forming a C-shaped curve. Acidic chyme from the stomach along with digestive juices from the pancreas and **bile** (digestive fluid produced by the liver and stored in the gallbladder) enter the duodenum via the common bile duct. This concoction neutralizes the acidic chyme and initiates further digestion, particularly of fats, proteins, and carbohydrates (NIDDK, 2017).

The **jejunum**, the middle portion of the small intestine, is primarily responsible for the absorption of nutrients,

including carbohydrates, proteins, fats, vitamins, and minerals. The inner surface of the jejunum is lined with millions of tiny fingerlike projections called villi and microvilli that increase its surface area for efficient absorption. These intricate features serve to amplify the absorptive surface area, facilitating the efficient uptake of nutrients (e.g., carbohydrates, proteins, fats, vitamins, minerals) into the bloodstream.

The **ileum** is the longest part of the small intestine and connects the small intestine to the large intestine. It continues the absorption process, particularly focusing on the uptake of vitamin B<sub>12</sub>, bile salts, and any remaining nutrients, as well as the reabsorption of some water and electrolytes. Together, the segments of the small intestine play a crucial role in bowel elimination by further digesting food, absorbing nutrients, and preparing waste products (e.g., undigested food, bacteria, cellular debris) for elimination through the large intestine.

### Large Intestine

The **large intestine** consists of the cecum and colon. This vital component of the GI tract is responsible for bowel elimination. The first 6 in (15 cm) of the large intestine is the **cecum**, which serves as the initial connection point between the small intestine and the colon. Measuring about 5 ft (1.5 m) in length, the **colon** consists of four segments, each with unique functions: ascending colon, transverse colon, descending colon, and sigmoid colon (Cleveland Clinic, 2021). The **ascending colon** travels upward from the cecum on the right side of the abdomen. The **transverse colon** runs horizontally across the abdomen, connecting the ascending and descending segments of the large intestine. The **descending colon** descends along the left side of the abdomen, while the **sigmoid colon** is the final S-shaped segment that leads to the rectum. Finally, the **rectum** serves as the last portion of the large intestine, where feces are stored before elimination. The **anus** is the opening at the end of the GI tract through which feces (solid waste) are expelled from the body.

### Nervous System Control of the Elimination Process

The nervous system plays a crucial role in orchestrating the intricate process of bowel elimination. Both the sympathetic and parasympathetic divisions of the autonomic nervous system contribute to this physiological function. By balancing the activities of these two branches of the autonomic nervous system, the body maintains optimal bowel function, ensuring regularity and effective elimination.

#### Sympathetic Nervous System

The sympathetic nervous system, a component of the autonomic nervous system, plays a significant role in the regulation of the bowel elimination process. During periods of stress or heightened arousal, the sympathetic nervous system becomes activated, triggering a cascade of physiological responses aimed at preparing the body for action, often referred to as the fight-or-flight response. In the context of bowel elimination, sympathetic activation leads to inhibition and constriction of bowel motility and sphincter tone. This can result in decreased peristalsis and slower movement of fecal matter through the intestines as well as increased constriction of the anal sphincter, making it more difficult to pass stool. In essence, the sympathetic nervous system acts to conserve energy and redirect blood flow away from the GI tract during times of stress, which can contribute to symptoms such as constipation or delayed bowel movements (Sharkey & Mawe, 2023).

#### Parasympathetic Nervous System

The parasympathetic nervous system, on the other hand, is often associated with the rest-and-digest response; the parasympathetic division promotes relaxation and facilitates GI function. In the context of bowel elimination, activation of the parasympathetic nervous system stimulates peristalsis, the rhythmic contractions of the intestinal muscles that propel food, water, and digestive juices forward through the digestive tract. Additionally, the parasympathetic system promotes relaxation of the anal sphincter, making it easier for stool to be expelled during **defecation**, or the process of eliminating feces from the body through the anus. Through its intricate network of nerves and neurotransmitters, the parasympathetic division ensures the efficient expulsion of waste from the body, contributing to regularity and effective bowel movements (Sharkey & Mawe, 2023).

### Functions of the Gastrointestinal Tract

In understanding the complexities of human physiology, the GI tract and its accessory organs emerge as a pivotal system responsible for vital functions that are essential for sustaining life. From the initial breakdown of ingested food to the absorption of nutrients and the elimination of waste, the GI tract is responsible for coordinating physiological processes crucial for maintaining health and well-being. This section examines the multifaceted roles

of the GI tract, including its functions of digestion, absorption, and elimination.

### Digestion

The GI tract serves a crucial role in the process of digestion, encompassing both mechanical and chemical processes. Mechanical digestion begins in the mouth with chewing, where food is broken down by the teeth into smaller particles to increase its surface area for enzymatic action. The tongue mixes the food with saliva. The food passes from the mouth through the pharynx and esophagus. This digestive process continues in the stomach, where muscular contractions churn and mix the food with gastric juices, forming chyme. Additionally, peristalsis (rhythmic contractions of the muscles lining the GI tract) propels food along its length, aiding in digestion and absorption (Ogobuiro et al., 2023).

Chemical digestion involves the action of the accessory organs of the GI system in the form of enzymes and acids secreted throughout the GI tract. For example, salivary amylase in the mouth starts the breakdown of carbohydrates into simpler sugars, while gastric acid and pepsin in the stomach break down proteins into amino acids. In the small intestine, pancreatic enzymes and liver bile further digest carbohydrates, proteins, and fats, allowing for the absorption of nutrients into the bloodstream. Overall, the digestive functions of the GI system ensure that ingested food is broken down into its basic components, which can then be absorbed and used by the body for energy, growth, and repair (Ogobuiro et al., 2023).

### Absorption

The GI tract plays a crucial role in the absorption of nutrients from ingested food. After food is broken down into smaller particles through the process of digestion, the segments of the small intestine, particularly the lining of the jejunum and ileum, are primarily responsible for absorbing these nutrients into the bloodstream. A specialized cell called an **enterocyte** lines the walls of the small intestine and is equipped with microvilli, tiny projections that greatly increase the surface area available for absorption. This extensive surface area allows for efficient absorption of nutrients, such as carbohydrates, proteins, fats, vitamins, and minerals.

The absorption process involves movement of nutrients across the intestinal lining into the bloodstream. This process has three components: active transport, facilitated diffusion, and passive diffusion. Energy is required for **active transport**, which involves the movement of nutrients against their concentration gradient, assisted by specific carrier proteins. The process of **facilitated diffusion** also relies on carrier proteins but does not require energy expenditure and moves nutrients down their concentration gradient. The process of **passive diffusion** occurs when nutrients move across the intestinal lining from an area of higher concentration to an area of lower concentration without the need for carrier proteins or energy.

After being absorbed, nutrients are transported via the bloodstream to various cells and tissues throughout the body, where they are used for energy production, growth, repair, and maintenance of bodily functions. Any unabsorbed nutrients, along with water and electrolytes, continue through the GI tract to the large intestine, where further absorption of water and electrolytes occurs before the remaining waste products are eliminated from the body.

### Elimination

The GI tract's role in elimination involves a series of coordinated actions to remove waste products from the body. As digestion progresses through the stomach and small intestine, nutrients and water are absorbed into the bloodstream, leaving behind undigested food particles, bacteria, and waste material. This residue, along with digestive secretions, enters the large intestine or colon.

In the colon, the main focus shifts to the absorption of water and electrolytes from the waste material. As the waste travels through the colon, water is reabsorbed, gradually transforming the material into solid **feces**, also known as **stools** or **bowel movements**, which are the solid waste products of digestion that are expelled from the body through bowel elimination. This process is crucial for maintaining proper hydration and electrolyte balance in the body.

Simultaneously, the muscles of the colon perform peristaltic contractions, moving the fecal material toward the rectum. The rectum acts as a storage chamber for feces, capable of sensing its volume and signaling the body when it is time for defecation. This sensory feedback triggers the urge to have a bowel movement (Nall, 2018).

When the rectum becomes adequately distended and the individual decides to defecate, the internal anal sphincter

relaxes reflexively, allowing feces to enter the anal canal. At the same time, conscious control over the external anal sphincter allows for the voluntary initiation and regulation of defecation (Nall, 2018). Finally, the feces are expelled through the anus during defecation, completing the process of elimination. This coordinated interplay of muscular contractions, sensory feedback, and sphincter control ensures effective waste removal while maintaining bowel continence and preventing involuntary leakage.

## LINK TO LEARNING

An interactive demonstration of [the GI system in action \(https://openstax.org/r/77GIsystem\)](https://openstax.org/r/77GIsystem) is presented in this video.

In some cases, individuals may undergo surgical procedures that alter the natural route of bowel elimination. One such intervention is the creation of a **stoma**, a surgically created opening in the abdomen that allows waste (fecal matter) to exit the body when the natural route of elimination through the rectum is no longer feasible. This procedure may be necessary as a result of conditions such as bowel obstructions, inflammatory bowel disease (IBD), or colorectal cancer.

Typically, a stoma extends beyond the skin's surface, displaying a moist, pink to red appearance and a rounded shape, devoid of nerve sensations ([Figure 27.3](#)). There are two types of ostomy procedures in which a stoma is created related to bowel elimination: colostomy and ileostomy. A **colostomy** involves forming a stoma using a section of the colon (large intestine), where a portion of the intestine is brought out through the abdominal wall and connected to the skin. This procedure diverts regular fecal matter away from the anus and through the stoma. Conversely, an **ileostomy** is created from the ileum (small intestine), similarly brought out through the abdominal wall to establish a stoma. Through an ostomy, waste products are diverted from the intestines and collected in a pouch attached to the abdomen. An ostomy may be permanent or temporary, depending on the reason for the surgery. Although this alteration in bowel function can significantly affect an individual's daily life and self-image, proper care and management of the ostomy can help maintain comfort and quality of life.

**FIGURE 27.3** A colostomy stoma, encircled by a wafer, is the section of the colostomy pouch that adheres to the skin. (credit: modification of “Ostomy wafer being worn by an ileostomy patient” by Eric Polsinelli (VeganOstomy)/Wikimedia Commons, CC BY 4.0)

## 27.2 Factors Affecting Bowel Elimination

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain developmental considerations affecting bowel elimination
- Identify how individual daily bowel habits affect elimination
- Discuss how medications can affect bowel elimination

Recognizing the developmental nuances influencing bowel elimination is essential for providing tailored care. From infancy to adulthood, individuals navigate unique stages where bowel habits evolve alongside physical and psychological growth. Understanding these developmental considerations sets the stage for exploring how daily habits shape elimination patterns. Additionally, awareness of medication effects on bowel function is crucial,

because medications can significantly affect bowel health. By exploring these interconnected topics, healthcare professionals gain insights into optimizing bowel health and enhancing patient outcomes.

## Developmental Considerations

Understanding the developmental considerations that affect bowel elimination is essential for promoting optimal GI health across the life span. From infancy through adulthood, bowel habits and functions evolve in response to physiological, psychological, social, and environmental factors. By exploring these developmental milestones and their effect on bowel elimination, individuals, caregivers, and healthcare professionals can better support digestive well-being and address any challenges that may arise. This comprehensive understanding allows for tailored interventions, lifestyle modifications, and healthcare strategies aimed at maintaining healthy bowel habits and optimizing overall GI function throughout all stages of life.

### Newborns and Infants

The first bowel movement of a newborn that appears sticky and dark green to black in color is referred to as **meconium** (Figure 27.4). During the neonatal period, infants primarily rely on a liquid diet, either breast milk or formula, which is easily digestible and promotes frequent bowel movements. Breast milk, in particular, contains components that facilitate digestion and promote the growth of beneficial gut bacteria, contributing to healthy bowel function. Additionally, breastfed infants may have more frequent bowel movements compared to formula-fed infants because of the composition of breast milk and the presence of laxative factors (American Academy of Pediatrics, 2021).

**FIGURE 27.4** Meconium is the term used to describe the first stool passed by a newborn baby. It is typically dark green to black in color and has a sticky, tar-like consistency. (credit: "Meconium" by Jeremy Kemp/Wikimedia Commons, Public Domain)

The GI tract of infants undergoes rapid growth and maturation during the first few months of life. The muscular walls of the intestines strengthen, and the nerve pathways controlling bowel movements mature, leading to improved coordination and control over defecation. As a result, many infants establish a regular pattern of bowel movements within the first few months, typically ranging from several times a day to once every few days (American Academy of Pediatrics, 2021).

Another developmental consideration in infant bowel elimination is the transition to solid foods. As infants begin to explore and consume solid foods around 4 to 6 months of age, their bowel habits may change. The introduction of new foods can affect the consistency, frequency, and odor of bowel movements. It is common for infants to experience changes in bowel patterns during this transition period, such as increased frequency or changes in stool color or texture (American Academy of Pediatrics, 2021).

Moreover, the development of bowel control and sphincter function progresses gradually during infancy. Newborns and young infants have little voluntary control over bowel movements; however, by around 18 to 24 months of age, many children begin to demonstrate awareness of bowel sensations and may start to show signs of readiness for toilet training (Johns Hopkins Medicine, n.d.). However, the timing and success of toilet training vary widely among individual infants and depend on factors such as developmental readiness, cultural practices, and caregiver support.

## PATIENT CONVERSATIONS

---

### Helping Parents to Understand Infant Bowel Function

**Nurse:** Good morning, Mrs. Chin. My name is April. I saw you both the last time you were here. How are you and little Li doing today?

**Patient's parent:** Good morning, April. I remember you too. We're doing well, thank you. Li has been a bit fussier than usual lately, and I've been a bit worried about her bowel movements.

**Nurse:** I understand. Changes in bowel habits can be concerning for parents. Can you tell me more about what you've been noticing?

**Patient's parent:** Sure. Well, Li used to have bowel movements several times a day, but lately, it seems like she's been going less frequently, maybe every two to three days. And when she does go, her stools seem harder than before.

**Nurse:** I see. It's not uncommon for babies' bowel habits to change as they grow. Remind me, how old is Li now?

**Patient's parent:** She just turned 4 months last week.

**Nurse:** Ah, I see. At 4 months, babies are often going through changes in their digestive system as they start to transition to solid foods. How has Li's feeding been lately?

**Patient's parent:** She's still breastfeeding, but we've started to introduce some pureed fruits and vegetables over the past few weeks.

**Nurse:** That's great to hear. The introduction of solid foods can sometimes lead to changes in bowel habits. It's normal for babies to have stools that vary in color, consistency, and frequency during this time.

**Patient's parent:** That's reassuring to know. Is there anything I can do to help with Li's bowel movements?

**Nurse:** Absolutely. You can try offering Li more breast milk or formula if she seems thirsty, because staying hydrated can help soften her stools. You can also continue with the pureed fruits and vegetables, because the fiber in these foods can help regulate her bowel movements. If Li seems uncomfortable or continues to have hard stools, you can try gently massaging her tummy or moving her legs in a motion like she is riding a bicycle to help move things along. And of course, if you have any concerns or if Li's symptoms persist, don't hesitate to give us a call or schedule an appointment.

**Patient's parent:** Thank you so much. That's really helpful advice. I'll give these suggestions a try and keep an eye on Li's symptoms.

**Nurse:** You're welcome, Mrs. Chin. I'm glad I could help. And remember, we're here to support you and Li every step of the way. If you have any questions or need further assistance, don't hesitate to reach out.

**Patient's parent:** Thank you. I really appreciate it.

---

### Toddlers

During the toddler years, bowel elimination continues to be influenced by various developmental considerations as children further progress in their growth and maturation. Understanding these factors is essential for caregivers and healthcare professionals to support toddlers' bowel health and address any challenges that may arise during this developmental stage.

One significant aspect of bowel elimination in toddlers is the ongoing development of bowel control and sphincter function. While toddlers may demonstrate increasing awareness of bowel sensations and show interest in toilet training, achieving full bowel control typically takes time and varies widely among individual children. Toddlers may experience occasional accidents or inconsistencies in bowel habits as they continue to refine their ability to recognize and respond to the urge to defecate.

The transition to a more varied and adultlike diet also influences bowel elimination in toddlers. As toddlers explore a wider range of foods and textures, their bowel movements may become more diverse in consistency, color, and odor. It is common for toddlers to experience changes in bowel patterns in response to dietary changes, such as increased fiber intake from fruits, vegetables, and whole grains, which can promote regularity and softer stools.

Moreover, the social and environmental factors surrounding toilet training play a significant role in toddlers' bowel elimination. Cultural norms, family dynamics, and caregiver attitudes toward toilet training can shape toddlers' experiences and expectations regarding toilet use. Providing a supportive and encouraging environment, offering praise and positive reinforcement, and allowing toddlers to progress at their own pace can facilitate successful toilet training and promote healthy bowel habits.

Additionally, toddlers' growing independence and desire for autonomy may influence their approach to bowel elimination. Some toddlers may resist or show reluctance toward toilet training, while others may eagerly embrace the opportunity to assert their independence. Understanding and respecting toddlers' individual preferences and temperaments can help caregivers navigate the toilet training process and foster a positive attitude toward bowel elimination. Supporting toddlers' bowel health and toilet training efforts requires patience, consistency, and sensitivity to their evolving needs and abilities.

### School-Age Children

As children progress into school age, bowel elimination undergoes further developmental considerations influenced by physical, psychological, and environmental factors. One significant developmental aspect during school-age years is the continued refinement of bowel control and toileting skills. While most school-age children have achieved daytime bowel control, nighttime bowel control may still be developing. Some children may experience occasional bedwetting or nocturnal bowel movements, which is considered normal until around age 5 or 6 years (Johns Hopkins Medicine, n.d.). However, persistent issues with bowel control, such as constipation or fecal incontinence, may require further evaluation and intervention by healthcare professionals.

Another consideration is the effect of social and environmental factors on bowel elimination in school-age children. Peer influences, school routines, and access to toilet facilities can all affect children's bowel habits and toileting behaviors. Children may experience anxiety or embarrassment related to using school restrooms, especially if they feel rushed or uncomfortable in shared facilities. Creating a supportive and inclusive environment at school, with adequate access to private restroom facilities and opportunities for regular bathroom breaks, can help alleviate these concerns and promote healthy bowel habits.

Additionally, dietary habits and lifestyle factors continue to play a role in bowel elimination during the school-age years. Children's diets may become influenced by peer preferences, school meals, and increased exposure to processed foods and snacks. Encouraging a balanced diet rich in fiber, fruits, vegetables, and water can support regular bowel movements and prevent constipation. Furthermore, promoting physical activity and regular exercise can help regulate bowel function and promote overall bowel health.

Psychologically, school-age children may experience stress or emotional challenges that can affect bowel elimination. Academic pressures, social dynamics, and changes within the family or home environment can all contribute to stress-related bowel symptoms, such as constipation or diarrhea. Creating opportunities for open communication and providing emotional support can help children navigate these challenges and maintain healthy bowel habits. Supporting children's bowel health during this stage requires a holistic approach that addresses their

developmental needs, dietary habits, toileting skills, and emotional well-being.

### Adults

In adulthood, bowel elimination continues to be influenced by various developmental considerations as individuals navigate through different life stages, lifestyles, and health conditions. One significant consideration in adulthood is the effect of lifestyle factors on bowel elimination. Lifestyle factors, diet, physical activity, stress levels, and medication use can all influence bowel habits and overall bowel health of adults. These factors are discussed in detail in [Individual Bowel Habits](#) and [Medications Affecting Bowel Elimination](#).

Other factors affecting bowel functioning in adults include stress, chronic conditions, and hormonal changes. Stress and emotional well-being play a role in bowel elimination in adulthood. Stress can affect the functioning of the digestive system, leading to symptoms such as diarrhea, constipation, or abdominal discomfort. Finding healthy ways to manage stress, such as relaxation techniques, exercise, or therapy, can help maintain bowel health and alleviate stress-related bowel symptoms. Chronic health conditions such as irritable bowel syndrome (IBS), IBD, diabetes, and thyroid disorders can also affect bowel function and require management by healthcare professionals. Furthermore, hormonal changes, particularly in women during menstruation, pregnancy, and menopause, can adversely influence bowel habits and bowel health. Fluctuations in hormone levels can affect GI motility, leading to changes in stool consistency, frequency, and bowel patterns.

As individuals age, they may also experience changes in bowel function as a result of natural aging processes and age-related conditions. Peristalsis, for instance, typically slows with aging. Bowel habits may become less predictable, and conditions such as constipation, fecal incontinence, or diverticulosis may become more prevalent. Maintaining a healthy lifestyle, including a balanced diet, regular exercise, and adequate hydration, can help mitigate age-related changes in bowel function and promote bowel health in older adults. By understanding and addressing these developmental considerations, individuals can take proactive steps to maintain healthy bowel habits and overall bowel health throughout adulthood.

### Individual Bowel Habits

Understanding the intricate interplay between individual daily bowel habits and their effect on elimination is essential for maintaining optimal GI health. Several key factors contribute to bowel function and regularity, including food and fluid intake, activity and muscle tone, lifestyle choices, and psychological factors. By exploring these elements comprehensively, we can gain valuable insights into how our daily habits influence bowel health and elimination patterns. From dietary preferences to exercise routines, stress management strategies, and even sleep patterns, each aspect plays a vital role in shaping our digestive health. By examining the multifaceted nature of these factors, we can better understand their collective influence on bowel function and work toward promoting more effective elimination and overall well-being.

#### Food and Fluid Intake

Food intake directly influences bowel habits by providing the essential nutrients, fiber, and fluids necessary for proper digestion and elimination. A diet rich in fiber, found in fruits, vegetables, whole grains, and legumes, adds bulk to the stool and promotes regular bowel movements. Fiber also helps regulate bowel function by softening the stool and facilitating its passage through the digestive tract. In contrast, a diet low in fiber and high in processed foods can lead to constipation or irregular bowel movements due to inadequate fiber intake and reduced stool bulk (Nall & Higuera, 2024).

Fluid intake is equally important for maintaining healthy bowel habits. Drinking an adequate amount of water throughout the day helps soften the stool and prevent dehydration, which can contribute to constipation. Adequate hydration also supports the lubrication of the intestines, facilitating the smooth movement of stool through the digestive tract. Inadequate fluid intake, on the other hand, can lead to dry, hard stools and difficulty passing stool, increasing the risk of constipation (Nall & Higuera, 2024).

Additionally, certain foods and beverages may have specific effects on bowel function. For example, caffeinated drinks (e.g., coffee, tea) can act as mild stimulants to the digestive system, promoting bowel movements in some individuals. Spicy foods, fatty foods, and large meals can sometimes trigger GI symptoms (e.g., diarrhea, abdominal discomfort) in sensitive individuals. Additionally, individuals with lactose intolerance may experience digestive symptoms (e.g., gas, bloating, diarrhea) after consuming dairy products. Identifying and avoiding dietary triggers

can help manage bowel symptoms and promote more comfortable digestion (Nall & Higuera, 2024).

## CULTURAL CONTEXT

---

### Cultural Influences on Bowel Habits: Examining Food and Fluid Intake Practices

Understanding how cultural norms affect bowel habits requires a closer examination of the specific dietary and hydration practices prevalent in various cultural settings. From traditional diets to hydration rituals, each cultural factor plays a significant role in GI health.

- Exploring cultural dietary patterns:
  - Various cultures have distinct dietary patterns shaped by geographical, historical, and religious factors. For instance, the Mediterranean diet, rich in fruits, vegetables, and whole grains, is associated with improved bowel movements due to its high fiber content.
  - Spices and herbs: Certain cultures incorporate spices and herbs known for their digestive benefits. For instance, ginger in Asian cuisine or mint in Middle Eastern dishes may aid in digestion and alleviate GI discomfort.
  - Meal structure: The timing and composition of meals vary widely across cultures. Some cultures prioritize large, communal meals with multiple courses, while others prefer smaller, more frequent meals. These differences can affect bowel regularity and transit time.
  - Food preparation methods: Cultural cooking techniques, such as fermenting, pickling, or slow cooking, can affect the nutritional content and digestibility of foods, thereby influencing bowel habits.
- The role of fluid intake:
  - Beverage preferences: Cultural preferences for beverages like tea, coffee, or herbal infusions can affect hydration levels and bowel function. For instance, caffeine-containing beverages may have a diuretic effect, while herbal teas like chamomile or mint can promote relaxation and aid digestion.
  - Hydration practices: Cultural norms regarding water consumption vary, affecting overall hydration levels. In some cultures, drinking water before or after meals is encouraged, while in others, it may be considered detrimental to digestion.
  - Traditional remedies: Many cultures have traditional remedies involving fluids like broths, soups, or herbal concoctions believed to promote GI health and relieve constipation.

Cultural factors significantly influence food and fluid intake, thereby shaping individual bowel habits. Healthcare providers should be culturally sensitive when discussing bowel habits, acknowledging the effect of cultural practices on dietary and fluid intake. Educating individuals about the importance of hydration, fiber intake, and balanced nutrition within the context of their cultural preferences can empower them to make informed choices for bowel health. Integrating evidence-based dietary recommendations with culturally relevant food choices and practices can optimize bowel function while respecting cultural diversity.

---

### Activity and Muscle Tone

Regular physical activity promotes healthy bowel movements by stimulating the muscles of the digestive tract and promoting bowel motility. Exercise helps to increase blood flow to the intestines, which can enhance the efficiency of digestion and elimination. Additionally, physical activity can help reduce stress levels, which can have a positive effect on bowel function. Incorporating regular exercise (e.g., walking, jogging, swimming, yoga) into daily routines can support optimal bowel health and promote regular elimination.

Furthermore, muscle tone in the pelvic floor and abdominal muscles plays a key role in maintaining continence and facilitating effective bowel movements. Weakness or dysfunction in these muscles can lead to difficulties with bowel control and evacuation. Pelvic floor exercises (or Kegel exercises) can help strengthen the muscles of the pelvic floor, improving bowel control and reducing the risk of fecal incontinence (Sissons, 2023). Similarly, exercises that target the abdominal muscles (e.g., crunches, planks) can support overall muscle tone and contribute to more efficient bowel movements.

In addition to physical activity and muscle tone, daily bowel habits, such as consistency, timing, and frequency of bowel movements, can provide valuable insights into bowel health. Changes in bowel habits, such as sudden onset

of constipation or diarrhea, should be noted and may indicate underlying issues that require further evaluation by a healthcare professional.

### Lifestyle

Individual daily bowel habits can significantly affect elimination, with lifestyle factors beyond food and fluid intake and activity and muscle tone also playing a crucial role in bowel function and regularity. Some of these lifestyle factors include toileting habits and routines, sleep patterns, and hygiene practices.

Establishing regular toilet habits and responding promptly to the urge to defecate can influence bowel health and elimination. Ignoring the urge to defecate or delaying bowel movements can disrupt normal bowel function and lead to constipation or fecal impaction. Conversely, having a consistent toilet routine can help train the body to evacuate stool efficiently. Sleep disturbances or irregular sleep patterns can affect bowel function and elimination. Adequate sleep is essential for maintaining overall health, including GI health. Disruptions in sleep can disrupt the body's natural rhythms and may adversely affect bowel habits, leading to changes in stool consistency or frequency. In addition, hygiene practices, particularly related to anal cleansing after bowel movements, can affect bowel health and comfort. Proper hygiene can help prevent irritation, infection, and discomfort in the anal area, promoting more comfortable and efficient elimination. Women and girls should always wipe from front to back to keep from spreading bacteria that can cause an infection. Wiping front to back can increase the risk of transferring bacteria to the urethra. Good handwashing after toileting is essential to help prevent the transmission of infectious organisms to yourself and others. Washing your hands every time you go to the bathroom decreases the risk of diarrheal illnesses and also foodborne illnesses.

### Psychological Factors

Psychological well-being, stress levels, emotions, and mental health can all play a role in bowel health and elimination. Stress and anxiety are known to affect the functioning of the digestive system, leading to symptoms such as diarrhea, constipation, or abdominal discomfort. The gut-brain axis, a bidirectional communication system between the brain and the GI tract, plays a key role in this relationship (Appleton, 2018). Stress and emotional distress can trigger changes in gut motility, sensitivity, and secretion, altering bowel habits and leading to GI symptoms. Chronic stress or unresolved emotional issues may contribute to long-term disruptions in bowel function and may exacerbate conditions such as IBS.

Emotional factors (e.g., fear, embarrassment, trauma) can also adversely affect bowel habits and elimination. Individuals may experience difficulty with bowel movements or altered bowel habits in response to emotional triggers or stressful situations. Additionally, negative emotions associated with bowel movements (e.g., shame, disgust) can lead to avoidance behaviors or reluctance to seek help for bowel-related concerns.

Furthermore, mental health conditions, such as depression or anxiety disorders, can have a significant impact on bowel function. Changes in appetite, alterations in neurotransmitter levels, and disruptions in the gut-brain axis associated with these conditions may contribute to GI symptoms and irregular bowel habits (Appleton, 2018).

Coping strategies and self-care practices for managing psychological factors can positively influence bowel health and elimination. Stress reduction techniques (e.g., mindfulness meditation, relaxation exercises) can help mitigate the effects of stress on bowel function. Seeking support from mental health professionals or support groups can also be beneficial for individuals experiencing psychological distress related to bowel habits. By addressing stress, managing emotions, and seeking appropriate support for mental health concerns, individuals can promote optimal bowel function and contribute to overall GI health and well-being.

### Medications Affecting Bowel Elimination

Medications can affect bowel elimination in various ways, depending on their mechanism of action and intended therapeutic effects. Some medications may directly affect bowel motility, stool consistency, or GI function, leading to alterations in bowel habits. Opioid analgesics (e.g., morphine, codeine, oxycodone, hydrocodone) are commonly prescribed for pain management. These medications bind to opioid receptors in the GI tract, slowing bowel motility and reducing intestinal secretions. As a result, opioid use can lead to constipation, a common side effect known as **opioid-induced constipation (OIC)**.

Certain antidepressant medications, particularly tricyclic antidepressants (TCAs) and selective serotonin reuptake inhibitors (SSRIs), may affect bowel function and contribute to GI side effects. The TCAs (e.g., amitriptyline [Elavil],

imipramine [Tofranil]) can cause constipation by slowing intestinal transit and reducing bowel motility. The SSRIs (e.g., fluoxetine [Prozac], sertraline [Zoloft]) may also lead to GI disturbances, including diarrhea or constipation, as well as changes in appetite and weight.

Antacids and proton pump inhibitors (PPIs) are commonly used to treat gastroesophageal reflux disease (GERD) and peptic ulcers by reducing stomach acid production. Although these are generally well-tolerated medications, they can sometimes cause GI side effects such as constipation or diarrhea. Antacids containing aluminum or calcium may cause constipation, while PPIs like omeprazole and esomeprazole may increase the risk of diarrhea caused by alterations in gut microbiome and nutrient absorption.

Diuretic medications (e.g., furosemide [Lasix], hydrochlorothiazide [HCTZ; Hydrodiuril]) are used to increase urine production and reduce fluid retention in conditions like hypertension and heart failure. However, diuretics can also lead to electrolyte imbalances, including potassium depletion, which may affect bowel function. Low potassium levels can lead to muscle weakness and intestinal dysmotility, potentially causing constipation or other bowel disturbances.

Iron supplements (e.g., ferrous sulfate [Feosol Iron], iron dextran [Infed]) are commonly prescribed for iron-deficiency anemia. Iron can cause stools to be black and can cause GI side effects (e.g., constipation, nausea, abdominal discomfort). Iron is known to be constipating, particularly in high doses or when taken on an empty stomach. Slow-release formulations of iron may be more likely to cause constipation compared to immediate-release formulations.

The examples in [Table 27.1](#) illustrate how medications can influence bowel elimination through various mechanisms, highlighting the importance of considering the effects of medications when assessing bowel symptoms and implementing appropriate management strategies. It is essential for healthcare providers to educate patients about potential GI side effects associated with medications and monitor for any changes in bowel habits during treatment. Adjustments to medication regimens, dietary modifications, and lifestyle interventions may be necessary to address medication-related bowel disturbances and promote optimal bowel health.

Medication	Common Gastrointestinal (GI) Effects	Mitigation Strategies
Nonsteroidal anti-inflammatory drugs (e.g., ibuprofen [Motrin], naproxen [Aleve])	Gastric irritation, ulcers, GI bleeding	<ul style="list-style-type: none"> <li>• Use lowest effective dose.</li> <li>• Take with food or milk.</li> <li>• Consider using a proton pump inhibitor (PPI) or H2 blocker (cimetidine, famotidine).</li> </ul>
Iron supplements (e.g., ferrous sulfate [Feosol Iron], iron dextran [Infed])	Constipation, nausea, abdominal pain	<ul style="list-style-type: none"> <li>• Use immediate-release formulations.</li> <li>• Take with vitamin C to enhance absorption.</li> <li>• Increase dietary fiber and fluid intake.</li> </ul>

**TABLE 27.1** Medications Problematic for the Gastrointestinal System and Mitigation Strategies

Medication	Common Gastrointestinal (GI) Effects	Mitigation Strategies
Tricyclic antidepressants (TCAs) (e.g., amitriptyline [Elavil], imipramine [Tofranil]) and selective serotonin reuptake inhibitors (SSRIs) (e.g., fluoxetine [Prozac], sertraline [Zoloft])	TCAs: Constipation by slowing intestinal transit SSRIs: Diarrhea, constipation, appetite changes, weight changes	<ul style="list-style-type: none"> <li>• TCAs: <ul style="list-style-type: none"> <li>◦ Increase dietary fiber and fluid intake.</li> </ul> </li> <li>• SSRIs: <ul style="list-style-type: none"> <li>◦ Monitor and adjust diet as needed.</li> <li>◦ Consider stool softeners or laxatives.</li> </ul> </li> </ul>
Antacids and proton pump inhibitors (PPIs) (e.g., omeprazole [Prilosec], esomeprazole [Nexium])	Antacids: Constipation (aluminum, calcium) or diarrhea PPIs: Increased risk of diarrhea	<ul style="list-style-type: none"> <li>• Antacids: <ul style="list-style-type: none"> <li>◦ Choose formulations carefully based on side effects.</li> </ul> </li> <li>• PPIs: <ul style="list-style-type: none"> <li>◦ Monitor bowel habits and consider probiotics.</li> </ul> </li> </ul>
Diuretics (e.g., furosemide [Lasix], hydrochlorothiazide [HCTZ; Hydrodiuril])	Electrolyte imbalances, constipation caused by low potassium levels	<ul style="list-style-type: none"> <li>• Monitor electrolyte levels regularly.</li> <li>• Increase dietary potassium intake.</li> <li>• Consider potassium supplements, if needed.</li> </ul>
Antibiotics (e.g., amoxicillin [Amoxil], doxycycline [Acticlate])	Diarrhea, nausea, abdominal cramping	<ul style="list-style-type: none"> <li>• Take with probiotics.</li> <li>• Ensure adequate hydration.</li> <li>• Take with food if not contraindicated.</li> </ul>
Opioids (e.g., morphine [MS Contin], oxycodone [OxyContin])	Constipation, nausea, vomiting	<ul style="list-style-type: none"> <li>• Use stool softeners or laxatives.</li> <li>• Increase dietary fiber and fluid intake.</li> <li>• Use the lowest effective dose.</li> </ul>
Bisphosphonates (e.g., alendronate [Fosamax], risedronate [Actonel])	Esophageal irritation, nausea, abdominal pain	<ul style="list-style-type: none"> <li>• Take with a full glass of water.</li> <li>• Remain upright for at least thirty minutes after taking.</li> <li>• Take on an empty stomach.</li> </ul>
Antidiabetic agents (e.g., glucophage [Metformin])	Diarrhea, nausea, abdominal discomfort	<ul style="list-style-type: none"> <li>• Start with a low dose and gradually increase.</li> <li>• Take with meals.</li> <li>• Consider extended-release formulations.</li> </ul>

**TABLE 27.1** Medications Problematic for the Gastrointestinal System and Mitigation Strategies

Medication	Common Gastrointestinal (GI) Effects	Mitigation Strategies
Calcium channel blockers (e.g., verapamil [Verelan], diltiazem [Cardizem])	Constipation, abdominal discomfort	<ul style="list-style-type: none"> <li>• Increase dietary fiber and fluid intake.</li> <li>• Use stool softeners, if needed.</li> </ul>
Anticholinergics (e.g., oxybutynin [Ditropan XL], scopolamine [Transderm-Scop])	Constipation, dry mouth, abdominal discomfort	<ul style="list-style-type: none"> <li>• Increase dietary fiber and fluid intake.</li> <li>• Use saliva substitutes or sugar-free gum for dry mouth.</li> </ul>
Minerals or electrolytes (e.g., potassium chloride [K-Tab])	Gastric irritation, nausea, abdominal pain	<ul style="list-style-type: none"> <li>• Take with meals.</li> <li>• Use extended-release formulations.</li> <li>• Ensure adequate hydration.</li> </ul>
Corticosteroids (e.g., prednisone [Sterapred], dexamethasone [Decadron])	Gastric irritation, peptic ulcers	<ul style="list-style-type: none"> <li>• Use lowest effective dose for the shortest duration.</li> <li>• Take with food.</li> <li>• Consider using a PPI or H2 blocker.</li> </ul>

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### Medications Affecting Bowel Functioning

Medications play a crucial role in managing various health conditions; however, they can also adversely affect bowel function, leading to disturbances such as constipation or diarrhea. As healthcare professionals, it is essential to understand how medications affect bowel functioning and to provide patient-centered care to minimize adverse effects. This QSEN box explores the competencies required to address medication-related bowel disturbances.

- Patient-centered care:
  - Assess the patient’s medication history to identify any medications that may affect bowel function.
  - Engage in open communication with the patient to discuss potential side effects of medications on bowel habits.
  - Collaborate with the healthcare team to develop individualized care plans that consider the patient’s unique medication regimen and bowel health needs.
- Teamwork and collaboration:
  - Work collaboratively with pharmacists and other healthcare providers to review medication lists and identify medications that may affect bowel function.
  - Communicate effectively with interdisciplinary team members to ensure coordinated care and management of medication-related bowel disturbances.
  - Participate in team-based discussions to develop strategies for minimizing medication-related bowel side effects and optimizing patient outcomes.
- Evidence-based practice:
  - Stay updated on current evidence and research regarding medications that affect bowel functioning.
  - Use evidence-based guidelines and protocols when assessing and managing medication-related bowel disturbances.

- Incorporate best practices into clinical decision-making to enhance patient safety and improve bowel health outcomes.
- Quality improvement:
  - Participate in quality improvement initiatives aimed at reducing medication errors related to bowel-affecting medications.
  - Implement strategies to monitor and evaluate the effectiveness of interventions for managing medication-related bowel disturbances.
  - Identify opportunities for enhancing medication safety and optimizing bowel health outcomes through continuous quality improvement efforts.
- Safety:
  - Prioritize patient safety by conducting thorough medication reconciliations and assessments to identify medications that may affect bowel function.
  - Educate patients and caregivers about the potential risks and benefits of medications affecting bowel habits, including proper administration and monitoring.
  - Implement safety measures, such as medication reconciliation processes and double-checking procedures, to prevent adverse drug events related to bowel-affecting medications.
- Informatics:
  - Use electronic health records and medication management systems to access comprehensive medication profiles and identify medications that may affect bowel function.
  - Document medication-related bowel disturbances and interventions in a timely and accurate manner using standardized documentation tools.
  - Use informatics resources to track and analyze medication-related outcomes and trends, facilitating data-driven decision-making and quality improvement initiatives.

By applying these competencies, healthcare professionals can effectively assess, prevent, and manage medication-related bowel disturbances, optimizing patient outcomes and enhancing overall bowel health. Continuous education, collaboration, and quality improvement efforts are essential to ensure safe and effective medication management in clinical practice.

---

## 27.3 Diagnostic Evaluation

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss diagnostic testing options for determining proper bowel functioning
- Identify the nurse's role in diagnostic testing for functional bowel elimination

Diagnostic testing serves as a cornerstone in the assessment of proper bowel functioning. From stool analyses to sophisticated imaging procedures, a range of diagnostic modalities empower healthcare professionals to delve into the intricacies of GI health. Nurses play an integral role in patient care, so understanding these diagnostic tests is essential for recognizing and addressing functional bowel disorders effectively. This section explores various diagnostic testing methodologies employed to evaluate bowel function, shedding light on their significance, procedures, and implications for patient care. Additionally, it underscores the crucial role that nurses play in the diagnostic process, emphasizing their contributions in supporting patients, collaborating with healthcare teams, and advocating for optimal outcomes in functional bowel assessment.

### Diagnostic Testing for Bowel Functioning

Diagnostic testing plays a pivotal role in the comprehensive evaluation of bowel functioning, offering invaluable insights into the health and integrity of the GI tract. From noninvasive procedures (e.g., stool analysis) to more invasive/surgical techniques (e.g., endoscopic examinations, laparoscopy), a wide array of diagnostic modalities are employed to assess bowel function, identify abnormalities, and guide appropriate management strategies. These diagnostic tests encompass various approaches (e.g., imaging studies, laboratory analyses, direct visualization) to the GI tract, each providing unique advantages in identifying the underlying causes of bowel dysfunction. With a thorough understanding of these diagnostic tools, nurses can effectively assist in the diagnosis of GI disorders, collaborate in the development of comprehensive treatment plans, and play a crucial role in promoting optimal

patient outcomes.

### Serum Laboratory Studies

Serum laboratory studies provide valuable insights into various aspects of bowel health by analyzing blood samples for specific markers and indicators. These tests can help healthcare providers identify underlying conditions, monitor disease progression, and guide treatment decisions. [Table 27.2](#) summarizes common serum laboratory studies used to assess bowel functioning, including normal ranges, as well as associated bowel conditions.

Serum Laboratory Study	Normal Range	Associated Bowel Conditions
Complete blood count (CBC)	<ul style="list-style-type: none"> <li>• Red blood cells (RBC):               <ul style="list-style-type: none"> <li>◦ Male: 4.5–6.1 million cells/mcL</li> <li>◦ Female: 4.0–5.4 million cells/mcL</li> <li>◦ Children: 4.0–5.5 cells/mcL</li> </ul> </li> <li>• Hemoglobin (Hgb):               <ul style="list-style-type: none"> <li>◦ Male: 13–17 g/dL</li> <li>◦ Female: 11.5–15.5 g/dL</li> <li>◦ Children: 11.5–14.5 g/dL</li> </ul> </li> <li>• Hematocrit (Hct):               <ul style="list-style-type: none"> <li>◦ Male: 40–55 percent</li> <li>◦ Female: 36–48 percent</li> <li>◦ Children: 33–43 percent</li> </ul> </li> <li>• White blood cells (WBC):               <ul style="list-style-type: none"> <li>◦ Adults: 4,000–10,000 cells/mcL</li> <li>◦ Children: 4,000–15,500 cells/mcL</li> </ul> </li> <li>• Platelets:               <ul style="list-style-type: none"> <li>◦ Adults: 150,000–400,000 cells/mcL</li> <li>◦ Children: 150,000–450,000 cells/mcL</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Anemia (low RBC, Hgb, and Hct)</li> <li>• Infection (elevated WBC)</li> <li>• Bleeding (low platelet count)</li> <li>• Inflammatory bowel disease [IBD] (elevated WBC and platelet count, low Hgb and Hct)</li> </ul>
Electrolyte panel	<p>Adults:</p> <ul style="list-style-type: none"> <li>• Sodium (Na): 136–144 mEq/L</li> <li>• Potassium (K): 3.7–5.1 mEq/L</li> <li>• Chloride (Cl): 97–105 mEq/L</li> <li>• Bicarbonate (<math>\text{HCO}_3^-</math>): 22–30 mmol/L</li> </ul> <p>Children <math>\geq 1</math> year of age:</p> <ul style="list-style-type: none"> <li>• Sodium (Na): 130–147 mEq/L</li> <li>• Potassium (K): 3.5–5.1 mEq/L</li> <li>• Chloride (Cl): 95–108 mEq/L</li> <li>• Bicarbonate (<math>\text{HCO}_3^-</math>): 19–25 mmol/L</li> </ul>	<ul style="list-style-type: none"> <li>• Dehydration (high Na, K, Cl)</li> <li>• Diarrhea (low Na, K, Cl)</li> <li>• Vomiting (low Na, K, Cl)</li> </ul>

**TABLE 27.2 Lab Values** (Sources: American College of Clinical Pharmacy, n.d.; Cleveland Clinic, 2024, 2022a, 2022c, 2022d, 2022e, 2022f, 2022g; Jewell, 2020.)

Serum Laboratory Study	Normal Range	Associated Bowel Conditions
Liver function tests (LFTs)	<p>Adults:</p> <ul style="list-style-type: none"> <li>Alanine aminotransferase (ALT): 0–45 U/L</li> <li>Aspartate aminotransferase (AST): 0–35 U/L</li> <li>Alkaline phosphatase (ALP): 30–120 U/L</li> <li>Total bilirubin: 0.2–1.7 mg/dL</li> </ul> <p>Children ≥1 year of age:</p> <ul style="list-style-type: none"> <li>ALT: 5–55 U/L</li> <li>AST: 20–60 U/L</li> <li>ALP: 100–420 U/L</li> <li>Total bilirubin: &lt;1.5 mg/dL</li> </ul>	<ul style="list-style-type: none"> <li>IBD (elevated ALT, AST, ALP, and bilirubin)</li> <li>Biliary obstruction (elevated ALP and bilirubin)</li> <li>Liver involvement in GI disorders (elevated ALT, AST, ALP, and bilirubin)</li> </ul>
Inflammatory markers	<ul style="list-style-type: none"> <li>C-reactive protein (CRP): &lt;0.9 mg/dL</li> <li>Erythrocyte sedimentation rate (ESR): varies by age and gender</li> </ul>	<ul style="list-style-type: none"> <li>IBD (elevated CRP and ESR)</li> <li>Perforation (elevated CRP and ESR)</li> <li>Infectious gastroenteritis (elevated CRP and ESR)</li> </ul>
Serum albumin	<p>Adults</p> <ul style="list-style-type: none"> <li>3.5–5.5 g/dL</li> </ul> <p>Children ≥1 year of age</p> <ul style="list-style-type: none"> <li>3.4–5.2 g/dL</li> </ul>	<ul style="list-style-type: none"> <li>Malnutrition (low albumin)</li> <li>Malabsorption disorders (low albumin)</li> <li>IBD (low albumin)</li> <li>Liver disease (low albumin)</li> </ul>
Thyroid function tests	<p>Adults:</p> <ul style="list-style-type: none"> <li>Thyroid-stimulating hormone (TSH): 0.27–4.2 mIU/L</li> </ul> <p>Children ≥1 year of age</p> <ul style="list-style-type: none"> <li>0.55–5.31 g/dL</li> </ul>	<ul style="list-style-type: none"> <li>IBD (low TSH)</li> </ul>

**TABLE 27.2 Lab Values** (Sources: American College of Clinical Pharmacy, n.d.; Cleveland Clinic, 2024, 2022a, 2022c, 2022d, 2022e, 2022f, 2022g; Jewell, 2020.)

A complete blood count (CBC) provides information about the number and types of blood cells present in the bloodstream. Abnormalities in the CBC, such as anemia (low red blood cell count), may indicate GI bleeding, IBD, or malabsorption disorders affecting nutrient absorption. An elevated white blood cell (WBC) count may suggest an inflammatory response in the body, which can occur in conditions like IBD where there is chronic inflammation of the GI tract. Increased platelet count, known as thrombocytosis, may occur in response to inflammation, infection, or bleeding associated with IBD. Low hemoglobin and hematocrit levels may indicate anemia, which is common in IBD and is caused by chronic blood loss from intestinal inflammation and ulceration.

An electrolyte panel measures the levels of electrolytes (e.g., sodium, potassium, chloride, bicarbonate) in the blood. It helps assess electrolyte balance, hydration status, and kidney function. Dehydration can lead to electrolyte disturbances, particularly hypernatremia. When water loss exceeds sodium loss, sodium concentrations in the blood rise, leading to hypernatremia. Conversely, diarrhea can result in hyponatremia caused by excessive loss of sodium-rich fluids in the stool. Potassium levels may also be affected by dehydration, causing hyperkalemia and diarrhea and leading to hypokalemia due to potassium losses in stool.

Vomiting, a common symptom of various GI disorders (e.g., gastroenteritis, gastritis, GI obstruction) can disrupt electrolyte balance through loss of gastric fluid containing electrolytes. Chronic vomiting may lead to hypochloremic metabolic alkalosis, characterized by low chloride levels, and metabolic alkalosis, caused by loss of hydrochloric (HCl) acid in vomit. Potassium losses in vomit can exacerbate electrolyte imbalances, leading to hypokalemia, which can manifest as muscle weakness and cardiac arrhythmias.

Furthermore, electrolyte imbalances can arise secondary to underlying GI disorders, such as IBD, malabsorption syndromes, or GI bleeding. In IBD, chronic inflammation of the bowel can impair electrolyte absorption and secretion, resulting in abnormalities such as hypokalemia, hypomagnesemia, and hypocalcemia. Gastrointestinal bleeding, a complication of conditions like peptic ulcers or colorectal cancer, can lead to iron-deficiency anemia and subsequent electrolyte disturbances, including hypokalemia and hyponatremia, caused by blood loss and fluid shifts.

Liver function tests (LFTs) assess the liver's health and function by measuring levels of enzymes, proteins, and bilirubin in the blood. They help diagnose liver diseases, monitor treatment response, and evaluate liver function. Abnormal LFT results may indicate liver diseases (e.g., hepatitis, cirrhosis, bile duct obstruction), which can affect bowel functioning and digestion. Biliary obstruction caused by certain conditions (e.g., gallstones, tumors, strictures in the bile ducts) can lead to elevated levels of alkaline phosphatase (ALP). This obstruction impedes the free flow of bile, causing its accumulation and subsequent elevation of ALP levels. Concurrently, total bilirubin levels may rise, resulting in jaundice, dark urine, and pale stools. Inflammatory bowel disease, including conditions like Crohn disease and ulcerative colitis, can adversely affect liver function. This manifests as elevated alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels indicative of hepatocellular injury. Additionally, elevated ALP levels in IBD may reflect bile duct injury or obstruction, while elevated total bilirubin levels may signify severe disease, suggesting impaired bilirubin metabolism or excretion due to liver dysfunction or bile duct involvement. Liver involvement in GI disorders (e.g., primary sclerosing cholangitis [PSC], autoimmune hepatitis) can further elevate liver enzymes (ALT, AST, ALP), caused by hepatocellular injury, bile duct inflammation, or cholestasis. Elevated total bilirubin levels in advanced liver diseases associated with GI disorders may indicate impaired bilirubin metabolism or excretion caused by liver dysfunction or bile duct obstruction.

C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are markers of inflammation that can change in response to bowel-related diseases. The CRP levels tend to rise in the presence of inflammation, making CRP a useful marker for assessing disease activity in bowel-related conditions such as IBD, Crohn disease, and ulcerative colitis. The CRP levels often correlate with the severity of inflammation and disease activity, making it a useful laboratory test result to monitor over time to assess response to treatment and guide therapeutic decisions in managing bowel-related diseases. Elevated CRP levels can also indicate complications of bowel-related diseases (e.g., abscesses, perforation, fistulas) that can trigger an acute inflammatory response. Like CRP, ESR tends to increase in the presence of inflammation, including bowel-related diseases such as IBD. An ESR elevation may be more pronounced in chronic inflammatory conditions like IBD compared to acute inflammatory processes. However, ESR changes are less specific than CRP and may be influenced by other factors such as anemia or infection, limiting its utility as a stand-alone marker for assessing disease activity in bowel-related diseases. Despite its limitations, ESR can still provide valuable information when interpreted in conjunction with other clinical findings and laboratory tests.

Albumin, a protein synthesized by the liver, serves as a crucial marker of nutritional status and liver function. In various GI conditions (e.g., malnutrition, malabsorption disorders, IBD, liver disease), albumin levels can undergo characteristic changes. In instances of malnutrition, insufficient intake of protein and calories leads to decreased albumin synthesis by the liver, resulting in hypoalbuminemia. Similarly, malabsorption disorders impair nutrient absorption, including protein, exacerbating hypoalbuminemia. Inflammatory bowel disease, marked by chronic GI inflammation, further contributes to decreased albumin synthesis and increased loss through the gut. Liver disease (e.g., cirrhosis hepatitis) significantly impairs albumin production because of chronic liver damage and inflammation, leading to hypoalbuminemia and associated complications. Monitoring albumin levels in these conditions offers valuable insights into nutritional status, disease severity, and liver function, guiding appropriate management strategies. However, interpretation of albumin levels should take into consideration other clinical findings to ensure comprehensive patient care.

Thyroid function tests assess thyroid-stimulating hormone (TSH) levels in the blood, which play a role in regulating

metabolism and bowel motility. Malabsorption disorders (e.g., celiac disease, IBD) can disrupt the absorption of essential nutrients, including iodine and selenium, which are crucial for thyroid hormone synthesis. Consequently, inadequate levels of these nutrients may lead to hypothyroidism, characterized by elevated TSH levels as the body attempts to stimulate thyroid hormone production. Additionally, medications commonly used to manage GI conditions, such as PPIs or certain antibiotics, may interfere with thyroid hormone absorption or metabolism, further altering thyroid hormone levels and subsequently affecting TSH levels.

By interpreting the results of these serum laboratory studies in conjunction with clinical findings and patient history, healthcare providers can gain valuable insights into proper bowel functioning, diagnose underlying conditions affecting bowel health, and develop targeted treatment plans to optimize GI function and overall well-being. Additionally, serial monitoring of these laboratory parameters allows for ongoing assessment of bowel health and treatment response over time.

### Stool Tests

Stool tests, also known as fecal tests or stool analyses, are diagnostic tools used to assess various aspects of bowel functioning by analyzing the composition, characteristics, and contents of stool samples. Examples of stool tests include **Cologuard**, **fecal occult blood test (FOBT)**, **fecal immunochemical test (FIT)**, **stool culture**, and **ova and parasite examination**. These tests are valuable diagnostic tools in assessing bowel function by detecting occult blood, identifying pathogens, and diagnosing intestinal infections. Stool tests play a crucial role in the evaluation and management of various GI conditions, aiding in early detection, diagnosis, and treatment decisions. [Table 27.3](#) provides an overview of the purpose, procedure, and interpretation of each stool test commonly used to evaluate bowel functioning.

Stool Test	Purpose	Procedure	Interpretation
Cologuard	<ul style="list-style-type: none"> <li>Screen for colorectal cancer and precancerous polyps.</li> </ul>	<ul style="list-style-type: none"> <li>A Cologuard kit is mailed to the patient's home. The patient collects a stool sample using the provided materials and mails the sample back to the laboratory in a prepaid, pre-labeled box.</li> </ul>	<ul style="list-style-type: none"> <li>Positive results indicate abnormal DNA and/or blood in the stool, warranting follow-up with a colonoscopy to further investigate and confirm findings.</li> </ul>
Fecal occult blood test (FOBT)	<ul style="list-style-type: none"> <li>Detect occult blood in stool samples, indicating gastrointestinal (GI) bleeding.</li> </ul>	<ul style="list-style-type: none"> <li>Collect stool sample and test for the presence of blood using chemical reagents.</li> </ul>	<ul style="list-style-type: none"> <li>Positive results may indicate GI bleeding, warranting further investigation (e.g., colonoscopy).</li> </ul>
Fecal immunochemical test (FIT)	<ul style="list-style-type: none"> <li>Detect occult blood in stool samples with improved sensitivity and specificity compared to FOBT.</li> </ul>	<ul style="list-style-type: none"> <li>Collect stool sample and test for human hemoglobin using immunochemical methods.</li> </ul>	<ul style="list-style-type: none"> <li>Positive results indicate the presence of blood in the stool, necessitating further evaluation to identify potential sources of bleeding.</li> </ul>

**TABLE 27.3 Stool Tests** (Sources: Nemours Kids Health, 2023; Cologuard, 2024.)

Stool Test	Purpose	Procedure	Interpretation
Stool culture	<ul style="list-style-type: none"> <li>Identify pathogenic bacteria, viruses, or parasites responsible for GI infections.</li> </ul>	<ul style="list-style-type: none"> <li>Collect stool sample and culture on specific media to facilitate the growth of microorganisms. Perform biochemical tests to characterize isolates.</li> </ul>	<ul style="list-style-type: none"> <li>Positive cultures reveal the presence of pathogens (e.g., <i>Salmonella</i>, <i>Shigella</i>, parasites), which guides appropriate antimicrobial therapy.</li> </ul>
Ova and parasite examination	<ul style="list-style-type: none"> <li>Detect parasite eggs, larvae, or cysts in stool samples, indicating intestinal parasitic infections.</li> </ul>	<ul style="list-style-type: none"> <li>Examine stool sample microscopically for the presence of parasite ova, larvae, or cysts using staining techniques.</li> </ul>	<ul style="list-style-type: none"> <li>Positive findings of parasites or their eggs confirm the diagnosis of intestinal parasitic infections, prompting initiation of appropriate treatment.</li> </ul>

**TABLE 27.3 Stool Tests** (Sources: Nemours Kids Health, 2023; Cologuard, 2024.)

### Breath Tests

A **breath test** is a noninvasive diagnostic tool used to assess various aspects of bowel functioning, particularly related to carbohydrate metabolism and bacterial overgrowth in the GI tract. Breath tests involve measuring the levels of specific gases exhaled in breath samples following the ingestion of a substrate, typically a sugar or other fermentable carbohydrate.

The **hydrogen breath test** is primarily used to detect bacterial overgrowth in the small intestine and assess carbohydrate malabsorption, particularly lactose intolerance. For this procedure, the patient ingests a **substrate** (a substance or compound that undergoes a chemical reaction or is acted on by an enzyme to produce a specific product) containing a fermentable carbohydrate, such as lactose or glucose. If bacterial overgrowth or malabsorption is present, bacteria in the small intestine ferment the carbohydrate, producing hydrogen gas, which is absorbed into the bloodstream and eventually exhaled through the lungs. Breath samples are collected at regular intervals over several hours, and the levels of hydrogen in the breath are measured. A significant increase in hydrogen levels compared to baseline suggests bacterial overgrowth or malabsorption, indicating improper bowel functioning.

The **methane breath test**, similar to the hydrogen breath test, evaluates bacterial overgrowth and carbohydrate malabsorption, focusing on methane-producing bacteria. After ingesting a fermentable carbohydrate substrate, breath samples are collected and analyzed for methane levels. Methane is produced by certain bacteria during carbohydrate fermentation in the gut. Elevated methane levels indicate the presence of methane-producing bacteria and can suggest bacterial overgrowth or carbohydrate malabsorption.

The **lactulose breath test** is specifically designed to diagnose small intestinal bacterial overgrowth by assessing the transit time and bacterial fermentation in the small intestine. The patient ingests a solution containing lactulose, a nonabsorbable sugar. As lactulose passes through the small intestine, it is fermented by bacteria, producing hydrogen and/or methane gas. Breath samples are collected at regular intervals to measure gas levels. Elevated levels of hydrogen and/or methane indicate bacterial overgrowth in the small intestine, suggesting improper bowel functioning.

### Genetic Testing

By identifying genetic mutations associated with specific GI disorders, **genetic testing** serves as a valuable diagnostic tool in evaluating proper bowel functioning. Primarily used in hereditary GI conditions like familial adenomatous polyposis and Lynch syndrome, genetic testing targets specific genes linked to these disorders. By detecting mutations in these genes, healthcare providers can assess an individual's risk of developing colorectal

cancer or other GI malignancies, facilitating early intervention and surveillance measures.

Additionally, genetic testing plays a role in clarifying the genetic basis of IBD, including Crohn disease and ulcerative colitis. While the genetic landscape of IBD remains complex, specific susceptibility genes can be identified through genetic testing, aiding in risk assessment and treatment decision-making. Moreover, in conditions like celiac disease, genetic testing helps identify individuals predisposed to gluten intolerance and autoimmune damage to the small intestine. Advancements in genomic technology offer promise in assessing an individual's overall genetic risk for GI disorders by aggregating information from multiple genetic variants across the genome.

### Imaging Studies

Imaging studies are essential diagnostic tools used to assess proper bowel functioning by providing detailed visualization of the GI tract and surrounding structures. They play a crucial role in diagnosing various GI disorders and assessing bowel functioning by providing detailed anatomical information and identifying structural abnormalities or pathological changes. Interpretation of imaging results requires collaboration between radiologists and gastroenterologists to guide appropriate management and treatment decisions for patients. [Table 27.4](#) provides an overview of the purpose, procedure, and interpretation of each imaging study commonly used to evaluate bowel functioning.

Imaging Study	Purpose	Procedure	Interpretation
X-ray	Evaluate bowel obstruction, perforation, or other structural abnormalities.	Patient may ingest contrast material before and/or during x-rays or undergo abdominal x-rays without contrast.	Abnormal findings (e.g., air-fluid levels, dilated loops of bowel, free air under the diaphragm) may indicate pathology.
Computed tomography (CT) scan	Assess bowel wall thickness, inflammation, tumors, or other abnormalities.	Patient may receive oral or intravenous contrast to enhance visualization of the gastrointestinal (GI) tract.	Abnormal findings may reveal signs of inflammatory bowel disease, tumors, strictures, or other pathologies affecting bowel functioning.
Magnetic resonance imaging (MRI)	Provide detailed imaging of the GI tract without ionizing radiation.	Patient may receive oral contrast or undergo MRI without contrast.	MRI scans can identify bowel wall thickening, inflammation, fistulas, or abscesses, aiding in the diagnosis of various GI disorders.
Barium swallow/upper GI series	Evaluate the upper GI tract, including the esophagus, stomach, and duodenum.	Patient ingests barium contrast, followed by x-rays to observe the passage of contrast through the upper GI tract.	Abnormalities (e.g., ulcers, strictures, tumors, motility disorders) may be detected in the upper GI tract.
Barium enema/lower GI series	Examine the lower GI tract, including the colon and rectum.	Barium contrast is introduced into the colon via an enema, followed by x-rays to visualize the colon and rectum.	Findings (e.g., polyps, diverticula, strictures, tumors) may be identified in the colon and rectum, aiding in the diagnosis of colorectal conditions.

**TABLE 27.4** Imaging Studies (Source: Sun et al., 2023.)

A special dye, called **contrast**, is administered to patients before some tests so that certain areas show up better on the x-rays, MRIs, and CT scans ([Figure 27.5](#)). If contrast is used, the patient may be required to remain NPO (nothing passed orally/by mouth) for four to six hours before the test. Contrast can be administered orally or intravenously

(IV). Oral contrast has a chalky taste and will pass out of the body through the stools. Patients receiving IV contrast may feel a slight burning sensation, metallic taste in the mouth, or warm flushing of the body that resolves in a few seconds.

**FIGURE 27.5** During a barium enema, the barium coats the lining of the colon, making it visible on the x-ray images. This allows the radiologist to evaluate the size, shape, and contour of the colon, as well as the presence of any abnormalities, such as polyps, tumors, or areas of inflammation. (credit: “Human intestinal tract, as imaged via double-contrast barium enema” by “Glitzy queen00”/Wikimedia Commons, Public Domain)

Before sending the patient for a procedure using contrast, check for previous allergies to iodine or other contrast dyes. Some patients may be prescribed diphenhydramine or corticosteroids before receiving the contrast if they have had a previous allergic reaction. Verify the patient’s kidney status because IV contrast can worsen kidney function. If the patient is currently taking the antidiabetic medication metformin, there may be restrictions placed on the administration of metformin before or after the procedure. This is because the contrast dye used in these imaging tests can affect kidney function, and metformin can accumulate in the body if the kidneys are not working properly, potentially leading to a serious condition called lactic acidosis. For example, patients may be advised to stop taking metformin forty-eight hours before the procedure and to refrain from resuming it until forty-eight hours after the procedure, pending the confirmation of normal kidney function. Jewelry should be removed before the procedure. After the procedure, encourage patients who have received contrast to increase their fluid intake to help eliminate it from their body, as appropriate (Medline Plus, 2022).

After undergoing a barium enema study, patients may experience a sense of relief after the enema is complete, and they can typically resume their normal activities shortly afterward. In the hours following the procedure, patients will likely pass the barium contrast material during bowel movements, resulting in stools that are white or light-colored because of the presence of the contrast material. This is a normal part of the process, and it is essential for the patient to stay hydrated to help flush the barium out of the system. Some patients may experience mild abdominal discomfort or cramping after the procedure, which should resolve within a few hours. Changes in stool consistency, such as firmer stools, may occur temporarily because of the presence of the contrast material; however, increasing fiber intake and staying hydrated can help normalize stool consistency. While rare, severe side effects such as allergic reactions to the contrast material or bowel complications may occur, requiring immediate medical attention if experienced.

## REAL RN STORIES

---

### Using Imaging Studies to Diagnose Bowel Conditions

**Nurse:** Marco, BSN

**Clinical setting:** Emergency department

**Years in practice:** 3

**Facility location:** The inner city of a large metropolitan area in Florida

A few years ago, I had a patient named Mr. Garcia who came into the emergency room with severe abdominal pain. You could tell by the look on his face that he was suffering greatly, and I knew immediate action was needed. The provider ordered an abdominal x-ray to get a clearer picture of what was going on inside his abdomen.

As Mr. Garcia underwent the imaging study, I couldn't help but feel a sense of urgency. The results were crucial; they could shed light on the severity of his condition and what action I needed to take next. The x-ray showed severe fecal impaction and significant colon distension, and we needed to act fast to relieve his suffering and prevent further complications.

With a sense of urgency, I assisted the medical team in implementing treatment strategies, including hydration, laxatives, and gentle disimpaction under the provider's guidance. Throughout the process, I stayed by Mr. Garcia's side, offering comfort and support as he endured the discomfort. Witnessing the relief on his face as the treatments took effect was incredibly rewarding, knowing we were making a positive difference in his recovery.

A while later, Mr. Garcia finally found relief, passing a substantial stool. It was a small victory, but it meant the world to him and to us. As he expressed his gratitude for our efforts, I felt a deep sense of satisfaction, knowing we had helped him through a difficult time.

This experience reinforced the importance of swift action, collaboration, and empathy in nursing. It's moments like these that remind me why I became a nurse—to make a difference in the lives of patients like Mr. Garcia, providing compassionate care when they need it most.

---

### Endoscopic Procedures

Endoscopic procedures are instrumental in assessing proper bowel functioning by allowing direct observation of the GI tract and obtaining tissue samples for analysis. Some examples of endoscopic procedures include **esophagogastroduodenoscopy (EGD)**, **colonoscopy**, **flexible sigmoidoscopy**, **endoscopic retrograde cholangiopancreatography (ERCP)**, and **capsule endoscopy**. Interpretation of endoscopic findings requires expertise and collaboration between endoscopists and pathologists to guide appropriate management and treatment decisions for patients. [Table 27.5](#) provides an overview of the purpose, procedure, and interpretation of each endoscopic procedure commonly used to evaluate bowel functioning.

Endoscopic Procedure	Purpose	Procedure	Interpretation
Esophagogastroduodenoscopy (EGD)	Evaluate the esophagus, stomach, and duodenum for abnormalities such as ulcers, inflammation, or tumors.	A flexible endoscope is passed through the mouth into the esophagus, stomach, and duodenum. Biopsies may be obtained for further analysis.	Findings such as esophageal ulcers, gastritis, peptic ulcers, or duodenal tumors may indicate pathology affecting the upper GI tract.
Colonoscopy	Examine the colon and rectum for abnormalities such as polyps, inflammation, or tumors.	A flexible colonoscope is inserted through the rectum into the colon. Polyps may be removed, and biopsies can be obtained for analysis.	Identification of polyps, inflammation, diverticula, or colorectal tumors can aid in the diagnosis of conditions such as colorectal cancer, inflammatory bowel disease, or diverticulitis.
Flexible sigmoidoscopy	Evaluate the rectum and sigmoid colon for abnormalities such as polyps, inflammation, or tumors.	A flexible sigmoidoscope is inserted through the rectum into the sigmoid colon. Biopsies may be obtained if necessary.	Findings such as sigmoid polyps, proctitis, or rectal tumors may indicate pathology affecting the lower GI tract.
Endoscopic retrograde cholangiopancreatography (ERCP)	Assess the bile ducts and pancreatic duct for abnormalities such as stones, strictures, or tumors.	A flexible endoscope is advanced through the mouth into the duodenum. Contrast dye is injected into the bile and pancreatic ducts for imaging.	Identification of bile duct stones, strictures, or pancreatic tumors can aid in the diagnosis and management of conditions such as choledocholithiasis or pancreatic cancer.
Capsule endoscopy	Evaluate the small intestine for abnormalities such as bleeding, inflammation, or tumors.	Patient swallows a capsule containing a camera, which captures images of the small intestine as it passes through the digestive tract.	Visualizing small intestinal abnormalities (e.g., bleeding sources, Crohn disease, small bowel tumors) can aid in the diagnosis of conditions affecting the small intestine.

**TABLE 27.5** Endoscopic Procedures (Sources: Cleveland Clinic, 2022b, 2023a, 2023b.)

### Laparoscopy

A minimally invasive surgical procedure, **laparoscopy** serves as a valuable diagnostic and therapeutic tool in assessing and addressing various GI conditions that may adversely affect bowel functioning. In a diagnostic laparoscopy, the abdominal cavity and its organs are meticulously examined for abnormalities (e.g., adhesions, tumors, inflammation) that could affect bowel function. This is achieved by inserting a laparoscope, a thin tube equipped with a camera, through small incisions in the abdomen, allowing direct observation of the abdominal

organs. Identification of such abnormalities during diagnostic laparoscopy provides crucial insights into the underlying causes of bowel dysfunction, such as adhesion-related bowel obstruction or IBD, guiding subsequent treatment decisions.

Therapeutic laparoscopy extends beyond diagnosis to address the underlying causes of bowel dysfunction identified during the diagnostic procedure. Through additional incisions, surgical instruments are introduced to perform therapeutic interventions such as **adhesiolysis** (removal of adhesions), tumor resection, or bowel resection. These interventions aim to alleviate obstructions, remove tumors, or address inflammatory processes, ultimately improving bowel functioning and alleviating symptoms associated with GI conditions. Laparoscopy offers several advantages over traditional open surgery, including smaller incisions, reduced postoperative pain, and shorter hospital stays, making it an effective and preferred approach in the evaluation and management of bowel-related issues.

## The Nurse's Role in Diagnostic Testing for Functional Bowel Elimination

Diagnostic testing for functional bowel elimination plays a crucial role in assessing and managing various GI conditions. Nurses, as frontline caregivers, play an integral role in facilitating this process, ensuring effective patient care and treatment outcomes. The nurse's involvement in diagnostic testing for functional bowel elimination spans a range of duties, including performing assessments, implementing nursing interventions, educating patients, preparing them for procedures, assisting during the procedures, and providing postprocedural care. By fulfilling these responsibilities with compassion, competence, and professionalism, nurses contribute significantly to the delivery of high-quality care and positive patient outcomes in the field of GI health.

### Nursing Assessment

In the realm of diagnostic testing for functional bowel elimination, nurses play a pivotal role through their expertise in conducting thorough nursing assessments. Nurses are uniquely positioned to gather comprehensive data regarding a patient's bowel habits, GI symptoms, dietary patterns, and overall health history. Through skilled assessment techniques, nurses can identify potential risk factors, symptoms of bowel dysfunction, and contributing factors such as dietary habits, stress levels, and medication use. For example, a nurse conducting a nursing assessment may ask a patient about their typical daily intake of fiber-rich foods, hydration status, and any recent changes in diet or lifestyle that could adversely affect bowel function.

Nursing assessment of stool characteristics includes carefully observing and documenting various aspects of the stool to gather valuable information about a patient's GI health. This comprehensive assessment involves evaluating the consistency, color, and odor of the stool. The texture of the stool is referred to as **consistency** and ranges from hard and formed to soft and loose, which can provide insights into bowel function and hydration status. Nurses also note the color of the stool, which can indicate different conditions or dietary factors. For instance, black, sticky, tarry stools (**melena**) may suggest upper GI bleeding, while pale or clay-colored stools may indicate issues with bile production or flow. On the other hand, **hematochezia** (also known as **rectal bleeding**), bright red blood in the stools, is a sign of bleeding from the lower GI tract. Any sign of blood should always be reported to the healthcare provider. Additionally, nurses assess the odor of the stool, which can offer clues about digestive processes or bacterial activity in the gut.

By establishing open communication and fostering a trusting relationship with patients, nurses create an environment in which individuals feel comfortable sharing sensitive information related to their bowel habits and GI concerns. By actively listening to patient concerns, validating their experiences, and providing education on healthy bowel habits and lifestyle modifications, nurses empower patients to actively participate in their own care and advocate for their needs. Additionally, nurses employ their clinical judgment and critical-thinking skills to interpret assessment findings, recognize patterns of bowel dysfunction, and determine the need for further diagnostic testing or interventions. For instance, if a patient reports symptoms suggestive of bowel obstruction (e.g., severe abdominal pain, distension, vomiting), the nurse promptly recognizes the need for urgent medical evaluation and intervention. Similarly, if a patient presents with chronic constipation or diarrhea, the nurse collaborates with the healthcare team to implement evidence-based interventions, such as dietary modifications, pharmacological therapies, or referral to a gastroenterologist for further evaluation. Through their holistic approach to nursing assessment, nurses not only contribute valuable insights to the diagnostic process but also serve as advocates for patients, ensuring their needs are addressed and promoting optimal bowel health outcomes.

### Nursing Interventions to Promote Bowel Elimination

Nurses play a crucial role not only in facilitating the diagnostic process but also in implementing nursing interventions to promote optimal bowel elimination. Through their expertise in GI health and patient-centered care, nurses employ a variety of interventions aimed at improving bowel function, alleviating symptoms, and enhancing overall bowel health. Some nursing interventions commonly used to promote bowel elimination include the following:

- **Education and lifestyle modifications:** Nurses provide patient education on healthy bowel habits, emphasizing the importance of adequate hydration, dietary fiber intake, regular exercise, optimal positioning to promote bowel elimination, and stress management techniques. By empowering patients with knowledge about factors that influence bowel function, nurses help individuals make informed lifestyle choices to support optimal bowel elimination.
- **Nutritional counseling:** Nurses collaborate with dietitians to develop individualized dietary plans tailored to each patient's needs and preferences. For instance, patients with constipation may benefit from increasing fiber-rich foods in their diet, while those with diarrhea may require dietary modifications to reduce irritants such as caffeine or spicy foods. Nurses monitor dietary intake, provide dietary counseling, and reinforce the importance of balanced nutrition for bowel health.
- **Medication management:** Nurses administer prescribed medications to manage symptoms of bowel dysfunction, such as laxatives for constipation or antidiarrheal agents for diarrhea. They also monitor medication effectiveness, assess for adverse effects, and educate patients on proper medication use and potential side effects. Additionally, nurses collaborate with healthcare providers to adjust medication regimens based on patient response and treatment goals.
- **Bowel training programs:** For patients with impaired bowel function (e.g., fecal incontinence, constipation), nurses implement bowel training programs to establish regular bowel habits and improve bowel control. These programs may include scheduled toileting routines, biofeedback therapy, pelvic floor exercises, and relaxation techniques to enhance sphincter control and promote efficient bowel evacuation.
- **Promotion of physical activity:** Nurses encourage patients to engage in regular physical activity because exercise can stimulate bowel motility and promote regular bowel movements. Nurses assess patients' mobility levels, provide recommendations for safe exercise routines, and collaborate with physical therapists to develop individualized exercise plans tailored to each patient's abilities and limitations.
- **Hygiene and skin care:** Nurses provide meticulous perineal care for patients with bowel incontinence to prevent skin breakdown, irritation, and infection. They assist patients with proper hygiene practices, including gentle cleansing, application of protective barrier creams, and frequent changes of incontinence products (disposable briefs, diapers), as needed.

Through these nursing interventions, nurses play a vital role in promoting bowel elimination, enhancing patient comfort, and improving overall quality of life for individuals with functional bowel disorders. By delivering compassionate, patient-centered care and collaborating with interdisciplinary healthcare teams, nurses contribute to positive outcomes and empower patients to achieve optimal bowel health.

## PATIENT CONVERSATIONS

### How to Educate a Patient on Strategies for Promoting Bowel Elimination

**Scenario:** Mrs. Perkins, a 65-year-old female, arrives at the clinic for her routine checkup. During her check-in process, she mentions that she has been experiencing discomfort caused by constipation lately and has tried various home remedies without much success. The office assistant has the patient complete a questionnaire to describe her diet, fluid consumption, activity levels, and medications taken.

**Nurse:** Hi Mrs. Perkins. My name is Macey and I'm the nurse who will be working with you today.

**Patient:** Hi Macey, I've been having some trouble with constipation lately, and it's really been bothering me. Do you have any suggestions to help relieve my constipation?

**Nurse:** Thank you for completing this questionnaire. It will really help you and I find some ways to relieve your

constipation. First, let's talk about your diet. According to the information you provided, it looks like you should consider increasing your fiber intake by incorporating more fruits, vegetables, and whole grains. This can help add bulk to your stool and promote regular bowel movements. Another thing that I noticed considering your response to the questionnaire, is that you probably ought to be drinking more fluids. It's important to stay hydrated by drinking plenty of water throughout the day because dehydration can contribute to constipation.

**Patient:** I'll definitely try to drink more water but I have trouble finding recipes that I like for cooking vegetables.

**Nurse:** Do you like raw vegetables like carrots, celery, radishes, cauliflower, and broccoli?

**Patient:** Actually, I do, especially if I dip them in salad dressing.

**Nurse:** That sounds great. Vegetables are even healthier if you eat them raw. You can also cut them up into a salad. By the way, the darker green lettuces are the best for your gut, like romaine and spinach. Do you like fruits?

**Patient:** I do but they seem to go bad too fast.

**Nurse:** Maybe try buying only two fruits each week like a container of strawberries and another of blackberries then switch to two different fruits next week like a few bananas and a container of raspberries. That way you should finish them before its time to buy two more.

**Patient:** You're right. I get excited about how good they look and buy too many at once. Do you recommend anything else?

**Nurse:** Physical activity can also help stimulate bowel movements. Regular exercise, such as walking, jogging, or yoga, can help promote bowel motility and alleviate constipation. Additionally, establishing a regular toileting routine can train your body to respond to the urge to defecate. Try to set aside time each day for bowel movements, and don't ignore the urge when it comes.

**Patient:** I'll make sure to incorporate some exercise into my daily routine and try to stick to a regular toileting schedule. Are there any other things I should consider?

**Nurse:** Yes, for some individuals, over-the-counter laxatives or stool softeners may be helpful in relieving constipation. However, it's important to use these medications under the guidance of a healthcare professional because they can have side effects and may not be suitable for everyone. Finally, managing stress and anxiety through relaxation techniques, such as deep breathing or meditation, can also help improve bowel function.

**Patient:** Thank you so much, Macey. I feel better knowing there are steps I can take to deal with my constipation. I'll definitely give these suggestions a try and let you know how it goes.

**Nurse:** You're welcome. Remember, everyone's body is different, so it may take some time to find the right combination of interventions that work for you. I've been taking notes on my computer while we've been talking so I'll print out a condensed description of all the things we talked about. That way you'll have something to review; but, don't hesitate to reach out if you have any questions or concerns along the way.

---

### Education for a Gastrointestinal Procedure

Nurses assume a critical role in educating patients about the procedures involved in diagnostic testing and therapeutic treatment for functional bowel elimination. As frontline healthcare providers, nurses serve as primary sources of information, guiding patients through the diagnostic and therapeutic processes and addressing their concerns and apprehensions. Before undergoing a GI procedure, nurses may reiterate explanations of the procedure, including its purpose, expected outcomes, potential risks, and any preparatory steps required. Through clear and concise communication, nurses ensure that patients understand what to expect before, during, and after the procedure, helping to alleviate anxiety and promote informed decision-making.

For example, when preparing a patient for a colonoscopy, nurses explain the necessity of bowel preparation to cleanse the colon and facilitate optimal visualization during the procedure. They provide detailed instructions on dietary restrictions, laxative use, and fluid intake, ensuring that patients adhere to the prescribed regimen for effective bowel cleansing. Nurses also discuss the sedation process, potential side effects, and postprocedure care instructions, empowering patients to actively participate in their own care and minimize procedural complications.

## PATIENT CONVERSATIONS

---

### Educating a Patient on Bowel Preparation

**Nurse:** Good morning, Mr. Johnson. My name is Jen. I'm a nurse here and ready to go over the details of your colonoscopy preparation with you. How are you feeling today?

**Patient:** Good morning, Jen. I'm a bit nervous about the whole process, to be honest.

**Nurse:** That's completely understandable. Let's take it step by step, and I'll make sure you have all the information you need. First, the purpose of the colonoscopy is to examine your colon for any abnormalities, such as polyps or signs of disease.

**Patient:** Okay, I understand. But what do I need to do to prepare for it?

**Nurse:** The preparation involves thoroughly cleansing your colon so that the provider can get a clear view during the procedure. You will need to follow a special diet for a few days before the colonoscopy, which typically involves avoiding solid foods and consuming only clear liquids. Then, the day before the procedure, you'll need to take a laxative solution to empty your bowels completely.

**Patient:** That sounds like a lot to manage. Will I be able to eat or drink anything before the colonoscopy?

**Nurse:** Unfortunately, no solid foods will be allowed the day before the procedure. You'll only be able to consume clear liquids like broth, water, and juice without pulp. You may also have sports drinks (Gatorade), popsicles, and gelatin dessert (Jell-O), but nothing you eat or drink can be red or purple. It is essential to stay hydrated, so please consume plenty of these fluids. But remember, you must avoid milk, smoothies, and soup even though they are liquids.

**Patient:** Got it. Is there anything else I should know or do to prepare?

**Nurse:** Yes, it's crucial to follow the instructions provided by your healthcare provider precisely. This includes when to start and stop eating and drinking as well as when to take the laxative solution. It's also important to arrange for someone to drive you home after the procedure because you'll be under the effects of sedation.

**Patient:** Thank you for explaining everything, Jen. I think I understand now and I'm not so nervous.

**Nurse:** You're welcome, Mr. Johnson. Here's description of all the things we talked about for you to take with you. Remember, we're here to support you every step of the way. If you have any more questions or concerns, don't hesitate to call.

---

In addition to procedural education, nurses play a key role in addressing patients' emotional and psychological needs throughout the process. They offer empathetic support, answer questions, and provide reassurance to alleviate anxiety and enhance patient comfort. By fostering a supportive and compassionate environment, nurses help patients feel more confident and empowered as they undergo GI procedures for functional bowel elimination.

### Administration of Bowel Prep

Nurses play a vital role in administering bowel prep to ensure optimal conditions for accurate examination of the GI tract. Often abbreviated as "bowel prep," **bowel preparation (bowel prep)** is a medical procedure that involves cleansing the GI tract, particularly the colon, in preparation for certain medical procedures or surgeries (e.g., colonoscopy, sigmoidoscopy, barium enema). The purpose of a bowel prep is to ensure that the colon is empty and free of stool, allowing for better visualization and examination of the intestinal lining during these procedures (Cleveland Clinic, 2022c; Patel et al., 2023). Bowel prep typically involves consuming a special liquid diet or taking laxatives to induce bowel movements and clear the colon of any remaining feces (Patel et al., 2023).

Nurses are responsible for guiding patients through the bowel preparation process, ensuring compliance with prescribed protocols, and providing support and education to facilitate successful bowel cleansing. Nurses begin by assessing patients' understanding of the bowel prep regimen and addressing any concerns or questions they may have. They provide detailed instructions on the type of bowel prep solution to be used, dosage, timing of administration, dietary restrictions, and fluid intake requirements. Additionally, nurses discuss potential side effects

of the bowel prep (e.g., nausea, bloating, diarrhea) and offer strategies to manage these symptoms effectively.

During administration of the bowel prep, nurses closely monitor patients' adherence to the prescribed regimen and provide ongoing support and encouragement. They offer reminders and guidance to ensure patients follow the recommended schedule for consuming bowel prep solutions and adhere to dietary restrictions. For example, patients may be instructed to eat a low-fiber diet for several days before beginning their bowel prep, followed by a clear liquid diet the day before the scheduled procedure. Nurses also assess patients' tolerance to the bowel prep and promptly address any concerns or complications that may arise, such as dehydration or electrolyte imbalances.

Moreover, nurses play a crucial role in assessing patients' readiness for the procedure following completion of the bowel prep. They monitor patients' hydration status, vital signs, and overall well-being, and communicate any pertinent information to the healthcare team. Nurses provide reassurance and emotional support to alleviate anxiety and discomfort associated with the bowel preparation process, helping patients feel more at ease as they undergo diagnostic testing for functional bowel elimination.

A key component of preprocedural education for a GI test or procedure under moderate sedation is to ensure that the patient will have a responsible adult available to take them home and stay with them for twenty-four hours. It is important to make sure that the patient understands that using a taxi or rideshare option (e.g., Lyft, Uber) is not an allowed method of going home after the procedure unless a responsible adult accompanies the patient on the ride home. Many patients ask why this is not allowed. The nurse must explain that the driver cannot be held accountable for providing care on the ride home; therefore, a responsible adult must accompany the patient.

## LINK TO LEARNING

Resources for learning about the [types of bowel prep kits and their instructions for use \(https://openstax.org/r/77BowelPrep\)](https://openstax.org/r/77BowelPrep) are provided by the Cleveland Clinic. This information can also be shared with patients who are undergoing bowel preparation.

Through their expertise in patient education, assessment, and support, nurses contribute significantly to the successful administration of bowel preparation and facilitate optimal conditions for GI procedures. Their compassionate care and attention to detail help ensure patient safety, comfort, and adherence to treatment protocols, ultimately enhancing the accuracy and effectiveness of diagnostic testing or therapeutic procedure for functional bowel elimination.

### Monitoring After Moderate Sedation

Also known as **conscious sedation**, **moderate sedation** is a medical technique used to induce a state of reduced consciousness and relaxation in patients undergoing certain medical procedures or interventions. Unlike general anesthesia, in which the patient is completely unconscious, moderate sedation aims to keep patients in a state where they can respond to verbal commands and physical stimulation. During moderate sedation, patients may experience drowsiness, reduced anxiety, and a decreased awareness of their surroundings. This sedation level is commonly used for procedures such as minor surgeries, endoscopies, and colonoscopies.

Before the procedure, nurses assess patients' medical history, current medications, allergies, and fasting status to determine their suitability for moderate sedation. They educate patients about the sedation process, including its purpose, potential side effects, and instructions to follow before and after the procedure. Nurses participate in the informed consent process by ensuring that all necessary preparations (e.g., placing IV access, initiating monitoring) are in place before sedation administration. The proceduralist is responsible for obtaining the patient's consent and signature.

During the procedure, nurses continuously monitor the patient's vital signs (e.g., heart rate, blood pressure, respiratory rate, oxygen saturation), observe their response to sedation, and watch for any signs of adverse reactions or complications. They maintain open communication with the procedural team, providing updates on the patient's condition and intervening promptly if necessary to ensure patient safety.

After the procedure, nurses monitor patients closely during the recovery period, assessing their level of consciousness, airway patency, and response to stimuli. They provide supportive care, such as positioning patients

to maintain airway patency and administering supplemental oxygen as needed. Nurses assess for signs of respiratory depression, hypotension, or allergic reactions to sedative medications and intervene promptly to address any complications that may arise.

Moreover, nurses provide thorough education and discharge instructions to patients and their caregivers before discharge from the recovery area. They review potential side effects of sedation, instructions for postprocedure care, and signs of complications to watch for at home. Nurses ensure that patients are stable, alert, and able to tolerate oral fluids before discharge, and ensure that the patient has safe transportation home with a responsible adult.

## 27.4 Common Conditions Affecting Bowel Elimination

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss how constipation affects bowel elimination
- Identify how diarrhea affects bowel elimination
- Recognize how fecal incontinence affects bowel elimination

Understanding how various conditions affect bowel elimination is crucial for nurses in providing comprehensive and effective patient care. Constipation, diarrhea, and fecal incontinence are common GI issues that can significantly affect bowel function and overall well-being. In this section, we analyze how constipation affects bowel elimination, followed by discussions on the effects of diarrhea and fecal incontinence. Nurses need to be well-versed in these topics to assess, manage, and educate patients about their bowel health. By recognizing the signs, symptoms, and implications of these conditions, nurses can develop tailored interventions to promote optimal bowel function, alleviate discomfort, and improve quality of life for their patients.

### Constipation

A common GI condition, **constipation** is characterized by infrequent or difficult passage of stool. It can be caused by slowed peristalsis caused by decreased activity, dehydration, lack of fiber, medications (e.g., opioids, diuretics), depression, or abdominal surgical procedures. As the stool moves slowly through the large intestine, additional water is reabsorbed, resulting in the stool becoming hard, dry, and difficult to move through the lower intestines.

#### Clinical Manifestations

Constipation disrupts the normal process of bowel elimination, leading to various physiological and psychological effects. Physiologically, constipation manifests as infrequent and difficult bowel movements, often defined as fewer than three bowel movements per week (Cleveland Clinic, 2023a). Bowel movements become challenging to pass, requiring increased straining and exertion. This condition is accompanied by abdominal discomfort and pain, characterized by cramping sensations and bloating. The accumulation of gas and stool in the intestines exacerbates this discomfort.

The **Bristol Stool Chart** is a diagnostic medical tool designed to classify the form of human feces into seven categories ([Figure 27.6](#)). These categories range from type 1, which indicates constipation, to type 7, which indicates diarrhea. The chart provides a visual reference for healthcare professionals to assess and discuss bowel movements with patients, helping to diagnose and manage various GI conditions. Each type of stool is described based on its appearance and consistency, allowing for better communication and understanding between patients and healthcare providers regarding bowel health. Types 1 and 2 are associated with constipation. Type 1 consists of separate hard lumps, while type 2 is characterized by lumpy, sausage-like stools with a hard consistency.

The Bristol Stool Scale			
Type 1	Severe constipation	Separate hard lumps, like nuts (hard to pass)	
Type 2	Mild constipation	Sausage-shaped but lumpy	
Type 3	Normal	Like a sausage but with cracks on the surface	
Type 4	Normal	Like a sausage or snake, smooth and soft	
Type 5	Lacking fiber	Soft blobs with clear-cut edges	
Type 6	Mild diarrhea	Fluffy pieces with ragged edges, a mushy stool	
Type 7	Severe diarrhea	Watery, no solid pieces; entirely liquid	

**FIGURE 27.6** The Bristol Stool Chart is used to assess the characteristics of stools according to seven types, ranging from constipation to diarrhea. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Other symptoms of constipation include changes in bowel pattern, such as alternating between hard, formed stool and liquid stool, as well as hypoactive bowel sounds. The straining with defecation can lead to complications such as a **hemorrhoids** (swollen and inflamed vein in the rectum and anus that can cause discomfort, itching, and bleeding) or an **anal fissure** (a small tear or cut in the lining of the anus, which can cause pain, bleeding, and discomfort during bowel movements). The accumulation of stool in the colon can also lead to distension, gas, and **bloating** (sensation of fullness or swelling in the abdomen), contributing to abdominal discomfort. Chronic constipation may result in **fecal impaction**, where a large mass of hardened stool becomes lodged in the rectum, resulting in a palpable abdominal mass and rectal pressure due to the buildup of stool, making it difficult or impossible to pass stool normally (Cleveland Clinic, 2023a). In severe cases, constipation may result in vomiting due to the backup of stool in the digestive tract.

Psychologically, constipation can lead to feelings of frustration, embarrassment, and anxiety. Individuals may become preoccupied with their bowel habits, leading to decreased quality of life and social isolation. Fear of experiencing pain or discomfort during bowel movements may also result in avoidance behaviors, exacerbating the problem.

### Nursing Management

Nursing management of constipation requires a comprehensive approach to address the varied aspects of the condition. Nurses begin by conducting thorough assessments to identify the underlying causes and contributing factors specific to each patient. This involves exploring dietary habits, fluid intake, medication regimens, mobility levels, and any existing medical conditions that may exacerbate constipation.

After performing an assessment, nurses play a crucial role in patient education, sharing knowledge about the significance of fiber-rich diets, adequate hydration, and regular physical activity in promoting bowel regularity. Nurses provide personalized guidance on dietary modifications, emphasizing the importance of incorporating fruits, vegetables, whole grains, and other high-fiber foods into daily meals. Some food sources (e.g., prune juice, prunes, apricots) are helpful in preventing constipation. Certain medications (e.g., opioids, antacids, antidepressants, diuretics) can cause constipation as a side effect. Nurses inform patients about these potential side effects and advise them on strategies to manage or mitigate constipation risk factors while taking these medications.

Nurses facilitate open communication with other healthcare providers to address medication-related concerns or explore alternative treatment options when necessary. In addition to lifestyle modifications, constipation management may involve the use of medications and interventions such as stool softeners, laxatives, suppositories,

enemas, and digital disimpaction.

A medication used to alleviate constipation by adding moisture to the stool, making it softer and easier to pass, is called a **stool softener** (e.g., docusate sodium [Colace]). Stool softeners work by drawing water into the stool, which helps to soften it and increase its bulk. This moisture retention in the stool makes it less dry and hard, reducing the need for straining during bowel movements and decreasing the likelihood of constipation. Stool softeners are particularly useful for individuals who need to avoid straining caused by medical conditions (e.g., hemorrhoids, anal fissures) or after certain surgeries. Unlike laxatives, stool softeners are generally gentler and do not stimulate bowel contractions or increase bowel movements. They are often recommended for long-term use in individuals prone to constipation or those who need to prevent the recurrence of hard stools. However, other methods (e.g., increasing fiber consumption, increasing activity) are typically more effective. Stool softeners are available over the counter or by prescription and come in various forms, including oral capsules, tablets, and liquid formulations.

A commonly used medication to manage constipation by promoting bowel movements is called a **laxative**. They come in various forms and work through different mechanisms to alleviate symptoms. Bulk-forming laxatives containing fiber (e.g., psyllium powder [Metamucil], methylcellulose [Citrucel]) increase the bulk and water content of stool, facilitating its passage. Stimulant laxatives (e.g., Dulcolax, Senokot) stimulate the muscles of the intestines, encouraging bowel contractions and movements. Osmotic laxatives (e.g., polyethylene glycol [MiraLAX], magnesium hydroxide [Milk of Magnesia]) draw water into the intestines, softening stool and increasing bowel movements. Stool softeners help soften stool by enhancing water absorption. While laxatives can provide relief from constipation, they should be used cautiously and under the guidance of a healthcare provider to avoid dependence and potential complications, and they are typically recommended for short-term use rather than as long-term solutions.

A **suppository** is a solid medication inserted into the rectum, where it dissolves to release medication locally. Suppositories may contain laxatives or stool softeners and work by softening stool and stimulating bowel movements. Suppositories offer a targeted approach to managing constipation, bypassing the digestive system and delivering medication directly to the site of action. Like other interventions for constipation, suppositories should be used cautiously and under medical guidance to ensure safe and effective relief. They are typically recommended for short-term use to address acute constipation, with attention to individual needs and potential adverse effects.

An **enema** is another intervention used to manage constipation, involving the introduction of a liquid solution into the rectum to stimulate bowel movements and evacuate stool. Enemas may contain saline solution, mineral oil, or medications, working by softening stool, lubricating the rectum, and prompting bowel contractions. While enemas can provide rapid relief from severe constipation, they should be used judiciously and under medical supervision because of the risk of electrolyte imbalances, rectal irritation, and dependence. Enemas are typically considered for short-term use to address acute constipation, with careful consideration of individual circumstances and potential contraindications.

A medical procedure performed to manually remove impacted stool from the rectum and lower colon using a lubricated, gloved finger is called **digital disimpaction** (Cleveland, 2023c). It is typically used as a last resort when other methods of relieving constipation, such as laxatives, enemas, or stool softeners, have been ineffective. Indications for digital disimpaction include severe fecal impaction that is causing symptoms such as severe abdominal pain, bloating, inability to pass stool, or rectal discomfort. It may also be necessary if there is a risk of bowel obstruction or if the patient is unable to evacuate stool on their own due to physical or neurological impairment.

To perform digital disimpaction, the patient is usually positioned in a side-lying or knee-chest position for easier access to the rectum. The healthcare provider then gently inserts a lubricated, gloved finger into the rectum and manually breaks up the impacted stool, gradually dislodging it and allowing it to be expelled. It is essential to use gentle and slow movements to avoid causing injury or discomfort to the patient. After the procedure, the patient may be instructed to take a warm sitz bath to soothe any discomfort or irritation and to promote relaxation of the pelvic muscles. Depending on the severity of the impaction and the patient's condition, additional treatments or interventions may be necessary to prevent recurrence and manage underlying causes of constipation.

Digital disimpaction should only be performed by trained healthcare professionals in a clinical setting because it carries risks of injury, bleeding, and infection if not performed correctly. It is crucial to follow proper hygiene protocols and use appropriate techniques to ensure patient safety and comfort throughout the procedure. Through

continuous monitoring and evaluation, nurses track the effectiveness of interventions, make adjustments as needed, and offer ongoing support to patients as they work toward optimal bowel health and comfort.

## Diarrhea

More than three unformed stools in twenty-four hours is known as **diarrhea**. It occurs when the intestines fail to properly absorb water or when excess fluid is secreted into the intestines, resulting in rapid transit of stool through the digestive tract. Diarrhea can be acute, lasting for a few days to a week, and often is caused by infections, food poisoning, food intolerances, anxiety, or certain medications (e.g., antibiotics, laxatives). Antibiotic therapy also places patients at risk of developing *Clostridium difficile* (*C. diff*) because some antibiotics eliminate the normal GI tract flora. Patients with *C. diff* have very watery, foul-smelling stools. Transmission-based precautions are implemented to prevent the spread of infection. It is essential to use soap and water for hand hygiene, because alcohol-based hand gels are not effective against *C. diff* spores. Chronic diarrhea, lasting for several weeks or longer, may be indicative of underlying health conditions such as IBD, IBS, or malabsorption disorders (Cleveland, 2023b).

### Clinical Manifestations

Diarrhea affects bowel elimination by altering the normal pattern and consistency of stool. Clinical manifestations of diarrhea include frequent, loose, and watery stools, often accompanied by urgency and a sense of incomplete evacuation. Individuals may experience abdominal cramping, bloating, and discomfort caused by increased intestinal motility. Hyperactive bowel sounds may be audible as the intestines work to expel stool rapidly. In some cases, individuals may experience bowel urgency, leading to a greater than usual number of stools in a twenty-four-hour period. Dehydration is a common complication of diarrhea, characterized by symptoms such as thirst, dry mouth, dark urine, fatigue, and dizziness. In severe cases, diarrhea can lead to electrolyte imbalances, malnutrition, and weight loss.

### Nursing Management

The focus of nursing management and treatment of diarrhea is on addressing the symptoms, restoring fluid and electrolyte balance, and identifying and treating the underlying cause. Nurses closely monitor patients for signs of dehydration and electrolyte imbalances, providing oral rehydration solutions (e.g., sports drinks) or intravenous (IV) fluids as needed to replenish lost fluids and electrolytes. Nurses offer supportive care to alleviate symptoms such as abdominal cramping and discomfort, often through the administration of antispasmodic medications and dietary modifications. Nutrition therapy may involve recommending a bland diet to ease digestive discomfort and avoid exacerbating symptoms. Foods such as bananas, plain rice, applesauce, and toast (BRAT diet) are commonly recommended. Avoiding spicy, greasy, and high-fiber foods may also help.
