## OPENSTAX

OpenStax provides free, peer-reviewed, openly licensed textbooks for introductory college and Advanced Placement® courses and low-cost, personalized courseware that helps students learn. A nonprofit ed tech initiative based at Rice University, we're committed to helping students access the tools they need to complete their courses and meet their educational goals.

## RICE UNIVERSITY

OpenStax is an initiative of Rice University. As a leading research university with a distinctive commitment to undergraduate education, Rice University aspires to path-breaking research, unsurpassed teaching, and contributions to the betterment of our world. It seeks to fulfill this mission by cultivating a diverse community of learning and discovery that produces leaders across the spectrum of human endeavor.

Preface 1

## UNIT 1 FOUNDATION OF NURSING AND THE HEALTHCARE ENVIRONMENT

---

### CHAPTER 1

#### **Introduction to the Nursing Profession: Evolution, Theories, and Practice** 9

Introduction	9
1.1 Evolution of Nursing and Nursing Practice	9
1.2 Nursing Education Programs	18
1.3 Nursing as a Profession	24
1.4 History and Evolution of Nursing Theories	32
1.5 Selected Nursing Theorist	37
1.6 Application of Theories in Nursing Practice	50
Summary	56
Key Terms	58
Assessments	60
References	64

### CHAPTER 2

#### **Communication** 67

Introduction	67
2.1 Types of Communication	68
2.2 Models of Communication	75
2.3 Effective Communication	79
2.4 Therapeutic Communication	85
2.5 Barriers to Communication	93
Summary	101
Key Terms	102
Assessments	103
References	106

### CHAPTER 3

#### **Healthcare Delivery Systems** 109

Introduction	109
3.1 Levels of Care	109
3.2 Organizational Frameworks and Structure	119
3.3 Barriers to Healthcare Access	127
3.4 Culture	134
Summary	141
Key Terms	141

Assessments	143
References	146

## CHAPTER 4

### Health, Wellness, and Community-Based Health Care 151

Introduction	151
4.1 Defining Health and Wellness	152
4.2 Models of Health	161
4.3 Health Promotion and Illness Prevention	167
4.4 Community-Based Health Care	172
4.5 Community-Based Healthcare Initiatives	180
4.6 Population Health	187
Summary	193
Key Terms	194
Assessments	196
References	200

## CHAPTER 5

### Cultural Competence 205

Introduction	205
5.1 Understanding Cultural Differences	206
5.2 Ethical Practice in Culture and Diversity	214
5.3 Cultural Practice in Nursing	217
5.4 Diversity, Equity, and Inclusion	225
Summary	232
Key Terms	232
Assessments	233
References	237

## CHAPTER 6

### Promoting Individualized Care 241

Introduction	241
6.1 Patient-Centered and Holistic Health Care	241
6.2 Foundations for Providing Person-Centered Care	249
Summary	260
Key Terms	260
Assessments	261
References	263

# UNIT 2 FUNDAMENTAL ASPECTS TO NURSING CARE

---

## CHAPTER 7

### Vital Signs 265

Introduction	265
7.1 Indicators of Physiologic Functioning	266
7.2 How to Perform Vital Signs	276
7.3 Teaching Patients to Perform Vital Signs	297

Summary	301
Key Terms	301
Assessments	303
References	306

## CHAPTER 8

### Admission, Transfer, and Discharge 309

Introduction	309
8.1 Patient Admission	310
8.2 Patient Transfer	327
8.3 Patient Discharge	333
Summary	345
Key Terms	345
Assessments	346
References	350

## CHAPTER 9

### Safety and Security 351

Introduction	351
9.1 Safety: Individual and Environmental	352
9.2 Safety: Violence	371
9.3 Security: Privacy and Informatics	380
Summary	388
Key Terms	389
Assessments	390
References	393

## CHAPTER 10

### Infection Control and Prevention 399

Introduction	399
10.1 Infection Cycle	399
10.2 Asepsis and PPE	408
10.3 Sterile Technique	416
10.4 Infection Control and Patient Safety	420
Summary	426
Key Terms	426
Assessments	428
References	431

## CHAPTER 11

### Medication Administration 435

Introduction	435
11.1 Medication Orders	436
11.2 Fundamental Principles of Medication Administration	441
11.3 The Medication Administration Process	448
Summary	464
Key Terms	465
Assessments	466
References	469

## UNIT 3 THE PROCESS OF NURSING CARE

---

### CHAPTER 12

#### **Assessment: Recognizing Cues** 471

Introduction	471
12.1 The Nurse's Role in Assessment	471
12.2 Types of Assessment	480
12.3 Collection of Assessment Data	486
12.4 Cognitive Process for Analyzing Assessment Data	494
Summary	501
Key Terms	502
Assessments	503
References	508

### CHAPTER 13

#### **Diagnosis and Planning: Analyzing, Prioritizing, and Generating Solutions** 511

Introduction	511
13.1 Evolution of Nursing Diagnosis	512
13.2 Focus of Nursing Diagnosis	519
13.3 Categories of Nursing Diagnosis	524
13.4 Focus of the Planning Phase	528
Summary	536
Key Terms	537
Assessments	537
References	541

### CHAPTER 14

#### **Implementation and Evaluation: Taking Action, Evaluating Outcomes, and Documentation** 543

Introduction	543
14.1 The Nurse's Role in Implementation	544
14.2 Types of Interventions	550
14.3 The Nurse's Role in Evaluation	557
14.4 Evaluation Methods	562
14.5 Guidelines for Effective Documentation	568
Summary	579
Key Terms	580
Assessments	581
References	587

## UNIT 4 COMPLEX THINKING IN NURSING CARE

---

### CHAPTER 15

#### **Evidence-Based Research, Quality Improvement, and Collaborative Practice** 591

Introduction	591
15.1 Evidence-Based Research	592

15.2 Evidence-Based Clinical Decisions	607
15.3 Quality Improvement in Nursing	613
15.4 Nursing Standards of Delegation	618
15.5 Collaborative Practice	622
15.6 Interprofessional Approach to Health Care	628
Summary	633
Key Terms	634
Assessments	636
References	640

## **CHAPTER 16**

### **Legal and Ethical Considerations** 645

Introduction	645
16.1 Value Considerations of Care	646
16.2 Ethics in Nursing Practice	651
16.3 Legal Dimensions of Care	663
16.4 Advocacy in Nursing Practice	676
Summary	684
Key Terms	684
Assessments	687
References	691

## **CHAPTER 17**

### **Patient and Family Education** 697

Introduction	697
17.1 Informed Decision Making and Self-Care	698
17.2 Methods and Approaches to Learning and Teaching	710
17.3 The Nurse's Role in Patient and Family Education	720
17.4 Evaluation of Teaching and Learning	730
Summary	736
Key Terms	737
Assessments	737
References	741

## **CHAPTER 18**

### **Leadership and Management in Nursing** 745

Introduction	745
18.1 Concepts of Leadership in Nursing	746
18.2 Concepts of Management in Nursing	753
18.3 Implementing Leadership and Management into Nursing Practice	762
18.4 Certifications for Nurse Leaders and Managers	768
Summary	772
Key Terms	773
Assessments	775
References	778

# UNIT 5 PHYSIOLOGICAL ASPECTS OF NURSING CARE

---

## CHAPTER 19

### **Oxygenation and Perfusion** 781

Introduction	781
19.1 Respiratory System	782
19.2 Cardiovascular System	792
19.3 Factors Affecting Cardiopulmonary Function	807
19.4 Management of Impaired Cardiopulmonary Functioning	824
Summary	842
Key Terms	843
Assessments	845
References	848

## CHAPTER 20

### **Fluid, Electrolyte, and Acid-Base Balance** 851

Introduction	851
20.1 Fluid and Electrolyte Balances	851
20.2 Acid-Base Balances	862
20.3 The Nurse's Role in Patient Care Management	874
Summary	881
Key Terms	882
Assessments	883
References	886

## CHAPTER 21

### **Nutrition** 891

Introduction	891
21.1 Nutritional Concepts	892
21.2 Factors Affecting Nutrition	903
21.3 Specialized Diets	912
21.4 Nutritional Assessment	922
Summary	928
Key Terms	928
Assessments	929
References	932

## CHAPTER 22

### **Activity** 935

Introduction	935
22.1 Importance of Activity, Movement, and Alignment	936
22.2 Factors Affecting Activity Level	955
22.3 Activities of Daily Living (ADLs)	962
Summary	970
Key Terms	970
Assessments	972
References	976

## CHAPTER 23

### Neuromuscular Function 981

Introduction	981
23.1 Foundations of Neuromuscular Functioning	981
23.2 Factors Affecting Neuromuscular Functioning	994
23.3 Considerations for Care of Neuromuscular Impairment	1005
Summary	1015
Key Terms	1015
Assessments	1017
References	1020

## CHAPTER 24

### Skin Integrity 1023

Introduction	1023
24.1 Structures and Function of the Skin	1023
24.2 Skin Integrity	1033
24.3 Wound Classification	1053
24.4 Wound Healing	1066
Summary	1080
Key Terms	1081
Assessments	1085
References	1088

## CHAPTER 25

### Hygiene 1091

Introduction	1091
25.1 Hygienic Practices	1091
25.2 Factors Affecting Hygienic Practices	1098
25.3 The Nurse's Role in Hygiene	1102
Summary	1112
Key Terms	1112
Assessments	1113
References	1115

## CHAPTER 26

### Urinary Elimination 1117

Introduction	1117
26.1 Urinary System	1118
26.2 Functions of the Urinary System	1123
26.3 Factors Affecting Urinary Elimination	1127
26.4 The Nurse's Role in Urinary Elimination	1140
Summary	1153
Key Terms	1154
Assessments	1156
References	1160

## CHAPTER 27

### Bowel Elimination 1163

Introduction	1163
--------------	------

27.1 Gastrointestinal Tract Structures and Functions	1164
27.2 Factors Affecting Bowel Elimination	1168
27.3 Diagnostic Evaluation	1178
27.4 Common Conditions Affecting Bowel Elimination	1193
Summary	1199
Key Terms	1200
Assessments	1202
References	1206

## CHAPTER 28

### **Sleep and Rest** 1209

Introduction	1209
28.1 Concepts of Sleep and Rest	1210
28.2 Factors Affecting Sleep and Rest	1218
28.3 Effects of Insufficient Sleep	1231
28.4 Nursing Care to Promote Sleep and Rest	1238
Summary	1250
Key Terms	1250
Assessments	1251
References	1255

## CHAPTER 29

### **Sensory Alterations** 1259

Introduction	1259
29.1 Sensory Functioning	1259
29.2 Impaired Sensory Function	1269
29.3 Factors Affecting Sensory Function	1276
Summary	1289
Key Terms	1289
Assessments	1291
References	1294

## CHAPTER 30

### **Pain Assessment** 1297

Introduction	1297
30.1 The Pain Process	1298
30.2 Responses to Pain	1308
30.3 Factors Affecting Pain	1314
30.4 Pain Assessment	1318
30.5 Pain Management	1326
Summary	1339
Key Terms	1340
Assessments	1341
References	1345

## CHAPTER 31

### **Perioperative Nursing Care** 1351

Introduction	1351
31.1 Surgical Concepts	1352

31.2 Preoperative Phase	1367
31.3 Intraoperative Phase	1379
31.4 Postoperative Phase	1391
Summary	1403
Key Terms	1404
Assessments	1406
References	1411

## UNIT 6 PSYCHOSOCIAL ASPECTS OF NURSING PRACTICE

---

### CHAPTER 32

#### **Self-Concept** 1415

Introduction	1415
32.1 Foundations of Self-Concept	1415
32.2 Factors Affecting Self-Concept	1431
Summary	1443
Key Terms	1443
Assessments	1444
References	1447

### CHAPTER 33

#### **Sexuality** 1451

Introduction	1451
33.1 Sexual Identity	1451
33.2 Sexual Fulfillment	1460
33.3 Factors Affecting Sexuality	1463
33.4 The Nurse's Role in Providing Care	1472
Summary	1479
Key Terms	1479
Assessments	1481
References	1485

### CHAPTER 34

#### **Stress, Adaptation, and Homeostasis** 1489

Introduction	1489
34.1 Stress and Adaptation	1490
34.2 Effects of Stress on Health and Wellness	1504
34.3 Factors Affecting Stress and Adaptation	1513
34.4 Adaptation Theories and Models	1518
Summary	1526
Key Terms	1527
Assessments	1528
References	1531

### CHAPTER 35

#### **Spirituality** 1535

Introduction	1535
--------------	------

35.1 Dimensions of Spirituality	1535	
35.2 Applications of Spirituality to Health Care		1554
Summary	1573	
Key Terms	1573	
Assessments	1574	
References	1576	

## CHAPTER 36

### Grief, Loss, Death, and Dying 1581

Introduction	1581	
36.1 Concepts of Grief and Loss	1582	
36.2 Concepts of Death and Dying	1594	
36.3 Factors That Affect Grief, Loss, Death, and Dying		1603
36.4 Legal and Ethical Considerations	1610	
Summary	1619	
Key Terms	1620	
Assessments	1621	
References	1624	

## UNIT 7 HEALTH PROMOTION ACROSS THE LIFE SPAN

---

## CHAPTER 37

### Family Dynamics 1629

Introduction	1629	
37.1 Family Concepts	1630	
37.2 Family Framework	1639	
37.3 Family Dynamics Influence on Health Outcomes		1646
37.4 The Nurse's Role in Caring for the Family Unit		1652
Summary	1659	
Key Terms	1660	
Assessments	1660	
References	1664	

## CHAPTER 38

### Growth and Development 1669

Introduction	1669	
38.1 Stages of Growth and Development		1670
38.2 Specific Developmental Theories		1674
38.3 Application to Care	1682	
Summary	1690	
Key Terms	1690	
Assessments	1691	
References	1694	

## CHAPTER 39

### Conception Through Adolescence 1695

Introduction	1695	
--------------	------	--

39.1 Growth and Development Stages	1695	
39.2 Theories Related to Growth and Development		1705
39.3 Health Risks for Each Stage	1708	
39.4 The Nurse's Role in Preventing Illness		1720
Summary	1728	
Key Terms	1729	
Assessments	1730	
References	1733	

## **CHAPTER 40**

### **Young and Middle-Aged Adults** 1739

Introduction	1739	
40.1 Growth and Development Stages	1740	
40.2 Theories Related to Growth and Development		1750
40.3 Health Risks for Young and Middle-Aged Adults		1757
40.4 The Nurse's Role in Preventing Illness		1768
Summary	1777	
Key Terms	1778	
Assessments	1779	
References	1783	

## **CHAPTER 41**

### **Older Adults** 1789

Introduction	1789	
41.1 Growth and Development Stages	1790	
41.2 Theories Related to the Older Adult		1796
41.3 Health Risks for Older Adults	1802	
41.4 The Nurse's Role in Preventing Illness		1812
Summary	1823	
Key Terms	1824	
Assessments	1825	
References	1829

# PREFACE

---

## About OpenStax

OpenStax is part of Rice University, which is a 501(c)(3) nonprofit charitable corporation. As an educational initiative, it's our mission to improve educational access and learning for everyone. Through our partnerships with philanthropic organizations and our alliance with other educational resource companies, we're breaking down the most common barriers to learning. Because we believe that everyone should and can have access to knowledge.

## About OpenStax Resources

### Customization

*Fundamentals of Nursing* is licensed under a Creative Commons Attribution 4.0 International (CC BY) license, which means that you can distribute, remix, and build upon the content, as long as you provide attribution to OpenStax and its content contributors.

Because our books are openly licensed, you are free to use the entire book or select only the sections that are most relevant to the needs of your course. Feel free to remix the content by assigning your students certain chapters and sections in your syllabus, in the order that you prefer. You can even provide a direct link in your syllabus to the sections in the web view of your book.

Instructors also have the option of creating a customized version of their OpenStax book. Visit the Instructor Resources section of your book page on OpenStax.org for more information.

### Art Attribution

In *Fundamentals of Nursing*, art contains attribution to its title, creator or rights holder, host platform, and license within the caption. Because the art is openly licensed, anyone may reuse the art as long as they provide the same attribution to its original source.

### Errata

All OpenStax textbooks undergo a rigorous review process. However, like any professional-grade textbook, errors sometimes occur. In addition, the wide range of evidence, standards, practices, data, and legal circumstances in nursing change frequently, and portions of the text may become out of date. Since our books are web-based, we can make updates periodically when deemed pedagogically necessary. If you have a correction to suggest, submit it through the link on your book page on OpenStax.org. Subject matter experts review all errata suggestions. OpenStax is committed to remaining transparent about all updates, so you will also find a list of past and pending errata changes on your book page on OpenStax.org.

### Format

You can access this textbook for free in web view or PDF through OpenStax.org, and for a low cost in print. The web view is the recommended format because it is the most accessible—including being WCAG 2.1 AA compliant—and most current. Print versions are available for individual purchase, or they may be ordered through your campus bookstore.

## About *Fundamentals of Nursing*

### Summary

*Fundamentals of Nursing* aligns with the core curriculum of a nursing fundamentals course and is designed to provide nursing students with the foundational knowledge and practical expertise essential for delivering holistic patient care. This textbook emphasizes the application of clinical judgment across diverse healthcare environments, ensuring readiness to deliver high-quality, compassionate, and patient-centered care to patients from various backgrounds and in different clinical scenarios. As the cornerstone of nursing education, the principles and practices presented in this text provide the foundational knowledge for students embarking on their journey into the nursing profession.

*Fundamentals of Nursing* features a variety of engaging and informative resources designed to prepare students for real-world practice. By simulating patient interactions, students develop critical communication skills essential for effective nursing care. Insights from practicing nurses provide real-world perspectives, helping bridge the gap between theory and practice. Focus on Quality and Safety Education for Nurses (QSEN) equips students with the skills necessary for providing safe, high-quality care.

*Fundamentals of Nursing* is more than just a textbook; it is a vital resource guiding students through the initial stages of their nursing education and beyond. By integrating a holistic approach and respecting inclusivity, this textbook prepares students for clinical rotations and provides a solid groundwork for their future careers as professional nurses.

### Pedagogical Foundation

*Fundamentals of Nursing* offers comprehensive instruction on fundamental nursing concepts such as hygiene, mobility assistance, vital signs assessment, medication administration, safety, and wound care. With 43 chapters, *Fundamentals of Nursing* offers an in-depth exploration of the roles and responsibilities of a nurse, the healthcare environment, and the application of critical thinking and evidence-based practice for effective care delivery. Structured to build confidence and competence, *Fundamentals of Nursing* starts with fundamental concepts and progressively introduces more complex topics. It emphasizes holistic care, addressing the physical, emotional, spiritual, and social needs of patients, and highlights the importance of communication, cultural competence, and ethical decision-making in nursing practice.

### Organizational Framework

The table of contents for *Fundamentals of Nursing* presents content in 43 chapters, organized into 7 thematic units.

- **Unit 1** introduces the evolution, theories, and practice of the nursing profession. It covers the history and development of nursing theories, effective communication strategies, and the structure and barriers within healthcare delivery systems. The unit also emphasizes health, wellness, community-based health care, and cultural competence, ensuring that students understand the diverse contexts in which they will work.
- **Unit 2** focuses on essential nursing skills and procedures, from taking vital signs to ensuring patient safety and administering medications. It provides the foundational skills necessary for effective patient care and emphasizes infection control, patient transfer, and discharge processes.
- **Unit 3** explores the nursing process, covering assessment, diagnosis, planning, implementation, and evaluation. It teaches students how to systematically approach patient care, ensuring thorough and effective management of patient needs.
- **Unit 4** addresses advanced topics such as evidence-based research, quality improvement, and collaborative practice. It also covers legal and ethical considerations, patient and family education, and leadership and management in nursing, preparing students for the complexities of professional practice.
- **Unit 5** provides in-depth coverage of physiological aspects, including oxygenation, perfusion, fluid and electrolyte balance, nutrition, and more. It prepares students to manage various physiological conditions effectively.
- **Unit 6** covers the psychosocial dimensions of nursing, including self-concept, sexuality, stress, adaptation, spirituality, and end-of-life care. It highlights the importance of holistic care that addresses both the physical and psychological needs of patients.
- **Unit 7** emphasizes health promotion and disease prevention across different stages of life. It covers family dynamics, growth and development from conception through older adulthood, and care for patients with disabilities and chronic illnesses. The unit also focuses on the development of clinical judgment and critical thinking skills through case studies and practical applications. The final chapter brings all the information together in an unfolding case study.

### Nursing Features

To further enhance learning, *Fundamentals of Nursing* includes the following features:

- **Clinical Judgment Measurement Model** boxes guide students through the application of the Clinical Judgment Measurement Model. The content explores the critical thinking and decision-making processes necessary to navigate patient care at different points in the process, from recognizing cues to evaluating outcomes.

- **Clinical Safety and Procedures (QSEN)** align with the Quality and Safety Education for Nursing competencies by providing detailed explanations of safety protocols and procedures specific to nursing fundamentals. This feature emphasizes the importance of patient safety and quality care and offers checklists, step-by-step, or tips on various safety practices.
- **Cultural Context** boxes explore the impact of cultural factors on nursing procedures and practices. Some features describe care provided in other countries, while other features discuss cultural considerations for patients in the United States. Cultural Context boxes encourage students to approach each patient individually, respecting their culture and values.
- **Life-Stage Context** features describe topics that are affected by a patient's age. Age-related topics allow the students to critically think about what influences certain conditions and the specific considerations needed for patients at different life stages.
- **Link to Learning** features provide a very brief introduction to online resources—videos, interactives, collections, maps, and other engaging resources that are pertinent to students' exploration of the topic at hand.
- **Patient Conversations** features provide students with key information about how to interact with patients, including patient assessment guidelines for various situations and steps describing how to teach specific skills, such as adopting a healthy lifestyle, to a patient.
- **Real RN Stories** feature firsthand accounts from registered nurses in the field. These stories help students make connections to topics on a deeper level.
- **Unfolding Case Studies** present a hypothetical client scenario that unfolds in three parts across chapters, with each subsequent part presenting new information on the same client, to help foster clinical judgment. In each part of an unfolding case feature, the scenario is followed by two questions that require students to apply their knowledge of evidence-based care and allow them to practice with questions that mimic the style of Next-Gen NCLEX. The answers to these questions, with explanations, are included in the Answer Key for students at the end of the book.

### Pedagogical Features

To support student learning, *Fundamentals of Nursing* includes the following standard elements:

- **Learning Outcomes:** Every chapter section begins with a set of clear and concise student learning outcomes. These outcomes are designed to help the instructor decide what content to include or assign and can guide students on what they can expect to learn and be assessed on.
- **Assessments:** A variety of assessments allow instructors to confirm core conceptual learning, elicit brief explanations that demonstrate student understanding, and offer more in-depth assignments that enable learners to dive more deeply into a topic or history-study skill.
  - **Review Questions** test for conceptual apprehension of key concepts.
  - **Check Your Understanding Questions** require students to explain concepts in their own words.
  - **Reflection Questions** and **Competency-Based Assessment Questions** dive deeply into the material to support longer reflection, group discussion, or written assignments.
  - **What Should the Nurse Do?** and **Critical Thinking About Case Study Questions** assess students' clinical judgment skills using case-based scenarios. Students review either a single case or an unfolding case that reveals information gradually. In response to their observations of the patient, students must decide how to navigate the Clinical Judgment Measurement Model process. This approach challenges them to apply theoretical knowledge to practical situations, determining the most appropriate interventions based on the patient's specific circumstances.
- **Answers to Questions in the Book:** The assessments are intended for homework assignments or classroom discussion; thus, student-facing answers are not provided in the book. Answers and sample answers are provided in the Instructor Answer Guide for instructors to share with students at their discretion, as is standard for such resources.
- **Chapter Summary:** Chapter summaries assist both students and instructors by outlining the primary subtopics addressed within the chapter.
- **Key Terms:** Key terms are presented in bold text and are followed by an explanation in context. Definitions of key terms are also listed in the end-of-chapter glossary.
- **References:** References are listed at the end of each chapter.

## About the Authors

### Senior Contributing Authors

Senior contributing authors: Christy Bowen (left), Lindsay Draper (middle), and Heather Moore (right)

**Christy Bowen, Chamberlain University.** Dr. Christy Bowen, DNP, RN serves as the Dean of Academic Affairs for Chamberlain University's BSN-Online. Dr. Bowen holds an ASN from Excelsior University, a BSN in Nursing and MSN in Nursing Education with a focus in Curriculum Development and Revision from Western Governor's University, and a Doctor in Nursing Practice in Nursing Leadership and Management from Capella University. Dr. Bowen has been a nurse for more than 20 years and is certified in the specialty of Critical Care nursing, and Wound Care. In her clinical practice she held roles such as Department Chair, Unit Educator, and Lead Nurse. In her Academia role, she has served as Lead Instructor, Curriculum Chair, Program Coordinator, Program Director, and Associate Dean of Faculty. Dr. Bowen has taught courses throughout all levels of nursing education such as associate, bachelor, master, and doctoral level programs. She enjoys teaching both clinical and didactic learning for nursing students. Dr. Bowen served as a key member of the curriculum team to develop a Concept-Based Curricula as part of the Texas Nursing Concept-Based Curriculum (TxNCBC) project; develop a standardized concept-based curriculum for the state of Texas. She has led over 50 Workshops as part of the Implementation and Customization service for schools across the US transitioning to Concept-based Nursing. She developed over 20 Board of Nursing Continuing Education (CE) Certified Workshops and presented as Keynote speaker for all workshops to Universities and Colleges across the US. Throughout Dr Bowen's career she has received many prestigious awards including Nurse of the Year, Clinical Nurse Leader of the Year, Employee of the Year, Top Requested Nursing Education Consultant (NEC), Phi Theta Kapa Faculty Member of the Year, and Presidential Award Outstanding Faculty Service.

**Lindsay L. Draper, University of North Carolina Greensboro.** Dr. Lindsay Draper, DNP, MSN/MBA, CNE, RN-BC, ACUE, is an Associate Professor and the Director of Faculty Credentialing, Compliance, and Special Initiatives at UNC Greensboro's School of Nursing. In this role, Dr. Draper provides leadership and systematic oversight to ensure compliance with regulatory and accrediting standards, oversees faculty onboarding, orientation, and mentoring programs, and spearheads the integration of artificial intelligence and virtual reality into teaching and learning. She holds a Bachelor of Science in Nursing from East Carolina University, a dual Master of Science in Nursing/Master of Business Administration in Health Management from UNC Greensboro, and a Doctor of Nursing Practice in Executive Leadership from UNC Greensboro. Dr. Draper brings over 14 years of nursing experience, with certifications in medical-surgical nursing and nursing education. Her clinical expertise encompasses both medical-surgical and occupational health nursing. Throughout her career, she has held a range of progressive leadership positions, including Assistant Director of Nursing, Associate Department Chair, Director, and Provost Fellow. Dr. Draper has actively contributed to curriculum development and has taught across a range of academic levels, including bachelor's, master's, and doctoral programs. Her work includes securing AI teaching grants and presenting on the utilization of AI in teaching, learning, and workforce development. Dr. Draper's contributions to the field have been recognized through prestigious awards, including the North Carolina Great 100 Nurse, Nursing Excellence awards, North Carolina Nurse Scholar distinction, Nurse of the Month, UNC Greensboro Graduate Leadership Award, and Gamma Zeta's Excellence in Leadership Award. She was selected through a competitive process to participate in the National League for Nurses' LEAD Institute, honored as the inaugural Helen Brooks Faculty Scholar, and had the privilege of serving as the keynote speaker at UNC Greensboro's commencement ceremony.

**Heather Moore, Xavier University.** Dr. Heather Moore, DNP, RN, CNL, serves as an Assistant Professor of Nursing at Xavier University. She holds a Bachelor of Science in Nursing (BSN) degree from Ohio Northern University, a Master of Science in Nursing (MSN) degree with a specialty in Education from Lourdes University, and a Doctor of Nursing

Practice (DNP) degree with a specialty in Healthcare Systems Leadership from Chamberlain University. Dr. Moore is a licensed Clinical Nurse Leader (CNL) and has completed specialized training in Universal Design for Learning (UDL), diversity and inclusion teaching practices, and curriculum design. She began her nursing career by completing a nurse residency program, followed by many years working in the general pediatric unit, pediatric intensive care unit (PICU), and neonatal intensive care unit (NICU). She has held key clinical leadership roles, including unit manager, clinical team leader, and education manager. Dr. Moore has demonstrated scholastic excellence in her faculty roles, mastering clinical and didactic courses through in-person, online, and hybrid formats. She has successfully taught courses in undergraduate, graduate pre-licensure, and graduate post-licensure nursing programs. During her time in academia, Dr. Moore has served on numerous college and university committees, including multiple terms in elected chair and co-chair positions. As an active member of Kappa Gamma Pi and Sigma Theta Tau International Honor Society, she works to improve the nursing profession in both clinical and academic realms. As a subject matter expert in nursing, Dr. Moore has written and reviewed licensing examination questions for the traditional NCLEX, NextGen NCLEX, and Clinical Nurse Leader (CNL) exams. She has published and presented at various national and international conferences over the last decade and has authored textbooks on fundamentals, public health, and nursing skills. Dr. Moore's specialty areas include pediatric and family care nursing, leadership and management, capstone projects, and community health. Her research interests include family-centered care, HCAHPS scores, international collaboration, infection prevention, nursing leadership, and pediatric pain management.

## Additional Resources

### Student and Instructor Resources

We have compiled additional resources for both students and instructors, including Getting Started Guides, an instructor's answer guide, test bank, and image slides. Instructor resources require a verified instructor account, which you can apply for when you log in or create your account on OpenStax.org. Take advantage of these resources to supplement your OpenStax book.

**Instructor's answer guide.** Each component of the instructor's guide is designed to provide maximum guidance for delivering the content in an interesting and dynamic manner.

**Test bank.** With more than 1,100 assessments, instructors can customize tests to support a variety of course objectives. The test bank includes review questions (multiple-choice, identification, fill-in-the-blank, true/false), short answer questions, and long answer questions to assess students on a variety of levels. The test bank is available in Word format.

**PowerPoint lecture slides.** The PowerPoint slides provide learning objectives, images and descriptions, feature focuses, and discussion questions as a starting place for instructors to build their lectures.

### Academic Integrity

Academic integrity builds trust, understanding, equity, and genuine learning. While students may encounter significant challenges in their courses and their lives, doing their own work and maintaining a high degree of authenticity will result in meaningful outcomes that will extend far beyond their college career. Faculty, administrators, resource providers, and students should work together to maintain a fair and positive experience.

We realize that students benefit when academic integrity ground rules are established early in the course. To that end, OpenStax has created an interactive to aid with academic integrity discussions in your course.

Visit our [academic integrity slider \(https://view.genial.ly/61e08a7af6db870d591078c1/interactive-image-defining-academic-integrity-interactive-slider\)](https://view.genial.ly/61e08a7af6db870d591078c1/interactive-image-defining-academic-integrity-interactive-slider). Click and drag icons along the continuum to align these practices with your institution and course policies. You may then

include the graphic on your syllabus, present it in your first course meeting, or create a handout for students. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

At OpenStax we are also developing resources supporting authentic learning experiences and assessment. Please visit this book's page for updates. For an in-depth review of academic integrity strategies, we highly recommend visiting the International Center of Academic Integrity (ICAI) website at <https://academicintegrity.org/> (<https://academicintegrity.org/>).

### Community Hubs

OpenStax partners with the Institute for the Study of Knowledge Management in Education (ISKME) to offer Community Hubs on OER Commons—a platform for instructors to share community-created resources that support OpenStax books, free of charge. Through our Community Hubs, instructors can upload their own materials or download resources to use in their own courses, including additional ancillaries, teaching material, multimedia, and relevant course content. We encourage instructors to join the hubs for the subjects most relevant to your teaching and research as an opportunity both to enrich your courses and to engage with other faculty. To reach the Community Hubs, visit [www.oercommons.org/hubs/openstax](http://www.oercommons.org/hubs/openstax).

### Technology partners

As allies in making high-quality learning materials accessible, our technology partners offer optional low-cost tools that are integrated with OpenStax books. To access the technology options for your text, visit your book page on [OpenStax.org](http://OpenStax.org).

### Special Thanks

The Division of Digital Learning at the Texas Higher Education Coordinating Board (THECB) has a history of dedicated research initiatives, services, and programs that have advanced open education in Texas by providing support, advocacy, and resources to Texas institutions in their OER efforts. The Division maintains a diverse OER portfolio including OERTX, a digital library and community space for open education work. The leadership and collaboration of the Division of Digital Learning staff made the OER Nursing Essentials (ONE) project possible, throughout research, planning, and development phases of the eight-textbook series.

This work was supported in whole or in part by the THECB. The opinions and conclusions expressed in this document are those of the author(s) and do not necessarily represent the opinions or policies of the THECB.

## CHAPTER 1

# Introduction to the Nursing Profession: Evolution, Theories, and Practice

**FIGURE 1.1** From its humble origins, nursing has evolved into a professional practice based on theory, standards of practice, and scope of duties. (credit: (left) "historyofnursing4nutt" by Internet Archive Book Images/Flickr, Public Domain; (middle) "09-8132-99" by Navy Medicine/Flickr, Public Domain; and (right) "071204-F-9930C-165.JPG" by U.S. Air Force photo/Tech. Sgt. D. Clare, Public Domain)

### CHAPTER OUTLINE

- 1.1 Evolution of Nursing and Nursing Practice
- 1.2 Nursing Education Programs
- 1.3 Nursing as a Profession
- 1.4 History and Evolution of Nursing Theories
- 1.5 Selected Nursing Theorist
- 1.6 Application of Theories in Nursing Practice

**INTRODUCTION** The evolution of nursing is a dynamic journey that spans centuries, marked by transformative shifts in practice, education, and the professional identity of nurses. These shifts follow the historical progression of nursing and nursing theories, revealing the foundations that have shaped the field. Nursing education programs have likewise undergone significant development, adapting to the evolving healthcare landscape to equip nurses with the knowledge and skills necessary for contemporary practice.

As nursing emerged as a distinct profession, it became characterized by a commitment to compassionate care and a dedication to advancing the health and well-being of individuals and communities. Delving into the history and evolution of nursing theories introduces us to the visionary minds that have contributed to the theoretical frameworks supporting these core commitments. This journey includes an exploration of selected nursing theorists and the application of their theories in the dynamic and multifaceted realm of **nursing practice**, the application of nursing knowledge, skills, and principles. Together, these elements form a comprehensive picture that illustrates the rich and ever-evolving nature of nursing as a profession.

## 1.1 Evolution of Nursing and Nursing Practice

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize the history of nursing and nursing practice
- Identify current trends in nursing
- Provide examples of the art and science of nursing practice

The profession of **nursing** encompasses the art and science of providing comprehensive care to promote and maintain health, prevent illness, and alleviate suffering for individuals, families, and communities. Nurses provide

holistic care: for each patient, they consider the whole entity rather than focusing solely on individual parts.

In **nursing practice**, nursing knowledge, skills, and principles are applied in the delivery of health care to individuals, families, and communities. Nursing practice is rooted in a foundation of knowledge, clinical skills, and ethical principles, and it involves assessing health needs, developing care plans, administering treatments, and advocating for patients within the healthcare system. It extends across various settings, such as hospitals, clinics, homes, schools, and community environments, and involves collaboration with other healthcare professionals to ensure optimal outcomes for all receiving care. Central to the profession is a commitment to the well-being of individuals and communities, fostering a compassionate and person-centered approach to health care.

## History of Nursing and Nursing Practice

The history of nursing and nursing practice is a rich tapestry that countless practitioners and theorists have transformed over centuries. From informal caregiving in ancient civilizations to the highly skilled and respected profession it is today, nursing is marked by profound shifts in approach (D'Antonio et al., 2010). These historical perspectives serve as a testament to the resilience and adaptability of nurses in every setting and to their unwavering commitment to the well-being of individuals and communities worldwide.

### Early Beginnings

The early beginnings of nursing can be traced back to ancient civilizations, where the care of the sick and injured was often a communal and familial responsibility. In these early societies, the role of a nurse was often fulfilled by family members, mainly women, who provided care within the home. Certain ancient cultures, such as Chinese and various American Indian, particularly valued individuals with specific knowledge of herbal remedies and healing practices. These individuals, often referred to as **herbalists**, played a role akin to what we now associate with nursing (Figure 1.2). Their knowledge of medicinal plants and holistic healing methods contributed to the well-being of their communities (D'Antonio et al., 2010).

**FIGURE 1.2** Medicine women have been central figures in many cultures, including (a) indigenous women in Chile, (b) a Zulu shaman in Basutoland, and (c) the proprietor of a traditional Chinese medicine shop in Malaysia. (credit: (a) “Mapuche medicine woman treating a patient, South Chile” by Wellcome Images/Wikimedia Commons, CC BY 4.0; (b) “A Zulu medicine woman or shaman practicing in Basutoland, So” by Wellcome Images/Wikimedia Commons, CC BY 4.0; (c) “Medical Hall” by Oxlaxey.com/Flickr, CC BY 2.0)

Throughout history, religious institutions have also played a significant role in caring for the sick. During the Middle Ages, when plagues and other illnesses were widespread, nursing duties in Western societies fell largely to religious orders. Monks and nuns provided care in monasteries and convents, demonstrating a commitment to service and compassion for the sick. The care provided during this period, however, was not formalized or regulated, and its quality varied widely (D’Antonio et al., 2010; Smith, 2023).

During the Renaissance period that began in Europe in the fourteenth century, a shift occurred in the perception of health care. The emergence of the scientific method and a greater understanding of anatomy and physiology began to influence medical practices. Despite these advancements, nursing remained an informal and often undervalued occupation for centuries. Yet these early beginnings of nursing, rooted in familial care and influenced by religious practices, set the stage for the professionalization and transformation of nursing into the vital and respected discipline it is today (D’Antonio et al., 2010).

### Birth of Modern Nursing

The birth of modern nursing is credited to Florence Nightingale, a British nurse who played a transformative role in shaping the profession during the nineteenth century. Nightingale’s impact was particularly significant during the Crimean War (1853–1856), as she led a team of nurses to address the deplorable conditions in military hospitals. Nightingale’s emphasis on sanitation, hygiene, and compassionate care revolutionized hospital practices,

fundamentally altering the landscape of health care and nursing. By implementing rigorous cleanliness measures, ensuring proper ventilation, and conducting statistical analysis of patient outcomes, she significantly reduced the spread of infectious diseases (Karimi & Masoudi Alavi, 2015; Smith, 2023).

The world's first nursing school at St. Thomas' Hospital was established in 1860 (Figure 1.3) which marked the formalization and professionalization of nursing education. The formal education of nurses, along with the establishment of professional standards and ethics, marked the transition from the informal caregiving of earlier centuries to the emergence of a dedicated and skilled nursing profession (D'Antonio et al., 2010).

**FIGURE 1.3** This statue, outside St. Thomas' Hospital, honors Mary Seacole, a Jamaican-born nurse who helped care for British soldiers during the Crimean War. (credit: "Mary Seacole statue, St. Thomas' Hospital, front view," by OwenBlacker/Wikimedia Commons, Public Domain)

### Development of Nursing in the Nineteenth to Twenty-First Centuries

The development of nursing over the past 200 years represents a dynamic evolution marked by significant milestones, professionalization, and adaptation to the changing landscapes of health care. In the early twentieth century, an expansion of nursing practice took place, with nurses playing crucial roles in World Wars I and II and contributing to the establishment of nursing organizations like the American Nurses Association (ANA) in 1911 (D'Antonio et al., 2010).

In the mid-twentieth century, there were further advancements, including the development of specialized nursing fields and the creation of advanced practice roles. Witnessed in the latter part of the twentieth century were increasing diversity in the nursing workforce and a growing emphasis on evidence-based practice—trends that have continued through today. The profession has also adapted to technological innovations, such as electronic health record (EHR)s and telehealth, and embraced interdisciplinary collaboration (D'Antonio et al., 2010).

Throughout these centuries, nurses have faced challenges such as workforce shortages and increased demands on healthcare systems, leading to ongoing efforts to address these issues. The nursing profession has also experienced a shift toward greater autonomy and leadership roles for nurses, including the recognition of nurse practitioners as primary care providers (D'Antonio et al., 2010).

In recent decades, there has been a renewed focus on nursing education, research, and the global impact of nursing practice. Nurses have played pivotal roles in responding to public health crises, including the HIV epidemic, Ebola outbreaks, and the ongoing challenges posed by infectious diseases. In the twenty-first century, there is increased

recognition of the importance of nursing in healthcare delivery (D'Antonio et al., 2010; Wakefield et al., 2021). Nurses contribute not only to direct patient care but also to health policy, research, and the development of innovative healthcare solutions. The COVID-19 pandemic further highlighted the indispensable role of nurses in providing frontline care and adapting to rapidly changing healthcare needs (Figure 1.4). Today's nurses continue to be at the forefront of health care, contributing to improved patient outcomes and shaping the future of the profession.

**FIGURE 1.4** Nurses, like these providers in a California hospital, helped lead the response to the COVID-19 pandemic in the United States. (credit: "USNS Mercy Medical Support at Skilled Nursing Facility Orange County," by Navy Medicine/Flickr, Public Domain)

## REAL RN STORIES

### Navigating Cultural Sensitivity in the COVID-19 Pandemic

**Nurse:** Maria, BSN

**Clinical setting:** Pulmonary intensive care unit

**Years in practice:** 15

**Facility location:** Urban town in New Mexico

In the heart of the COVID-19 pandemic, I found myself at the frontline of a bustling urban hospital, facing the challenges of caring for patients from diverse cultural backgrounds. Our unit had transformed into a dedicated COVID-19 unit, and every day brought new hurdles, both physically and emotionally demanding. One particular day stands out, emphasizing the critical role of cultural competence in providing effective care. A patient from a close-knit immigrant community was admitted with severe COVID-19 symptoms. However, the family hesitated to follow some of the recommended treatments due to cultural beliefs and language barriers. Recognizing the need for cultural sensitivity, I took the initiative to connect with the patient's family. With the assistance of a hospital interpreter fluent in their native language, we engaged in thoughtful conversations to understand their concerns and fears.

This challenging situation prompted collaboration with the hospital's cultural competence team. Together, we developed a personalized care plan that respected the family's cultural background, making adjustments to certain aspects of the treatment while ensuring essential medical interventions. Educational materials were provided in their native language to facilitate clear communication about the patient's condition and the tailored care plan. Building trust with the patient's family took time, but as we worked together, they began to see us as partners in their loved one's care. The patient showed signs of improvement, and I continued to provide support, addressing their emotional needs during this challenging time.

This experience reinforced the significance of cultural competence in health care. It taught me and my colleagues the importance of understanding and respecting diverse perspectives, traditions, and beliefs. Embracing cultural competence enabled us to provide more effective and compassionate care, fostering trust and collaboration within the community we served. In reflecting on my experiences caring for COVID-19 patients and navigating cultural sensitivity, I couldn't help but draw parallels to the timeless legacy of nursing pioneers like Florence Nightingale. Much like Nightingale, who revolutionized nursing during the Crimean War, the challenges posed by the pandemic prompted a transformation in our approach to patient care.

Nightingale emphasized the significance of holistic care, recognizing that it goes beyond merely treating the physical symptoms of an illness. As I encountered diverse patients from various cultural backgrounds, I realized that embracing cultural competence aligned with Nightingale's principles of compassionate and patient-centered care. The tailored care plan we developed for the patient from the immigrant community reflected the ongoing evolution of nursing practices. Just as nursing pioneers adapted to the changing landscape of health care in their time, we, too, had to adapt and integrate cultural competence into our care strategies to meet the unique needs of our patients.

---

## Current Trends in Nursing

Current trends in nursing reflect a dynamic landscape shaped by technological advancements, evolving healthcare needs, and recognition of the crucial role nurses play in patient care. Notable current trends in nursing include an ongoing nursing shortage, emphasis on higher education requirements, increase in online nursing education programs, expanded integration of telehealth and technology, and heightened focus on self-care for nurses (Wakefield et al., 2021). These trends collectively highlight the adaptability of nursing in response to contemporary challenges, positioning the profession to meet the diverse and evolving healthcare needs of society.

### Continued Nursing Shortage

One prevailing trend in contemporary nursing is the continued shortage of nurses, a challenge that has persisted for several years, impacting the ability of healthcare systems to meet the growing demand for patient care. Several factors contribute to this shortage, including the expanding scope of healthcare services, an aging population with increased healthcare needs, and a similarly aging workforce that has seen many veteran nurses choosing to retire. Additionally, the limited number of qualified nursing instructors and available clinical sites impedes the possible growth of new nurses. The shortage is further exacerbated by factors such as inadequate nurse staffing ratios, high levels of burnout, and the demanding nature of the profession (Morris, 2023).

Efforts to address the nursing shortage include initiatives to attract individuals to the nursing profession, enhance educational opportunities, and create supportive work environments to retain experienced nurses. The ongoing shortage underscores the importance of strategic planning and collaborative efforts across healthcare stakeholders to ensure the sustainability and resilience of the nursing workforce in meeting the evolving healthcare needs of society.

## LINK TO LEARNING

This PBS video discusses the [effects of burnout from the COVID-19 pandemic on the ongoing nursing shortage](https://openstax.org/r/77COVIDPan) (<https://openstax.org/r/77COVIDPan>) in the United States.

### Higher Education Requirements

A notable trend in contemporary nursing is the increasing emphasis on higher education requirements for entry into

the profession. While the traditional path of obtaining an associate degree in nursing (ADN) or a diploma in nursing remains common, there is a growing recognition of the benefits associated with a bachelor of science in nursing (BSN) as the minimum educational standard (Wakefield et al., 2021). This trend is influenced by a desire to elevate the overall quality of patient care, align nursing education with the complexities of modern health care, and enhance critical-thinking and leadership skills among nursing professionals. Many healthcare institutions and employers are now encouraging or requiring nurses to pursue BSN degrees, and some are advocating for a future in which the BSN becomes the standard entry-level qualification. This shift reflects a broader movement in health care toward fostering a highly educated and skilled nursing workforce capable of meeting the diverse and evolving needs of patients and the healthcare system.

### Increase in Online Nursing Programs

Another notable trend in contemporary nursing education is the substantial increase in online nursing programs, reflecting the broader shift toward digital learning platforms. This trend has been accelerated by advancements in technology, the recognition of the need for flexible education options, and the impact of the COVID-19 pandemic. Online nursing programs offer accessibility and convenience, allowing aspiring nurses and working professionals to pursue their education without geographical constraints. These programs often integrate virtual simulations, interactive modules, and remote clinical experiences to provide a comprehensive and engaging learning experience. The surge in online nursing education is reshaping the traditional landscape of nursing programs, making education more accessible to a diverse student body and contributing to the ongoing evolution of nursing as a dynamic and technologically advanced profession.

### Rise of Technology in Health Care

A significant contemporary trend in nursing is the accelerated adoption of telehealth, the use of digital communication technologies to deliver healthcare services and information remotely. The COVID-19 pandemic has expedited the integration of telehealth platforms, allowing nurses to provide patient care remotely through virtual consultations. This shift not only ensures continuity of care during unprecedented times but also aligns with the broader trend of incorporating technology into various aspects of health care.

## PATIENT CONVERSATIONS

---

### Preparing a Patient for a Telehealth Visit

**Nurse:** Good morning. This is Nurse Sarai calling from Dr. Johnson's office. Am I speaking with Mrs. Singh?

**Patient:** Yes, this is she. How can I help you?

**Nurse:** Hello, Mrs. Singh. Dr. Johnson has scheduled a telehealth visit with you today. Have you ever had a telehealth visit before?

**Patient:** No, it's my first time. How does it work?

**Nurse:** You will be meeting with Dr. Johnson over a video call. It helps if you're in a quiet room with good lighting. Do you have a smartphone, tablet, or computer with a camera?

**Patient:** Yes, I have a laptop.

**Nurse:** Perfect! Before the visit, make sure your laptop is charged and you have a stable internet connection. Also, test your camera and microphone to ensure they are working. Dr. Johnson will discuss your health, medications, and any concerns you might have, just like in a regular appointment.

**Patient:** Okay, that sounds pretty straightforward. Do I need to download any special software?

**Nurse:** No software is needed. We will send you a secure link via email and text just before the appointment time. All you have to do is click on the link, and it will take you to the virtual waiting room.

**Patient:** Okay, I will be looking for the link. Is there anything else I should be aware of?

**Nurse:** If you have a list of your current medications or any specific health concerns, it would be helpful to have that on hand.

**Patient:** Thank you for walking me through it, Nurse Sarai.

**Nurse:** You're welcome, Mrs. Singh. If you have any questions or need assistance before or during the call, feel free to reach out. Dr. Johnson is looking forward to seeing you virtually today.

**Patient:** Thank you, Nurse Sarai. I appreciate your help.

**Nurse:** My pleasure! Take care, and we'll talk to you soon.

---

Nurses are increasingly utilizing electronic health and medical records to streamline documentation, enhance communication among healthcare providers, and facilitate data-driven decision-making. An **electronic health record (EHR)** is a digital version of a patient's medical history, maintained and shared by multiple providers. In contrast, only a single provider maintains and uses an **electronic medical record (EMR)**. While both EHRs and EMRs serve as digital repositories for a patient's medical information, they differ in terms of scope, accessibility, and functionality. The intent is for EMRs to feed into the EHR, providing a holistic approach to healthcare data, fostering coordination and collaboration among multiple entities involved in a patient's care. The rise of wearable health technology and mobile health applications further empowers individuals to actively engage in their care, while nurses leverage these tools to monitor health metrics remotely.

### LINK TO LEARNING

The video [“I Am a Telehealth Nurse”](https://openstax.org/r/77telenurse) (<https://openstax.org/r/77telenurse>) features a pediatric nurse at Cincinnati Children's Hospital who primarily uses digital tools to provide care.

---

The integration of telehealth and other forms of technology not only enhances healthcare accessibility but also transforms nursing practice, requiring nurses to adapt to evolving modes of patient interaction and data management. As technology continues to advance, nurses are at the forefront of harnessing its potential to optimize patient outcomes, promote preventive care, and contribute to the ongoing transformation of the healthcare landscape.

#### Essential Need for Nurses' Self-Care

Another essential trend in contemporary nursing is the increasing recognition of the critical need for nurses' **self-care**, intentional actions and practices that individuals engage in to promote their physical, mental, and emotional well-being. The demanding and often emotionally taxing nature of nursing, particularly exacerbated by the challenges posed by the COVID-19 pandemic, has underscored the importance of prioritizing nurses' well-being. Healthcare institutions are placing a greater emphasis on creating supportive work environments, offering resources for mental health and resilience training, and implementing initiatives that address burnout. Nurses are encouraged to engage in self-care practices to mitigate stress, promote mental and physical health, and sustain their overall well-being. Acknowledging the essential role of nurses in the healthcare system, this trend reflects a broader understanding that fostering a culture of self-care is not only beneficial for individual nurses but is integral to sustaining a resilient and effective nursing workforce capable of delivering high-quality patient care (Morris, 2023).

#### Art and Science of Nursing

The art and science of nursing represent the dual nature of the nursing profession, encompassing both the humanistic and technical aspects of health care. The art of nursing emphasizes the interpersonal and compassionate dimensions of care. It involves the ability to connect with patients on a personal level, provide emotional support, and understand the unique needs and experiences of individuals under care. This aspect of nursing involves effective communication, empathy, and the cultivation of a therapeutic relationship between the nurse and the patient.

On the other hand, the science of nursing centers on the application of evidence-based knowledge, clinical skills, and technical expertise to deliver safe and effective patient care. It involves a thorough understanding of anatomy, physiology, pharmacology, and other scientific principles. Nurses use this scientific knowledge to assess, diagnose, plan, implement, and evaluate patient care, applying a systematic and analytical approach to clinical decision-making.

The integration of art and science is essential for holistic patient care. While the art of nursing ensures a human-centered and compassionate approach, the science of nursing provides the foundation for delivering evidence-based, quality health care. The synergy of these elements allows nurses to address the physical, emotional, and social dimensions of health, fostering a comprehensive and person-centered approach to nursing practice.

### Soft Skills of Nursing

The **soft skills** in nursing are the interpersonal abilities and personal attributes that enhance a nurse's ability to interact effectively with patients, families, and colleagues. Communication, empathy, cultural competence, collaboration and teamwork, adaptability, resilience, and problem-solving are examples of fundamental soft skills (Deering & Bal, 2023).

- Communication skills are paramount, encompassing the ability to listen attentively, convey information clearly, and show empathy.
- Empathy enables nurses to connect with patients on an emotional level, fostering trust and understanding.
- Cultural competence allows nurses to respect and navigate diverse backgrounds and beliefs, ensuring culturally sensitive care.
- Collaboration and teamwork are vital, as nurses often work within interdisciplinary teams, requiring effective communication and cooperation.
- Adaptability, resilience, and problem-solving skills are essential in the ever-evolving healthcare environment, enabling nurses to navigate challenges and overcome obstacles to providing person-centered care.

Ultimately, the cultivation of these soft skills enhances the holistic and compassionate nature of nursing practice, contributing to positive patient outcomes and a supportive healthcare environment.

## REAL RN STORIES

---

### Utilizing Soft Skills of Nursing

**Nurse:** Emily, BSN

**Clinical setting:** Emergency department

**Years in practice:** 8

**Facility location:** Rural town in North Dakota

One day, a distressed family arrived at the emergency department seeking updates about their older mother, who was admitted after a sudden cardiac event. The family was anxious, emotional, and struggling to comprehend the medical information. Recognizing the importance of effective communication and empathy, I took the time to sit down with the family in a private room. I actively listened to the family, allowing them to express their concerns and fears. I provided clear and compassionate explanations about the patient's condition, the ongoing treatment plan, and what to expect in the coming days.

Understanding the family's emotional state, I also offered comfort and reassurance, demonstrating empathy. I wanted to ensure the family felt heard and understood, addressing not only the medical aspects but also the emotional and psychological needs of the family. I felt like engaging in open and honest communication helped me to build trust with the family and foster a collaborative approach to care.

Throughout the patient's stay, I continued to check in with the family, providing updates and maintaining a supportive presence. My ability to navigate these sensitive conversations, show empathy, and communicate effectively played a crucial role in easing the family's anxiety and enhancing their overall experience during a challenging time. The family expressed gratitude for the personalized care and the sense of connection they felt and even gave me a hug before they were discharged home. This is just an example of how important it is for us nurses to be skilled in effectively using soft skills to provide holistic and person-centered care.

---

### Hard Skills of Nursing

The **hard skills** in nursing encompass the technical and clinical competencies that are crucial for providing safe and effective patient care. These skills are typically acquired through formal education, training, and hands-on clinical experience. Clinical assessment and critical thinking are foundational hard skills, allowing nurses to analyze patient

data, make accurate diagnoses, and develop appropriate care plans. Proficiency in administering medications, performing various medical procedures, and utilizing medical equipment are essential hard skills that ensure the delivery of precise and evidence-based care. Technical skills related to charting and documentation are crucial for maintaining accurate and comprehensive patient records. Advanced life support and emergency response skills are imperative for handling critical situations.

Throughout their career, nurses are expected to continuously update their hard skills to align with advancements in medical technology and evidence-based practices, ensuring they remain competent and capable in their clinical roles. In combination with soft skills, hard skills form a comprehensive skill set that equips nurses to deliver high-quality and proficient care across diverse healthcare settings.

## **CLINICAL SAFETY AND PROCEDURES (QSEN)**

---

### Mastery of Hard Skills in Nursing

The Quality and Safety Education for Nurses (QSEN) project stands as a cornerstone for the development and enhancement of hard nursing skills. The QSEN provides a structured framework for nurses to master essential competencies by focusing on the cultivation and application of evidence-based practice, technical proficiency, and rigorous clinical judgment.

The six core competencies within the QSEN framework highlight the importance of hard nursing skills. These competencies include patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics, all of which demand a solid foundation in hard skills for their effective implementation.

- **Patient-centered care:** The QSEN emphasizes the critical role of hard nursing skills in patient-centered care, urging nurses to master competencies such as effective health assessments, patient education techniques, and advocacy for patients' rights and preferences. This core competency relies on a solid foundation of hard skills to ensure comprehensive and personalized patient care.
- **Teamwork and collaboration:** Within the QSEN framework, teamwork and collaboration necessitate hard nursing skills such as interprofessional communication, collaborative care planning, effective delegation, conflict resolution, and shared decision-making. Nurses are encouraged to cultivate these technical abilities to foster cohesive teamwork and enhance the overall quality of patient care.
- **Clinical excellence:** The QSEN underscores the significance of hard skills in achieving clinical excellence. Proficiency in medical procedures, accurate clinical judgment, and adherence to evidence-based practices are central components. The initiative serves as a guide for nurses to sharpen their technical skills and ensure a high standard of care.
- **Evidence-based practice:** As an advocate for evidence-based practice, QSEN places a premium on the integration of the latest research and clinical evidence into nursing care. This emphasis reinforces the importance of hard skills in critically assessing and applying scientific knowledge to inform decision-making.
- **Continuous quality improvement:** The QSEN encourages a commitment to continuous quality improvement, aligning closely with the development of hard nursing skills. Nurses are prompted to refine their technical abilities, embrace innovations in health care, and actively contribute to elevating the overall quality of patient care.
- **Patient safety:** Focused on patient safety, QSEN highlights hard skills as the foundation for creating a secure healthcare environment. Proficiency in medical procedures, precise clinical assessments, and a vigilant approach to safety protocols are vital components in ensuring patient well-being.

---

## 1.2 Nursing Education Programs

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Compare and contrast levels of nursing education
- Describe the licensure process for nursing practice

Navigating the landscape of nursing education involves exploring the available levels of education, each of which

contributes uniquely to the development of nursing professionals. Aspiring nurses encounter distinct educational pathways, ranging from practical and vocational nursing programs to more advanced degrees like associate, bachelor, and graduate levels. Each tier not only shapes the depth of clinical knowledge but also influences critical-thinking skills and leadership capabilities. Alongside the diverse educational avenues, the licensure process stands as a pivotal gateway for nursing practice. This process, governed by regulatory bodies, establishes a standardized framework to ensure that nurses meet essential qualifications and competencies. Understanding the licensure journey is crucial for aspiring nurses, as it encompasses examinations, practical assessments, and adherence to ethical standards that are prerequisites to a rewarding and impactful career in health care.

## Nursing Education

Nursing education encompasses a range of programs designed to prepare individuals for diverse roles within the healthcare profession. Entry-level pathways into the nursing profession include licensed practical nurse (LPN)/licensed vocational nurse (LVN), ADN, and BSN programs, each offering a tiered progression of education and skills development for individuals aspiring to become nurses. Graduate-level nursing programs—such as Master of Science in Nursing (MSN), doctor of nursing practice (DNP), and Doctor of Philosophy (PhD) in Nursing—are designed to provide advanced education and specialized training for registered nurses seeking to enhance their clinical expertise and leadership skills and engage in research to contribute to the advancement of nursing practice and knowledge. These diverse educational pathways cater to individuals with varying career aspirations, contributing to a well-rounded and skilled nursing workforce capable of meeting the evolving demands of the healthcare landscape.

### Licensed Practical Nurse/Licensed Vocational Nurse

The positions of **licensed practical nurse (LPN)** and **licensed vocational nurse (LVN)** are fundamentally equivalent; the particular term depends on the state in which the nurse is licensed, but all LPNs and LVNs have completed a specialized nursing education program that equips them with the skills and knowledge required for entry-level positions in health care. Typically offered by vocational schools, community colleges, or technical institutes, these programs span 12 to 18 months, with a curriculum focused on practical nursing skills and basic nursing education (*A guide to the different types of nursing degrees*, n.d., Ko, 2023; Mills, 2023; *Types of nursing degrees and levels*, 2023).

Following program completion, graduates must pass the National Council Licensure Examination for Practical Nurses (NCLEX-PN) to obtain licensure. The LPNs/LVNs work under the supervision of registered nurses or providers, providing basic nursing care such as administering medication, treating wounds, monitoring vital signs, and assisting with activities of daily living. The LPNs/LVNs contribute to overall patient care but may have limited involvement in complex decision-making or creation of the patient care plan (*A guide to the different types of nursing degrees*, n.d.; Ko, 2023; Mills, 2023; *Types of nursing degrees and levels*, 2023). Their scope of practice varies by state and includes roles in hospitals, long-term care facilities, physician's offices, and community clinics. The LPNs/LVNs may choose to advance their career by pursuing further education, such as becoming a registered nurse (RN) through an LPN-to-RN bridge program.

### Associate Degree in Nursing

The **associate degree in nursing (ADN)** is a two-year program offered by various educational institutions, including community colleges and technical schools, designed to prepare individuals for a career as a **registered nurse (RN)**. The ADN curriculum encompasses a blend of general education courses and nursing-specific content, providing a broader and more comprehensive foundation than does the LPN/LVN curriculum (*A guide to the different types of nursing degrees*, n.d.; Ko, 2023; Mills, 2023; *Types of nursing degrees and levels*, 2023).

Upon program completion, graduates are eligible to take the National Council Licensure Examination for Registered Nurses (NCLEX-RN), a prerequisite for obtaining licensure as a registered nurse. The RNs have a broader scope of practice than LPNs/LVNs. In addition to assessing patients and administering medication, they are involved in planning care. The ADN-prepared nurses are trained to make independent clinical decisions and collaborate with other healthcare professionals in complex patient situations (*A guide to the different types of nursing degrees*, n.d.; Ko, 2023; Mills, 2023; *Types of nursing degrees and levels*, 2023). Consequently, they often have more immediate opportunities for career advancement, and they can pursue additional education, such as a BSN degree, to open up further career prospects.

### Bachelor of Science in Nursing

A **bachelor of science in nursing (BSN)** is a comprehensive degree program designed to prepare an individual for a career as an RN; the robust educational requirements typically take four years to complete, though some accelerated programs can be completed in a shorter time frame. Compared to the ADN program, the BSN program offers a broader education, including a more extensive range of general education courses. It covers not only clinical skills but also theory, research, leadership, and public health. Emphasizing critical thinking and evidence-based practice, BSN programs equip nurses with a holistic understanding of health care. The BSN-prepared nurses have an expanded scope of practice, engaging in more complex patient care, decision-making, and coordination of care. The BSN curriculum also includes components on leadership and management, preparing nurses for supervisory roles and leadership within healthcare teams (*A guide to the different types of nursing degrees*, n.d.; Mills, 2023; *Types of nursing degrees and levels*, 2023).

Graduates of BSN programs are eligible to take the NCLEX-RN, which is a prerequisite for obtaining licensure as an RN. The BSN-prepared nurses are positioned for career advancement, with increased opportunities in management, education, research, and specialized nursing roles. The emphasis on professional development encourages ongoing education, certifications, and advanced degrees, reflecting the evolving standards in the nursing profession.

### Master's Degree in Nursing

A **Master of Science in Nursing (MSN)** is an advanced graduate degree that provides nurses with a higher level of education and specialization in various areas of nursing practice. Typically pursued after obtaining a BSN degree, an MSN degree is designed to equip nurses with advanced knowledge, skills, leadership, and critical-thinking abilities. The curriculum of an MSN program varies based on the chosen specialty track, which may include options such as nurse practitioner, nurse educator, nurse administrator, or clinical nurse specialist. The program often integrates advanced coursework in areas such as nursing theory, research methods, health policy, and leadership. Clinical experiences and practicums are common components, allowing students to apply advanced theoretical concepts in real-world healthcare settings (*A guide to the different types of nursing degrees*, n.d.; *Types of nursing degrees and levels*, 2023).

Graduates of MSN programs are prepared for advanced practice roles, leadership positions, and specialized nursing functions. The MSN degree serves as a pathway for nurses seeking career advancement, increased autonomy, and the ability to contribute to shaping healthcare policies and practices. Additionally, the MSN is often a prerequisite for pursuing doctoral-level education in nursing, such as a DNP or a PhD in nursing. The pursuit of an MSN reflects a commitment to ongoing professional development and a desire to play a pivotal role in addressing the evolving challenges and complexities within the healthcare system (*A guide to the different types of nursing degrees*, n.d.; *Types of nursing degrees and levels*, 2023).

### Doctoral Degrees in Nursing

Doctoral degrees in nursing education are terminal degrees, representing the highest level of academic achievement in the nursing profession. Doctoral degrees provide nurses with advanced knowledge, leadership skills, and expertise in specialized areas. Two primary doctoral degrees in nursing education are the **Doctor of Nursing Practice (DNP)** and the **Doctor of Philosophy (PhD) in Nursing** degrees. The DNP is a practice-focused doctoral degree that emphasizes advanced clinical practice, leadership in healthcare systems, and evidence-based decision-making. The DNP-prepared nurses are equipped to lead and innovate in clinical settings, shaping healthcare policy and practice. The PhD in nursing is a research-focused doctoral degree that emphasizes the generation of new knowledge through rigorous scientific inquiry (Bal, 2023; *Types of nursing degrees and levels*, 2023). The PhD-prepared nurses contribute to the development of nursing science through research, scholarly publications, and academic teaching. Pursuing a doctoral degree in nursing education reflects a commitment to advancing the nursing profession, contributing to evidence-based practice, and shaping the future of health care through leadership, research, and education.

### American Association of Colleges of Nursing Essentials of Associate Education for Professional Nursing Practice

The American Association of Colleges of Nursing (AACN) is a professional organization that represents schools of nursing in the United States. Founded in 1969, the AACN is dedicated to advancing nursing education, research, and practice. It serves as a national voice for nursing education, influencing policy, promoting quality standards in

nursing education, and advocating for the nursing profession (AACN, 2021).

The **AACN Essentials of nursing education** delineate the core principles and competencies for various levels of nursing education. Each set of AACN *Essentials*, whether for associate, baccalaureate, master, or doctoral education, serves as a framework to guide the development of nursing programs and ensure the preparation of competent and professional nurses. Collectively, they define the standards and expectations for nursing education in the United States, ensuring a continuum of excellence in nursing practice across various roles and responsibilities (AACN, 2021).

The current AACN *Essentials*, introduced in April 2021, are structured around ten domains (AACN, 2021):

1. Knowledge for Nursing Practice
2. Person-Centered Care
3. Population Health
4. Scholarship for Nursing Practice
5. Quality and Safety
6. Interprofessional Partnerships
7. Systems-Based Practice
8. Informatics and Healthcare Technologies
9. Professionalism
10. Personal, Professional, and Leadership Development

Each domain includes level 1 and level 2 subcompetencies, tailored to differentiate between entry-level and advanced-level nursing education. Eight professional nursing practice concepts, such as clinical judgment, communication, compassionate care, social determinant of health, and ethics, are emphasized. *The Essentials* are intentionally designed using a competency-based education model to bridge the gap between education and practice; they are intended to be applicable across different educational stages and adaptable to various curricular models. The ultimate goal is to ensure graduates of nursing programs demonstrate competency in relevant areas, aligning with the evolving needs of health care and improving overall learning outcomes (AACN, 2021).

## LINK TO LEARNING

The AACN's *The Essentials 2021* (<https://openstax.org/r/77essent21>) outlines curriculum requirements and expected competencies for each level of nursing education.

## Licensure

Nursing licensure is a critical regulatory process that ensures individuals practicing nursing meet established standards of competency and adhere to ethical and legal guidelines. Licensure is typically granted by the state's nursing regulatory board, or a similar governing body, and signifies that an individual has successfully completed the required education and training to practice as a nurse. The process involves passing a standardized examination, most commonly the NCLEX-RN for RNs or the NCLEX-PN for LPNs/LVNs (National Council of State Boards of Nursing, 2023).

Licensure for advanced practice registered nurse (RN), such as nurse practitioners, nurse anesthetists, nurse-midwives, and clinical nurse specialists, is a specialized regulatory process that acknowledges the advanced education, training, and clinical expertise of these professionals. The licensure process for APRNs typically involves obtaining an advanced practice nursing license in addition to, or as part of, the RN license. Key components of advanced practice licensure often include completing a master's or doctoral degree in nursing, obtaining national certification in the respective advanced practice specialty, and fulfilling clinical practice hours. National certification is usually granted by specialty nursing organizations or certification boards and is often a prerequisite for state-level advanced practice licensure (National Council of State Boards of Nursing, 2023).

In addition to examination requirements, licensure for RNs and APRNs may involve meeting specific educational criteria, accruing clinical experience hours, and adhering to professional and ethical standards. Nursing licensure not only validates a nurse's competence but also provides a legal framework for accountability and protection of the

public. Licensure requirements vary by jurisdiction, and maintaining an active license often requires ongoing professional development through continuing education (CE) to ensure nurses stay current with advancements in healthcare practices and technologies (National Council of State Boards of Nursing, 2023). The licensure process plays a crucial role in upholding the quality and safety of patient care while regulating the nursing profession to meet the evolving needs of healthcare delivery.

### Continuing Education

Ongoing educational activities known as **continuing education (CE)** are a vital component of nursing practice. The CE activities include workshops, seminars, conferences, online courses, and formal academic programs on a broad spectrum of topics, such as new treatment modalities, advances in technology, changes in healthcare laws and regulations, cultural competency, and patient safety measures. The purpose of CE is multifaceted. It ensures nurses remain competent and knowledgeable in their practice and stay current with evolving medical knowledge, technological advancements, and best practices in patient care. Additionally, CE fosters professional growth and development and helps nurses adapt to the dynamic landscape of health care, integrating evidence-based practices into their clinical care.

Compliance with CE requirements is often a condition for license renewal. The specific requirements vary by jurisdiction, and each state's nursing board establishes guidelines for CE that nurses must follow. This commitment to lifelong learning not only benefits individual practitioners, it also maintains high standards of patient care and safety throughout healthcare systems, enhancing their overall quality.

### Career Development and Specialty Certification

Career development and specialty certification play crucial roles in advancing nursing practice, providing opportunities for professional growth and enhancing the quality of patient care. In nursing, **career development** encompasses a broad spectrum of activities aimed at advancing a nurse's professional trajectory. This may include pursuing advanced degrees (such as a master's or doctoral degree), assuming leadership roles, engaging in research, or transitioning into educational roles. Career development activities are often driven by a nurse's individual goals, interests, and aspirations for their professional journey.

As nurses progress in their careers, pursuing a **specialty certification** becomes a valuable means of demonstrating expertise and dedication to a particular area of nursing. While licensure grants the legal authority to practice as a nurse, specialty certifications offer a way for nurses to showcase advanced knowledge and skills within a specific niche. Specialty certification involves meeting established criteria: often a combination of education, clinical experience, and successful completion of a certification exam. Certifications are available in various specialties, such as critical care, pediatric nursing, oncology, and nurse anesthesia, among others. These certifications not only validate a nurse's proficiency in a specialized area but also contribute to their overall career development.

Both career development and specialty certification contribute to the continuous improvement of patient care. Nurses who actively engage in career development contribute to the overall advancement of the nursing profession, taking on leadership positions, participating in research initiatives, and shaping healthcare policies. Nurses with specialized certifications bring enhanced knowledge and skills to their roles, resulting in improved patient outcomes. While licensure provides the foundation for nursing practice, career development and specialty certification serve as dynamic elements that empower nurses to excel in their chosen areas, contribute to the advancement of health care, and shape the future of nursing.

## REAL RN STORIES

---

### Career Development through National Certification

**Nurse:** Lindsay, BSN

**Clinical setting:** Medical-surgical department

**Years in practice:** 13

**Facility location:** Suburban area in North Carolina

Early in my nursing career, I knew that I wanted to obtain a national certification in my specialty area of medical-surgical nursing. After establishing a robust practical foundation as a medical-surgical nurse, I started to research

what additional steps I would need to take. After confirming that I had met the practice requirements of two years full-time as an RN and had completed the required thirty CE credits, I began studying and registered to take the certification exam.

I became certified in medical-surgical nursing during my third year as a nurse and have maintained it ever since. This certification became a transformative milestone, allowing me to deepen my expertise in medical-surgical nursing. It equipped me with the latest evidence-based practices, significantly enhancing the quality of care for a diverse range of medical-surgical patients in the fast-paced environment of the hospital. Not only did my journey to certification help my own practice, but it also became a source of inspiration for my nursing colleagues. I actively engaged in mentorship, encouraging fellow medical-surgical nurses to explore the unique opportunities that certification brings to our specialty. A year or two after I became certified, four of my colleagues became certified as well, which furthered the expertise and care our department could provide to our patients.

---

### In-Service Education

Many healthcare institutions offer licensed nurses opportunities for ongoing training, known as **in-service education**. Often these programs address the evolving nature of health care, licensure renewal prerequisites, or other specific needs of the nursing staff. They cover a spectrum of topics, including clinical updates, patient safety measures, quality improvement, and regulatory compliance. By providing opportunities for ongoing learning and skill enhancement, in-service education not only helps nurses stay current with best practices but also ensures they adhere to ethical standards, legal obligations, and regulatory requirements, ultimately promoting optimal patient care and safety.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### In-Service Education for Clinical Safety

In-service education programs play a pivotal role in ensuring clinical safety and adherence to best practices in health care. Addressing the core principles of QSEN, these initiatives aim to enhance the competence and skills of healthcare professionals in delivering safe and effective patient care.

- **Focus on QSEN principles:** In-service education programs aligned with QSEN principles prioritize areas such as patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics. By integrating these principles into ongoing training, healthcare institutions foster a culture of continuous learning and improvement.
- **Clinical updates and best practices:** In-service education initiatives in clinical safety and procedures provide healthcare professionals with essential updates on clinical protocols, safety measures, and evidence-based procedures. This ensures that nurses stay abreast of the latest advancements, contributing to enhanced patient safety.
- **Ethical standards and regulatory compliance:** Beyond clinical skills, in-service education emphasizes ethical standards, legal obligations, and regulatory requirements. By promoting adherence to these principles, these programs contribute to maintaining the highest standards of professional conduct and safeguarding patient well-being.
- **Optimizing patient care:** In-service education in clinical safety and procedures is not only a requirement for professional growth but also a commitment to optimizing patient care. The continuous enhancement of skills and knowledge empowers healthcare professionals to deliver high-quality, safe, and patient-centered care in evolving clinical environments.

As an integral part of healthcare education, in-service programs aligned with QSEN principles demonstrate the industry's dedication to maintaining excellence in clinical safety and procedures. These initiatives support healthcare professionals in upholding the highest standards of care and contribute to the ongoing improvement of patient outcomes.

---

### Professional Nursing Organizations

A **professional nursing organization** is a collective body formed by nurses to represent and advocate for the interests of the nursing profession. Professional nursing organizations share a symbiotic relationship with licensing

bodies. Organizations such as the ANA, National Council of State Boards of Nursing, and various specialty-specific groups play a vital role in shaping the standards and guidelines for nursing licensure. They actively engage in advocacy efforts, influencing legislative decisions and policies to ensure that licensure processes are fair, transparent, and reflective of the current healthcare landscape.

Professional nursing organizations also collaborate with regulatory bodies to establish educational requirements, competency assessments, and CE expectations, contributing to the continuous professional development of nurses. Through networking opportunities and collaborative initiatives, these organizations provide a platform for nurses to collectively address challenges, share best practices, and contribute to the ongoing improvement of licensure standards. Additionally, professional nursing organizations emphasize the importance of ethical standards, research, and evidence-based practice, influencing the ethical considerations and scientific foundations embedded in the licensure process. The collaboration between professional nursing organizations and licensure ensures that nursing standards evolve to meet the dynamic needs of health care, uphold ethical principles, and foster the highest quality of patient care.

## LINK TO LEARNING

The website Nurse.org maintains a [list of professional nursing organizations \(https://openstax.org/r/77profnrlist\)](https://openstax.org/r/77profnrlist) at the state, national, and international levels.

## 1.3 Nursing as a Profession

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the scope of practice for the nursing profession
- Explain standards of practice for the nursing profession
- Discuss nursing roles and responsibilities within the profession

Within the realm of health care, nursing stands as a dynamic and essential profession marked by a holistic commitment to patient care and well-being. The scope of practice for nurses encompasses a wide spectrum of responsibilities, ranging from direct patient care to collaboration with interdisciplinary teams. As professionals dedicated to promoting health and preventing illness, nurses play pivotal roles in various healthcare settings. The nursing profession adheres to rigorous standards of practice, ensuring that practitioners maintain the highest level of competence and ethical conduct. These standards guide nurses in delivering safe, effective, and person-centered care. Within this professional landscape, nurses experience diverse roles and responsibilities, encompassing caregiver, decision-maker, collaborator, communicator, advocate, and educator. This section explores the multifaceted nature of nursing as a profession, delving into its scope and standards and the critical roles and responsibilities that define and elevate the practice of nursing in the complex and ever-evolving healthcare environment.

### Scope of Practice

The **scope of practice** refers to the defined limits and parameters within which a professional is authorized to work, make decisions, and provide services. It is a set of regulations, guidelines, and standards that delineate the range of duties, responsibilities, and activities that individuals within a specific profession are educated, trained, and legally permitted to perform. The scope of practice is established by regulatory bodies, licensing boards, and professional organizations to ensure that professionals operate within their competencies, uphold ethical standards, and provide safe and effective care (ANA, n.d.b).

The scope of nursing practice encompasses the range of roles, responsibilities, activities, and interventions that a RN or LPN/LVN is educated, trained, and authorized to perform within the legal and ethical boundaries of their licensure. The scope of practice is defined by regulatory bodies, such as state Boards of Nursing in the United States, and informed by national and international professional organizations like the ANA and the International Council of Nurses (ICN). The specific scope of practice for a nurse is influenced by factors such as education, experience, and additional certifications or specialties. It is important to note that the specific details of the scope of

practice can vary by jurisdiction (ANA, n.d.b). Nurses must know the regulations and guidelines set by their state's or country's regulatory authority and engage in regular updates and ongoing education to stay current with evolving healthcare practices and maintain competence within the defined scope of nursing practice.

## REAL RN STORIES

---

### Knowing Scope of Practice Boundaries

**Nurse:** Julian, BSN

**Clinical setting:** Urgent care

**Years in practice:** 28

**Facility location:** Suburban city in Alabama

As a nurse, it is important to know your scope of practice to ensure you stay within your practice guidelines. There is one situation in particular that stands out for testing the boundaries of my scope of practice. One day, my charge nurse approached me with a request to administer a medication to a patient before the provider had written the order for the medication.

Recognizing the potential risks and ethical considerations involved in the situation, I hesitated and expressed my concerns about administering medication without an order. The charge nurse explained the provider was attending to an emergency and would be delayed in providing the order. Despite the urgency conveyed by the charge nurse, I emphasized the importance of obtaining a proper order to ensure the patient's safety and well-being.

This experience took an even more critical turn when it was later discovered that the patient had a known allergy to the medication in question. Had I proceeded without an order, it could have led to severe consequences for the patient. This just reinforced the importance of adhering to established protocols and emphasized the potential risks associated with deviating from them.

This experience highlighted the importance of advocating for patient safety, even in challenging circumstances. It also underscored the significance of effective communication within the healthcare team and the commitment to upholding professional standards, ensuring that patient care aligns with established protocols and maintains the highest standards of safety and professionalism.

---

### International Council of Nurses

The **International Council of Nurses (ICN)** holds a pivotal role in shaping and advancing the global nursing profession, providing essential guidance on the scope of practice for nurses. As a worldwide federation of national nursing associations, the ICN serves as a unifying force, representing millions of nurses with a shared mission to elevate the nursing profession and contribute to improved global health (ICN, n.d.).

Recognizing the inherent diversity in nursing practices across countries and regions, the ICN establishes overarching principles and guidelines that underscore the foundational elements of nursing practice. Central to its framework is the acknowledgment of nurses as autonomous professionals, empowered to make independent judgments and decisions within their designated scope of practice. This emphasis on autonomy is complemented by a commitment to accountability, ensuring that nurses are responsible for the outcomes of their practice (ICN, n.d.).

Collaboration is another cornerstone of the ICN's vision for nursing. The framework underscores the importance of nurses working in close partnership with other healthcare professionals, fostering a collaborative approach to deliver comprehensive and well-coordinated care to individuals and communities. Advocacy features prominently in the ICN's guidance, emphasizing the vital role of nurses as advocates for patients (ICN, n.d.). Nurses are entrusted with the responsibility to ensure that the needs, preferences, and rights of patients are not only acknowledged but also respected within the broader healthcare system.

Education and professional development are encouraged by the ICN, recognizing the dynamic nature of health care and the need for nurses to continually enhance their knowledge and skills. This commitment to ongoing learning is vital for staying abreast of evidence-based practices and ensuring the delivery of high-quality care. Ethical practice is another core tenet outlined by the ICN, emphasizing the importance of nurses upholding stringent ethical standards. This includes safeguarding patient confidentiality, respecting cultural diversity, and promoting the well-

being and dignity of those under their care (ICN, n.d.).

The ICN's guidance serves as a global compass for nursing, fostering consistency, excellence, and a shared commitment to advancing health care on an international scale. Crucially, the ICN acknowledges that the scope of nursing practice is context dependent, varying based on local regulations, laws, and educational standards (ICN, n.d.). The organization provides a flexible framework that countries and regions can adapt to their specific needs, allowing for a nuanced approach to nursing practice that aligns with local requirements and priorities.

### American Nurses Association

The **American Nurses Association (ANA)** is a national professional nursing organization formed by nurses to represent and advocate for the interests of the nursing profession. It is one of the largest and most influential such organizations in the United States, advocating for the interests of nurses and the nursing profession. The ANA works to advance the profession of nursing by promoting high standards of nursing practice, providing guidance on ethical issues, and influencing healthcare policy (ANA, n.d.a).

The ANA plays a central role in shaping and defining the scope of practice for nurses in the United States. As the premier professional organization representing the interests of RNs, the ANA provides leadership, guidance, and advocacy to ensure the highest standards of nursing practice. The ANA recognizes the dynamic and evolving nature of health care and nursing, and as such, it continually updates and revises its *Scope and Standards of Practice* to reflect contemporary healthcare needs and professional advancements (ANA, n.d.a).

Through publications such as the *Scope and Standards of Practice*, the ANA delineates the competencies, responsibilities, and ethical considerations that define the scope of nursing practice. This document serves as a comprehensive guide for nurses, educators, policymakers, and the public, outlining expectations for the delivery of safe, quality, and person-centered care (ANA, n.d.b). The ANA's influence extends beyond individual practice, contributing to the development of policies and regulations that govern nursing practice at local, state, and national levels, thereby shaping the landscape of healthcare delivery in the United States.

### State Boards of Nursing

A **board of nursing (BON)**, typically established at the state or territorial level, is a regulatory body tasked with overseeing the practice of nursing within its jurisdiction. One of the primary responsibilities of a BON is defining and regulating the scope of practice for nurses. The board sets guidelines and standards that govern the legal and ethical boundaries within which nurses can provide care. These guidelines outline the permissible activities, responsibilities, and competencies for different levels of nursing professionals, ensuring safe and effective patient care. The BONs collaborate with professional nursing organizations, educators, and other stakeholders to regularly review and update these standards to reflect advances in health care, changes in legislation, and evolving societal needs. Additionally, BONs are responsible for licensing nurses, establishing educational requirements, and enforcing regulations to uphold the integrity of the nursing profession.

Licensing is a state-specific process overseen by state BONs, ensuring nurses meet the qualifications and standards set by the respective state for safe and competent practice. The Nurse Licensure Compact is an agreement among participating states that allows nurses to hold one multistate license, granting them the privilege to practice in other compact states without obtaining additional licenses. This compact enhances mobility for nurses and facilitates access to healthcare services across state borders, while still maintaining regulatory standards and patient protection. Through these mechanisms, BONs play a crucial role in safeguarding public health while providing a framework that allows nurses to practice within well-defined parameters.

### Standards of Practice

The **Standards of Practice** are comprehensive guidelines that articulate the expectations and ethical conduct required of nurses in their professional roles. These standards serve as a foundational framework, ensuring uniformity, quality, and safety in patient care. While specific criteria may vary across regions, many standards align with overarching principles advocated by professional nursing organizations.

Fundamental aspects found in these standards include the promotion of professionalism, integrity, and accountability among nurses. The emphasis on person-centered care underscores the importance of respecting individual values, preferences, and autonomy. Safety and quality considerations prioritize a culture of continuous improvement and a sanitary and secure healthcare environment. Effective communication and collaboration with

patients and healthcare colleagues are highlighted, promoting interdisciplinary teamwork. The integration of evidence-based practice encourages nurses to utilize the best available evidence in conjunction with clinical expertise to inform decision-making.

Commitment to ongoing education and professional development is emphasized, ensuring nurses stay abreast of evolving healthcare practices. Ethical conduct, legal compliance, and cultural competence are integral components of these standards, ensuring nurses uphold ethical principles, adhere to legal regulations, and provide culturally sensitive and equitable care. Adherence to standards of practice is crucial for upholding the integrity of the nursing profession and delivering safe, ethical, and high-quality patient care.

### Code of Ethics

An ethical principle is a fundamental concept that guides individuals and professionals in determining what is right or wrong in a given situation. Ethical principles provide a framework for appropriate decision-making and behavior, helping to ensure that actions align with moral values and standards. Within nursing, these ethical principles are collated into the nursing **code of ethics**, a comprehensive set of principles that defines the ethical responsibilities and standards expected of nurses in their professional practice (ANA, 2015; Gaines, 2023).

The nursing code of ethics, as articulated by organizations like the ANA, is based on five main ethical principles: **nonmaleficence**, **beneficence**, autonomy, justice, and **confidentiality** (Table 1.1).

Ethical Principle	Definition	Example
Nonmaleficence	The principle that nurses have an obligation to do no harm intentionally	Nurses take the time to double-check patients' allergies before administering medications.
Beneficence	The principle that nurses have an obligation to do good and promote the well-being of patients	Nurses spend extra time providing emotional support to terminally ill patients, demonstrating compassion and empathy, even though no specific medical intervention is required.
Autonomy	The principle that an individual has the right to make their own decisions about their own life and body, even when those decisions might be different from what healthcare providers recommend	Nurses discuss treatment options with patients, allowing them to make informed decisions aligned with their personal values.
Justice	The principle that all individuals should be treated with fairness and equity	Nurses allocate resources, such as time and attention, equitably among patients to ensure fair and unbiased care.
Confidentiality	The principle that nurses should respect and safeguard their patients' personal and health information	Nurses safeguard patient information and only share it with authorized individuals, maintaining trust in the nurse-patient relationship.

**TABLE 1.1** Ethical Principles for Nurses

In adhering to this code, nurses commit to upholding the highest standards of ethical practice, ensuring the well-being and safety of patients. The code encompasses a set of principles that underscore the essential values and obligations of nursing professionals. Central to the nursing code of ethics is the principle of patient-centered care. Nurses prioritize the needs and preferences of patients, recognizing and respecting their autonomy, individuality, and right to make informed decisions about their health care. This commitment extends to fostering open communication, building trust, and maintaining confidentiality to uphold the privacy of patients. Another

fundamental principle is the obligation to provide competent and safe care. Nurses continually strive to enhance their knowledge and skills, staying abreast of advancements in health care to deliver evidence-based and quality care (ANA, 2015; Gaines, 2023). This includes advocating for a supportive work environment that facilitates ongoing education and professional growth.

The nursing code of ethics underscores the importance of maintaining integrity and honesty in all professional interactions. Nurses are expected to uphold the trust placed in them by the public and colleagues, fostering a culture of transparency and accountability. This involves addressing any conflicts of interest and ensuring that decisions are guided by ethical considerations rather than personal gain. Collaboration and advocacy are integral components of the nursing code of ethics. Nurses work collaboratively with interdisciplinary teams to optimize patient outcomes, promoting a holistic approach to health care. Additionally, they serve as advocates for patients, ensuring that their rights are upheld and that they receive equitable and compassionate care. Finally, the nursing code of ethics emphasizes the responsibility of nurses to contribute to the advancement of the profession (ANA, 2015; Gaines, 2023). This involves engaging in scholarly activities, participating in professional organizations, and actively contributing to the ongoing development of nursing knowledge and practice.

## LINK TO LEARNING

Take some time to review the [Code of Ethics for Nurses \(https://openstax.org/r/77codethic\)](https://openstax.org/r/77codethic) as set forth by the ANA.

### Quality and Safety Education for Nurses

The **Quality and Safety Education for Nurses (QSEN)** initiative serves as a framework for nursing education and practice, emphasizing the integration of quality and safety principles into nursing education and clinical care. While QSEN itself is not a set of formal nursing standards of practice like those established by regulatory bodies or professional organizations, it has influenced nursing education and practice standards by promoting key competencies essential for delivering safe and high-quality patient care (QSEN Institute, n.d.).

The QSEN identifies six core competencies that align with nursing standards and guide nursing education:

1. Patient-centered care focuses on the individual needs, preferences, and values of patients. This competency aligns with nursing standards that emphasize a person-centered approach, recognizing the importance of involving patients in their care and decision-making.
2. Teamwork and collaboration together promote effective communication and cooperation among healthcare team members, aligning with standards that highlight the significance of interdisciplinary teamwork and communication to enhance patient outcomes.
3. Evidence-based practice (EBP) integrates the best available evidence with clinical expertise and patient values to guide nursing practice. Evidence-based practice is a foundational standard in nursing, emphasizing the importance of using the latest evidence to inform decision-making.
4. Quality improvement involves continuous efforts to enhance patient care and outcomes, which aligns with nursing standards that advocate for ongoing quality assessment and improvement within healthcare organizations.
5. Safety prioritizes the safety of both patients and healthcare providers. It is a core principle in nursing practice standards, and the existence of QSEN reinforces the importance of creating a culture of safety within healthcare settings.
6. Informatics promotes the use of information and technology to support and improve healthcare delivery, which aligns with nursing standards that recognize the role of these tools in enhancing patient care and communication.

### Nursing Roles and Responsibilities

Nursing roles and responsibilities encompass a diverse array of critical functions within the healthcare system. At its core, nursing involves being a compassionate caregiver, providing holistic and person-centered care that addresses physical, emotional, and psychological needs. Nurses act as decision-makers, exercising clinical judgment, prioritizing care, and contributing to ethical discussions. In the role of a manager of care, nurses coordinate and optimize healthcare services, overseeing interdisciplinary teams and navigating complex healthcare systems. As

communicators, nurses bridge the gap between patients, their families, and the healthcare team, facilitating effective information exchange and fostering therapeutic relationships. Nurses also serve as advocates, ensuring that patients' voices are heard, their rights are respected, and their choices are considered in decision-making processes. Additionally, nurses act as educators, imparting essential knowledge to patients and communities, promoting health literacy, and empowering individuals to actively participate in their well-being.

## REAL RN STORIES

---

### Navigating Nursing Roles and Responsibilities

**Nurse:** Thara, BSN

**Clinical setting:** Intensive care unit (ICU)

**Years in practice:** 10

**Facility location:** Urban hospital in New York

Working in the ICU of a bustling urban hospital, my daily responsibilities extend beyond the traditional image of a nurse. In the ICU, I play a pivotal role in patient advocacy, acting as a liaison between patients, their families, and the interdisciplinary healthcare team. As a patient advocate, effective communication is critical, not only in delivering medical information but also in offering emotional support during challenging times. The ICU environment demands sharp critical thinking and quick decision-making. I face dynamic situations that require immediate intervention and adaptability. Whether it's responding to sudden changes in a patient's condition or collaborating with physicians on treatment plans, my ability to think on my feet is a constant asset.

As an experienced ICU nurse, I often find myself in leadership roles during emergencies. I lead resuscitation efforts, coordinate the response to critical events, and ensure seamless communication among the healthcare team. My leadership extends to mentoring newer nurses, fostering a culture of continuous learning and collaboration. I also provide leadership and expertise across the hospital as the rapid response nurse. In this role, I am called on when patients are deteriorating to help to problem-solve and stabilize the patient until the provider can arrive.

Despite the high-stress environment, I remain committed to providing person-centered care. I take the time to understand each patient's unique needs, involving them in care decisions and ensuring their voices are heard. My compassion and empathy create a therapeutic relationship that contributes to the overall well-being of my patients.

Recognizing the importance of advocating for the nursing profession, I actively participate in initiatives aimed at improving healthcare policies and practices. I engage in professional development, stay informed about advancements in critical care, and advocate for the well-being of both patients and fellow nurses. I embrace change as an opportunity for growth. I also actively seek out training on new technologies, stay informed about evidence-based practices, and contribute to the implementation of innovative approaches in the ICU.

Balancing the emotional toll of critical care nursing with the fulfillment of making a positive impact on patients' lives can be challenging yet rewarding. I emphasize the importance of self-care and teamwork in navigating the complexities of my role. Though nursing has a multitude of roles and responsibilities that come with providing care to our patients, we must never forget that we also have a responsibility to take care of ourselves.

---

### Caregiver

A **caregiver** is an individual who provides physical, emotional, or practical support to individuals in need of assistance due to illness, disability, age-related challenges, or other conditions that impact their ability to perform daily activities independently. As a caregiver, one of the primary roles and responsibilities of a nurse is to provide compassionate and holistic care to individuals, families, and communities. This aspect of nursing involves addressing the physical, emotional, social, and psychological needs of patients, with a focus on promoting health, preventing illness, and facilitating healing. Cultural competence is woven into the role, as nurses recognize and respect the diverse backgrounds, beliefs, and values of their patients; tailoring their approaches to care to accommodate individual cultural preferences.

The caregiving role encompasses several key responsibilities, such as assessment, planning, implementation, and evaluation. In the first phase of caregiving, the nurse conducts thorough assessments to understand the unique

health circumstances of each individual, considering factors such as health history and environmental influences. Following the assessment, nurses take on the responsibility of developing personalized care plans in collaboration with patients, their families, and the healthcare team. These plans establish specific goals and interventions tailored to the individual's needs and preferences. In the implementation phase, caregivers carry out the care plan by administering medications, performing treatments, and coordinating various healthcare services. Simultaneously, they provide emotional support and education, aiming to empower patients and their families in their health journey. Nurses also continuously monitor patient health status, evaluate the effectiveness of interventions, and make necessary adjustments to optimize outcomes. Finally, during crises or emergencies, caregivers respond swiftly and effectively to stabilize the patient's condition. This requires quick thinking, adaptability, and the ability to work effectively under pressure.

### Decision-Maker

As a **decision-maker**, an individual or entity responsible for making choices or reaching conclusions in a particular context, in the healthcare setting, nurses bear a crucial responsibility in influencing and determining various aspects of patient care. At the core of this role is the exercise of clinical judgment. Drawing on their knowledge, experience, and analytical skills, nurses assess patient data, discern patterns, and determine interventions that best address the unique needs of each individual. This process extends to active participation in the development of patient care plans, as nurses collaborate with a diverse healthcare team to establish goals and interventions aligned with patient conditions and preferences.

A central responsibility in the decision-making realm involves prioritization. In the dynamic and often fast-paced healthcare environment, nurses must adeptly discern the urgency and importance of various tasks, ensuring that critical aspects of care receive immediate attention. Resource allocation is another critical facet of the decision-making role. Nurses are tasked with judiciously utilizing limited healthcare resources, including time, staff, and equipment, to optimize care delivery. Adaptation to change is also an essential aspect of decision-making, as nurses must make informed decisions that enable them to navigate shifts in patient conditions, treatment modalities, and healthcare policies.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Take Action: Prioritizing Nursing Care

The nurse is caring for two patients, Mr. Johnson and Mrs. Rodriguez. Mrs. Rodriguez calls out complaining of a "bad headache." Immediately after, Mr. Johnson rings the call bell complaining that he is having trouble breathing. The nurse quickly assesses Mr. Johnson's respiratory status, noting increased respiratory rate, use of accessory muscles, and decreased oxygen saturation. Recognizing that respiratory distress can lead to life-threatening complications, the nurse analyzes the severity of the situation and the need for prompt intervention. Applying clinical judgment, the nurse prioritizes care based on the urgency and potential impact on patient outcomes and decides to prioritize addressing Mr. Johnson's respiratory distress first due to the immediate threat to his physiological stability. The nurse initiates interventions to improve Mr. Johnson's respiratory status, such as administering supplemental oxygen, positioning for optimal breathing, and notifying the healthcare team for further assessment. The application of clinical judgment in prioritizing nursing care ensures that the most urgent and critical needs are addressed promptly. This structured approach contributes to enhanced patient safety, improved clinical outcomes, and the delivery of person-centered care.

### Manager of Care

In the capacity of a **manager of care**, nurses assume a pivotal role in directing and overseeing the comprehensive delivery of healthcare services. This multifaceted responsibility encompasses various key aspects of patient care coordination and management. Nurses are charged with organizing and optimizing care delivery by planning and prioritizing interventions based on patient needs and available resources. Nurses play a crucial role in coordinating interdisciplinary teams, fostering effective communication and ensuring seamless collaboration among healthcare professionals.

As managers of care, nurses also navigate the complexities of healthcare systems, utilizing their leadership skills to advocate for patients and optimize the use of healthcare resources. This role involves overseeing the

implementation of care plans, monitoring patient outcomes, and making timely adjustments to interventions as needed. Furthermore, nurses in this role are instrumental in promoting a culture of safety, quality improvement, and adherence to evidence-based practices within the healthcare setting. Through their managerial responsibilities, nurses contribute significantly to enhancing the overall efficiency, effectiveness, and quality of patient care.

## **CLINICAL SAFETY AND PROCEDURES (QSEN)**

---

### Embracing QSEN Principles for Effective Management of Patient Care

Quality and Safety Education for Nurses (QSEN) is a cornerstone in shaping the nurse's role in managing patient care. As nurses take on the responsibility of managing care, the principles of QSEN become fundamental in shaping effective leadership and decision-making to deliver safe and high-quality health care.

Key aspects of QSEN in managing care include the following:

- **Patient-centered care:** Embracing the principles of QSEN emphasizes the significance of patient-centered care, aligning with the nurse's role in managing patient care. Nurses ensure that care delivery is personalized to meet individual patients' needs, preferences, and values, fostering a patient-centric approach.
- **Teamwork and collaboration:** Effective patient care management requires collaboration among healthcare team members. The QSEN principles advocate for teamwork, encouraging nurses to create a collaborative environment where communication and cooperation thrive, ultimately benefiting patient outcomes.
- **Evidence-based practice:** As frontline caregivers, nurses play a pivotal role in promoting EBP. The QSEN emphasizes the integration of the latest evidence into decision-making, guiding nurses in adopting practices that are rooted in research and proven to enhance patient safety and care quality.
- **Quality improvement:** Managing patient care involves overseeing processes for continuous improvement. The QSEN's focus on quality improvement aligns with the nurse's responsibility to assess, monitor, and enhance care delivery processes to ensure optimal patient outcomes.
- **Patient safety:** In the role of managing patient care, nurses are crucial to the success of patient safety initiatives. The QSEN's focus on safety science guides nurses in implementing strategies to prevent errors, minimize risks, and create a culture of safety within their practice.

The integration of QSEN into nursing care management positively influences patient outcomes. Nurses, equipped with QSEN principles, deliver care based on best practices, contributing to improved patient safety and well-being. The QSEN's emphasis on communication aligns with the nurse's role in fostering open and effective communication within the healthcare team. This, in turn, promotes better coordination of care and a more responsive healthcare environment. Nurses, influenced by QSEN's focus on continuous improvement, are better equipped to adapt to changes in healthcare practices and technologies. This adaptability ensures that patient care remains aligned with the latest advancements.

---

### Communicator

The role of a nurse as a **communicator** (an individual who engages in the process of conveying information, ideas, or messages to others) is integral to effective healthcare delivery and patient outcomes. Nurses serve as the primary liaisons between patients, their families, and the broader healthcare team, translating complex medical information into understandable and actionable insights. Communication involves not only the dissemination of information but also active listening, empathy, and the fostering of therapeutic relationships. Nurses communicate critical details about patients' conditions, treatment plans, and progress to other healthcare professionals, ensuring a coordinated and comprehensive approach to care. Additionally, they advocate for patients' needs and preferences, facilitating shared decision-making in the care process.

The ability to communicate effectively extends to providing emotional support, addressing concerns, promoting health literacy, and empowering patients and their families/caregivers to actively participate in their care. In emergencies or critical situations, nurses must convey information swiftly and clearly to ensure prompt and appropriate interventions. Effective communication is paramount in fostering understanding and trust among patients, families, and the interdisciplinary healthcare team.

### Advocate

An **advocate** is an individual who actively and vocally supports, defends, or promotes the rights, interests, and well-being of another person or a group. The nursing role as an advocate is a cornerstone of person-centered care, reflecting a commitment to safeguarding the rights, well-being, and preferences of individuals within the healthcare system. Nurses serve as vocal proponents for patients, ensuring their voices are heard, concerns addressed, and choices respected. Advocacy involves not only communicating patients' needs to the healthcare team but also empowering patients to actively participate in decision-making regarding their care. Nurses navigate complex healthcare systems on behalf of patients, assisting them in understanding their rights, treatment options, and available resources (Morris, 2023).

Beyond the individual level, nurses engage in systemic advocacy, contributing to policy discussions and initiatives aimed at improving overall healthcare delivery and outcomes. The advocacy role extends to at-risk populations, where nurses work to address disparities and promote equitable access to quality care. In essence, the nursing responsibility as an advocate is rooted in the principles of justice, autonomy, and beneficence, aiming to ensure that each patient receives the highest standard of care in a supportive and respectful environment.

### Educator

The nursing role as an **educator** (an individual who engages in the process of facilitating teaching and learning) is foundational to promoting health literacy, empowering patients, and fostering informed decision-making. Nurses are entrusted with the responsibility of providing clear and accessible information to patients, their families, and communities. This educational role involves explaining medical conditions, treatment plans, and preventive measures in a comprehensible manner, taking into account individual differences and cultural considerations. Nurses utilize their expertise to enhance patients' understanding of their health status, medications, and self-care practices.

Beyond the bedside, nurses contribute to community health education, offering insights on disease prevention, healthy lifestyles, and wellness promotion. In the context of chronic conditions, nurses guide patients in managing their health proactively, emphasizing the importance of adherence to treatment plans. By serving as educators, nurses play a vital part in empowering individuals to take an active role in their health, ultimately contributing to better health outcomes and the overall well-being of the communities they serve.

## 1.4 History and Evolution of Nursing Theories

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize the evolution of nursing theory
- Identify the elements of a nursing theory
- Discuss the domains of nursing philosophy in relation to clinical practice

A **theory** is a framework of related ideas intended to guide and support action. A **nursing theory**, therefore, is a structured and systematic framework composed of concepts, principles, and propositions that collectively guide and shape the understanding of nursing practice. Developed by nursing theorists, nursing theories provide a comprehensive foundation for nurses to conceptualize and interpret various aspects of health care, encompassing not only the delivery of patient care but also education, research, and administration within the nursing profession. At their core, nursing theories articulate fundamental principles and beliefs about the nature of nursing, health, and the dynamic interactions between nurses and their patients. These theories serve as invaluable guides for practitioners, educators, and researchers, contributing to the ongoing evolution and refinement of nursing knowledge and practice in response to the ever-changing landscape of health care (Alligood, n.d.; Gaines, 2023; Wayne, 2023).

### Evolution of Nursing Theory

The evolution of nursing theory reflects the dynamic nature of the nursing profession, responding to changes in health care, advancements in research, and shifts in societal perspectives. Historically, nursing lacked recognition as an academic discipline or a fully realized profession. Before the development of nursing theories, the profession was characterized as a task-oriented occupation, with nurses operating under the direction and control of the medical profession. The significance of nursing theories lies in their explicit description of nursing, setting the foundation for

practice and offering a framework that defines the purpose and role of nurses in healthcare settings. These theories serve as a rationale for nursing interventions, providing scientific reasons and a knowledge base to guide appropriate actions in care situations. Additionally, nursing theories contribute to the ongoing development of nursing practice, offering a basis for the further generation of knowledge and indicating the direction in which the profession should evolve (Alligood, n.d.; Gaines, 2023; Wayne, 2023).

By providing nurses with a sense of identity, nursing theories contribute to the acknowledgment and understanding of the unique contributions that nurses make to the healthcare service, fostering a common language for communication and practice. Nursing theories not only guide research but also influence EBP, contributing to the development of nursing education and training programs. Overall, nursing theories, education, research, and practice are interconnected, mutually influencing and shaping each other as the nursing profession continues to evolve (Alligood, n.d.; Gaines, 2023; Wayne, 2023).

### Historical Nursing Theories

The earliest nursing theories emerged in the nineteenth century with the work of pioneers such as Florence Nightingale. Nightingale's environmental theory (discussed in [Nightingale's Environmental Theory](#)) laid the groundwork for considering the impact of the environment on health. During this period, nursing was primarily seen as a task-oriented and apprenticeship-based profession. In the mid-twentieth century, nursing theories began to take a more systematic and conceptual form. Theories such as Virginia Henderson's nursing need theory (discussed in [Henderson's Nursing Need Theory](#)) and Hildegard Peplau's interpersonal relations theory (discussed in [Peplau's Theory of Interpersonal Relations](#)) emphasized the importance of understanding patient needs and interpersonal relationships in nursing practice.

In the late twentieth century, there was a proliferation of nursing theories addressing various aspects of nursing, health, and care. Betty Neuman's systems model, Dorothea Orem's self-care deficit nursing theory (discussed in [Orem's Self-Care Deficit Nursing Theory](#)), and Madeleine Leininger's culture care theory (discussed in [Leininger's Culture Care Theory](#)) are examples of theories developed during this period, reflecting a diversity of perspectives within the field. With the increasing emphasis on EBP, nursing theories have become more integrated with research over time. Theories such as Roy's adaptation model (discussed in [Roy's Adaptation Model](#)) and the model of nursing as caring by Anne Boykin and Savina Schoenhofer highlight the importance of research in refining and validating theoretical concepts (Alligood, n.d.; Gaines, 2023; Wayne, 2023).

Many contemporary nursing theories in the twenty-first century have emphasized holistic and person-centered care. Theories like Jean Watson's theory of human caring (discussed in [Watson's Theory of Human Caring](#)) and Patricia Benner's "novice to expert" model of nursing (discussed in [Patricia Benner](#)) underscore the significance of understanding the whole person and the nurse's role in promoting well-being. In response to increasing globalization and cultural diversity, nursing theories have expanded to incorporate cultural competence and global health considerations. Leininger's Culture Care Theory and the Transcultural Nursing Model exemplify this shift in focus. The current landscape of nursing theory has also seen an increasing emphasis on interdisciplinary collaboration. Theories, such as the general systems theory (discussed in [General Systems Theory](#)), underscore the interconnected nature of systems, which can include not only biological and organizational systems but also interdisciplinary collaborations within the healthcare field.

Throughout their history, nursing theories have adapted to changes in healthcare delivery, technological advancements, and a deeper understanding of human experiences. Theories continue to evolve as nurses and theorists engage with new evidence, technologies, and societal challenges, ensuring the ongoing relevance and advancement of nursing knowledge and practice.

### Elements of a Nursing Theory

A nursing theory typically consists of concepts, phenomena, definitions, and assumptions. These key elements work together to form a coherent and comprehensive framework that shapes the understanding and practice of nursing, providing a guide for nurses to approach patient care, education, and research.

#### Concepts

A **concept** is an idea that serves as a foundational element of a theory, contributing to its overall structure and coherence. Concepts are like building blocks that capture essential aspects of nursing practice and collectively

provide a theoretical framework that guides the profession. Concepts may be abstract, representing general notions rather than specific instances, or **concrete**, representing specific and tangible ideas or objects that can be directly observed or experienced. Regardless of whether a concept is abstract or concrete, it is accompanied by a precise definition to ensure clarity and consistency in interpretation (Wayne, 2023).

The interrelatedness of concepts within a nursing theory illustrates the dynamic relationships that exist among them, contributing to the theory's coherence and ability to explain how the concepts influence each other. Concepts must be operationalized to make them observable, relevant, and transferable to research and clinical practice (Wayne, 2023). Examples of concepts that are fundamental to nursing are **holism** (individuals should be viewed and treated as whole beings), **caring** (nurses should give patients compassionate and empathetic attention), adaptation (people adjust to changes in the internal and external environments to maintain optimal health), and self-care (activities that individuals perform to maintain their own health and well-being).

### Phenomena

A **phenomenon** is a specific aspect of interest or an observable occurrence that is the focus of theoretical exploration and study. Phenomena in nursing theories refer to whatever theorists seek to understand, describe, explain, or predict within the context of nursing practice. They are often complex and multifaceted, encompassing various dimensions of human health and nursing care (Wayne, 2023).

Examples of phenomena include the experience of pain, coping mechanisms for chronic illness, nurse-patient interactions, health promotion strategies, and cultural competence in nursing. Theories in nursing are developed to explore, describe, explain, or predict these phenomena, providing a structured framework for understanding the complexities of health care. Phenomena are not only the subjects of theoretical exploration but also the catalysts for advancing EBP, guiding nursing research, and enhancing the quality of patient care. As nurses engage with and seek to address phenomena, theoretical frameworks offer valuable perspectives and insights, contributing to the ongoing evolution and refinement of nursing knowledge.

### Definitions

A **definition** is a clear and precise explanation of the meaning attributed to a specific concept or term within the theoretical framework. Definitions serve to establish a shared understanding among theorists, researchers, educators, and practitioners who engage with the theory. The clarity of definitions is essential for consistency in communication and application of the theory across diverse contexts (Wayne, 2023).

Definitions within nursing theories aim to articulate the intended meaning of key concepts, ensuring that these concepts are interpreted and used in a standardized manner. Clear definitions contribute to the conceptual clarity and coherence of a nursing theory, fostering a common language within the nursing discipline. They provide a foundation for theoretical development, research design, and practical application of the theory in clinical settings. As nursing theories evolve, definitions may be refined or expanded to accommodate new insights and understandings within the dynamic field of health care (Wayne, 2023).

### Assumptions

An **assumption** is a foundational belief or proposition that is accepted without direct empirical evidence. For instance, assumptions may revolve around the inherent worth of individuals, the impact of the environment on health, or the nurse's role in promoting well-being. While assumptions are not subjected to direct testing, they lay the groundwork for the theoretical framework, providing a lens through which the theorist explores, explains, and contributes to the evolving body of nursing knowledge. As nursing theories advance, assumptions may be reevaluated in light of new evidence and insights, ensuring the ongoing relevance and applicability of the theoretical perspectives within the dynamic field of health care (Wayne, 2023).

## The Domains of Nursing Philosophy

In its broadest sense, **philosophy** involves the exploration of fundamental questions about existence, values, and the human experience through critical inquiry and reflection. When applied to nursing, a **nursing philosophy** becomes the compass that guides a nurse's practice, encompassing beliefs about the nature of nursing, patient care, ethical considerations, and the nurse's role within the healthcare system (Alligood, n.d.; Gaines, 2023; Wayne, 2023). Clinical nursing incorporates philosophy by grounding actions in foundational beliefs, proven theories, and EBPs, facilitating a more comprehensive and patient-centered approach to care.

A theoretical **domain** refers to a broad and overarching area of theoretical exploration or study. It encompasses a set of concepts, assumptions, and other principles that collectively form a comprehensive framework for understanding and explaining phenomena within that particular domain (Wayne, 2023).

The domains of nursing philosophy are commonly articulated through the concepts of person, environment, health, and nursing. These domains provide a framework, known as a **metaparadigm**, a set of overarching concepts and principles that are key to understanding a particular discipline or field of study. A metaparadigm represents the most abstract level of a theoretical structure and serves as a unifying element that guides the development of theories within the discipline. The **nursing metaparadigm** is a conceptual framework that emphasizes the interconnectedness of the person, environment, health, and the unique role of nursing in facilitating and optimizing the health and well-being of individuals within their broader contexts (Gaines, 2023; Wayne, 2023).

### Perspective on Person

The **person domain**, often referred to as the patient or client domain, is the central focus of nursing philosophy. This domain emphasizes the individual as a holistic being with physical, psychological, social, cultural, and spiritual dimensions. It acknowledges each individual's inherent dignity, autonomy, and interconnectedness with the environment (Gaines, 2023; Wayne, 2023).

Nursing philosophy underscores the importance of approaching patients with a person-centered perspective, considering not only their physical health but also their values, preferences, and experiences. Person-centered care recognizes the uniqueness of each individual and aims to provide care that is tailored to their specific needs, values, and preferences. The domain of the person reflects a commitment to providing individualized and culturally competent care that respects the uniqueness of each individual.

## REAL RN STORIES

---

### Recognizing the Importance of Person

**Nurse:** Gannon, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 17

**Facility location:** Suburban city in Alabama

I specifically remember this particular patient who exemplified the nursing metaparadigm concept of a person. This individual was an older woman facing a complex web of chronic illnesses and emotional challenges. Despite her frailty and physical limitations, she maintained a vibrant spirit and a deep sense of resilience.

As her nurse, my focus extended beyond merely addressing her physical symptoms; it encompassed understanding her unique life history, values, and aspirations. Through therapeutic communication, I discovered her love for painting, which had been a lifelong passion. Recognizing the significance of maintaining her identity beyond the confines of illness, I collaborated with the healthcare team to incorporate art therapy into her care plan. We were able to contact volunteer services and request some crayons, colored pencils, watercolors, and paper. You should have seen her face when I walked in with the supplies. You could see the joy on her face.

This approach not only provided relief from physical discomfort but also cared for her emotional well-being. By acknowledging her as a holistic being with individual needs and aspirations, we created an environment that supported her overall health and quality of life. This experience reinforced my commitment to viewing each patient as a unique person with multifaceted dimensions.

---

### Perspective on Environment

The **environment domain** encompasses the surroundings, context, and external factors that influence a person's well-being. This domain recognizes that health is not solely determined by individual factors but is also shaped by the broader physical, social, cultural, economic, and global environment ([Table 1.2](#)) (Gaines, 2023; Wayne, 2023). Nurses consider the impact of these environmental factors on the health and well-being of the person and adapt care accordingly.

Factor	Definition	Relevant Considerations for Nurses
Physical	The immediate physical surroundings in which care is provided, such as the healthcare facility, patient's room, or community setting	Is the patient's environment clean? Is it safe? What are the lighting and noise levels?
Social	The relationships, family dynamics, and support systems surrounding a person	How strong is the patient's support system? Does the patient live alone or with family? What impact do these relationships have on the patient?
Cultural	A person's beliefs, values, customs, and traditions	What do I need to understand about the patient's culture to provide effective and respectful care? How does the patient's culture influence their approach to and preferences for their care?
Economic	The patient's access to nutrition, housing, and other resources relevant to well-being	Does the patient feel stressed when thinking about their economic situation? What barriers prevent the patient from achieving and maintaining optimal health, and how can I help address them?
Global	The broader influences and conditions that extend beyond local or national boundaries, affecting health on a global scale	Are there any prevalent international health concerns that may affect the patient directly or indirectly? Has the patient recently traveled to regions with prevalent health risks or outbreaks? Are there any potential exposures to infectious diseases that have global implications?

**TABLE 1.2** Environmental Factors of Health

### Perspective on Health

The **health domain** goes beyond the absence of illness. In nursing philosophy, health is a dynamic and holistic concept that encompasses the overall well-being of the person, including physical, mental, social, and spiritual dimensions. The understanding of health in nursing philosophy is broad, recognizing that individuals exist on a continuum of wellness and that health is influenced by various factors. The focus is on promoting optimal health, which includes preventing illness but also supporting individuals in achieving their highest level of functioning and quality of life (Gaines, 2023; Wayne, 2023).

Health emphasizes preventive measures and wellness promotion, placing a strong emphasis on patient education and empowerment. Cultural sensitivity is paramount, as nursing philosophy recognizes that diverse cultural perspectives influence perceptions of health and that nursing must ensure care aligns with the individual's cultural beliefs and practices related to health and well-being. By placing the person at the center of care, nurses collaborate with patients to set goals and develop care plans that align with the individual's personal definitions of health and well-being. By supporting individuals in building resilience and coping mechanisms to maintain or restore their health, nurses may positively influence the individual's ability to adapt and cope with life's challenges.

### Perspective on Nursing

The **nursing domain** is a fundamental and central concept that defines the unique role, purpose, and responsibilities of the nursing profession. This domain encompasses the art and science of nursing, outlining the scope of practice and guiding principles that underpin the delivery of care. It captures the essence of the profession,

guiding nurses in their dedication to providing high-quality, ethical, and person-centered care that positively impacts the health and well-being of those served (Gaines, 2023; Wayne, 2023).

At its core, nursing is envisioned as a holistic and person-centered discipline, extending beyond the treatment of illness to encompass the promotion of health, the prevention of disease, and the enhancement of overall well-being for individuals and communities. Nurses operate with a commitment to delivering care that is both comprehensive and individualized, recognizing the intricate interplay of physical, emotional, social, cultural, and spiritual dimensions in each person. Advocacy and empowerment are integral elements, with nurses championing the rights and voices of their patients, fostering autonomy, and facilitating shared decision-making. The philosophy underscores the importance of health promotion, compassionate interactions, and continuous pursuit of knowledge through evidence-based practices. Ethical considerations form a foundation for nursing practice, emphasizing integrity, confidentiality, and delivery of care that aligns with moral principles.

### Relation to Clinical Judgment

You have seen the term *clinical judgment* several times in this chapter, but what exactly does it mean? Essentially, **clinical judgment** utilizes nursing knowledge, critical thinking, and clinical reasoning, drawing from evidence, theories, and interdisciplinary insights to make informed and patient-centered decisions. It involves the practical application of the domains of nursing philosophy: person, environment, health, and nursing. Together, these domains comprise a conceptual framework that informs clinical judgment, guiding nurses to make sound decisions and provide effective care. They provide a holistic perspective, emphasizing individualized care, consideration of environmental influences, promotion of health, and adherence to the principles of nursing.

More concretely, clinical judgment involves the nurse's ability to assess and understand the unique characteristics, needs, and responses of each individual receiving care. By recognizing the holistic aspects of the person, including their physical, emotional, social, and cultural dimensions, nurses can make informed and person-centered decisions, tailoring interventions to the individual's specific context. Clinical judgment also requires nurses to consider environmental factors—including the patient's physical, social, and cultural contexts—when assessing and planning care. Understanding the impact of the environment on an individual's health and well-being helps nurses adapt interventions, identify potential challenges, and create a setting conducive to optimal patient outcomes. The domain of health guides nurses in setting goals, preventing complications, and promoting well-being. Continually assessing the patient's health status enables the nurse to determine the most appropriate intervention at a given time. Finally, the domain of nursing directly informs clinical judgment by defining the scope of nursing practice. Nurses draw on their knowledge, skills, and ethical principles to make decisions aligned with the philosophy of nursing.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Using Clinical Judgment to Address Environmental Factors

A patient recovering from surgery was becoming increasingly agitated and disoriented. The attending nurse recognized environmental cues in the room such as loud noises, bright lights, and constant interruptions in sleep and concluded the patient was likely experiencing delirium. The nurse collaborated with the healthcare team to adjust the environment, such as reducing the noise level, dimming the lights in the room, and clustering care so the patient could sleep with fewer interruptions. After implementing these strategies, the nurse noted significant improvements to the patient's mental clarity and overall well-being, demonstrating the importance of recognizing and addressing environmental factors in patient care.

## 1.5 Selected Nursing Theorist

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe different nursing theorists throughout history
- Identify the interdisciplinary foundation for nursing theories
- Recognize nursing theories used in current practice

Nursing theorists have played a pivotal role in shaping the profession of nursing, contributing theoretical

frameworks that guide and inform nursing practice, education, and research. These visionaries have brought forth diverse perspectives, philosophies, and models that enhance our understanding of the complex and dynamic nature of health care and the nurse-patient relationship. From Florence Nightingale's foundational work during the Crimean War to contemporary thinkers like Jean Watson and Martha Rogers, each theorist has left an unforgettable mark on the discipline, influencing the way nurses approach patient care, view their roles, and contribute to the overall advancement of health care. As the nursing profession continues to evolve, the theories crafted by these luminaries remain crucial in providing a theoretical foundation that aligns with the holistic and person-centered nature of nursing practice.

## Nursing Theorists

A **nursing theorist** is an individual, typically a nurse with advanced education and experience, who has made significant contributions to the development of nursing theory. Nursing theorists engage in the systematic development of concepts, frameworks, and models that help to explain, predict, and guide nursing practice. These individuals often draw from their clinical experiences, academic research, and philosophical perspectives to articulate theories that shape the understanding of nursing and contribute to the professional identity of nurses. The first part of this module highlights some of the most prominent nursing theorists, past and present.

### Florence Nightingale

Florence Nightingale (1820–1910), known as the founder of modern nursing, was a nurse pioneer and social reformer (Figure 1.5). Named after her birthplace (Florence, Italy), Nightingale is best known for her work during the Crimean War, which led to groundbreaking contributions to nursing and public health. Her unique legacy encompasses not only hands-on nursing but also pioneering work in statistics and epidemiology (Alexander, 2019). Nightingale's legacy is complicated by her participation in colonialist practices, including advising governments on repressing anti-colonial uprisings, and publications in which she expressed belief in the superiority of the British over Indigenous people. Nurses, researchers, and historians debate how the community should incorporate and celebrate Nightingale's contributions to the field (Robinson-Lane & Patel, 2022; D'Antonio, 2022).

**FIGURE 1.5** Florence Nightingale, known as the founder of modern nursing, was a social reformer, statistician, and pioneer for the nursing profession. (credit: "Florence Nightingale," by JamesGardinerCollection/Flickr, Public Domain)

Nightingale's prominence rose during the Crimean War, to which she and a team of nurses were called to care for soldiers. Upon arriving at the wards, they were horrified to find unsanitary conditions, such as overcrowded wards, sewage on the floors, and patients covered in filth. Using statistics, Nightingale was able to track the number of

deaths; she proved that more soldiers were dying from diseases they picked up in hospitals than from battlefield wounds. She implemented improved sanitation practices and enhanced medical care for wounded soldiers, which significantly reduced mortality rates from 40 to 2 percent (Alexander, 2019). Her statistical analysis of disease was instrumental in establishing the science of epidemiology, which is still used today to track the spread of diseases.

Known for carrying a lamp while she made rounds to check in on soldiers during the night, Nightingale was commonly referred to as “the Lady with the Lamp” by the British soldiers. Her legacy remains strong today; her lamp continues to be an international symbol of nursing and is incorporated into the most important nursing ceremonies. Her 1860 book, *Notes on Nursing: What It Is, and What It Is Not*, remains a foundational text in nursing education, emphasizing the importance of cleanliness, fresh air, and proper nutrition in patient care (Alexander, 2019).

Also in 1860, Nightingale established the first secular nursing school, at St. Thomas’ Hospital in London. Her pivotal role in formalizing and professionalizing nursing education continues to shape the field today. The Nightingale Pledge, recited by nurses during graduation ceremonies, reflects the ethical commitment she advocated for so strongly. Nightingale’s legacy is also remembered on International Nurses Day, celebrated on May 12 (her birthday), a day that honors her enduring influence on nursing and health care and her dedication to evidence-based practices and patient well-being (Alexander, 2019).

### Hildegard Peplau

Hildegard Peplau (1909–1999) was a distinguished nurse, educator, and theorist who made significant contributions to the field of psychiatric nursing (Figure 1.6). Born in Reading, Pennsylvania, Peplau played a crucial role in the development of a theory that revolutionized the approach to nursing care. This theory of interpersonal relations (discussed in [Peplau’s Theory of Interpersonal Relations](#)) emphasized the nurse-patient relationship as a therapeutic and collaborative partnership, shifting the focus from a task-oriented model to one centered on understanding and meeting the psychological needs of patients. Peplau’s groundbreaking work laid the foundation for modern psychiatric nursing, stressing the importance of communication, empathy, and mutual respect in facilitating the healing process. Her influential book, *Interpersonal Relations in Nursing* (1952), remains a seminal text in nursing education. Throughout her career, Peplau held various leadership positions and contributed significantly to the professionalization of nursing. Her enduring legacy extends beyond her theoretical contributions, as she played a pivotal role in shaping the way nurses approach patient care, particularly in mental health settings (Gonzalo, 2023c).

**FIGURE 1.6** Hildegard Peplau was a nursing educator who played a major role in developing the theory and practice of psychiatric and

mental health nursing. (credit: “Hildegard-Peplau-1931 Pottstown Hospital Training School Yearbook,” by Pottstown Hospital School of Nursing Yearbook/Wikimedia Commons, Public Domain)

### Virginia Henderson

Virginia Henderson (1897–1996) is often referred to as the “First Lady of Nursing.” Born in Kansas City, Missouri, she dedicated her life to nursing and played a crucial role in the development of nursing theory and practice. Henderson’s most notable contribution is her definition of nursing: “The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge” (Henderson & Nite, 1978, p. 5). This definition suggests that nurses help individuals achieve their highest level of independence in activities of daily living. Henderson’s conceptualization of nursing was encapsulated in her nursing need theory (discussed in [Henderson’s Nursing Need Theory](#)), which articulates fourteen basic needs that individuals require assistance with during illness. According to Henderson, nurses should focus on meeting these needs to promote health and well-being (*Virginia Henderson—Nursing theorist*, n.d.).

Throughout her career, Henderson worked in various capacities, including clinical practice, education, and research. She held teaching positions at several prestigious institutions, including Yale University. Henderson also served as a consultant to the United States Public Health Service, the World Health Organization, and the ICN (*Virginia Henderson—Nursing theorist*, n.d.).

In addition to her theoretical contributions, Henderson authored numerous publications, including the classic *Textbook of the Principles and Practice of Nursing* (*Virginia Henderson—Nursing theorist*, n.d.). Her work laid the foundation for modern nursing practice and education, emphasizing the importance of a holistic and person-centered approach. Her legacy continues to shape the field, and her impact is evident in the continued evolution of nursing theory and practice.

### Faye Abdellah

Faye Abdellah (1919–2017) was a pioneering researcher and educator who significantly influenced the development of nursing theory and practice ([Figure 1.7](#)). Born in New York City, Abdellah developed her theory of patient-centered approaches to nursing (PCAN) in the 1960s. The theory of PCAN focuses on comprehensive patient care, emphasizing the importance of individualized care plans based on patients’ unique needs. Abdellah identified twenty-one nursing problems that could be addressed through nursing interventions, emphasizing a holistic and person-centered approach to health care (Atkins, 2017).

**FIGURE 1.7** Faye Abdellah was a pioneer in nursing research and the first nurse and woman to serve as the deputy surgeon general of the United States. (credit: “abdellah-4” by NIH, Public Domain)

Throughout her career, Abdellah held various leadership positions within the U.S. Public Health Service, as well as teaching positions at Yale University and the Uniformed Services University of the Health Sciences. Abdellah’s

commitment to nursing research and education extended beyond her theoretical contributions. She played a key role in advancing nursing research methodology and promoting the integration of research into nursing practice (Atkins, 2017). Her work laid the groundwork for a more systematic and evidence-based approach to nursing care. Abdellah's impact on nursing is enduring, as her theories and contributions continue to shape nursing education, research, and practice.

### Patricia Benner

Patricia Benner is a highly regarded nursing theorist, educator, and author known for her groundbreaking work in the field of nursing education and practice. Born in 1942, Benner has had a profound impact on the way nursing is taught and understood. Benner is perhaps best known for her “novice to expert” model of nursing, which she introduced in 1982. This theory outlines the stages of skill acquisition and development in nursing practice, emphasizing the transition from novice to expert over time. Benner's model includes five stages: novice, advanced beginner, competent, proficient, and expert. According to her theory, as nurses gain experience, they move through these stages, developing clinical expertise and intuitive understanding of patient care (*Dr. Patricia Benner novice to expert—Nursing theorist*, n.d.).

Throughout her career, Patricia Benner has held various academic positions. She has also contributed extensively to nursing literature, authoring and coauthoring numerous books and articles that explore topics related to nursing education, clinical practice, and skill development (*Dr. Patricia Benner novice to expert—Nursing theorist*, n.d.). Benner's work has had a lasting impact on nursing education and has influenced the way nurses are trained and evaluated in clinical settings. Her emphasis on experiential learning and the importance of practical knowledge in nursing has been instrumental in shaping the profession and promoting the development of competent and expert nurses. Patricia Benner's contributions continue to be foundational in the field of nursing, influencing both educators and practitioners alike.

### Jean Watson

Jean Watson is a distinguished nursing theorist, academic, and author recognized for her significant contributions to the field of nursing. Born in 1940, Watson is renowned for her development of the theory of human caring (discussed in [Watson's Theory of Human Caring](#)), often referred to as the “caring theory.” Introduced in the late 1970s and further expanded in subsequent years, this theory emphasizes the importance of the nurse-patient relationship and views nursing as a holistic and transpersonal experience. According to Watson, caring is at the core of nursing and involves the intentional and genuine connection between the nurse and the patient, incorporating both the physical and spiritual dimensions of care (Watson Caring Institute, n.d.a).

Throughout her career, Jean Watson has held various academic positions and authored numerous books and articles on nursing theory, philosophy, and the importance of caring in health care. Watson's work has had a profound impact on nursing education, research, and practice, influencing the way nurses approach patient care and highlighting the significance of compassion and human connection in the healing process. Her caring theory continues to be a guiding framework for nurses seeking to provide person-centered and holistic care in diverse healthcare settings.

### Dorothea Orem

Dorothea Orem (1914–2007) was a prominent nursing theorist known for her influential work in developing the self-care deficit nursing theory (discussed in [Orem's Self-Care Deficit Nursing Theory](#)). This theory, first proposed in the 1950s and further refined in subsequent decades, revolves around three interrelated concepts: self-care, self-care deficit, and nursing systems. Self-care refers to the activities individuals perform to maintain their health; self-care deficit occurs when individuals cannot meet their own self-care needs. Nursing systems are interventions designed to assist individuals in meeting their self-care needs. According to Orem, individuals have the ability and responsibility to engage in self-care to maintain their health and well-being (*Orem's self-care deficit nursing theory*, n.d.).

Throughout her career, Orem held various positions in nursing education and practice. She served as a consultant and held faculty positions at several universities, including Catholic University of America and Case Western Reserve University (*Orem's self-care deficit nursing theory*, n.d.). Orem's theoretical framework has had a significant impact on nursing education, research, and practice, providing a structured approach to understanding and addressing patients' self-care needs. Her contributions have influenced the development of nursing curricula and the design of

patient care plans, emphasizing the importance of empowering individuals to participate in their own care. Orem's legacy endures as her theory continues to be a foundational component of nursing knowledge and practice.

## Interdisciplinary Foundation for Nursing Theories

Interdisciplinary foundations for nursing theories acknowledge the interconnectedness of various disciplines and their influence on the development and application of nursing knowledge. Several disciplines contribute to the diverse theoretical frameworks within nursing, including biology, medicine, psychology, sociology, anthropology, philosophy, and education.

The biological and medical sciences, for instance, provide the foundation for understanding human anatomy, physiology, and pathology. They contribute to nursing theories by informing concepts related to health, illness, and the physiological basis of nursing interventions. Psychology contributes to nursing theories by providing insights into human behavior, cognition, and emotions. Psychosocial aspects of patient care, therapeutic communication, and mental health nursing draw heavily from psychological theories. Sociology informs nursing theories about social determinants of health, cultural influences, and the impact of social structures on individuals and communities. Anthropology contributes by providing a cross-cultural perspective, enriching nursing theories with an understanding of diverse practices, beliefs, and health-seeking behaviors. Philosophical concepts contribute to nursing theories by addressing fundamental questions about ethics, morality, and the nature of human existence. Ethical theories and frameworks guide nurses in making morally sound decisions in complex healthcare situations. Educational theories play a role in shaping nursing education and training models. Theories related to pedagogy, adult learning, and curriculum development influence how nursing knowledge is disseminated and applied in academic and clinical settings.

### General Systems Theory

The **general systems theory** in nursing is a theoretical framework that draws on principles from systems theory to understand and explain the complex and dynamic nature of health care and nursing practice. Developed by biologist Ludwig von Bertalanffy in the mid-twentieth century, the general systems theory posits that any system, including a healthcare system or an individual patient, can be viewed as a complex organization of interacting and interrelated components (Von Bertalanffy, 1972).

In the context of nursing, the general systems theory emphasizes the multifaceted nature of healthcare delivery and the interactions between various components, such as patients, healthcare providers, technology, and organizational structures. This theoretical approach encourages nurses to consider the entire healthcare system rather than focus solely on individual aspects. It underscores how different elements within the healthcare environment are interconnected and how changes in one part of the system can have ripple effects throughout.

The general systems theory has been particularly influential in nursing administration and management, as it provides a framework for understanding how healthcare institutions are organized and how changes in policies, procedures, or personnel can impact the overall functioning of the system. It also emphasizes the importance of holistic and person-centered care by recognizing that patients are dynamic systems influenced by biological, psychological, social, and environmental factors.

### Descriptive Theories

A **descriptive theory** aims to describe phenomena systematically and objectively through the observation and analysis of behaviors and experiences (Wayne, 2023). In psychology, for example, Ivan Pavlov's work on classical conditioning can be considered descriptive theory, as it systematically describes the process of learning through observing the association of stimuli and responses in animals. Within the field of nursing, these theories focus on providing detailed accounts, categorizations, and classifications of various aspects of nursing, such as patient behaviors, nursing interventions, or healthcare settings. Descriptive theories contribute to the understanding of the complexities within nursing and may serve as a foundation for further research, education, and development of prescriptive theories (Wayne, 2023).

### Prescriptive Theories

A **prescriptive theory** provides guidance on how nursing care should be conducted (Wayne, 2023). These theories go beyond describing phenomena and offer recommendations, interventions, or strategies for achieving specific nursing goals. They are often more action oriented, outlining the steps or principles that should be followed. For

example, the theory of experiential learning, developed by David Kolb, prescribes a learning process that involves concrete experiences, reflective observation, abstract conceptualization, and active experimentation. It suggests that individuals learn best when they engage in hands-on experiences, reflect on those experiences, derive abstract principles from their reflections, and then apply these principles in new situations. This prescriptive theory has influenced educational practices that support learning. Within nursing, prescriptive theories guide nursing practice by providing a framework for decision-making and intervention planning (Wayne, 2023).

### Adaptation Theories

An **adaptation theory** focuses on the dynamic process of adaptation that individuals undergo in response to changes in their environment (Wayne, 2023). These theories posit that individuals strive to maintain balance and well-being through adaptive responses to stressors. In ecology, for example, Charles Darwin's theory of evolution by natural selection is an adaptation theory that explains how species adapt to their environments over time. In nursing, adaptation theories guide the understanding of how patients respond to health challenges and provide a framework for nurses to support and facilitate adaptive processes for optimal patient outcomes.

### Developmental Theories

A **developmental theory** is influenced by broader theories of human development, exploring the stages and transitions individuals go through across their life span (Wayne, 2023). These theories consider physical, cognitive, emotional, and social aspects of development. In nursing, developmental theories are applied to understand the unique needs and challenges faced by individuals at different life stages, guiding nurses in providing age-appropriate and developmentally sensitive care. Erik Erikson's stages of psychosocial development is an example of a developmental theory that has been applied in nursing to understand the psychological challenges individuals face at different life stages. For instance, applying Erikson's theory helps nurses recognize and address the unique psychosocial needs of adolescents, adults, and older adults in their care (Wayne, 2023).

## LIFE-STAGE CONTEXT

### Application of Erik Erikson's Developmental Theory to Nursing

Erik Erikson's developmental theory, often referred to as the theory of psychosocial development, outlines a series of stages individuals go through across their life span. Erikson proposed eight stages, each characterized by a psychosocial crisis or challenge that individuals must navigate to achieve healthy development. The stages are as follows:

- Trust versus mistrust (infancy, 0–1.5 years): The challenge for infants is to develop a sense of trust in caregivers and the environment, laying the foundation for a trusting worldview.
- Autonomy versus shame and doubt (early childhood, 1.5–3 years): Young children seek to develop a sense of independence and autonomy while learning to control their impulses.
- Initiative versus guilt (preschool, 3–5 years): The focus in this stage is on developing a sense of purpose and the ability to initiate activities, balanced with a growing awareness of responsibility.
- Industry versus inferiority (school age, 5–12 years): Children in this stage work to master new skills and tasks, aiming to feel competent and industrious in their endeavors.
- Identity versus role confusion (adolescence, 12–18 years): Adolescents explore and develop a stable sense of self, including values, beliefs, and life goals.
- Intimacy versus isolation (young adulthood, 18–40 years): Young adults seek to form intimate relationships and commit to long-term connections with others.
- Generativity versus stagnation (middle adulthood, 40–65 years): Adults focus on contributing to society and future generations, fostering a sense of purpose.
- Ego integrity versus despair (late adulthood, 65+ years): The challenge in the final stage is to reflect on one's life and feel a sense of accomplishment and fulfillment rather than regret.

Erikson's theory emphasizes the importance of successfully navigating each stage for overall psychological well-being. The outcomes of these psychosocial crises influence an individual's ability to form healthy relationships, cope with challenges, and find meaning in life. Erikson's developmental theory is discussed in greater detail in [Chapter 38 Growth and Development](#). Nurses can apply Erikson's stages to comprehend and address the unique needs of

patients. For instance, in pediatric nursing, understanding the challenges related to trust, autonomy, and initiative can guide nurses in fostering a supportive environment for children's emotional and psychological development. In geriatric care, the stage of integrity versus despair becomes pertinent as nurses assist older adults in reflecting on their lives and finding fulfillment.

---

## Selected Nursing Theories in Clinical Practice

Nursing theories form the intellectual backbone of clinical practice, providing a structured framework that guides nurses in understanding, analyzing, and responding to the diverse needs of patients. These theories are not merely abstract concepts but also practical tools that shape the way nurses think, communicate, and deliver care at the bedside. In the dynamic landscape of clinical practice, nursing theories serve as compass points, directing practitioners toward person-centered, evidence-based, and holistic care. From addressing the physical aspects of illness to considering the intricate interplay of psychological, social, and cultural factors, nursing theories equip healthcare professionals with a robust foundation to navigate the complexities of clinical scenarios. The final part of this module will highlight some of the most influential nursing theories.

---

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### Clinical Safety and Procedures: Applying Nursing Theories in Practice

Nursing theories serve as guiding frameworks that shape the understanding and application of clinical practices. Within the QSEN initiative, the integration of nursing theories is crucial for ensuring clinical safety and effective procedures. Let's explore how nursing theories are connected to the QSEN competencies:

- **Person-centered care:** Nursing theories emphasize viewing individuals as holistic beings with interconnected physical, psychological, social, cultural, and spiritual dimensions. This perspective significantly impacts patient safety and satisfaction in clinical settings, fostering an environment that recognizes and addresses the unique needs of each individual.
- **Teamwork and collaboration:** Theoretical frameworks provide a common language and understanding, facilitating effective communication and coordination in a collaborative work environment. This collaborative approach contributes to improved patient safety outcomes and ensures comprehensive care delivery.
- **Evidence-based practice:** Evidence-based practice is a cornerstone of clinical decision-making. The incorporation of the latest evidence into practice ensures that interventions are not only rooted in theoretical knowledge but also informed by the most current and relevant research. This approach enhances clinical decision-making, contributing to safe and effective patient care.
- **Quality improvement:** Nursing theories further support a culture of continuous quality improvement within clinical settings. The theoretical foundations provide a basis for identifying and addressing clinical issues, fostering an environment in which ongoing assessment and enhancement of care processes contribute to positive patient outcomes.
- **Safety:** In the realm of safety practices and procedures, nursing theories offer specific guidance. From preventing errors to ensuring a secure healthcare environment, these theoretical frameworks inform safety measures that are crucial for maintaining the well-being of both patients and healthcare providers.
- **Informatics:** The integration of informatics within nursing practice—involving the management, analysis, and utilization of health information—is in harmony with the principles of nursing theories. This alignment emphasizes the crucial role of informatics in facilitating efficient and accurate data-driven decision-making, ultimately contributing to the enhancement of patient safety within healthcare settings.

---

### Nightingale's Environmental Theory

Florence Nightingale's environmental theory, developed during the nineteenth century, is a foundational framework that significantly influenced nursing practice and healthcare environments. Based on her observations and experiences during the Crimean War, the environmental theory posits that the environment plays a critical role in influencing the health and well-being of individuals. Nightingale emphasized the significance of a clean, well-ventilated, and aesthetically pleasing environment in promoting healing and preventing illness. She believed that by modifying the environment, nurses could positively impact patients' recovery outcomes (Gonzalo, 2023b).

Nightingale's theory incorporates several key environmental factors, including fresh air, pure water, efficient drainage, cleanliness, and appropriate nutrition. She emphasized the importance of natural light and noise control, recognizing their impact on patient comfort and the overall healing process. Additionally, Nightingale stressed the need for nursing interventions to create a supportive and therapeutic environment, considering factors beyond the physical space, such as social, psychological, and spiritual aspects (Gonzalo, 2023b).

Nightingale's environmental theory remains relevant today, guiding nurses in the design of healthcare settings that prioritize the creation of environments conducive to healing and recovery. It highlights the interconnectedness of the physical, social, and psychological elements in nursing practice and serves as a reminder of the enduring importance of a health-promoting environment in patient care.

### Peplau's Theory of Interpersonal Relations

Hildegard Peplau's theory of interpersonal relations, developed in the 1950s, is a landmark framework in nursing that focuses on the interpersonal relationship between the nurse and the patient as a therapeutic process. Peplau emphasized the importance of understanding the dynamics of the nurse-patient relationship in promoting positive health outcomes. The theory consists of four phases: orientation, identification, exploitation, and resolution (Gonzalo, 2023c):

1. In the orientation phase, the nurse and the patient establish a connection, and the patient seeks help.
2. The identification phase involves the patient clarifying their thoughts and feelings, while the nurse assists in defining the problem.
3. During the exploitation phase, the patient utilizes the help offered by the nurse to address the identified problem and gain a better understanding of their situation.
4. Finally, in the resolution phase, the patient resolves the problem and achieves independence with the nurse's support.

Peplau's theory views nursing as an interpersonal and therapeutic process, with the nurse acting as a facilitator, resource, and counselor. It underscores the significance of communication, empathy, and mutual understanding in building a therapeutic relationship. Peplau believed this relationship could positively influence the patient's emotional well-being and contribute to their overall health (Gonzalo, 2023c).

The theory of interpersonal relations has had a lasting impact on nursing practice, guiding nurses in developing meaningful connections with their patients. It has been influential in psychiatric and mental health nursing and has broader applications across various healthcare settings. In the context of mental health care, where trust and empathy are foundational, the theory of interpersonal relations provides a guiding framework for nurses to make connections that extend beyond conventional caregiving. The theory encourages active listening and a deep understanding of patients' experiences, emotions, and perspectives, proving invaluable to mental health nursing. It fosters collaboration in treatment planning and promotes a nonjudgmental and empathetic attitude, contributing to reducing the stigma associated with mental health conditions. Peplau's emphasis on the interpersonal aspect of nursing has contributed to the humanization of patient care and remains relevant in contemporary nursing practice.

### Leininger's Culture Care Theory

Madeleine Leininger's culture care theory, also known as transcultural nursing theory, is a comprehensive framework that emphasizes the importance of cultural competence in nursing care. Developed in the 1950s, Leininger's theory posits that culture plays a crucial role in shaping an individual's health beliefs, practices, and responses to illness. The central tenet of this theory is that culturally congruent care, which aligns with the patient's cultural values, beliefs, and practices, leads to improved health outcomes (Lancellotti, 2008).

Leininger classified nursing care into three modes: cultural care preservation (or maintenance), cultural care accommodation (or negotiation), and cultural care repatterning (or restructuring). Cultural care preservation focuses on maintaining cultural practices that promote health. Cultural care accommodation involves adapting nursing care to align with the patient's cultural values. Cultural care repatterning aims to assist individuals in changing cultural practices that may be detrimental to their health (Lancellotti, 2008).

The culture care theory emphasizes the need for nurses to be culturally competent and to provide care that respects and incorporates the cultural context of each patient. It recognizes that individuals from diverse cultural backgrounds may have different health beliefs and practices, which must be taken into account to deliver effective

and person-centered care. This theory has had a profound impact on nursing education, research, and practice by promoting cultural sensitivity and competence. It encourages healthcare professionals to recognize and respect cultural diversity, fostering a more inclusive and person-centered approach to care. Leininger's culture care theory remains a foundational framework in transcultural nursing, guiding nurses in delivering culturally congruent and competent care to individuals from various cultural backgrounds.

### Orem's Self-Care Deficit Nursing Theory

Dorothea Orem's self-care deficit nursing theory is a conceptual framework developed to guide nursing practice by focusing on the individual's ability to perform self-care activities. Orem introduced this theory in the 1950s and expanded it over subsequent decades. The core premise is that individuals have the capacity for self-care, and nursing interventions are required when individuals are unable to meet their own self-care needs (*Orem's self-care deficit nursing theory*, n.d.).

The theory identifies three related components: self-care, self-care deficit, and nursing systems. Self-care encompasses the activities individuals initiate and perform on their own behalf to maintain life, health, and well-being. Self-care deficit occurs when an individual is incapable of meeting their self-care needs adequately. Nursing systems, in this context, refer to actions taken by nurses to assist and support individuals with self-care deficits (*Orem's self-care deficit nursing theory*, n.d.).

Orem categorized self-care into two types: universal self-care requisites, which are common to all individuals, and developmentally based self-care requisites, which vary according to an individual's life stage, health status, and sociocultural factors. The theory proposes that nursing care should be designed to supplement or substitute for an individual's self-care abilities, aiming to promote independence and prevent or alleviate self-care deficits (*Orem's self-care deficit nursing theory*, n.d.).

Orem's self-care deficit nursing theory has had a profound impact on nursing education, research, and practice. It provides a systematic and comprehensive framework for nurses to assess, plan, and implement interventions that address the self-care needs of individuals. This theory has been instrumental in shaping nursing curricula and guiding the development of person-centered care plans, emphasizing the importance of empowering individuals to participate actively in their own care and promoting optimal health outcomes.

### Henderson's Nursing Need Theory

Virginia Henderson's nursing need theory is a foundational framework in nursing that delineates the essence and responsibilities of nursing practice. Developed in the 1950s, Henderson's theory focuses on the role of the nurse in assisting individuals to achieve and maintain health, or to achieve a peaceful death when health is no longer possible (*Henderson's nursing need theory*, n.d.).

Central to Henderson's theory are the fourteen basic needs that individuals require assistance with during times of illness. These needs encompass physiological, psychological, social, and spiritual dimensions ([Figure 1.8](#)) (*Henderson's nursing need theory*, n.d.).

Virginia Henderson's Nursing Need Theory	
<b>Physiological</b> 	<ol style="list-style-type: none"> <li>1. Breathe normally</li> <li>2. Eat and drink adequately</li> <li>3. Eliminate body wastes</li> <li>4. Move and maintain desirable postures</li> <li>5. Sleep and rest</li> <li>6. Select suitable clothes—dress and undress</li> <li>7. Maintain body temperature within normal range by adjusting clothing and modifying environment</li> <li>8. Keep the body clean and well groomed, and protect the integument</li> </ol>
<b>Psychological</b> 	<ol style="list-style-type: none"> <li>9. Work in such a way that there is a sense of accomplishment</li> <li>10. Learn, discover, or satisfy the curiosity that leads to normal development and health and use the available health facilities</li> </ol>
<b>Social</b> 	<ol style="list-style-type: none"> <li>11. Communicate with others in expressing emotions, needs, fears, or opinions</li> <li>12. Avoid dangers in the environment and avoid injuring others</li> <li>13. Play or participate in various forms of recreation</li> </ol>
<b>Spiritual</b> 	<ol style="list-style-type: none"> <li>14. Worship according to one's faith</li> </ol>

**FIGURE 1.8** Virginia Henderson's need theory identifies fourteen basic needs. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Nursing need theory has played a crucial role in shaping nursing education and practice, providing a comprehensive framework for understanding and meeting the diverse needs of individuals across the health-illness continuum. Henderson's emphasis on the holistic nature of nursing care and the promotion of patient independence remains influential in contemporary nursing theories and practices.

### Roy's Adaptation Model

Sister Callista Roy's adaptation model, developed in the 1970s, is a prominent nursing theory that focuses on the idea of adaptation as the goal of nursing care. This model is based on the belief that individuals are in constant interaction with their environment and that adaptation is a fundamental process for promoting health and well-being (*Roy's adaptation model of nursing*, n.d.).

Roy's theory identifies four key adaptive modes: physiological, self-concept, role function, and interdependence. The physiological mode encompasses the physical processes that contribute to an individual's health, while the self-concept mode relates to the individual's perception of themselves. The role function mode involves the roles and responsibilities individuals take on in life, and the interdependence mode focuses on the relationships and connections individuals have with others (*Roy's adaptation model of nursing*, n.d.).

The adaptation model proposes that individuals strive for adaptation; when faced with stimuli or stressors, they use adaptive responses to maintain balance and achieve a state of well-being. Nursing, in this context, is viewed as a science and practice that helps individuals adapt to changes in their physiological and psychosocial environment. Nurses assess the adaptive capabilities of individuals and provide interventions to support their adaptation processes.

Roy's theory has been influential in guiding nursing practice, education, and research. It provides a holistic perspective on the individual as an adaptive system, considering both the biological and psychosocial aspects of health. The adaptation model is particularly applicable in situations where individuals are experiencing changes or challenges, as it emphasizes the importance of nursing interventions that facilitate adaptation and promote optimal health outcomes.

## REAL RN STORIES

---

### Applying Roy's Adaptation Model in Practice

**Nurse:** Juanita, BSN

**Clinical setting:** Cardiac department

**Years in practice:** 27

**Facility location:** Rural town in South Carolina

I recently cared for a patient named Mr. Anderson, an 80-year-old individual admitted for heart failure exacerbation. When caring for Mr. Anderson, I applied Roy's adaptation model by assessing Mr. Anderson's physiological, psychological, and social needs to provide individualized care for the patient.

In considering the physiological adaptations, I closely monitored Mr. Anderson's vital signs, administered prescribed medications, and collaborated with the healthcare team to stabilize his cardiac function, recognizing the threat his failing heart posed to his physiological integrity. By considering psychological adaptations, I was able to understand the emotional impact of chronic illness, particularly in the older adult. I engaged Mr. Anderson in open communication, provided emotional support, and addressed his fears and anxieties surrounding the implications of heart failure on his daily life. In terms of social adaptation, I collaborated with the hospital's social work team to evaluate Mr. Anderson's living situation, support systems, and potential challenges he might face upon discharge. Ensuring he had a safe and supportive environment was crucial for his recovery.

By applying Roy's adaptation model (RAM), I aimed to individualize Mr. Anderson's care based on his unique needs and responses. Recognizing the interconnectedness of his physiological, psychological, and social aspects allowed me to enhance his ability to adapt to the challenges posed by his health condition, ultimately promoting overall well-being and a smoother transition back to his home environment.

---

### Roger's Science of Unitary Human Beings Theory

Martha Rogers's science of unitary human beings theory is a nursing theory that diverges from traditional medical models by focusing on the unitary nature of human beings within the universe. Developed in the 1970s, Rogers's theory posits that individuals are inseparable from their environment and are characterized by irreducible, indivisible energy fields. In this model, human beings are viewed as open, infinite energy fields that interact with the environment in continuous and evolving patterns (*Rogers's theory of unitary human beings*, n.d.).

Rogers's theory emphasizes the concept of "universe-human-environment process," considering individuals as integral parts of the broader cosmic environment. The unitary human being is seen as a unified field, not reducible to the sum of its parts, and continuously evolving in patterns of organization and complexity. The science of unitary human beings theory has profound implications for nursing practice, as it underscores the holistic and individualized nature of care. Rogers proposed that nursing interventions should be directed toward patterning and repatterning the energy fields of individuals to promote health and well-being. She advocated for innovative and alternative approaches to health care that recognize the uniqueness of each individual and the dynamic interactions between the person and the environment (*Rogers's theory of unitary human beings*, n.d.).

While Rogers's theory has been considered abstract and challenging to apply in certain healthcare settings, it has contributed significantly to the evolution of nursing thought. It has influenced the development of holistic nursing practices, emphasizing a nonreductionist perspective and encouraging nurses to explore innovative ways of understanding and enhancing the well-being of individuals within the broader context of the universe. Some argue, however, that the lack of robust empirical evidence supporting the theory, complex terminology, and its limited applicability across diverse nursing contexts raises questions about its practical utility. Despite these criticisms, Rogers's science of unitary human beings theory has sparked important discussions in the nursing community and continues to shape the theoretical landscape of the profession.

### Watson's Theory of Human Caring

Jean Watson's theory of human caring, introduced in the 1970s and further developed over the years, is a foundational nursing theory that emphasizes the importance of the interpersonal relationship between the nurse and the patient. At the core of Watson's theory is the belief that caring is central to the discipline of nursing and

constitutes the essence of the nurse-patient connection. Watson’s theory incorporates both humanistic and holistic elements, focusing on the spiritual, emotional, and psychological dimensions of care in addition to the physical aspects (Watson Caring Institute, n.d.b). The theory of human caring outlines ten “carative factors” (now called 10 Caritas Processes), which is a framework for caring-healing arts to complement conventional medicine, that serve as a guide for nursing practice (Table 1.3) (Watson Caring Institute, n.d.b).

Carative Factor	Explanation	Example
Formation of a humanistic-altruistic system of values	Involves cultivating a sense of commitment to the well-being and dignity of others. This factor emphasizes the importance of altruism and a value system centered on human needs.	A nurse takes time to genuinely listen to a patient’s concerns, demonstrating a commitment to understanding and supporting their well-being.
Instillation of faith-hope	Focuses on fostering and sustaining a positive outlook and belief in the possibilities of healing and recovery. This factor aims to instill faith and hope in the patient’s ability to overcome challenges.	A nurse provides encouragement and support to a patient diagnosed with a chronic illness, emphasizing the potential for improvement and recovery.
Cultivation of sensitivity to self and others	Involves developing an awareness and appreciation of one’s own experiences and emotions, and those of others. This factor emphasizes the importance of empathy and sensitivity in nursing care.	A nurse reflects on personal experiences to better understand the emotions of a grieving patient, creating a more empathetic and supportive connection.
Promotion of a helping-trusting, human-caring relationship	Emphasizes the creation of a trusting and supportive relationship between the nurse and the patient. This factor underscores the significance of the therapeutic alliance in promoting healing.	A nurse establishes trust with a new patient by actively listening, being transparent about treatment plans, and demonstrating genuine care and empathy.
Promotion and acceptance of the expression of positive and negative feelings	Encourages an open and nonjudgmental environment where patients feel free to express a range of emotions. This factor recognizes the therapeutic value of emotional expression.	A nurse validates a patient’s frustration or anxiety, creating a safe space for the patient to openly discuss and cope with their emotions.
Systematic use of the scientific problem-solving method	Involves the application of critical thinking and evidence-based practice to address healthcare challenges. This factor emphasizes the importance of a systematic and analytical approach.	A nurse analyzes a complex patient case, incorporating evidence-based guidelines and collaborating with the healthcare team to develop an effective care plan.
Promotion of interpersonal teaching-learning	Focuses on facilitating a dynamic and interactive teaching-learning process between the nurse and the patient. This factor highlights the significance of education and mutual learning in health care.	A nurse engages in a conversation with a patient, providing information about their condition and involving them in decision-making to enhance understanding and collaboration.

**TABLE 1.3** Carative Factors of the Theory of Human Caring

Carative Factor	Explanation	Example
Provision for a supportive, protective, and/or corrective mental, physical, sociocultural, and spiritual environment	Involves creating an environment that promotes the patient's well-being on multiple levels, including mental, physical, social, cultural, and spiritual aspects.	A nurse ensures a quiet and calm environment for a patient recovering from surgery, incorporating cultural considerations and addressing spiritual needs.
Assistance with gratification of human needs	Focuses on helping patients meet their basic and higher-level needs, recognizing the importance of addressing both physical and existential requirements for well-being.	A nurse assists a bedridden patient with activities of daily living while also exploring ways to fulfill the patient's psychological and spiritual needs during their recovery.
Allowance for existential-phenomenological forces	Involves acknowledging and exploring the unique lived experiences and perspectives of individuals. This factor emphasizes the significance of recognizing the patient's existential journey.	A nurse engages in reflective conversations with a terminally ill patient, allowing them to share their thoughts and feelings about the meaning and purpose of life during their end-of-life care.

**TABLE 1.3** Carative Factors of the Theory of Human Caring

Watson's theory encourages nurses to move beyond task-oriented care and connect with patients on a deeper, more meaningful level. It emphasizes the transformative power of caring, not only in promoting physical healing but also in fostering a sense of well-being and dignity. The theory of human caring has influenced nursing education, practice, and research, contributing to the development of person-centered approaches to health care and promoting the idea that caring is an essential and transcendent aspect of the nursing profession.

## 1.6 Application of Theories in Nursing Practice

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the link between nursing theory and nursing knowledge
- Discuss how nursing theories help shape the future of nursing
- Recognize the use of nursing theory in the application of standards of nursing practice

In the dynamic realm of nursing practice, the application of theoretical frameworks guides the approach to patient care. This section delves into the multifaceted ways in which nursing theories are integrated into daily nursing practice, shaping the actions and decisions of healthcare professionals. As we explore the practical application of these theoretical foundations, we uncover the pivotal role they play in informing and elevating the standards of nursing care. From providing a structured decision-making framework to influencing ethical considerations and patient outcomes, nursing theories emerge as essential tools that bridge the gap between knowledge and practice.

### Link Between Theory and Knowledge in Nursing

The link between theory and knowledge is the foundation on which the entire practice of nursing stands. Nursing theory acts as the compass that guides how nurses approach patient care. It also provides a structured framework shaping the knowledge that nurses acquire through education. This **theoretical knowledge** of established concepts forms the basis for understanding the complexities of health care and the unique role of nursing within it. As nurses apply what they have learned to real-life situations, the theoretical knowledge becomes **experiential knowledge**—it is the practical, hands-on learning that happens when directly caring for patients. This practical experience, in turn, feeds back into theoretical knowledge, enriching and shaping it based on the real-world scenarios encountered. The interplay between nursing theory and knowledge is dynamic and continuous, creating a cycle that ensures theoretical understanding evolves with the practical realities of patient care. This connection highlights the

importance of a well-rounded, dynamic approach to knowledge that encompasses both theory and hands-on experience.

### Theoretical Knowledge

Nursing theory and theoretical knowledge are interconnected and mutually beneficial. The link between them is integral to the development and advancement of the nursing profession. Nursing theory provides a framework for understanding and organizing knowledge within the field, guiding nursing practice, education, and research. Theoretical knowledge encompasses the concepts, principles, and models derived from nursing theories. These theories serve as the foundation for guiding nursing practice, influencing the way nurses approach patient care and fostering a deeper understanding of the nurse's role.

Theoretical knowledge in nursing, derived from nursing theories, empowers nurses with a structured framework for critical thinking, enabling them to make informed decisions and provide holistic care. This knowledge not only informs nursing education, in which students learn the principles and concepts that underpin the profession, but also facilitates ongoing research efforts. Nursing theories guide research design, hypothesis formulation, and results interpretation, contributing to the growth of EBP. Moreover, the link between nursing theory and theoretical knowledge is essential for nurturing a professional identity among nurses, emphasizing the unique contributions of nursing to health care. As healthcare landscapes evolve, this theoretical foundation helps nurses adapt to new challenges while maintaining the core principles of the profession, ultimately enhancing the quality of patient care and the professionalism of the nursing field.

### Experiential Knowledge

The link between nursing theory and experiential knowledge is dynamic and integral to providing safe and effective care. Imagine nursing theory as a roadmap for understanding and guiding patient care. Theoretical knowledge, born from these theories, is the foundational understanding gained through education, offering nurses a structured framework for practice. As nurses apply these theories in real-life scenarios, theoretical knowledge transforms into experiential knowledge—a hands-on, practical understanding gained through patient interactions and clinical experiences. The link between nursing theory and experiential knowledge is a dynamic loop, in which theoretical understanding both informs and evolves through hands-on experience, ensuring nursing knowledge remains adaptable and responsive to the ever-changing landscape of health care.

### Reflective Skills

The connection between nursing theory and **reflective skills** is pivotal in fostering a culture of continuous learning and improvement within the nursing profession. Reflective skills involve the ability to critically analyze and thoughtfully contemplate one's own experiences, actions, and decisions and then learn from them. The application of nursing theory in practice provides a rich source of experiences for nurses to reflect on. Through reflective practices, nurses can assess the alignment of their actions with theoretical principles, identify areas for improvement, and refine their approaches to patient care. This reflective process enhances self-awareness, encourages critical thinking, and contributes to ongoing professional development.

The synergy between nursing theory and knowledge gained from reflection allows nurses to bridge the gap between theory and practice, fostering a deeper understanding of the complexities inherent in healthcare delivery. As nurses engage in reflective practices, they not only refine their clinical skills but also contribute to the evolution of nursing theories by providing real-world insights and feedback. This iterative relationship between nursing theory and reflective knowledge ultimately promotes a culture of continuous improvement, ensuring that nursing practice remains evidence based, person centered, and adaptable to the ever-changing landscape of health care.

### Shaping the Future Development of Nursing

Nursing theories are guiding forces that shape the future development of nursing, contributing to the profession's evolution and ensuring its continued relevance in dynamic healthcare landscapes. These theoretical frameworks play a crucial role in defining nursing as a profession, providing a conceptual roadmap that delineates the unique identity and contributions of nurses within the healthcare spectrum. Simultaneously, they guide the establishment of professional limits and ethical boundaries, maintaining the integrity and trustworthiness of nursing practice. Additionally, nursing theories direct the recommendations for future education, ensuring that curricula and learning strategies align with the evolving needs of health care and equip nurses with the knowledge and skills required for

contemporary practice. Furthermore, these theories inform the development of practice guidelines, guiding nurses in delivering person-centered care while navigating technological advancements and ethical considerations.

### Defining Nursing as a Profession

Nursing theories play a pivotal role in shaping the future of nursing by contributing to the definition of nursing as a distinct and evolving profession. These theoretical frameworks provide a conceptual foundation that extends beyond the technical aspects of patient care, offering a philosophical understanding of the nursing role. By delineating the fundamental principles and values inherent in nursing practice, theories serve as a guidepost for current and future nurses, shaping their professional identity. They emphasize not only the acquisition of clinical skills but also the importance of empathy, advocacy, and holistic patient care.

Nursing theories also contribute to the nursing profession by articulating the unique body of knowledge that constitutes the nursing profession. This body of knowledge encompasses not only clinical expertise but also the ability to navigate the intricate dynamics of the nurse-patient relationship and the broader healthcare context. As nursing adapts to advancements in technology, changes in healthcare delivery, and evolving patient needs, nursing theories provide a stable foundation, ensuring that the essence of the profession remains rooted in its foundational values.

### Professional Limits and Boundaries

Nursing theories play a crucial role in shaping the future of nursing by providing a framework that helps delineate professional limits and boundaries. These theoretical frameworks establish ethical guidelines and standards that guide nurses in navigating complex situations and making decisions within their scope of practice. By emphasizing the importance of ethical considerations, patient autonomy, and confidentiality, nursing theories contribute to defining the boundaries of professional conduct. As health care evolves and technology advances, nursing theories help establish limits on the integration of new practices and technologies, ensuring that ethical principles and patient safety remain at the forefront.

Additionally, nursing theories assist in clarifying the collaborative nature of health care and the boundaries between different healthcare professions. They provide a foundation for interdisciplinary collaboration, defining the unique contributions of nursing within the broader healthcare team. This collaborative understanding is essential for shaping the future of nursing as healthcare systems become increasingly integrated and team oriented.

Nursing theories also contribute to the ongoing development of ethical guidelines and policies that regulate the profession. By engaging with ethical frameworks, nurses are better equipped to address emerging ethical challenges, set professional limits, and advocate for the well-being of their patients. This proactive approach to defining professional limits ensures that nursing remains a trusted and ethical profession in the face of evolving healthcare landscapes.

### Directing Future Education Recommendations

Nursing theories significantly influence the future of nursing by serving as guiding principles for directing education recommendations. These theoretical frameworks contribute to the ongoing development and refinement of nursing education by providing a structured foundation for curricula and educational programs. By incorporating nursing theories into educational strategies, educators can impart not only technical skills but also a deeper understanding of the profession's underlying values and principles. Nursing theories guide the identification of essential competencies, shaping the educational landscape to align with the evolving needs of health care.

In addition, nursing theories contribute to the creation of educational pathways that emphasize critical thinking, cultural competence, and ethical decision-making. As the healthcare environment becomes increasingly complex, these theoretical foundations help educators prepare future nurses to navigate diverse patient populations, emerging technologies, and evolving healthcare systems. The integration of nursing theories into education recommendations ensures that students are equipped not only with practical skills but also with the ability to think critically and adapt to dynamic healthcare challenges.

Additionally, nursing theories inform recommendations for continuous professional development, encouraging a lifelong learning mindset among nurses. By emphasizing the importance of staying abreast of theoretical advancements and incorporating EBPs, nursing theories guide education recommendations that foster a culture of continuous learning. This approach ensures that nurses are prepared to meet the changing demands of health care

and contribute meaningfully to the advancement of the profession.

### Directing Future Practice Guidelines

Nursing theories exert a profound influence on the future of nursing by directing and shaping the practice of the profession. These theoretical frameworks provide a structured foundation for nursing practice, guiding the delivery of person-centered care, and influencing the development of evidence-based protocols. By incorporating nursing theories into practice, nurses gain a deeper understanding of the philosophical underpinnings of their profession, leading to more thoughtful and intentional caregiving.

Nursing theories also contribute to the evolution of future practice by emphasizing holistic and patient-focused approaches. As the healthcare landscape continues to evolve, nursing theories guide practitioners in recognizing the importance of addressing not only the physical needs of patients but also their psychological, social, and cultural dimensions. This holistic perspective fosters a more comprehensive and compassionate delivery of care, aligning with the changing expectations and demographics of healthcare recipients.

Moreover, nursing theories inform the integration of technology and innovation into practice while maintaining ethical standards. As healthcare technologies advance, these theoretical foundations help nurses navigate the ethical considerations of incorporating new tools and interventions, ensuring that patient safety and well-being remain at the forefront of practice.

Additionally, nursing theories contribute to the professional autonomy and decision-making abilities of nurses. By offering a theoretical framework, these theories empower nurses to critically assess situations, make informed decisions, and advocate for the best interests of their patients. This empowerment is crucial for shaping the future of nursing practice in a healthcare environment that demands adaptability, critical thinking, and a strong ethical foundation.

### Application of Theory in Nursing Practice Standards

The application of nursing theory in nursing practice standards is a fundamental aspect that enriches and informs the delivery of high-quality patient care. Nursing theories provide a theoretical framework that guides the development and refinement of practice standards, ensuring that they align with the profession's core values and principles. By incorporating nursing theories into practice standards, healthcare organizations and professionals establish a solid foundation for decision-making, care planning, and evaluation of outcomes. For instance, a theory emphasizing person-centered care may influence practice standards to prioritize individualized and holistic approaches to patient care. Furthermore, nursing theories contribute to the establishment of ethical guidelines within practice standards, guiding nurses in navigating complex ethical dilemmas and upholding the integrity of the profession. This integration of theory into practice standards not only elevates the overall quality of care but also fosters a shared understanding among healthcare professionals, reinforcing a commitment to evidence-based and theoretically informed practice.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Linking Nursing Theories to Patient Safety

The QSEN initiative plays a crucial role in enhancing clinical safety and promoting excellence in patient care. The QSEN focuses on integrating essential competencies into nursing education and practice to ensure that nurses are equipped to deliver safe and high-quality care. When examining the link between nursing theories and clinical safety within the QSEN framework, it becomes evident that theoretical foundations contribute significantly to shaping nurses' understanding of safety principles, risk mitigation, and delivery of patient-centered care.

- **Integration of EBP:** Nursing theories serve as the backbone for EBP, a fundamental component of QSEN. Theoretical frameworks guide nurses in critically evaluating evidence, making informed decisions, and implementing best practices to enhance patient safety. The integration of nursing theories into education ensures that nurses understand the theoretical underpinnings of evidence-based care, promoting a culture of continuous improvement and patient safety.
- **Patient-centered care:** QSEN emphasizes patient-centered care as a key competency, aligning with many

nursing theories that prioritize holistic and individualized approaches. Theoretical perspectives such as Watson's theory of human caring or Peplau's theory of interpersonal relations provide a foundation for understanding the importance of establishing meaningful nurse-patient relationships, communicating effectively, and addressing patients' unique needs. This theoretical grounding contributes to safer and more patient-focused clinical practices.

- **Teamwork and collaboration:** Nursing theories that highlight the collaborative nature of health care, such as Roy's adaptation model or Orem's self-care deficit nursing theory, align with QSEN's focus on teamwork and collaboration. Theoretical frameworks guide nurses in understanding their roles within interdisciplinary teams, fostering effective communication, and promoting a collaborative approach to patient care. This integration enhances clinical safety by ensuring clear communication and coordination among healthcare team members.
- **Safety competencies:** The QSEN identifies safety as a core competency, and nursing theories provide the theoretical basis for understanding the principles of safety in health care. Theoretical perspectives, such as Leininger's culture care theory or Henderson's nursing need theory, contribute to nurses' understanding of factors influencing patient safety, including cultural considerations and meeting patients' basic needs. This theoretical knowledge informs safe and culturally competent care delivery.
- **Informing continuous quality improvement:** Many nursing theories emphasize the importance of continuous quality improvement, aligning with QSEN's commitment to ongoing enhancement of healthcare practices. Theoretical foundations guide nurses in critically assessing their actions, reflecting on patient outcomes, and implementing changes to improve care processes. This integration supports a culture of continuous learning and adaptation, contributing to sustained clinical safety improvements.
- **Informatics integration:** Nursing theories contribute to the integration of informatics skills, aligning with QSEN's focus on informatics competency. Theoretical frameworks guide nurses in understanding how to use information and technology to support decision-making, enhance communication, and improve patient outcomes. The theoretical grounding in informatics ensures that nurses can navigate and utilize health information systems effectively, promoting safe and efficient care practices. This integration supports QSEN's goal of preparing nurses to use technology and information systems to deliver and enhance patient care while aligning with theoretical perspectives that emphasize the role of technology in health care.

---

### Decision-Making Framework

The application of nursing theory as a decision-making framework is a cornerstone of effective and person-centered care. Nursing theories provide a structured and comprehensive foundation that guides nurses in making informed decisions across various healthcare scenarios. These theoretical frameworks help nurses analyze situations, understand patient needs, and prioritize care based on established principles. For instance, a nursing theory emphasizing the importance of environmental factors may prompt a nurse to consider how the individual's surroundings impact their well-being.

Moreover, theories focused on the nurse-patient relationship contribute to decision-making by highlighting the significance of communication, empathy, and collaboration. By integrating nursing theory into their decision-making processes, nurses can ensure a more holistic approach that encompasses not only the physical aspects of care but also the psychological, social, and cultural dimensions. This application of nursing theory serves as a valuable tool for enhancing critical-thinking skills, fostering ethical decision-making, and elevating the overall quality of patient care.

### Directing Future Research

The application of nursing theory plays a pivotal role in guiding and shaping future research endeavors within the nursing field. Nursing theories provide a conceptual framework that informs the identification of research priorities, the formulation of research questions, and the interpretation of findings. By grounding research in established nursing theories, researchers can build on a solid theoretical foundation, ensuring that studies align with the core principles and values of the profession.

Additionally, nursing theories offer a lens through which researchers can explore and understand complex phenomena, guiding the development of hypotheses and conceptual frameworks. For example, a nursing theory emphasizing patient empowerment may direct research efforts toward interventions that enhance patient engagement in their care. This application of nursing theory not only contributes to the generation of new

knowledge but also ensures that research outcomes are relevant and applicable to the practical realities of nursing practice. As nursing continues to evolve, the integration of nursing theory in research remains instrumental to advancing the profession's evidence base and promoting EBP.

## Summary

### 1.1 Evolution of Nursing and Nursing Practice

The discipline and practice of nursing have undergone significant transformations throughout their history, evolving from a variety of primarily task-oriented roles to a dynamic and complex profession. Dating back to figures like Florence Nightingale, nurses have likewise evolved, shifting their focus from basic care to a holistic approach that considers the physical, emotional, and social aspects of patient well-being. In the contemporary landscape, several trends shape nursing practice, including the increasing emphasis on technology, with EHRs and telehealth becoming integral to healthcare delivery. Other important trends to consider are the continued nursing shortage; increased requirements for higher education, including the proliferation of online nursing programs; and recognition of nurses' essential need for self-care. Today, the art and science of nursing practice are evident in the balance between the compassionate, interpersonal aspects (art) and the evidence-based, technical components (science). This balance underscores the multifaceted nature of contemporary nursing, reflecting its rich history and adaptability to the evolving healthcare landscape.

### 1.2 Nursing Education Programs

The diverse landscape of nursing education is composed of various levels of education, from practical and vocational programs to advanced degrees, each contributing uniquely to the development of nursing professionals. The licensure process, overseen by regulatory bodies, serves as a crucial gateway to nursing practice, ensuring that individuals meet essential qualifications and competencies. The culmination of this journey in examinations and practical assessments marks the entry point to a fulfilling career in health care. It also lays the foundation for a lifelong commitment to learning and adherence to best practices and ethical standards.

Nursing education encompasses a range of programs, each tailored to specific career aspirations. Licensed practical nurses and LVNs undergo specialized 12- to 18-month programs that focus on practical nursing skills and basic education, enabling them to work under supervision in roles such as medication administration and wound care. Associate degree in nursing programs, spanning two years, prepare individuals for RN roles, offering a broader foundation than LPN/LVN programs. Nurses prepared with ADN engage in patient assessments, care planning, and medication administration, with training for more independent clinical decisions. Bachelor of science in nursing programs, which are typically four years, provide comprehensive education covering clinical skills, theory, research, leadership, and public health, enabling graduates to participate in complex patient care, decision-making, and coordination. The BSN is a notable option for entry into professional nursing practice, reflecting the evolving complexity of health care and offering expanded career opportunities.

Graduate-level degrees such as MSN and doctoral degrees (DNP/PhD) equip nurses for advanced roles in leadership and research. The AACN contributes to education standards through *The Essentials*, which outlines the core principles for ensuring competency at each level of education. The licensure process ensures that nurses, from LPNs to advanced practitioners, adhere to competency and ethical standards, while ongoing education, career development, and specialty certifications foster continuous professional growth and contribute to the highest quality of patient care.

### 1.3 Nursing as a Profession

The scope of practice in nursing delineates the authorized limits within which nurses operate, encompassing roles, responsibilities, and interventions shaped by education, experience, and certifications. Regulatory bodies like state BONs and national and international organizations such as the ANA and the ICN establish and guide these scopes, emphasizing autonomy, collaboration, advocacy, education, and ethical conduct. The ICN plays a global role, focusing on principles that acknowledge nurses as autonomous professionals, stressing collaboration, advocating for patients, and promoting ongoing education and ethical standards. The ANA significantly shapes practice within the United States through documents like the *Scope and Standards of Practice*, influencing policies and maintaining high-quality nursing standards. State BONs define, regulate, and update the scope of practice at the jurisdictional level.

Nursing standards, including a code of ethics, provide a comprehensive framework for conduct, emphasizing person-centered care, professionalism, safety, and continuous learning. The Quality and Safety Education for

Nurses (QSEN) initiative, though not establishing formal standards, influences nursing education by emphasizing core competencies such as person-centered care, teamwork, EBP, quality improvement, safety, and informatics.

Nursing roles encompass caregiving, decision-making, management of care, communication, advocacy, and education. As caregivers, nurses address holistic patient needs, utilizing assessments, care plans, and ongoing monitoring. Decision-making involves clinical judgment, prioritization, resource allocation, and adaptation to change. In the role of a manager of care, nurses coordinate interdisciplinary teams, navigate healthcare systems, and ensure safety and quality. Communication is integral to nurses' roles as liaisons, advocates, and educators, fostering understanding and trust among patients and the healthcare team. Advocacy involves vocal support for patients' rights and well-being, extending to systemic efforts for equitable health care. Last, as educators, nurses empower patients and communities through clear and accessible health information, contributing to informed decision-making and better health outcomes.

## 1.4 History and Evolution of Nursing Theories

The evolution of nursing theory highlights the progressive development of conceptual frameworks that guide the nursing profession. Over time, nursing theories have evolved from early models emphasizing basic care to more complex and comprehensive frameworks that consider various factors influencing health care. Elements of a nursing theory typically include concepts, definitions, assumptions, and phenomena that collectively provide a systematic and organized approach to nursing practice. These elements help nurses understand and interpret their roles with respect to patient care and the broader healthcare environment.

In discussing the domains of nursing philosophy in relation to clinical practice, it is essential to consider the metaparadigm concepts of person, environment, health, and nursing. Philosophical perspectives guide nurses in understanding the interconnectedness of these domains and how they shape the delivery of care. Clinical judgment in nursing involves the application of these domains, enabling nurses to adopt a holistic approach that not only addresses the physical needs of each patient but also considers their unique experiences, the environment, and overall well-being. This integration of philosophy into clinical practice contributes to a more thoughtful and person-centered approach to nursing care.

## 1.5 Selected Nursing Theorist

Nursing theorists throughout history have played crucial roles in shaping the profession by developing frameworks and models that guide nursing practice. One prominent figure is Florence Nightingale, often considered the founder of modern nursing, whose environmental theory emphasized the impact of the environment on health. Later theorists like Hildegard Peplau focused on interpersonal relationships in nursing, while Virginia Henderson emphasized the importance of meeting patients' basic needs. Jean Watson's theory, grounded in human caring, and Madeleine Leininger's cultural care theory further expanded the scope of nursing. The interdisciplinary foundation for nursing theories is evident as these theories draw from various fields such as psychology, sociology, and biology to provide comprehensive frameworks for understanding and improving patient care. In current practice, nursing theorists continue to influence health care: for example, Patricia Benner's novice to expert model guides professional development, and Dorothea Orem's self-care deficit theory informs approaches to person-centered care. Recognizing and integrating these nursing theories into practice enhances the profession's ability to deliver holistic and person-centered care.

## 1.6 Application of Theories in Nursing Practice

The interconnection between nursing theory and nursing knowledge serves as the cornerstone of the nursing profession. Nursing theories provide a conceptual framework that guides the acquisition and application of knowledge in practice. They serve as guiding principles that not only shape current nursing practice but also play a pivotal role in envisioning the future of the profession. By defining the unique identity and contributions of nurses within health care, nursing theories contribute to the professionalization of the field. Moreover, these theoretical foundations actively influence the development of standards in nursing practice, ensuring that ethical guidelines and person-centered care remain central. As nurses apply these theories in real-life situations, they navigate complex scenarios with a structured decision-making framework, ultimately elevating the overall quality and integrity of patient care. In essence, the symbiotic relationship between nursing theory, nursing knowledge, and practice standards underscores their collective role in shaping the current and future landscape of nursing.

## Key Terms

- AACN Essentials of nursing education** the core principles and competencies set by the American Association of Colleges of Nursing for each level of nursing education
- adaptation theory** a theory that focuses on the dynamic process of adaptation that individuals undergo in response to changes in their environment
- advocate** an individual who actively and vocally supports, defends, or promotes the rights, interests, and well-being of another person or a group
- American Nurses Association (ANA)** one of the largest and most influential professional nursing organizations in the United States
- associate degree in nursing (ADN)** a two-year program offered by various educational institutions that is designed to prepare individuals for a career as a registered nurse (RN)
- assumption** a foundational belief or proposition that is accepted without direct empirical evidence
- autonomy** an individual's ability to make decisions and determine courses of actions based on being well informed, giving consent, and volunteering without coercion
- bachelor of science in nursing (BSN)** comprehensive four-year degree program designed to prepare individuals for a career as a registered nurse (RN)
- beneficence** ethical principle that underscores the obligation to do good and promote the well-being of patients
- board of nursing (BON)** a regulatory body tasked with overseeing the practice of nursing within its jurisdiction, typically a state or territory
- career development** a broad spectrum of activities aimed at advancing a nurse's professional trajectory
- caregiver** an individual who provides physical, emotional, or practical support to individuals in need of assistance due to illness, disability, age-related challenges, or other conditions that impact their ability to perform daily activities independently
- caring** concept of providing compassionate and empathetic attention to individuals
- clinical judgment** utilizing nursing knowledge, critical thinking, and clinical reasoning, drawing from evidence, theories, and interdisciplinary insights to make informed and patient-centered decisions
- code of ethics** comprehensive set of principles that defines the ethical responsibilities and standards for an individual or a group
- communicator** an individual who engages in the process of conveying information, ideas, or messages to others
- concept** an idea that serves as a foundational element of a theory, contributing to its overall structure and coherence
- concrete** representing specific and tangible ideas or objects that can be directly observed or experienced
- confidentiality** maintaining patient privacy in terms of health and personal information
- continuing education (CE)** ongoing educational activities
- decision-maker** an individual or entity responsible for making choices or reaching conclusions in a particular context
- definition** a clear and precise explanation of the meaning of a concept or term
- descriptive theory** a theory that aims to systematically and objectively describe phenomena
- developmental theory** a theory that is influenced by broader theories of human development and that explores the stages and transitions individuals go through across the life span
- Doctor of Nursing Practice (DNP)** a practice-focused doctoral degree that emphasizes advanced clinical practice, leadership in healthcare systems, and evidence-based decision-making
- Doctor of Philosophy (PhD) in Nursing** a research-focused doctoral degree that emphasizes the generation of new nursing knowledge through rigorous scientific inquiry
- domain** a broad and overarching area of theoretical exploration or study
- educator** an individual who engages in the process of facilitating teaching and learning
- electronic health record (EHR)** a digital version of a patient's medical history, maintained and shared by multiple providers
- electronic medical record (EMR)** a digital version of a patient's medical history, maintained and used by a single provider
- environment domain** the surroundings, context, and external factors that influence a person's well-being
- experiential knowledge** practical knowledge acquired through direct engagement and hands-on experiences
- general systems theory** the theory that any system, including a healthcare system or an individual patient, can be

viewed as a complex organization of interacting and interrelated components

**hard skills** technical and clinical competencies

**health domain** a dynamic and holistic concept that encompasses the overall well-being of the person, not just the absence of illness or disease

**herbalists** individuals with specific knowledge of herbal remedies and healing practices

**holism** concept that individuals should be viewed and treated as whole beings

**holistic care** a care approach that considers the whole entity, encompassing the physical, psychological, emotional, and spiritual dimensions of an individual patient

**in-service education** ongoing training initiatives provided within healthcare institutions

**International Council of Nurses (ICN)** a worldwide federation of national nursing associations

**licensed practical nurse (LPN)** a graduate of a practical nursing program, possessing the skills and knowledge required for entry-level positions in health care and a passing score on the national licensing examination; synonymous with licensed vocational nurse (LVN)

**licensed vocational nurse (LVN)** a graduate of a practical nursing program, possessing the skills and knowledge required for entry-level positions in health care and a passing score on the national licensing examination; synonymous with licensed practical nurse (LPN)

**manager of care** directing and overseeing the comprehensive delivery of healthcare services

**Master of Science in Nursing (MSN)** an advanced graduate degree that provides nurses with a higher level of education and specialization in various areas of nursing practice

**metaparadigm** a set of overarching concepts and principles that provides a comprehensive framework for understanding a particular discipline or field of study

**nonmaleficence** ethical principle that emphasizes the obligation to do no harm intentionally

**nursing** a profession that encompasses the art and science of providing comprehensive and holistic care to promote and maintain health, prevent illness, and alleviate suffering for individuals, families, and communities

**nursing domain** a fundamental and central concept that defines the unique role, purpose, and responsibilities of the nursing profession

**nursing metaparadigm** a conceptual framework that encompasses four fundamental concepts (person, health, environment, and nursing) central to the discipline of nursing

**nursing philosophy** the compass that guides a nurse's practice, encompassing beliefs about the nature of nursing, patient care, ethical considerations, and the nurse's role within the healthcare system

**nursing practice** the application of nursing knowledge, skills, and principles in the delivery of health care to individuals, families, and communities

**nursing theorist** an individual, typically a nurse with advanced education and experience, who has made significant contributions to the development of nursing theory

**nursing theory** a structured and systematic framework composed of concepts, principles, and propositions that collectively guide and shape the understanding of nursing practice

**person domain** the central focus of nursing philosophy, involving the patient or client

**phenomenon** a specific aspect of interest or an observable occurrence that is the focus of theoretical exploration and study

**philosophy** the exploration of fundamental questions about existence, values, and the human experience through critical inquiry and reflection

**prescriptive theory** a theory that provides guidance on how nursing care should be conducted

**professional nursing organization** collective body formed by nurses to represent and advocate for the interests of the nursing profession

**Quality and Safety Education for Nurses (QSEN)** a collaborative effort to advance and promote the integration of quality and safety competencies into nursing education and practice

**reflective skill** process of examining and evaluating one's own experiences and learning from them

**registered nurse (RN)** a licensed graduate of a nursing program, capable of a broad scope of practice that includes assessing patients, planning care, and collaborating with other healthcare professionals on complex cases

**scope of practice** defined limits and parameters within which a professional is authorized to work, make decisions, and provide services

**self-care** intentional actions and practices that individuals engage in to promote their physical, mental, and emotional well-being

**soft skills** interpersonal abilities and personal attributes

**specialty certification** official recognition of a nurse's expertise in a particular area of nursing

**Standards of Practice** standards designed by the ANA and based on the nursing process that provides a problem-solving-focused approach to nursing practice

**theoretical knowledge** knowledge that is based on established theories and concepts

**theory** a framework of related ideas intended to guide and support action

## Assessments

### Review Questions

- During the Middle Ages, who primarily undertook nursing duties, and where did they provide care?
  - family members in their homes
  - monks and nuns in monasteries and convents
  - herbalists in communities
  - military personnel in wartime hospitals
- What advancements occurred in the nursing profession during the mid-twentieth century?
  - expansion of nursing roles during World War II
  - establishment of the first nursing school
  - embrace of EHRs and telehealth
  - recognition of nurse practitioners as primary care providers
- What milestone marked Florence Nightingale's influence on the formalization and professionalization of nursing education?
  - establishment of the ANA
  - creation of the first nursing school
  - introduction of evidence-based practice
  - development of specialized nursing fields
- What does the "art of nursing" primarily emphasize in patient care?
  - application of evidence-based knowledge
  - technical expertise in medical procedures
  - proficiency in administering medications
  - interpersonal and compassionate dimensions of care
- What nursing program is designed to prepare individuals for entry-level positions in health care and requires graduates to pass the NCLEX-PN for licensure?
  - associate degree in nursing (ADN)
  - bachelor of science in nursing (BSN)
  - master of science in nursing (MSN)
  - licensed practical nurse (LPN)/licensed vocational nurse (LVN)
- What is a common prerequisite for obtaining licensure as a registered nurse (RN) for both ADN and BSN graduates?
  - completion of a clinical practicum
  - passing the NCLEX-PN
  - completion of a doctoral program
  - passing the NCLEX-RN
- What is the primary goal of the doctor of nursing practice (DNP) program?
  - preparation for leadership roles in academia
  - research-focused doctoral education
  - emphasis on advanced clinical practice, leadership, and evidence-based decision-making

- d. integration of theory, research, and public health in nursing practice
- 8.** What distinguishes BSN-prepared nurses from ADN-prepared nurses?
- a. broader education including leadership, research, and public health
  - b. shorter duration of education
  - c. limited involvement in patient care
  - d. increased focus on practical nursing skills
- 9.** Which global organization significantly influences the development of the nursing profession on a global scale and offers guidance regarding the scope of practice for nurses around the world?
- a. state BONs
  - b. QSEN
  - c. ICN
  - d. ANA
- 10.** Which organization primarily oversees the regular review and updating of guidelines within a given jurisdiction to align with advances in health care, changes in legislation, and evolving societal needs related to nursing practice within a specific state or jurisdiction?
- a. ANA
  - b. QSEN
  - c. state BONs
  - d. ICN
- 11.** The nurse is precepting a nursing student during a clinical rotation. What statement made by the student would warrant further education?
- a. “Nursing standards serve as a framework for providing safe, quality care.”
  - b. “Nursing standards align with the overarching principles of the nursing profession.”
  - c. “Nursing standards articulate the expectations and ethical conduct required of nurses.”
  - d. “Nursing standards may be incorporated into practice if the nurse chooses to do so.”
- 12.** The nurse takes proactive measures to prevent falls, such as using bed alarms and assisting patients with mobility. What ethical principle do these measures emphasize?
- a. autonomy
  - b. privacy
  - c. nonmaleficence
  - d. justice
- 13.** What is the primary purpose of nursing theories?
- a. to dictate medical interventions
  - b. to provide a framework for nursing practice
  - c. to establish healthcare policies
  - d. to replace medical guidelines
- 14.** How did nursing theories contribute to the historical development of the nursing profession?
- a. by focusing on task-oriented practices
  - b. by discouraging research in nursing
  - c. by offering a basis for nursing interventions
  - d. by limiting the roles of nurses
- 15.** In the late twentieth century, what shift occurred in the development of nursing theories?
- a. a decline in the emphasis on evidence-based practice
  - b. a move toward task-oriented approaches
  - c. a decrease in the importance of research integration

- d. a proliferation of theories addressing various aspects of nursing, health, and care
- 16.** How do assumptions contribute to the theoretical framework in nursing?
- by providing empirical evidence
  - by establishing shared understanding
  - by forming foundational beliefs
  - by guiding research design
- 17.** What does the term “environment” in nursing philosophy encompass?
- a multifaceted combination of physical, social, cultural, economic, and global factors
  - solely individualized influences
  - physical surroundings without cultural implications
  - exclusively cultural values and customs without broader influences
- 18.** Who emphasized the nurse-patient relationship as a therapeutic and collaborative partnership in psychiatric nursing?
- Jean Watson
  - Patricia Benner
  - Hildegard Peplau
  - Dorothea Orem
- 19.** Who defined nursing as helping individuals achieve their highest level of independence in activities of daily living?
- Faye Abdellah
  - Patricia Benner
  - Florence Nightingale
  - Virginia Henderson
- 20.** What type of nursing theory provides recommendations, interventions, or strategies for achieving specific nursing goals?
- adaptation theory
  - descriptive theory
  - developmental theories
  - prescriptive theory
- 21.** What nursing theory views individuals as open, infinite energy fields that interact with the environment in continuous and evolving patterns?
- Orem’s self-care deficit nursing theory
  - Roger’s science of unitary human beings theory
  - Leininger’s culture care theory
  - Watson’s theory of human caring
- 22.** In what phase of Peplau’s theory of interpersonal relations does the patient utilize the help offered by the nurse to address problems and gain a better understanding of their situation?
- orientation phase
  - identification phase
  - exploitation phase
  - resolution phase
- 23.** A nursing instructor is talking with a student about the link between theory and knowledge in nursing practice. What statement made by the nursing student would warrant further education?
- “Nursing theory benefits theoretical knowledge, and theoretical knowledge benefits nursing theory.”
  - “Theoretical knowledge is derived from theory and provides a framework for critical thinking.”

- c. “Theories are applied within clinical practice as experiential knowledge.”
  - d. “Although reflection impacts knowledge in nursing practice, it does not impact the basic nursing theories.”
- 24.** What is the foundational role of nursing theory in the practice of nursing?
- a. providing hands-on clinical experience
  - b. guiding patient communication
  - c. shaping the approach to patient care
  - d. offering administrative insights
- 25.** What comment from a nursing student reflects the need for further education regarding how incorporating nursing theory into research enhances the evidence base of the nursing profession?
- a. “Nursing theories ensure studies align with the core principles and values of the profession.”
  - b. “The alignment of EBP with the core principles of the nursing profession is not contingent upon the incorporation of nursing theory into research.”
  - c. “The integration of nursing theory in research ensures research outcomes are relevant and applicable to the practical realities of nursing practice.”
  - d. “Understanding how nursing theory informs research priorities is key to advancing the evidence base and promoting evidence-based practice in nursing.”

### Check Your Understanding Questions

1. List three current trends in nursing.
2. What is the difference between soft skills and hard skills in nursing?
3. Why is there an increasing emphasis on higher education requirements for entry into the nursing profession?
4. What is the primary purpose of licensure in nursing?
5. What is the primary advantage of ADN-prepared nurses over LPNs/LVNs?
6. What is the primary purpose of defining the scope of practice for nurses?
7. What are the six QSEN core competencies that align with nursing standards and guide nursing education?
8. Name and define at least three of the key elements that comprise nursing theories.
9. What are the four domains that make up the nursing metaparadigm?
10. Why is Florence Nightingale referred to as the founder of modern nursing?
11. List three carative factors from Jean Watson’s theory of human caring.
12. How do theories help to define nursing as a profession?
13. In directing future research, how do nursing theories contribute to the formulation of research questions?

### Reflection Questions

1. How has the COVID-19 pandemic influenced the rise of telehealth in nursing?
2. How does continuing education contribute to the professional growth and development of nurses?
3. How do cultural competence and diversity play a role in your responsibilities as a caregiver?
4. How does the QSEN competency of teamwork and collaboration align with the standards of nursing practice?
5. How do concepts, phenomena, definitions, and assumptions collectively contribute to the development of a nursing theory?
6. How can Dorothea Orem’s self-care deficit nursing theory be applied to promote patient empowerment in contemporary nursing practice?

## What Should the Nurse Do?

1. A patient is expressing emotional distress and requires empathetic support. How should the nurse demonstrate the soft skill of empathy to establish trust and understanding with the patient?
2. A nurse working in a specialized area is considering pursuing specialty certification. What steps should the nurse take to achieve certification?
3. A nurse witnesses a colleague making inappropriate comments about a patient's cultural background. What should the nurse do to uphold standards of professionalism and person-centered care?

In a busy medical-surgical unit, Nurse Rodriguez is assigned to care for Mr. Suarez, a 65-year-old patient admitted with a complex medical history, including diabetes and heart failure. Mr. Suarez has been experiencing difficulty managing his medications at home, leading to frequent hospital admissions. He appears frustrated and overwhelmed.

As Nurse Rodriguez begins her shift, she recognizes the need for a holistic approach to Mr. Suarez's care, considering not only his physical health but also his emotional and social well-being. Applying Dorothea Orem's self-care deficit nursing theory, Nurse Rodriguez assesses Mr. Suarez's ability to engage in self-care and identifies areas where he may need assistance.

During their interactions, Nurse Rodriguez encourages Mr. Suarez to share his challenges and concerns. She involves him in the development of a personalized care plan, emphasizing self-care strategies that align with his capabilities and preferences. Drawing from Orem's theory, Nurse Rodriguez collaborates with the healthcare team to address Mr. Suarez's deficits in self-care, providing education on medication management, diet, and lifestyle modifications.

Throughout the shift, Nurse Rodriguez continuously evaluates Mr. Suarez's response to the care plan, adjusting interventions based on his feedback and observed progress. By the end of the shift, Mr. Suarez expresses gratitude for the personalized approach to his care, and Nurse Rodriguez reflects on how the application of Orem's theory facilitated a person-centered and empowering care experience.

4. Identify and discuss the specific elements of Dorothea Orem's self-care deficit nursing theory that Nurse Rodriguez applied in this scenario.
5. How did the self-care deficit nursing theory guide Nurse Rodriguez's assessment, intervention, and evaluation of Mr. Suarez's care?
6. What aspects of patient empowerment and self-care were evident in her nursing actions?

## Competency-Based Assessments

1. Which do you feel is most important in nursing: soft skills or hard skills? Pick a side and debate your position.
2. Research your state board of nursing requirements for RN licensure. Explain the steps involved in obtaining licensure as an RN, including examination requirements and educational criteria, as well as renewing a license.
3. Create an infographic that explains the responsibilities for each of the following nursing roles: caregiver, decision-maker, manager of care, advocate, and educator.
4. Create a five-minute video explaining how Patricia Benner's novice to expert theory can be applied to clinical practice in nursing.

## CHAPTER 2

# Communication

**FIGURE 2.1** Healthcare providers communicate to provide safe, effective care for patients. (credit: “JACKSONVILLE, Fla. (July 19, 2017) – Cmdr. Julie Conrardy” by Jacob Sippel, Naval Hospital Jacksonville, Public Domain)

### CHAPTER OUTLINE

- 2.1 Types of Communication
- 2.2 Models of Communication
- 2.3 Effective Communication
- 2.4 Therapeutic Communication
- 2.5 Barriers to Communication

**INTRODUCTION** Communication was developed thousands of years ago, as people attempted to warn each other about threats and create social communities with nonauditory and auditory methods of communicating. Eventually, communication became making sounds, speaking words, and talking. Communication evolved to pictograms or cave paintings, and finally written word, in the form of hieroglyphics. Methods of communication continue to evolve today, fueled by technological advances. Health care has a similar trajectory, evolving from primitive care to present-day technologies treating and curing diseases. Communication in health care is reliant on both healthcare providers and the patients requiring the care. For example, both the healthcare provider and the patient need to be able to communicate clearly with each other. Healthcare communication was generally unregulated until the 1970s, when the U.S. government decided to moderate communication in health care. In 1975, the Health Communication Division of the International Communication Association was founded, creating a researchable entity of communication and a definition for healthcare communication (Society for Health Communication, 2016). The American Nurses Association (ANA) devotes nine of the Standards of Nursing Practice and Professional Performance entirely to communication, thereby establishing a level of competency for all nurses (ANA, 2015).

Nurses can benefit from understanding the types and models of effective communication to establish therapeutic relationships with patients and encourage health promotion. Communication is foundational in health care and helps patients meet their individual healthcare goals.

## 2.1 Types of Communication

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Compare and contrast different forms of communication
- Define and describe the four levels of communication

Communication in health care is essential. The act of **communication** involves the sharing of ideas and thoughts among people, and it should be clear, honest, and confidential. For healthcare providers to offer care, they require information from the patient, and effective communication is the best way to obtain that information. Patients should feel comfortable sharing medical information with their healthcare providers, and they must never feel intimidated, fearful, or disrespected. This includes sharing trauma from life experiences, such as rape or previous medical incidents involving themselves or their family members. Healthcare communication also includes helping patients navigate the healthcare system, fill out forms, and make appointments.

Healthcare providers must consider the patient's health and general literacy levels when engaging in communication. The ability of a patient to understand and use information to make health-related decisions is known as **health literacy**. For example, does the patient fully comprehend the benefits and drawbacks of a prescription, or does the patient understand the benefit of a follow-up appointment? When a patient has health literacy, they understand the health information being provided.

Healthcare providers should offer culturally competent care to the patient. Providing **culturally competent care** includes meeting and respecting a patient's social, cultural, and linguistic needs while providing care. For example, to provide culturally competent care for a patient who is deaf, the nurse should include an interpreter who is fluent in American Sign Language, which meets the linguistic needs of the patient. When the healthcare provider does not prioritize culturally competent care, gaps in communication occur, and the health care provided may be deficient. Providing for the patient's needs during communication challenges is paramount to patient-centered, high-quality care.

Healthcare providers need to communicate effectively with other members of the healthcare team while maintaining patient confidentiality. The healthcare team is considered **interdisciplinary**, or relating to more than one branch of knowledge, and interdisciplinary care includes team members from other healthcare professions, such as physical therapists or pharmacists. When multiple healthcare professionals from various disciplines collaborate on patient care, communication breakdowns may result. Inadequate or inappropriate communication can lead to errors, compromising patient care and outcomes.

### CULTURAL CONTEXT

---

#### Healthcare Interpreters

Healthcare interpreters used in a healthcare setting should not be family members or healthcare staff members. Family members should not be used because they may not be familiar with medical terms, which may lead to incorrect translation. Healthcare staff members should not be used as interpreters because it can be a violation of patient privacy. Nurses should seek out healthcare interpreters who are certified by the National Board of Certification for Medical Interpreters. The legal requirements for medical interpreters (Title VI of the Civil Rights Act) require organizations that receive federal funds, including Medicare, Medicaid, and the Affordable Care Act, to provide a professional medical interpreter (Patient Engagement Hit, 2022). Healthcare facilities should have lists of preapproved medical interpreters for better communication with patients. Some facilities may use electronic means, such as video chat or a telephone, for interpretation (NCBMI, 2016).

---

#### Forms of Communication

Communication is the sharing of ideas and thoughts among people and the means of sending or receiving information. Communication requires a sender and a receiver. There are five forms of communication: verbal, nonverbal, written, visual, and electronic ([Table 2.1](#)). These forms may be used alone or in combination with another. Communication is better received and understood if more than one form is utilized (Mosaic Projects, n.d.).

For example, when a nurse attends a verbal lecture on the latest medical equipment and has the opportunity to ask questions during the lecture, they are more likely to receive all the intended communication because more than one communication method was utilized: verbal and visual. Combining different forms of communication can make the message clearer for the receiver. To be most effective, nurses should ask the patient their preferred form of communication.

Type of Communication	Example
Verbal	Spoken word
Nonverbal	Facial expressions and gestures
Written	Text messages
Visual	Emojis
Electronic	Electronic health record

**TABLE 2.1** Types of Communication

### Verbal Communication

The term **verbal communication** can be defined as the production of spoken language to send to a listener. Verbal communication can include aspects of pitch, tone, volume, pace, clarity, pronunciation, and content. The pitch of verbal communication can be affected by the situation. For instance, a person who is communicating with an infant may use a higher pitch when talking so the infant can learn sound patterns to develop speech. The tone of the verbal communication can convey information to the listener. For example, an angry person may have a curt or rude tone, which may change the way the communication is received.

Content is important in verbal communication, especially among healthcare providers. When healthcare providers speak medical jargon to patients, much of the intended communication can be lost. Healthcare providers should carefully consider their words when communicating with patients.

Healthcare providers need to recognize that some patients have specific considerations for communication. For example, the patient may be a non-native speaker of the language the healthcare provider is speaking, making communication difficult. Or a patient could have a clinical condition that affects their ability to communicate verbally, such as a stroke or a cleft palate. In these instances, the healthcare provider should carefully consider their communication techniques and make appropriate accommodations when necessary. It is important for nurses to assess the patient's level of health literacy, any medical condition impacting communication, or other barriers when first providing care.

There are specific standards that healthcare providers must respect when providing communication. The **Health Insurance Portability and Accountability Act (HIPAA)**, a federal law creating the national standards to protect sensitive patient health information from being disclosed, describes the dangers of violating patient privacy with careless or unmonitored communication. The HIPAA laws govern not only verbal communication but also all other forms of communication. Healthcare providers need to be familiar with HIPAA laws so that they can assure the patient's privacy and avoid violating the law. For instance, a patient has the right to specify who has access to their chart, and if it is discovered that this right has been violated by the healthcare provider, the healthcare provider can incur criminal penalty with possible fines or jail time (U.S. Department of Health and Human Services, n.d.).

### Nonverbal Communication

The term **nonverbal communication** can be defined as all communication that is not spoken, including facial expressions, posture, eye contact, gestures, and physical touch. When a healthcare provider communicates with a patient, they should make their verbal and nonverbal communication congruent. When noncongruent messages are sent, the receiver is more likely to pay attention to the nonverbal communication than the verbal communication. Head nodding conveys acceptance, and the healthcare provider should use this nonverbal communication when agreeing verbally with the patient.

Eye contact is important for healthcare providers, especially when delivering verbal communication that is unpleasant. If the healthcare provider maintains eye contact throughout the communication, the healthcare provider is more likely to be viewed as respectful and honest (Baugh et al., 2020). Some patient conditions may rely heavily on nonverbal communication. For example, if a patient is blind, using nonverbal communication like touch is appropriate. The healthcare provider should use caution when communicating nonverbally, assessing the patient's situation carefully (Bambaerero & Shokrpourm, 2017).

Healthcare providers should be attuned to diverse cultural norms in nonverbal communication. For example, in some cultures, eye contact is considered disrespectful. When providing culturally competent care, the nurse should ask the patient about their cultural beliefs and respect those beliefs. Healthcare providers can use touch to convey encouragement; however, the healthcare provider should respect the patient's boundaries and cultural norms when using touch.

## UNFOLDING CASE STUDY

### Unfolding Case Study #1: Part 1

The nurse is conducting the initial assessment on a 28-year-old patient who presents to the family walk-in clinic. The patient is accompanied by her 10-year-old son.

Past Medical History	<p>Patient is a mother of one, who cares for her child and older mother in a small apartment. The older mother is homebound and is not present at the appointment. The patient engages in housecleaning to financially support her family; however, the income is inconsistent. Patient has an eighth-grade education, is a native Spanish speaker, and does not speak English. Medical history includes seasonal allergies, sinusitis, and two episodes of COVID-19 in the past two years.</p> <p><b>Family history:</b> Patient's father is deceased, and patient's mother has stage II Alzheimer disease. Patient's son is in good health, talkative, and attentive to his mother.</p> <p><b>Social history:</b> Patient is primary caregiver for older mother and son. No other support systems available. Patient has difficulty shopping and making doctor appointments due to lack of care for the mother. Patient has difficulty communicating in English, so the son translates for his mother.</p> <p><b>No current medications and no known allergies.</b></p>
Nursing Notes	<p><b>1630: Triage Assessment</b></p> <p>Patient responds to gestures but speaks little English. Son provides translation for his Spanish-speaking mother. Patient reports frequent coughing episodes with production of large amounts of yellow sputum, which are exacerbated with activity. Patient is alert and cooperative, but son reports frequent periods of lethargy, sleepiness, and states "Momma feels hot and sweaty." Patient holds the side of her head in her hands. Son reports patient has been complaining of an earache for three days. Patient intermittently grabs at ear and grimaces.</p>
Flow Chart	<p><b>1630: Triage Assessment</b></p> <p>Blood pressure: 142/88 mmHg  Heart rate: 100 beats/minute  Respiratory rate: 24 breaths/minute  Temperature: 101.1°F (38.4°C)  Oxygen saturation: 95 percent on room air  Pain: 8/10 (ear)</p>
Lab Results	<p>CBC: (Abnormal) WBC 17,000 WBCs per microliter (4.5 to 11.0 × 10<sup>9</sup>/L).  Rapid strep test: negative  Rapid COVID test: negative</p>

1. Recognize cues: Which findings from the information provided are most relevant? Which are the highest priority?
2. Analyze cues: Based on the current history and findings, what additional information should be obtained from the patient at this time?

### Written Communication

Any written message, from formal letters to text messages, is considered **written communication**. Written communication may be thought of as the most prevalent form of communication; however, miscommunication can occur with written communication, dependent on the person's learning style and ability to read (Vermeir et al., 2015). To create clear written communication, the healthcare provider should concentrate on providing good structure, clarity, and content. Using paragraphs, punctuation, and line breaks may help the reader better receive the written communication, as reading long paragraphs of text can increase miscommunication. Clarity and content are equally important, as is understanding the patient receiving the message. Written communication can be referred back to by patients for clarification after the encounter with the healthcare provider is over.

Because text messages are not secure, they should not be used for discussing protected health information with other providers. Text messaging is appropriate for providers to communicate with patients if the patient has provided written consent. Utilizing text messaging for patient communication should only be done by following the policies of the healthcare organization. Text messaging can also be used among providers, with secure electronic messaging, using either healthcare facility internal messaging or certain platforms recommended by the healthcare facility as secure, as unsecure communication between providers is more likely to violate HIPAA guidelines.

### Visual Communication

In **visual communication**, visual elements are used to create the message for communication. Visual communication includes forms of communication that can be seen, such as charts, photographs, sketches, videos, models, graphs, and emojis. Healthcare providers rely on visual communication as it can help to explain complex concepts of health (Osbourne, 2006; [Figure 2.2](#)). When creating visual communication, choose images, fonts, and colors carefully, keeping in mind the audience. If the nurse is creating a visual presentation for patients who have visual challenges, such as a patient who has red-green color deficiency, attention to color, font, and background of the communication should be addressed. For example, a patient with visual challenges may have difficulty reading smaller font or distinguishing between colors for font and background.

**FIGURE 2.2** Healthcare providers use communication boards, like this one shown, in patient rooms to communicate with patients. (credit: "Patient Communication Board" by Michel Curi, Flickr, CC BY 2.0)

### Electronic Communication

All communication transmitted electronically is **electronic communication**. Electronic communication can include faxes and text messages that are broadcast, transmitted, stored, or viewed using electronic media like computers or cell phones. Electronic communication is growing in popularity in health care (Yang et al., 2022). Patient portals provide patient access to their own health information. Healthcare providers can readily access most patient records through electronic communication. Electronic communication may help healthcare providers treat patients more effectively, reduce medical errors, and improve patient safety (Rodiewicz et al., 2023). For instance, a healthcare provider could view imaging reports, lab values, or consult with a specialist all in one place to possibly avoid medical error. The **electronic health record (EHR)** and the **electronic medical record (EMR)** are the most common forms of electronic communication between patients and healthcare providers. An EHR is a digital format of a complete medical record of a patient that is able to be shared across multiple healthcare organizations. In contrast, EMRs capture the medical chart within a single healthcare organization and are not transferable to other settings. HIPAA laws govern this electronic information with the HIPAA Security Rule, a national standard to protect a patient's electronic personal health information.

### Listening

The ability to thoughtfully receive and interpret messages is called **listening**. The listener should be able to restate someone's words after the speaker has finished. Listening can be active or passive. When someone listens by giving their full attention, listening to understand, and providing thoughtful input, they are **active listening**; when someone listens to simply hear the messages being sent but may not be mentally or emotionally present and does not engage in the communication process, they are **passive listening**. Healthcare providers should use active listening including both verbal and nonverbal communication. Passive listening includes nonverbal communication only, and if the listener speaks, then it is considered active listening.

Healthcare providers must be actively listening as patients are giving them information that helps them treat the patient safely and effectively. Nurses also need to recognize when the patient may not understand the messages received, even though the patient provided nonverbal communication like a head nod that they understood. For example, when the patient is asked to repeat the instructions received, the nurse may find that there are discrepancies. The nurse needs to ensure the listener understands, preventing discrepancies regarding the patient's medical care.

## Levels of Communication

There are four levels of communication: intrapersonal, interpersonal, small-group, and public communication. The nurse should consider the levels of communication when providing health care. For example, a healthcare provider does not want to use public communication when providing a patient with their test results, as doing so would violate the patient's right to privacy and HIPAA laws. A healthcare provider must use interpersonal communication when speaking with other healthcare providers on the interdisciplinary healthcare team.

### Intrapersonal Communication

Communication with oneself is called **intrapersonal communication**. The practice of reviewing past communication experiences is known as **reflective thinking**, and it plays a crucial role in health care, enabling healthcare providers to adapt and improve their care delivery methods. The practice of reflective thinking in nursing allows the nurse to not only think about communication errors but also reexamine the corresponding actions and lack of communication that occurred. For example, if a nurse makes a medical error when providing the patient with their morning medications, the nurse uses intrapersonal communication to reflect on the incident after it happens, and the chance that the episode would happen again can be decreased.

## REAL RN STORIES

### Using Reflective Thinking about Medical Errors

**Nurse:** Shaleena, RN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 12

**Facility location:** A large metropolitan teaching hospital in Illinois

I was working a twelve-hour shift when I was assigned to a premature infant who weighed 7.1 lb (3.2 kg) and was admitted to the newborn intensive care unit eight weeks ago. During morning rounds, the attending healthcare provider reviewed the laboratory work with me and noted the patient's potassium level was low and prescribed potassium to be given intravenously (IV). I received the prepared potassium IV from the pharmacy and prepared to give the patient the potassium IV. The healthcare provider's order stated the potassium should be given over two hours, so I programmed the medication pump for a two-hour delivery. After one hour, I checked the patient and the medication pump and saw that the medication was done infusing. I immediately reported the medical error to the attending healthcare provider. I closely monitored the patient for the next four hours and completed the necessary paperwork as dictated by the healthcare facility for the medical error. Luckily, the patient did not have any adverse effects from the medical error.

At the end of my shift, I engaged in reflective thinking and strategized ways to prevent future medical errors like this one from occurring. I thought about other situations I had witnessed with errors during medication pump infusions. I journaled about the experience, making sure to describe my feelings and thoughts. I realized after reviewing my journal that I still felt uncomfortable with medication administration and the medication pump, so I decided to ask the nurse manager for additional training with the medication pump. The nurse manager was supportive of my efforts to gain more training.

### Interpersonal Communication

Communication that occurs between two or more people is called **interpersonal communication**. A healthcare provider uses interpersonal communication to establish a relationship with the patient and to communicate with other healthcare providers on the team to provide safe and effective care for the patient. Interpersonal communication can be used during shift report for continuity of care for the patient (Dahm et al., 2022).

## PATIENT CONVERSATIONS

### Establishing a Relationship with a Patient and Family

**Scenario:** A nurse is working in a pediatric healthcare provider's office in a small rural town in Montana, when a

parent presents for a wellness check with a 9-month-old infant.

**Nurse:** Hello, my name is Evan, and I am going to help the healthcare provider care for your child during this visit. What can I help you with today?

**Parent:** Hello, we are here today for Leo's 9-month checkup. He has been fine since our last checkup.

**Nurse:** Has he had any illnesses or problems since his last checkup at 6 months of age?

**Parent:** No, he has been fine.

**Nurse:** Which milestones have you observed since his last checkup? Is he babbling words? Is he crawling? How is he eating?

**Parent:** He is babbling, and it sounds like he is saying "mama," but he does not just say it to me. He is not yet crawling but getting up on his hands and knees and rocking sometimes. I have some questions about his eating.

**Nurse:** What are your questions about his eating? I would be happy to help answer them, you can ask the healthcare provider as well.

**Parent:** I would like to ask you, I feel like you listen when I ask questions, thank you.

**Nurse:** Thank you, now what did you want to ask?

**Parent:** We are feeding him two times a day. When should we move up to three times a day?

**Nurse:** You can move to three times a day. Does Leo seem to want to eat with you?

**Parent:** Yes, he sits at the table with us for breakfast, lunch, and dinner. I feed him at breakfast and lunch, but for dinner we just give him a snack on his tray and a bottle of formula. Should we give him dinner too?

**Nurse:** It is appropriate at his age to be fed three times a day. After nine months you can also start giving Leo two healthy snacks a day.

**Parent:** Thank you so much for this information. I really appreciate you.

**Nurse:** You are welcome. I am willing to answer any questions you have, and if there is anything I have not currently addressed, please feel free to reach out to me again.

---

### Small-Group Communication

When communication occurs among three or more people, it is called **small-group communication**. Small-group communication is a formal process of interacting verbally and nonverbally within a group where individuals perform certain roles. Some examples of small-group communication among healthcare providers could be bedside rounds or a more formal care conference about the patient. Each healthcare provider brings their expertise to add to the care of the patient.

The nurse functions in small-group communication as both a care provider and an advocate for the patient. The nurse as advocate for the patient is one of the many roles a nurse can have on the healthcare team. The nurse uses small-group communication to plan and participate in interdisciplinary conferences, serving as educator, supervisor, and manager. For instance, the nurse, along with other healthcare team members, can provide diabetes education to patients. The nurse can be responsible for patient referrals, ensuring continuity of care, such as referring a newborn and family to home care for additional care. Nurses may perform evaluation of patient outcomes, reporting the findings to the healthcare team. The nurse may collect the data from a research study on the unit they work on, and then present the research to peers and colleagues. All these nursing roles are integral parts of the interdisciplinary healthcare team, and often the nurse is the leader of these examples of small-group communication.

### LINK TO LEARNING

The [Agency for Healthcare Research and Quality TeamSTEPPS program \(https://openstax.org/r/77TeamSTEPPS\)](https://openstax.org/r/77TeamSTEPPS)

offers additional information about providing safe and effective care for patients by having good small-group communication among healthcare providers.

### Public Communication

Communication to any size audience is called **public communication**. Public speaking is a form of public communication in which one or more people speak to a larger group. Public communication does not include communication to an audience when there is an expectation of privacy, like when a healthcare provider speaks with a patient, their four family members, a care manager, and an allied health worker.

Public communication includes verbal and nonverbal feedback. Anyone who has attended a lecture or classroom period has provided verbal and nonverbal feedback to the speaker. Verbal and nonverbal feedback can take many forms, from asking questions and taking notes to not paying attention to the speaker. Nurses provide public communication by hosting community vaccination education sessions, safe sitter or newborn care sessions, or healthy nutrition seminars for the community. Public communication can induce anxiety, yet healthcare providers should recognize that it is inherent in their role, whether during team meetings about a patient or at research conferences.

## 2.2 Models of Communication

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the process of the transmission model of communication
- Discuss the interactional model of communication
- Summarize the transactional model of communication

Communication can be conveyed in a variety of ways. Transmission, interactional, and transactional models are three of the models that can be used for communication. Communication in health care relies on all three of these models to ensure safe and effective care of patients. Nurses may use the transmission model to speak with patients directly, the interactional model for communication with the healthcare team, and the transactional model for communicating with other providers within a healthcare system. The nurse interchangeably uses the three models of communication depending on the situation with the patient ([Table 2.2](#)).

Communication Models	Message	Channel
Transmission	Burden on sender to make sure message was received and understood	Used mostly with verbal communication
Interactional	Allows for feedback between sender and receiver	Can be verbal, nonverbal, written, visual, or electronic
Transactional	Sender and receiver can be sending and receiving simultaneously	Can be verbal, nonverbal, written, visual, and electronic

**TABLE 2.2** Communication Models

### Transmission Model

In the 1940s, the **transmission model** of communication was created as a linear model that describes how communication happens between sender and receiver. Also known as the action model, the transmission model is a one-way process of communication, with up to five elements including the sender, the message, the transmitter or message channel, the receiver, and noise ([Figure 2.3](#)).

**FIGURE 2.3** In the transmission model of communication, the sender, the channel, the message, the receiver, and noise are in a linear format. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Sender

In the transmission model, the **sender** is the person who initiates a message. The sender can use verbal, nonverbal, written, visual, or electronic communication. Verbal communication is used most often (Vermeir et al., 2015). The sender should strive to be clear and concise in their message. The sender should convey credibility and honesty with their message as it may help with the tone, while pitch and content are also important. For example, a sender could be a nurse manager who emails an employee about an important department meeting.

### Receiver

The **receiver** is the person who receives the message and interprets it. The receiver can also be called the listener, reader, or observer depending on how the communication is sent. The receiver is the responsible audience who decodes the message from the sender (Nordquist, 2019). The receiver in the previous example would be the employee who received the email about the important department meeting from the nurse manager.

### Message Channel

The message channel can be broken into two parts: the message and the channel. The **message** is the information to be conveyed or communicated. The **channel** is the mode in which the communication is sent. In the transmission model, the message channel most commonly used is verbal communication. The burden is placed on the sender to make sure the message sent was received and understood. Either environmental or **semantic noise** can make the interpretation of the message difficult. Semantic noise refers to a type of communication barrier that occurs when the sender and receiver of a message have different understandings of the meanings of words, phrases, symbols, or language in general (Vrana et al., 2018). For example, medical jargon used by healthcare providers is semantic noise that is difficult for patients to interpret.

## REAL RN STORIES

### Interpreting Information

**Nurse:** Sudita, RN

**Clinical setting:** Telemetry unit

**Years in practice:** 15

**Facility location:** Philadelphia, Pennsylvania

I was working an eight-hour shift caring for a patient who was admitted with a myocardial infarction and was preparing to be discharged. I was assigned to give discharge instructions to the patient including the heart-healthy diet instructions. I started by asking the patient about their current diet and discussing how to modify their current diet to include healthier eating habits. The patient, however, told me that they ate snowballs and drank whole milk as their daily snack. I was the receiver of the patient's message. Living in the Northeast, I understood a snowball to be a "snow cone," the sugary, fruit-flavored ice ball often served from roadside vendor trucks. And was I ever confused! I understood how to deal with the whole milk issue, but I could only think that a snowball was not the worst thing this heart patient could snack on. I was further confused because I wondered how the patient made these at home. The semantic noise in the message made it hard for me to interpret. Was I to understand from the message that the patient ate snowballs and drank whole milk as a snack during the day, which although did not meet healthy-heart standards could be modified to include skim milk? In the transmission model of communication, I needed to interpret the information received in the best way I could, which did not allow for me to make the best decision about safe and effective care for the patient. After asking the patient several additional questions, I found they were actually referring to the gooey, marshmallow, coconut, and chocolate rounded cakes that are called

snowballs and that they ate them several times a day, washed down with whole milk. Based on the information gathered from the patient, I changed the plan of care and the teaching information.

## Interactional Model

The **interactional model** of communication describes communication as a process in which a person alternates as both sender and receiver. Instead of the transmission model (linear, one-way), the interactional communication model allows for feedback, or a two-way process (Figure 2.4). The main difference between the interactional and transmission models is that the interactional model includes feedback in the communication process to allow for better understanding of the messages being sent and received.

**FIGURE 2.4** The interactional model of communication shows feedback and changing roles. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Sender/Receiver

The sender in the interactional model is also the receiver. The model permits the sender to change roles and become the receiver. The sender and receiver interchange the roles, sending messages rapidly during the communication process. The quick pace and interchanging roles can sometimes lead to miscommunication.

### Message Channel

The message channel in the interactional model is similar to the transmission model. The form of communication for the interactional model can be verbal, nonverbal, written, visual, or electronic. Communication in the interactional model can be complex; sometimes messages can be sent and not received. The messages can be affected by the physical and psychological context of the communication. For instance, if the message is sent in a room that is noisy and busy, the intended message may not be completely received, and because the interactional model relies on feedback, when feedback is not present because of noise, the message is lost.

### Feedback Channel

The feedback channel distinguishes the interactional model from other communication models. The response given by a receiver to a sender is the **feedback**. Feedback permits clarification of the message sent so that the receiver can better interpret it. The feedback loop allows for senders/receivers to exchange messages simultaneously. This feedback loop can help with clarification of the message sent.

## Transactional Model

The **transactional model** of communication is a two-way model of creating communication to develop social relationships and engage with others. The transactional model differs from the interactional model because the sending and receiving of messages happen simultaneously (Figure 2.5). Healthcare providers rely on the transactional model to develop relationships with patients, allowing safe and effective care to occur (Kwame & Petrucka, 2021). The transactional model is the preferred model of communication between healthcare providers and patients because it allows for the sender and receiver to share information.

**FIGURE 2.5** The transactional model of communication shows simultaneous communication. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Sender/Receiver

Like in the interactional model, the sender is also the receiver in the transactional model. The senders/receivers are also called communicators, which allows senders to simultaneously be receivers. The transactional model allows for adaptation of communication within the encounter, changing modes while sending and receiving messages.

### Message Channel

The message channel within the transactional model allows for all forms of communication including verbal, nonverbal, written, visual, and electronic. The nurse could be using verbal communication with a patient while observing the patient's nonverbal communication. The nurse might observe the patient's nonverbal communication while listening to the patient's verbal communication, observing for congruence between the modes of communication. The healthcare provider who asks the patient to use a pain rating scale would monitor for visible signs of pain while observing the patient use the pain rating scale.

### Feedback Channel

Feedback is present in the transactional model and is influenced by the social, relational, and cultural context of the communication. With feedback, the sender and receiver are influenced by their culture, literacy, social context, and native language when interpreting the message, and possibly shifting the context of the message. Because the transactional model is designed to develop social relationships, nurses should respect the context of the feedback and the message.

## PATIENT CONVERSATIONS

### Using the Transactional Model of Communication with Patients

**Scenario:** A nurse is caring for a mother and partner in an obstetric unit of a local hospital. The mother recently delivered a healthy baby who is in the nursery being assessed.

**Nurse:** [walking into the room] Hello, my name is Tallulah, and I will be your nurse today. Wow, it is really hot in here isn't it? [Nurse walks over to the thermostat in the room.] It is set at 80° in here, I am going to lower it. [Nurse lowers the thermostat to 68°F (20°C).]

**Partner:** It is nice to meet you [slightly bows]. We are Mr. and Mrs. Chow; we thank you for caring for us today.

**Nurse:** I need to check your name band, what is your name and date of birth?

**Patient:** Emily Chow, September 27, 1986.

**Nurse:** I will do a quick assessment of you and then check on your baby, is that okay?

**Patient:** Thank you [slightly bows].

[Nurse completes assessment while complaining about the temperature of the room.]

**Nurse:** I am done, is there anything else I can do for you at this time?

**Patient:** No, thank you.

**Scenario follow-up:** Nurse leaves the room, and patient asks partner to return thermostat to 80°F. Patient and partner are of East Asian descent and practice Taoism and *toa (tos)*, with the emphasis on returning heat to the postpartum body to prevent future illness from occurring. Nurse returns to the room after thirty minutes.

**Nurse:** Oh, my goodness, it is still so hot in here, is the thermostat broken? [Nurse checks the thermostat to see it has been returned to 80°F.] Did either of you touch the thermostat? I cannot give care in this hot room.

**Partner:** Yes, we returned the thermostat to 80°F once you left, because my wife is practicing the maternal medicine of our culture and would like the room to remain warm.

**Nurse:** I am sorry, I did not realize it was a part of your culture to have a warm room after delivery. I will be sure to respect your wishes and tell all future caregivers your preferences. Is there anything else I should know about your cultural practices after giving birth? I am so glad you shared this information with me.

Source: Bazzano et al., 2020.

### Context

When attempting to communicate with a patient through their culture and engage in a social relationship, the use of multiple forms of communication is necessary. The use of faces and objects in the place of words during communication encounters is called **referent communication**. In electronic communication or text messages, the use of referent is seen in the form of emojis or pictures used to describe words like smiley faces or a picture of a chair. Referent communication can be used during texting but may not always be appropriate when speaking with patients. Nurses can use referent communication when checking for pain with a patient who is unable to speak. In this instance, referent communication is helpful in assessing a patient's pain scale as is done when using the Wong-Baker FACES Pain Rating Scale.

### UNFOLDING CASE STUDY

#### Unfolding Case Study #1: Part 2

Refer back to [Unfolding Case Study #1: Part 1](#) for a review of the patient data.

Nursing Notes	<p><b>1700: Intervention</b></p> <p>Patient appears to be in distress from frequent coughing episodes with expectoration of yellow sputum. Patient is tearful and begins to cry. Son attempts to console patient. Interpreter has been called and will arrive when their current patient encounter is complete. Nurse utilizes a picture board to assist with communication with patient. Oxygen at 2 L per nasal cannula applied per orders and warm cloth given to wipe her face. Patient is instructed by nurse to take slow, deep breaths and to sit in an upright position to improve breathing.</p>
Provider's Orders	<p><b>1710: New orders</b></p> <p>Chest x-ray Close observation</p>

3. Prioritize hypotheses: What factors are present that may make communication with this patient difficult? What are some other ways the nurse could communicate with the patient despite these factors?
4. Generate solutions: How could the nurse use the transactional model as a basis for communicating with this patient?

## 2.3 Effective Communication

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the importance of effective communication
- Discuss the fundamentals of professional communication
- Identify uses of motivational interviewing

Healthcare providers should be skilled in effective communication in order to provide safe and effective care for patients. Professional communication with other healthcare providers and with patients is a priority for healthcare providers which leads to better, collaborative, high-quality, and safe patient care. Nurses and other healthcare providers use motivational interviewing to elicit information from patients.

### Importance of Communication

Nurses need to communicate effectively with patients and other members of the healthcare team. Effective communicators build empathy and trust among patients and the healthcare team. When patients and healthcare providers feel understood and heard, better healthcare outcomes occur, and job satisfaction among healthcare providers improves. Nurses who are good communicators are also self-aware and strive to create better relationships among patients and the healthcare team. Good communication among healthcare providers also

promotes better handling of conflicts.

### Elements of Effective Communication

Effective communication is paramount in health care. Healthcare providers need to provide factual, practical, clear, concise, and persuasive communication to patients to deliver safe and effective health care ([Table 2.3](#)).

Element	Factual	Practical	Clear and Concise	Persuasive
Example	Your heart has three arteries on the outside of your heart that oxygenate the muscle. These are the arteries that are bypassed during open-heart surgery.	The measles, mumps, and rubella virus vaccine is recommended at 18 months of age following the Centers for Disease Control and Prevention (CDC) schedule. You will want to make sure to schedule a healthcare provider visit for the vaccine if desired.	You will need to take this antibiotic with meals. Take one pill with breakfast, lunch, and dinner.	After surgery, you will need to get out of bed and walk every day so that you recover more quickly. Do you prefer to walk with your cane or a walker when ambulating this evening?

**TABLE 2.3** Examples of the Elements of Effective Communication

#### Factual

Healthcare communication must be factual. Health care is based on science, and nursing is an evidence-based practice. Providing patients with communication that is anything other than factual erodes the patient-provider relationship and deems the provider as untrustworthy. Patients deserve factual communication about their bodies. Nurses should refrain from speaking about their own feelings or hopes when interacting with patients as this can lead to confusion and miscommunication. For instance, when a nurse uses factual communication to speak with a post-op patient, the nurse could say that research has proven that patients who attempt to ambulate within twenty-four hours after a surgical procedure are less likely have postoperative complications. The nurse can explain to the patient that they might be in some pain afterward, but the nurse can provide pain medications as needed. If the nurse was to provide nonfactual communication to the same patient, the nurse would tell the patient it is time to get up and ambulate and that ambulating will not hurt.

#### Practical

Healthcare communication must be practical. A nurse who communicates and does not give practical information can seem untrustworthy. For instance, a post-op surgical patient might be asked if they are ready to ambulate into the hallway when medically appropriate. The patient would be hesitant to trust the nurse, as that is not a practical goal. Instead, the nurse should ask if the patient is ready to try and ambulate around the room. This sharing of practical information builds trust—the patient recognizes the nurse understands their limitations.

#### Clear and Concise

The nurse should communicate in a clear, concise manner. Effective communication occurs when the nurse clearly thinks through the purpose of the message. The message should be clear so that feedback can be elicited. An example of unclear communication is when the nurse informs the patient that ambulating after surgery is necessary for healing but adds words such as “if you can” or offers other options such as waiting. The nurse could add that they think waiting might be good, as the patient can rest and have a snack, or maybe take a shower. This communication is unclear because the nurse has stated that ambulation after surgery is important but then is allowing the patient the option to not ambulate. If the nurse used clear and concise communication, they would tell the patient that they should try and ambulate today to help reduce post-op complications, right now or in an hour after the pain level has decreased.

#### Persuasive

Nurses need to know how to be persuasive in their communication. Many times, nurses are required to persuade

patients to change their behaviors. With a postoperative patient who is required to ambulate after surgery, the nurse could give the statistics of reduced postoperative complications if early ambulation is performed, or the nurse might reiterate that they will stay with the patient throughout the process and have pain medications available if they are needed. Nurses should present facts and make recommendations but also listen to the wishes of the patient. If the patient is unsure about taking pain medication, the nurse should explore this ambivalence and use another tool like motivational interviewing (MI).

## Essentials of Professional Communication

Professional communication is essential in health care. Communication is part of any successful working relationship, and collaborative, working relationships are integral in health care. Nurses work with people from different professions, class, status, careers, and vocations. To communicate respectfully with different types of people, the nurse should use professional communication (Table 2.4).

Element	Example
Courtesy	Hello, Mr. Lee, I am so glad to meet you. What can I help you with today?
Understanding	Yes, Ms. Awolowo, thank you for sharing your reason for being late to your appointment, we are happy to accommodate you. We will be able to see you soon.
Use of names and titles	Hello, I am your nurse today. Would you please tell me your preferred name, title, and pronoun so that I may refer to you correctly?
Trustworthiness	I will be back in thirty minutes to check on you and your pain level, Mrs. Kuznetsova. Is that okay with you?
Empathy	This must be a hard time for you, Mx. Takahashi. How are you coping?
Assertiveness	I hear what you are saying, Mr. Diaz-Gomez. Would you like me to be present when you speak to your doctor so we can make sure they are addressing your concerns?
Resolution	You were given the wrong medication this morning. I have notified your healthcare provider, and I will be monitoring you closely for the next four hours.

**TABLE 2.4** Elements of Professional Communication

### Courtesy

Using **courtesy** in healthcare communication is important. Courtesy refers to the practice of being polite, respectful, and considerate when interacting with patients, their families, and colleagues. It involves using polite language and maintaining a friendly and professional demeanor. A nurse should try to always acknowledge their audience, speaking politely. Nurses experience many patients who are not courteous to them; however, the nurse should always be courteous to the patient. Nurses who are courteous in all communication encounters are more likely to deliver safe, effective care for their patients (Sibiya, 2018). Initiation of the nurse-patient relationship depends on the nurse's ability to begin with a pleasant greeting and friendly smile. These actions can build trust and place the patient at ease. By maintaining qualities of politeness and friendliness, the nurse conveys continuous acceptance of the patient and interest in discussing the patient's feelings and concerns.

### Understanding

Communication is most effective if all messages received are understood. Patients are more likely to follow directions provided during an educational session if the information is supplied in a way the patient readily understands. If the patient receives the communication in several forms, like verbal, written, and electronic, the patient will likely better understand the message. A patient who does not understand the directions given to them is less likely to obtain positive health outcomes.

### Use of Names and Titles

Nurses should respect the professionals that they work with on the healthcare team and use their correct name and title. Nurses should ask patients and healthcare team members to respect their titles and ask that they be used. Nurses should ask patients what they prefer to be called—their name, title, and pronouns; doing so helps establish a positive patient-provider relationship.

### Trustworthiness

Nursing is considered the most trusted profession since the 1990s when the Gallup poll of most trusted professions was first conducted (Gaines, 2023). Nurses are considered honest in their words and actions. They are trusted to deliver honest care with compassion, providing education and answering questions with patience.

## LINK TO LEARNING

---

Results of a [2022 Gallup poll about the trustworthiness of the nursing profession \(https://openstax.org/r/77nursingpoll\)](https://openstax.org/r/77nursingpoll) are presented and discussed at the Gallup website.

---

### Empathy

Empathy is a key element of nursing communication, embodying the ability to understand and share the feelings of patients. The term **empathy** can be defined as the ability for one person to understand and share the feelings of another person. A nurse not only reacts in a caring manner, which is considered sympathy, but fully understands the patient, placing value on the patient as a unique individual capable of making decisions. Empathy involves showing genuine concern, using active listening, and responding in a way that acknowledges and validates the patient's emotions. Nursing empathy helps create a trusting and therapeutic nurse-patient relationship, leading to improved patient outcomes and overall satisfaction (Babaii et al., 2021). Empathy goes beyond mere sympathy or a caring demeanor; it is about deeply comprehending the patient's emotional and psychological state. When nurses exhibit empathy, they foster an environment where patients feel heard, valued, and supported, which is vital for delivering safe and effective care. Empathetic care often leads to better adherence to treatment plans and a more positive attitude toward recovery. Patients who feel supported and understood are more likely to actively engage in their care (Bas-Sarmiento et al., 2019).

### Assertiveness

Showing confidence in oneself is **assertiveness**. Nurses who are assertive are more likely to build effective communication among healthcare team members. Some facilities provide assertiveness training for nurses, recognizing that nurses who are positively assertive improve patient care (Nakamura et al., 2017). An assertive nurse advocates for patients until their concern is addressed. Assertive nurses are a necessity for patients who are unconscious, nonverbal, or have no advocate at their side as they must speak up as the voice of the patient.

### Resolution

Determination of an act is the **resolution**. In health care, resolution often refers to the communication used when addressing adverse events or risk management concerns. Resolution also involves reaching a point where both parties involved in the communication feel satisfied and understood and that their objectives have been achieved. Effective resolution contributes to clear understanding, improved relationships, and the achievement of desired goals. Adverse events and risk management concerns occur when something has gone wrong. An adverse event could be a medication error or the unintentional death of a patient. Resolution includes healthcare providers discussing through clear and structured communication what went wrong and how to prevent adverse events from occurring again. Resolution depends on both parties agreeing on an outcome. When an outcome is agreed upon, effective resolution has usually been obtained.

### Motivational Interviewing

Nurses may use **motivational interviewing (MI)**, an evidence-based counseling approach that involves discussing feelings and incentives with the patient. Motivational interviewing can be used as a clinical communication tool to better understand the motivation behind a patient's desire to change their behavior (Droppa & Lee, 2014). Nurses can use MI by expressing empathy about the patient's current point of view. A nurse should help a patient better understand their current practice by highlighting discrepancies between their current behavior and their goal

behavior. The nurse uses MI to understand patient ambivalence, which is part of the change process, but they should encourage patients to reach their goals, supporting self-efficacy. For instance, a patient may understand the importance of postoperative pain medication but be ambivalent about receiving it. Motivational interviewing can help the nurse empathize about the patient's concern while highlighting the importance of pain relief after surgery to help meet postsurgical goals like ambulating.

## PATIENT CONVERSATIONS

---

### Using Focusing with Motivational Interviewing

**Scenario:** The nurse, Robin, walks into the patient's room to complete an assessment, and the patient starts complaining about pain.

**Nurse:** Hi, my name is Robin, and I am going to be your nurse today. Do you mind verifying your name and date of birth for me?

**Patient:** Yes, Diane Bock, date of birth 10/12/1940. I am having a lot of pain, like I did last time I was here, and the last time I had a lot of pain, things went wrong, and I had to stay at the hospital longer than I wanted to, and I missed my friends' eightieth birthday party, and she ended up falling after her party and breaking her hip. I don't want that to happen to me, but my knee hurts so bad I feel like I could fall. The doctor said I should start physical therapy to help with my knee pain, but I don't want to, what do you think?

**Nurse:** You have given me a lot of information, what would be most helpful to discuss first?

**Patient:** Can we talk about the pain in my knee first?

**Nurse:** Yes, let me ask some follow-up questions about your pain. Where are you having pain? What is the level of your pain on a scale of 1 to 10 with 10 being the most intense and 1 being the least intense. When did your pain start?

**Patient:** My knee hurts, it's an 8 on a scale of 1 to 10, and it started about one hour ago, I just did not want to bother you.

**Nurse:** You are not bothering me, and I am sorry you are in pain. I can check to see when your next pain medication is due and get that for you. Is it okay if I leave and come back with your pain medication and then we can discuss what you think is most important next?

**Patient:** Yes, please check on my pain medication. I think I had some last night.

**Scenario follow-up:** The nurse returns to the room with pain medication for the patient.

**Nurse:** You can have the pain medication now. Here it is.

**Patient:** Thank you for the pain medication. I hope it works soon. I do not want to be in the hospital again and go home and have no answers about my knee pain.

**Nurse:** Would you like to talk to me more about the comment you made earlier about your friend? It seems like you are worried about being in the hospital.

**Patient:** Yes, I am worried about having to stay in the hospital again, I really don't like the hospital.

**Nurse:** I can understand why you do not like the hospital, but it is a good place for you to be in to figure out what is wrong with your knee. Do you think you will be okay to stay until the healthcare providers have run all the necessary tests?

**Patient:** Yes, I will try to stay until I have an answer about why my knee hurts.

---

When assessing a motivational problem, always consider the patient's cultural values, their general and health literacy, and their psychosocial needs. Motivational interviewing should support the patient's sense of self-confidence. It includes using engaging communication and open-ended questions, helping the patient focus, while evoking the patient to think about change and planning how the patient will accomplish the change. An example of

MI is a nurse equating the patient's love of caring for their grandchild as a reason to slowly add healthy food and exercise to their daily life to improve their health.

Effective MI should include the following processes:

- **Engaging:** By engaging in communication with a patient, the healthcare provider establishes a relationship with the patient. To **engage** in communication, the healthcare provider should use active listening, use nonverbal communication, and ask for feedback when necessary.
- **Focusing:** Focusing is finding a clear direction and a goal. Nurses need to help provide focus with communication and MI. Nurses need to help the patient choose goals for change. Nurses use focusing techniques to help the patient define and refine those goals.
- **Evoking:** Evoking is the part of the MI process that helps the patient make the change. The nurse encourages the patient to speak in terms of change but understands the patient may be ambivalent for that change. The nurse should use the patient's natural motivation to invoke the change.
- **Planning:** The patient needs to plan for the future with their new goal for change. During the planning phase of MI, the goals should be small and achievable. Small victories increase patients' motivation. The nurse should discuss with the patient the development of **SMART goal**, an acronym for goals that are specific, measurable, attainable, relevant, and timely (Figure 2.6). Developing goals with the patient during MI increases the probability that the patient will change the behavior.

**FIGURE 2.6** SMART goals can be used with patients during MI. (credit: modification of work by Joint Base Charleston, Public Domain)

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Using Motivational Interviewing to Counsel Patients to Increase Self-Care

When taking actions, nurses can use MI to counsel patients to increase self-care. For example, if a patient has experienced a myocardial infarction or heart attack, the nurse recognizes that they should teach the patient about decreasing saturated fat in their diet. Telling the patient how to decrease saturated fat in their diet is not the best way to motivate the patient. The nurse may ask questions like, "You want to decrease saturated fat in

your diet, what is your understanding of the complications of eating a high-fat diet?” Or “What will it look like in five years for you if you do not lower your saturated fat intake?” Or “What would you gain by cutting back on your saturated fat intake?” The patient’s responses provide detailed information that helps the nurse set goals with the patient to lower the patient’s intake of saturated fat. Nurses can use the acronym OARS to help patients develop goals to increase self-care (Figure 2.7) (Schultz, 2021).

<b>OARS</b>	
	<b>O</b> pen questions lead to more explanation and further contemplation.
	<b>A</b> ffirmations promote positive feelings in the exchange.
	<b>R</b> eflections prove the healthcare provider has heard and truly understood the patient.
	<b>S</b> ummaries foster momentum or generate interest in making changes built on simple reflections.

**FIGURE 2.7** The acronym OARS can help nurses to remember steps to take when employing MI with patients. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## 2.4 Therapeutic Communication

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe therapeutic communication techniques
- Recognize how to evaluate therapeutic communication
- Identify nontherapeutic communication techniques

The most used form of communication in health care is **therapeutic communication**, a specialized form of communication used by healthcare professionals, such as nurses, doctors, and therapists, to establish a therapeutic or healing relationship with patients (Martin & Chanda, 2016). Florence Nightingale discussed the importance of communication between patient and nurse in the 1800s. In the 1950s, the concept of therapeutic communication was developed to provide therapeutic benefit, especially with patients who were diagnosed with mental illness. The nursing theorist Hildegard Peplau developed the Theory of Interpersonal Relations that cemented the concept of therapeutic communication to advance the healing process in patients. Therapeutic communication has progressed to include verbal and nonverbal communication, helping patients overcome illnesses of the body and mind. Nurses should use therapeutic communication in all communication encounters with patients (Martin & Chanda, 2016).

### **CLINICAL SAFETY AND PROCEDURES (QSEN)**

QSEN Competency: Patient-Centered Care

**Definition:** Recognize the patient or designee as the source of information and a full partner in providing

compassionate and coordinated care based on respect for patient's preferences, values, and needs.

**Skill:** The nurse will do the following:

- Discuss principles of effective communication.
- Describe basic principles of consensus building and conflict resolution.
- Examine nursing roles in assuring coordination, integration, and continuity of care.

If the nurse and other members of the healthcare team do not provide therapeutic communication, the expected outcomes for the patient could be impacted negatively. If there is conflict between the patient and the healthcare team, negative health outcomes could occur.

**Knowledge:** The nurse must have an understanding of the key therapeutic communication delivery techniques so that they can use the most appropriate approach for the specific patient or designee and are able to evaluate its effectiveness.

**Attitude:** The nurse should engage in active listening, indicating an understanding of what the patient or designee is saying.

## Therapeutic Communication Techniques

Therapeutic communication allows patients to express themselves. There are various therapeutic communication techniques in health care. Nurses should be very familiar with these different techniques, using them with each patient communication encounter. These techniques include providing information; sharing observations, feelings, empathy, hope, and humor; using touch and silence; focusing and clarifying; asking relevant questions; **offering self**, which is contributing support by being present or spending time with a patient; and active listening ([Table 2.5](#)). Using all these techniques as the situation warrants helps the nurse provide safe and effective care for the patient. The nurse should recognize that the use of open-ended questions supports therapeutic communication.

Technique	Definition	Example
Providing information	Nurses are responsible for educating and informing patients and families. Patient education should be ongoing, with nurses using every encounter as an opportunity to educate.	As the nurse dispenses the morning medications, the nurse educates the patient about each medication, encouraging the patient to ask questions.
Sharing observations	Nurses should share their observations about the patient while providing care. Being mindful about the patient's appearance and mood can give the nurse clues about the patient's health.	The nurse states: I noticed you are crying; would you like to share with me what is making you sad?
Sharing feelings	Patients should be encouraged to share their feelings. Because patients are often frustrated with health care, nurses can create safe spaces where the patient feels comfortable sharing their feelings.	A nurse asks a patient to describe what they are feeling after the patient is given a particular diagnosis.
Sharing empathy	A nurse who expresses empathy may tell the patient that they hear and understand what the patient is saying, which helps the patient feel they are being cared for.	A nurse asks a patient about their cultural beliefs surrounding pregnancy.

**TABLE 2.5** Therapeutic Communication Techniques

Technique	Definition	Example
Sharing hope	Nurses should be ready to share a sense of possibility for the patient, even when the news is bad. Sharing hope through active listening might be included for the patient who has just received a terminal diagnosis; however, information dispensed must remain factual.	A nurse should be present with the parent who has received bad news about their child, giving the parent time to talk.
Sharing humor	The nurse can use patient-driven humor as a gauge for deciding when and if to use humor with the patient. Recognize that there are many circumstances in which humor may not be appropriate as a therapeutic technique.	The nurse listens when a family member shares a funny story about the patient and then shares a related story.
Using touch	A nurse's touch may be the only positive or healing touch the patient receives. However, a patient who is receiving many treatments may regard some touch as negative. An episode of handholding with the nurse after procedures can uplift their spirits. Some patients find touch to be unsettling, so the nurse must ask the patient before engaging.	The nurse asks the parent if it is okay to touch their infant before assessing them.
Using silence	Allowing a patient the time to think and process is important. Nurses should respectfully let the patient break the silence.	The nurse is quiet while the patient shares their rape experience from college.
Clarifying	Nurses should clarify communication received from patients. Often, patients use confusing and ambiguous communication when describing health issues. Nurses ask questions to help clarify the communication so that both parties better understand the issues.	The patient has described stomach pain. The nurse asks several follow-up questions about location, intensity, quality, radiation, onset, character, and exacerbating and relieving factors.
Asking relevant questions	Nurses should ask relevant questions about the healthcare issue before helping the patient make a decision about their care. The nurse uses the relevant question technique to gather information, while not overwhelming the patient with questions.	The patient discusses with the nurse their previous hospital experience. The nurse asks about the length of stay, the admitting diagnosis, and the outcome of treatment.

**TABLE 2.5** Therapeutic Communication Techniques

Technique	Definition	Example
Offering self	Patients in any setting can be lonely, scared, and stressed. A nurse who offers themselves by sitting with the patient or spending time talking with the patient is offering self. Some patients report a boost in mood once a nurse has spent one-on-one time with them.	The nurse comforts the child when asked, before and during a vaccination.
Actively listening	Active listening includes using both verbal and nonverbal cues to convey interest in the patient's communication. Simply saying "Go on" gives patients courage to continue a discussion of health issues.	The patient describes a previous medication reaction and the nurse clarifies some of the information the patient presents, encouraging the patient to share all aspects of their experience.

**TABLE 2.5** Therapeutic Communication Techniques

### UNFOLDING CASE STUDY

#### Unfolding Case Study #1: Part 3

Refer back to [Unfolding Case Study #1: Part 1](#) and [Unfolding Case Study #1: Part 2](#) for a review of the patient data.

Nursing Notes	<p><b>1700: Assessment</b></p> <p><b>Physical examination:</b> Patient appears disheveled with clothes inappropriate for the cold weather, including short-sleeve shirt and shorts. While waiting for the interpreter, patient appears agitated with frequent coughing episodes. Begins to pace the room as son attempts to console her.</p> <p><b>HEENT:</b> Pupils equal, reactive to light and accommodating, mucous membranes moist and intact, pharynx without lesions, palate intact. No thyroid enlargement noted.</p> <p><b>Lymphatic:</b> Tonsillar and cervical lymph nodes slightly enlarged. Hard, palpable left axillary lymph nodes, tender to touch. No enlargement of right axillary or inguinal nodes, no pain or tenderness noted.</p> <p><b>Respiratory:</b> Rales and rhonchi auscultated bilaterally. No stridor or murmur present.</p> <p><b>Cardiovascular:</b> Sinus tachycardia on monitor, no edema, peripheral pulses 2+.</p> <p><b>Abdomen:</b> Bowel sounds present in all four quadrants, no tenderness present.</p> <p><b>Musculoskeletal:</b> Full range of motion, no issues noted.</p> <p><b>Skin:</b> Pale and dry, no bruising.</p> <p><b>Mental assessment:</b> Patient reports (per son) that she is stressed from coughing and anxious about her mother left alone at home. Patient requests the nurse “hurry and give me some medicine so I can go home.”</p> <p>Interpreter arrived to room at 2030.</p>
Flow Chart	<p><b>2000: Assessment</b></p> <p>Blood pressure: 148/87 mmHg</p> <p>Heart rate: 110 beats/minute</p> <p>Respiratory rate: 26 breaths/minute</p> <p>Temperature: 102.2°F (39°C)</p> <p>Oxygen saturation: 97 percent on 2 L nasal cannula</p> <p>Pain: 8/10 (ear)</p>
Provider's Orders	<p><b>2030: New orders</b></p> <p>Sputum sample</p> <p>Wean from oxygen before discharge home</p> <p>Medications:</p> <ul style="list-style-type: none"> <li>• Acetaminophen 1,000 mg PO Q6 hours PRN fever</li> <li>• Amoxicillin 500 mg PO twice daily for ten days</li> </ul>

**5.** Take action: How would the nurse use therapeutic communication to address the patient’s concerns?  
**6.** Evaluate outcomes: After providing information to the patient about the newly prescribed medications, how would the nurse evaluate the patient’s understanding?

## Evaluating the Effectiveness of Therapeutic Communication

Nurses should be adept at evaluating the effectiveness of therapeutic communication. Communication should go two ways, using the feedback loop, as feedback ensures the therapeutic communication has been effective. Nurses rely on the feedback loop to make this evaluation. If the communication has not been effective, the nurse should revise their approach, making sure they are providing effective communication for the patient.

### Reflect on the Response

Nurses who use reflection on the response during therapeutic communication should restate what the patient has said. This allows the patient to hear their own words and encourages them to continue to communicate. Reflection helps the patient understand that the nurse is actively listening to them, further establishing the nurse-patient relationship.

### Compare Response to the Desired Goals

After the nurse reflects on the patient's response, they should compare the response to the desired goals of the communication. The nurse should consider various factors at play during communication. It is crucial to compare the patient's response to the desired goal. If they align, it confirms effective therapeutic communication.

### Revise Message if Communication Is Ineffective

If the nurse determines the therapeutic communication was not effective, revision of the message is needed. The nurse needs to revise the message and employ the feedback loop to again check if the intended message has been received. For instance, if a nurse was teaching a patient about their surgical care, the nurse would use a feedback loop to make sure the patient understood the instructions. If the patient is not able to repeat the instructions, the nurse should revise the message until the patient can repeat the instructions.

## PATIENT CONVERSATIONS

---

### A Therapeutic Conversation with a Patient

**Scenario:** Linda has been a nurse in New Orleans, Louisiana, for four years. Her patient is Mr. Michael Boudreaux, a 62-year-old Army veteran who has lived in Louisiana his whole life. The nurse walks into the patient's room to complete an assessment.

**Nurse:** Hi, my name is Linda, and I am going to be your nurse today. Do you mind verifying your name and date of birth for me?

**Patient:** Michael Boudreaux, date of birth 01/26/1961.

**Nurse:** Hi, Mr. Boudreaux, I would like to do an assessment of you, if that is okay?

**Patient:** Of course, I am just sitting here, worried about what is happening to me.

**Nurse:** Would you like to discuss with me some of the things that you are worried about?

**Patient:** Sure, I am worried that I have something really bad wrong with me and no one is telling me.

**Nurse:** Let me clarify, you feel like no one is talking to you and that makes you think that there is something bad happening?

**Patient:** Yes, do you know anything about my test results?

**Nurse:** None of the results are available at this time, but that doesn't help you, does it? Would you like me to have the healthcare provider speak to you and explain why they are doing certain tests and what they might be looking for?

**Patient:** Yes, that would be helpful, and maybe make me less anxious. Thank you.

**Nurse:** You are very welcome, please don't hesitate to ask me any other questions. I am here to help you feel better. I'll need to touch you to do my assessment. Is that okay?

---

### Nontherapeutic Communication Techniques

Unfortunately, **nontherapeutic communication** can also occur between the patient and nurse. Nontherapeutic communication can be defined as negative expressions, attitudes, and actions that make a patient feel uneasy. Both the patient and the nurse are subjected to many influences that can muddle communication. Nurses should try to avoid nontherapeutic communication and strive to revise the communication if nontherapeutic communication has occurred.

## LINK TO LEARNING

---

Learn more about [therapeutic and nontherapeutic communication techniques \(https://openstax.org/r/therapeutic-and-nontherapeutic-communication-techniques\)](https://openstax.org/r/therapeutic-and-nontherapeutic-communication-techniques)

[77commtechniques](#)) in this video.

Nontherapeutic communication can lead to miscommunication between the nurse and patient, and among healthcare providers, ultimately affecting the care the patient receives (Amoah et al., 2019). Nontherapeutic communication techniques include attacking and interrogating patients; changing the subject; giving automatic responses that are not helpful; giving **false reassurance**, which is comfort that is not based in facts, and advice; providing passive, aggressive, judgmental, or defensive responses; and arguing with the patient. Another nontherapeutic communication technique is not listening to the patient or not being actively present when with a patient, like scrolling on a phone during a patient encounter. All these nontherapeutic responses can negatively affect the nurse-patient relationship ([Table 2.6](#)).

Techniques	Definition	Examples
Attacking	Verbal attacking is meant to criticize, dominate, or manipulate the patient. Attacking a patient will likely cause the patient to shut down and stop communicating or elicit an anger defense. Nurses must avoid verbally attacking patients. If the patient's perception is that the nurse attacked them, the nurse should apologize and try to reestablish therapeutic communication.	The nurse tells the patient, "You came in here drunk and started hitting people."
Interrogating	Interrogation of a patient is often described as asking "why" questions. When "why" questions are asked, the patient can become defensive or uncomfortable and stop communicating altogether. The nurse should avoid asking "why" questions, rephrasing questions to prevent the patient from becoming defensive.	The nurse asks the patient, "Why did you not take the medication like I instructed you to do?"
Changing the subject	When a nurse changes the subject while a patient is talking, the patient perceives that their communication is not important. Sometimes nurses rush patients through a communication encounter and can change the subject to meet the nurse's goals for the encounter. The patient may see this as a form of disrespect or a way to silence them. The nurse needs to recognize factors influencing their own communication and allow the patient to speak uninterrupted to establish a positive nurse-patient relationship.	The patient tells the nurse about their chest pain, and the nurse asks, "What kind of insurance do you have?"
Automatic response	Automatic responses are ready-made sayings or statements that are used without any thought to the patient as an individual. Nurses should avoid these types of statements when communicating with patients because they can be interpreted as generalizations or stereotypes. Phrases like "I am sorry for your loss" seem automatic. Patients who receive automatic responses from the nurse may refrain from communicating at all.	The nurse tells the patient several times in the day that they will be right back and each time does not return to the room unless the patient specifically calls them.

**TABLE 2.6** Nontherapeutic Communication Techniques

Techniques	Definition	Examples
False reassurance	Giving false reassurance that everything will be all right may do more harm than good. The nurse should allow the patient to voice their fears and concerns and then offer hope without devaluing the patient's feelings.	The nurse tells the patient the medication they are given for nausea during chemotherapy will make all the nausea go away, and the patient will feel much better in a few minutes.
Giving advice	Nurses should not give advice when communicating with patients. Patients often ask for the nurse's opinion, and the nurse should try to communicate therapeutically by giving factual information without personal experience and advice. Giving advice can prevent the patient from developing their own healthcare goals.	The nurse states, "You know, if it were me, I would not go to that healthcare provider."
Defensive responses	Nurses should refrain from being defensive in all communication with patients. Patients sometimes express criticism about their health care, and nurses should not respond defensively. Nurses need to actively listen to the criticism as there is often a deeper meaning that the patient is attempting to convey.	The nurse states, "I didn't do anything" when the patient states that the nurse took their belongings.
Passive or aggressive responses	Passive or aggressive responses should be avoided, if possible. Passive responses are those that try to avoid conflict or circumvent issues. Aggressive responses are responses that are meant to provoke confrontation. When the nurse attempts to avoid conflict or is angry with the patient, they should not let the patient know. Nurses should use assertive communication when they are tempted to use the passive or aggressive responses that can damage the nurse-patient relationship.	The patient soils themselves for the third time in the shift, and the nurse has to change the sacral dressing. The patient apologizes profusely to the nurse, and the nurse responds "yeah, yeah I know."
Judgmental responses	Nurses should not make value judgments about the patients' healthcare decision. Making judgments that the patient has done something right or wrong implies the nurse is the only person who has the ability to make those decisions. In a positive nurse-patient relationship, the nurse should not be seen as superior to the patient.	The nurse tells the patient, "You know the reason you have lung cancer is because you smoked for forty years."
Arguing	Arguing with patients must be avoided at all costs. Arguing or challenging a patient implies that the nurse thinks the patient is lying or misinformed, damaging the nurse-patient relationship. Arguing usually prevents the patient from trusting the nurse.	The nurse argues with patient about their diet, the patient raises their voice, and the nurse does too.

**TABLE 2.6** Nontherapeutic Communication Techniques

## REAL RN STORIES

### An Argument Averted

**Nurse:** Louisa, BSN

**Clinical setting:** Catheter Laboratory Recovery Unit (CLRU)

**Years in practice:** 1.5 in CLRU

**Facility location:** Santa Rosa, California

My patient, a 74-year-old male named Lenny, was a Vietnam War veteran who was also held as a prisoner of war for two years before being freed. He had a femoral access right leg angiogram. He was scheduled to recover in the unit for six hours. After the six hours had expired, according to the unit policy, the patient was to be driven home by a responsible adult because the patient had received conscious sedation. I informed the patient of the policy, and then he quickly became angry saying that he would be getting a taxi home and would not be released to a responsible adult. I clarified the patient's response, explaining to the patient if he was unable to be released to a responsible adult, he would need to be admitted and released the next day. He became enraged and tried to get out of bed, swinging his fists at me, as he screamed that he was going home and did not need to be babysat like a child. Another nurse who worked on the unit called the nurse manager to the patient's room because they heard the patient's screaming. After much deliberation between the patient, the nurse manager, and me, the patient agreed to stay another four hours, to be released to themselves.

## 2.5 Barriers to Communication

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze different types of communication barriers
- Recognize how emotional intelligence can overcome communication barriers
- Describe the nurse's role in overcoming communication barriers

Communication barriers are anything that prevent the message sent from being received or understood (Kunsmann, 2022). Communication barriers can impact the health care that is delivered and produce negative outcomes. Miscommunication can cause breakdowns in the healthcare team and the nurse-patient relationship and can affect entire healthcare facilities, costing money and time. Nurses need to prevent miscommunication from occurring by recognizing common communication barriers and preventing them from occurring in the first place.

### Types of Communication Barriers

There are many types of communication barriers. The nurse should analyze all of the possible communication barriers and develop or use strategies to overcome those challenges. Nurses who use effective strategies to overcome communication barriers can engage in effective communication with their patients and families promoting safe, effective healthcare.

#### Physical Barriers

A **physical barrier** is one of the biggest challenges to communication. Physical barriers include noise, architecture, environment, time, or distance ([Table 2.7](#)). Each of these physical barriers can cause difficulties with communication, and if more than one is present, communication breakdown can occur. Physical barriers with communication can also be language and hearing barriers. When these physical barriers are present, healthcare providers should use medical interpreters to overcome them ([Figure 2.8](#)).

Physical Barriers	Definition	Example
Environment	The environment can prevent a message from being delivered clearly, and it is not always controllable. To prevent the environment from creating communication barriers, nurses should establish and practice emergency action plans for natural disasters.	A hurricane occurs and floods the first floor of the hospital. Patients are moved throughout the hospital in response.
Stimuli/noise	Noise is present in every setting. Nurses should strive to reduce extraneous noise for their patients, like attending to alarms on machines that are being used to care for the patient or closing a door to decrease noise in a patient's room. Nurses can use written communication if they are unable to decrease the noise to overcome the communication barrier. Other stimuli, such as cell phones and televisions, also can prevent messages from being received.	The healthcare clinic is under construction, and there is the sound of drilling and sawing throughout the day as nurses take care of patients.
Space configuration	Healthcare providers need to have common areas for patient care along with private areas. Respect for a patient's confidentiality demands certain designs for facilities. Nurses should be aware of the architecture when delivering sensitive information to patients, and change venue as warranted.	The clinic rooms have thin walls, and voices can be heard between the rooms.
Time	Health care is a time-relative profession, and nurses should always try to respect the timeliness of communication. Nurses may not be able to check all orders immediately; however, the nurse should recognize the timeliness of their response can overcome the communication barrier.	The nurse interrupts the patient to explain they have to return and will be right back, but the nurse does not return for two hours.
Distance	Distance is the physical area separating a patient from a healthcare provider, and it can include the patient being in a remote area without healthcare access. Sometimes technology can overcome a distance barrier, but that implies that the patient has access to technology. Telehealth, the delivery of health care remotely with telecommunication, can be used to bridge the distance.	The nurse on a remote island in Hawaii uses telehealth to connect to the university hospital on the mainland for a patient who has uncommon symptoms of a disease.

**TABLE 2.7** Physical Barriers

Physical Barriers	Definition	Example
Technical difficulties	Technical difficulties are any unplanned or unexpected equipment problems. Nurses can help overcome technical difficulties by performing maintenance of communication and presentation tools, testing performance before use, troubleshooting difficulties with other peers, and utilizing information technology support staff.	The nurse works with information technology to fix a problem with the lectern during an education session for patients about heart disease and diet.
Volume of information	Information overload can occur easily, and each person's threshold for information will be different. The healthcare provider or the patient can stop listening or tune out the information. Health care is an information-based industry, and when the volume of information has reached maximum capacity, healthcare outcomes are negatively impacted.	A patient at the clinic has researched their diagnosis, inguinal hernia, on the internet and is expressing concern about surgery based on the information they read.

**TABLE 2.7** Physical Barriers

(a)

(b)

**FIGURE 2.8** (a) Physical communication barriers include many facets. Concert noise and the venue itself may interfere with conversation. (b) Nurses combat distance barriers using telehealth at satellite facilities. ## PATIENT CONVERSATIONS

### Getting a Patient Ready for Open-Heart Surgery

**Scenario:** A patient is scheduled for coronary artery bypass graft surgery in three days, and the presurgical nurse calls the patient on their mobile phone to discuss the upcoming surgery.

**Nurse:** Hello, Mr. Stanley, my name is Laura, and I am the presurgical nurse to check on you before your open-heart surgery.

**Patient:** Please call me Tom.

**Nurse:** Okay, Tom, how are you doing?

**Patient:** Well . . . not well considering I am having open-heart surgery, but I feel okay right now.

**Nurse:** Can I verify your name and date of birth before we continue this conversation, please?

**Patient:** Yes, Tom Stanley, DOB 4/30/1942.

**Nurse:** Thank you, so I am hearing you feel all right right now. Have you been feeling bad in the last couple of days?

**Patient:** No, I have been feeling all right physically for a couple of weeks, but I am overwhelmed about all of the preparation for this surgery.

**Nurse:** I am sorry you are feeling overwhelmed. What can I do to help?

**Patient:** So many people are contacting me—the healthcare provider’s office, the nurse practitioner for the surgeon, the laboratory, and radiology. I cannot answer them all back, I have stopped trying.

**Nurse:** I am hearing that you are finding it hard to navigate through the appointments required for the open-heart surgery, is that right? I have some suggestions to help you.

**Patient:** I would love to hear them.

**Nurse:** I can contact the laboratory and radiology for you and make you an appointment at a time you find acceptable, would that help?

**Patient:** Yes, that would be a great start, thank you.

**Nurse:** Then we can make a list together of priorities for the rest of the calls you need to make. Do you think that would be helpful?

**Patient:** Yes, thank you so much, Laura. I already feel better.

### Emotional Barriers

Emotional barriers can also hinder communication. An **emotional barrier** is a mental limitation or block that influences how others’ actions are perceived. All people process things differently, attaching emotions to the processes. In health care, the additional emotions of fear, pride, anger, and anxiety cause disruption in the communication process (Table 2.8). Nurses should attempt to mitigate emotional barriers to communication when possible, as often these kinds of barriers can cause the most miscommunication.

Emotional Barriers	Definition	Examples
Fear	Fear occurs when a patient feels frightened or intimidated by the facility, procedure, personnel, or consequences. When patients are afraid, they are less likely to seek out help or information.	The patient states they did not hear what the nurse said because they are worried about the upcoming antibiotic injection they will receive, as they are afraid of injections.
Pride	Pride is a feeling of great satisfaction in oneself or one’s own achievements. Patients who are proud may delay seeking out health care because they might be perceived as weak. Healthcare providers can also disrupt communication with feelings of pride. Healthcare providers may not ask for help because they want to appear competent. In many situations, help is necessary, and not seeking help can cause detrimental healthcare outcomes.	A patient falls when getting out of bed after insisting they did not need help.

**TABLE 2.8** Emotional Barriers

Emotional Barriers	Definition	Examples
Anger	Anger is a strong feeling of annoyance, antagonism, or displeasure. Patients who are angry at either healthcare providers or healthcare processes are less likely to accept and interpret communication appropriately. Nurses should try to deescalate anger when it is present in communication.	A family member yells at a healthcare provider, upset about continuity of care for their significant other.
Anxiety	Patients in any healthcare setting often experience some form of anxiety. Anxiety is a feeling of unease, trepidation, or uncertainty. Patients who are anxious are less likely to hear and correctly interpret an entire message, hearing only parts of the message. Healthcare providers can also experience anxiety and may change the way they send the message to the patient.	The nurse prepares the patient for surgery, the patient is visibly upset and shaking their head, stating they cannot understand anything.

**TABLE 2.8** Emotional Barriers

## Emotional Intelligence

Sometimes referred to as emotional quotient, **emotional intelligence (EI)** is the capacity to control and express emotions. Emotional intelligence can be used to improve communication as healthcare providers who are emotionally intelligent are more likely to handle interpersonal relationships empathetically (Meng & Qi, 2018). Emotional intelligence includes self-management, self-awareness, social awareness, and social management ( [Figure 2.9](#)).

**FIGURE 2.9** Healthcare providers need to be aware of their EI and be actionable for both themselves and others. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LINK TO LEARNING

Take this [quiz to test your emotional intelligence \(https://openstax.org/r/77emotionquiz\)](https://openstax.org/r/77emotionquiz) so you can improve your communication with patients.

### Self-Management

The ability to control impulsive feelings and behaviors is called **self-management**. Self-management includes being able to manage emotions in healthy ways, like exercise and mediation. Healthcare providers who practice self-management take initiative on projects and follow through on commitments to themselves and those around them. When practicing self-management, healthcare providers can adapt to changing circumstances, which are ever present in healthcare environments.

### Perceptual Barriers

A **perceptual barrier** to communication is an internal bias that influences the way an individual perceives others. Perceptual barriers can include personal experiences, beliefs, preferences, and individual triggers, and they can cause a breakdown in communication. For instance, if a patient has experienced sexual assault, they may be triggered by any experience in which they may perceive they are being dominated, causing miscommunication to occur. Nurses can ask patients about their personal experiences, belief preference, and triggers before and during care to overcome this barrier. Be aware of your own perceptual barriers and how they might impact your communication.

### Expectations

Managing expectations can eliminate emotional reactions. An expectation is the belief that something will happen. Once emotional reactions are managed, expectations are managed in return. Healthcare providers who manage expectations are better able to care for patients. For example, a patient may have the expectation that they will feel better immediately postoperatively from knee replacement surgery, only to find that they are in pain from the surgery. The nurse should help the patient manage their expectations for the postoperative period, thereby helping to manage the emotional reactions the patient might have.

### Self-Awareness

Having **self-awareness** is being able to recognize and understand one's own emotions that are occurring in communication encounters. Healthcare providers should attempt to have self-awareness when caring for patients. Healthcare providers can encounter circumstances in which their nonverbal communication may show their thoughts that may not always be positive. For instance, a patient who has a large, necrotic wound with a foul odor will probably be embarrassed about the wound and will appreciate healthcare providers who can care for them without betraying their emotions in their facial expressions like holding their breath or making a facial expression of disgust.

### Biases

A **bias** includes prejudice for or against a person or group compared to another group. Biases in healthcare providers obstruct the nurse-patient relationship, nurses' assessments, and patient care. An **implicit bias** is unconscious bias that can affect both patients and nurses, defining how care is given and received (Bedford, 2018; FitzGerald & Hurst, 2017). Bias is most often directed toward people who have a higher weight, older people, and people who identify as lesbian, gay, bisexual, transgender, queer/questioning, intersex, and asexual (LGBTQIA+) (Gopal et al., 2021). However, bias can occur toward a different race, religion, ethnicity, sexual orientation, age, or even someone's size. Nurses should address biases by working to eliminate them from their practice.

## LINK TO LEARNING

Nurses can take free courses at the [Institute for Healthcare Improvement \(IHI\) \(https://openstax.org/r/77IHI\)](https://openstax.org/r/77IHI) in the IHI Open School. Search for the Triple Aim for Population Courses, focusing on TA 101 (Introduction to the Triple Aim for Populations), TA 102 (Improving Health Equity), and TA 104 (Building Skills for Anti-Racism Work). These courses help healthcare providers examine their responsibilities in order to care for patients and families optimally.

### Stereotypes

A **stereotype** is defined as an oversimplified image of a certain people or group. For example, a stereotype might be assuming all older people are hard of hearing. Stereotypes can be described as a prejudgment of a patient based on their appearance, for example. Nurses should attempt to avoid stereotyping patients, which can lead to negative outcomes. Stereotypes can be present for a patient's sexual identity, socioeconomic status, education level, age,

disability, and geographic location. Healthcare providers should be aware of their stereotypes and replace them with new perspectives whenever possible. Healthcare providers should also educate themselves about stereotypes and prevent those stereotypes from negatively affecting the care they provide.

### Social Awareness

Another dimension of EI is **social awareness**. Social awareness is an understanding of the strong emotions one might encounter as part of their experiences and how they can empathize with others. For instance, a nurse who witnessed a fetal demise during delivery may develop intense emotions of sadness with subsequent deliveries. Being socially aware of the perspective of a parent who is experiencing fetal demise gives the healthcare provider a new perspective to understand the behavior of others who experienced fetal demise. Healthcare providers who have emotionally charged experiences should engage in self-care to relieve the intense emotions so that they can continue to serve patients (Fessell & Goleman, 2020). Healthcare providers who are depleted and not self-aware of or unable to manage emotions will not be able to provide care to patients. During the COVID-19 pandemic, nurses experienced deeply emotional experiences caring for many patients who died; patients who included coworkers, friends, and families. Nurses needed to participate in self-care to prevent burnout.

### Cultural Barriers

A **cultural barrier** can affect the delivery of health care. Healthcare providers should strive for cultural competence as well as cultural humility when caring for patients. Cultural competence is the ability to understand a patient's cultural context to effectively provide quality care (AACN, 2021). Cultural humility involves continuous self-reflection to identify personal cultural characteristics and how those may impact actions toward those with similar or different cultural contexts. While cultural competence is a solid foundation to understanding a patient's cultural context, cultural humility allows for deeper execution of these conceptualized ideals.

## LINK TO LEARNING

Resources for healthcare providers to [take steps toward cultural competence \(https://openstax.org/r/77culturalsteps\)](https://openstax.org/r/77culturalsteps) are provided by the Agency for Healthcare Research and Quality.

### Social/Relationship Management

The final aspect of EI is **social/relationship management**. Relationship management includes building and maintaining good relationships, with empathy and patience as the tenets of those relationships. Relationship management can close the feedback loop for communication in which healthcare providers make sure their communications are frequent, clear, and open to feedback, creating a stable base for a good working relationship.

### Interpersonal Barriers

An **interpersonal barrier** can cause conflict within relationship management. Nurses know good communication with patients increases quality healthcare delivery and influences patient satisfaction and better health outcomes. When interpersonal barriers are present within the nurse-patient relationship and communication fails, catastrophe can occur leading to patient injury or death. Nurses should strive to avoid interpersonal barriers.

## Nurse's Role in Overcoming Communication Barriers with Patient Teaching

Patient teaching helps nurses overcome communication barriers and in turn helps patients overcome poor health outcomes. Good communication in the nurse-patient relationship helps the patient understand and apply the concepts being taught, which leads to more positive health outcomes for the patient. Nurses who teach without overcoming communication barriers give ineffective instruction that can lead to poor health outcomes for the patient because they could not understand what the nurse was teaching.

### Effective Teaching Strategies

Effective teaching strategies allow the nurse to address the communication barriers first. Once the nurse has determined what the communication barrier is—for example, a patient has a vision impairment—the nurse can use effective teaching strategies to help the patient better understand the concepts being taught. In this case, the nurse would ask the patient for their preferred accommodations. The nurse could then obtain the form of educational information the patient prefers, whether it is Braille, audiotape, extra-large print, or electronically formatted

handouts.

### Evaluating Patient Learning

Once the nurse has determined the patient's preferred form of communication, the nurse is tasked with evaluating the patient's learning. With deference to the patient's communication preference, the nurse should assess the patient's learning by return demonstration, asking the patient to restate the instructions or asking questions to check learning. All these approaches should include questioning and clarification from the nurse.

### Document Teaching-Learning Process

The nurse must document the teaching-learning process. The nurse should document all teaching to the patient and the patient's response to the teaching that occurred and describe or list the educational materials that were given to the patient. The nurse should use the correct forms as dictated by the facility. The nurse should include in the documentation the teaching strategies that were used, the communication barriers that may be present, and further learning needs and recommendations for further education.

## Summary

### [2.1 Types of Communication](#)

Nurses are responsible for providing good communication in all healthcare settings and facilities. The nurse should establish a trusting relationship with the patient and use appropriate communication demonstrating active listening, pertinent inquiry, and empathy throughout each patient encounter. The nurse should use verbal communication with the patient, making sure there is congruency with nonverbal communication during the patient encounter. The nurse can use written and electronic communication as a means of communicating with the patient, noting what the patient prefers. The nurse can use four levels of communication—intrapersonal, interpersonal, small-group, and public communication—when providing safe and effective care for the patient. Reflecting on care provided for the patient encompasses intrapersonal communication and is a powerful tool allowing growth of the nurse. The nurse should use both interpersonal and small-group communication while engaged in patient care, as each helps the nurse provide safe and effective care. Using public communication for health care is paramount to disseminate research findings.

### [2.2 Models of Communication](#)

Nurses should recognize that there are several models of communication that they can employ when communicating with patients and other healthcare team members. For example, if the nurse would like to communicate without feedback, such as when providing presurgical directions, the nurse should use the transmission model of communication, establishing a linear, one-way model of communication. If the nurse is providing discharge instructions, the nurse should use the interactional model in which two-way communication is established between the patient and nurse, allowing for feedback from either the patient or the nurse. If the nurse is responsible for presenting research findings from a research study conducted where they work, they should use the transactional model of communication, in which the nurse can establish social relationships with other researchers who have interest in the topic. Nurses need to recognize which model of communication is most useful in each situation.

### [2.3 Effective Communication](#)

Nurses help to establish effective communication among patients and the healthcare team. Effective communication that is factual, clear, concise, practical, and persuasive is important as many ideas and thoughts are exchanged between the patient and their healthcare team. Professional communication should be part of effective communication among healthcare team members and the patient, establishing trustworthiness in the relationship. Professional communication should include courtesy and empathy, which assist in developing trustworthiness. Patients are more likely to change health behaviors if they trust their healthcare team. To assist patients in changing their health behaviors, healthcare team members should use MI. Motivation interviewing uses the processes of engaging, focusing, evoking, and planning to help the patient adopt healthier behaviors. The use of effective, professional communication with MI should help the patient to meet their health goals.

### [2.4 Therapeutic Communication](#)

Therapeutic communication is a technique that should be used by all healthcare providers because it allows patients the ability to better express themselves. Patients who can express themselves better are more likely to be engaged in the nurse-patient relationship and be more interested in improving their health outcomes. Nurses should use open-ended questions and engage in respectful communication with the patient. Nurses should be able to evaluate their own therapeutic communication with the use of a feedback loop. Nurses should avoid nontherapeutic techniques for communication, as they prevent further communication from occurring between the nurse and the patient.

### [2.5 Barriers to Communication](#)

Nurses need to recognize communication barriers and work with patients and the healthcare team to overcome them. Patients receive better, more comprehensive health care if communication barriers, such as noise or physical environment that occur often in healthcare settings, are removed. Healthcare providers should be cognizant of their EI to overcome communication barriers. If the healthcare provider regularly practices self-management, their ability to provide effective communication is increased. Because the healthcare environment can be fraught with

communication barriers, using EI to disable some of those barriers serves patients well. Nurses have a unique opportunity to overcome communication barriers; they are usually the main communicator with the patient, and if nurses recognize and address the communication barriers present, then safe, effective care that the patient is satisfied with will result. Communication is the basis of health care, and surmounting the barriers effectively positively affects the health care delivered.

## Key Terms

- active listening** when someone **listens by** giving their full attention, listening to understand, and providing thoughtful input
- assertiveness** showing confidence in oneself
- bias** prejudice for or against a person or group compared to another group
- channel** the mode in which the communication is sent
- communication** the sharing of ideas and thoughts among people
- courtesy** the practice of being polite, respectful, and considerate
- cultural barrier** a mental limitation or block about other cultures
- culturally competent care** meeting and respecting a patient's social, cultural, and linguistic needs while providing care
- electronic communication** all communication transmitted electronically
- electronic health record (EHR)** a digital format of a complete medical record of a patient that is able to be shared across multiple healthcare organizations
- electronic medical record (EMR)** a digital format of a patient's medical chart specific to a single medical facility or practice
- emotional barrier** a mental limitation or block that influences how others' actions are perceived
- emotional intelligence (EI)** the capacity to control and express emotions
- empathy** the ability for one person to understand and share the feelings of another person
- engage** active listening, with nonverbal communication, asking for feedback when necessary
- false reassurance** giving comfort that is not based in facts
- feedback** the response given by a receiver to a sender
- Health Insurance Portability and Accountability Act (HIPPA)** a federal law creating the national standards to protect sensitive patient health information from being disclosed
- health literacy** the ability of a patient to understand and use information to make health-related decisions
- implicit bias** unconscious prejudice
- interactional model** communication as a two-way process that allows for feedback, and a person alternates as both sender and receiver
- interdisciplinary** relating to more than one branch of knowledge
- interpersonal barrier** negative pattern of behavior that hinders communication and impacts relationship management
- interpersonal communication** exchange of information between two or more people
- intrapersonal communication** exchange of information with oneself
- listening** the ability to thoughtfully receive and interpret messages
- message** the information to be conveyed or communicated
- motivational interviewing (MI)** an evidence-based counseling approach that involves discussing feelings and incentives with a patient
- nontherapeutic communication** negative expressions, attitudes, and actions that make a patient feel uneasy
- nonverbal communication** exchange of information without the use of words; with facial expressions, posture, eye contact, gestures, and physical touch
- offering self** contributing support by being present or spending time with a patient
- passive listening** when someone listens to simply hear the messages being sent but may not be mentally or emotionally present and does not engage in the communication process
- perceptual barrier** internal bias that influences the way an individual perceives others
- physical barrier** tangible external or internal obstruction to communication
- public communication** exchange of information between any size audience
- receiver** the person who receives the message and interprets it

**referent communication** the use of faces and objects in the place of words during communication encounters

**reflective thinking** the practice of reviewing past communication experiences

**resolution** determination of an act that depends on both parties agreeing to an outcome

**self-awareness** being able to recognize and understand one's own emotions

**self-management** the ability to control impulsive feelings and behaviors

**semantic noise** type of communication barrier that occurs when the sender and receiver of a message have different understandings of the meanings of words, phrases, symbols, or language in general

**sender** the person who initiates a message

**small-group communication** exchange of information between three or more people

**SMART goal** an acronym for goals that are specific, measurable, attainable, relevant, and timely

**social awareness** an understanding of the strong emotions one might encounter as part of their experiences and how they can empathize with others

**social/relationship management** building and maintaining good relationships with empathy and patience as the tenets of those relationships

**stereotype** an oversimplified image of certain people or group

**therapeutic communication** a specialized form of communication used by healthcare professionals to establish a therapeutic or healing relationship with patients

**transactional model** a two-way process of communication where the sending and receiving of messages happen simultaneously

**transmission model** a one-way, linear process of communication

**verbal communication** the production of spoken language to send to a listener

**visual communication** using visual elements to create messages or impart information

**written communication** any written message, from formal letters to text messages

## Assessments

### Review Questions

1. A nurse is developing a plan of care for a patient who has self-identified communication needs. What would be the most appropriate question for the nurse to ask to assess the communication needs of the patient?
  - a. What is your preferred form of communication?
  - b. Do you speak English?
  - c. Have you ever engaged in self-talk?
  - d. Do you like to talk with your family?
2. What form of communication is the nurse using when she notices the patient is crocheting a blanket and, speaking directly to the patient, asks them about the blanket?
  - a. public
  - b. interpersonal
  - c. intrapersonal
  - d. small group
3. The nurse is preparing to discharge Mr. Francois who is 42 years old and speaks only French. What action by the nurse best provides discharge teaching?
  - a. Thoroughly explain his discharge instructions using simple words.
  - b. Give him a brochure and show him a website that has information in French and English.
  - c. Ask the registered nurse on your unit who speaks French to help explain the discharge information.
  - d. Use the hospital-provided translation services even though it will take time to set it up.
4. A nurse provides discharge instructions for a patient and family. Which model of communication should the nurse use to assess learning?
  - a. transmission model
  - b. transactional model
  - c. interactional model

- d. action model
5. A nurse provides discharge instructions for a patient. While the nurse is checking if the patient understands the discharge instructions, the patient cannot recall any of the instructions. The nurse assesses the communication and determines that semantic noise caused a breakdown in communication. What is an example of semantic noise?
- machines alarming in the room
  - increased foot traffic in the hallway
  - frequent public address system announcements
  - use of medical jargon
6. When conducting MI with a patient, what should the nurse say to encourage the patient?
- Let's discuss how you think the change you want to make can be done in small, achievable goals.
  - Please tell me about what the healthcare provider said to you about your health.
  - You think you will give up something if you make this change.
  - Help me understand how this change will affect your lifestyle.
7. A nurse discovers a patient on the floor. The patient states they fell out of bed, they could not reach the call light, and no one answered when they yelled. After checking the patient for injuries, the nurse addresses this adverse event and wants to bring resolution. What is an appropriate action by the nurse?
- Find out who was responsible for placing the call light and discuss proper call light placement.
  - Ask the charge nurse to talk to the patient about fall risk.
  - Discuss with the healthcare provider keeping all four side rails up at all times.
  - Assemble a care team and discuss ways to prevent falls and positioning of personal essential items.
8. What would be an example of a therapeutic response by a nurse?
- Why are you still smoking?
  - My mom had a mastectomy after she was diagnosed with breast cancer, I think you should do the same.
  - Don't you want to be considered a good patient? You better eat all your peas.
  - Would you tell me more about your fear of magnetic resonance imaging (MRI)?
9. What would be an example of a nontherapeutic response by a nurse?
- The nurse is silent while the patient is crying.
  - The nurse holds the patient's hand during IV line insertion.
  - The nurse jokes with the patient about weather.
  - The nurse defends a peer's actions during the previous shift.
10. What physical communication barrier would the nurse be able to intervene in when providing discharge education for a patient?
- unit construction on patient rooms
  - severe thunderstorm occurring in the geographical area
  - a hospital-wide computer failure
  - short educational sessions to prevent information overload
11. Which aspect of EI should the nurse consider when faced with caring for a patient who has been physically assaulted, as the nurse has experienced physical assault themselves?
- self-management
  - relationship management
  - social awareness
  - self-awareness
12. What would be a nurse's response that demonstrates an evaluation of patient learning?

- a. Do you need help checking your pulse?
- b. You should take your medication at the same time each day with food.
- c. I will provide written instructions on how to administer your insulin.
- d. Would you please demonstrate to me how to suction your child's tracheostomy?

### Check Your Understanding Questions

1. Describe which level of communication you would use if talking with a patient and their family.
2. Describe how the nurse would incorporate all three models of communication when speaking with a patient and their family about their wishes for end of life. Defend your answer.
3. Describe how you would use MI to educate a patient about diabetes and diet.
4. Describe ways a nurse can change nontherapeutic communication to therapeutic communication.

### Reflection Questions

1. What information might you need when assessing the communication needs of a patient?
2. Why does the transmission model of communication not work for many patient situations?
3. What is the priority for the nurse who is assigned to care for a patient who is in a medically induced coma and unable to communicate? What models of communication would the nurse use with the patient and family and why?
4. When would the use of silence as therapeutic communication not work?

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #1: Part 1](#).  
Do you think the patient has a high level of health literacy? Why or why not?
2. Refer to [Unfolding Case Study #1: Part 2](#).  
Which model of communication (transmission, interactional, or transactional) do you think is most appropriate to use with the patient and why?
3. Refer to [Unfolding Case Study #1: Part 3](#).  
What would be an example of nontherapeutic communication between the nurse and patient?

### What Should the Nurse Do?

1. A nurse provides discharge teaching to a patient for who is only Spanish speaking. What is a priority for the nurse?
2. A nurse is working with a healthcare provider who wants to send the nurse text messages about patients on their personal phone, which is not secured by the clinic. What should the nurse tell the healthcare provider?
3. The nurse is caring for a patient who states that the COVID-19 virus is a hoax, the pandemic response was not necessary, and this was all just a way for the government to control people. What aspect of effective communication should the nurse use to educate the patient?
4. What is the priority for the nurse who is assigned to care for a patient who has experienced a traumatic brain injury and is having difficulty communicating? What communication barriers could possibly be present? How should the nurse overcome those communication barriers?

### Competency-Based Assessments

1. Use the internet to research healthcare communication. Discuss how these processes are helping healthcare providers provide safe and effective care for patients. Discuss one communication tool you found and its advantages.
2. Use the internet to research MI. Discuss the type of patient who would best benefit from the MI process.

3. Read the journal article [“More than words”—Interpersonal communication, cognitive bias, and diagnostic errors”](https://openstax.org/r/77MoreThanWords) (<https://openstax.org/r/77MoreThanWords>) in *Patient Education and Counseling*. What do you think about this article? What is your bias? How do you plan to overcome your bias when caring for patients?

# CHAPTER 3

## Healthcare Delivery Systems

**FIGURE 3.1** Healthcare delivery systems include all aspects of public and private health, wellness, and prevention and must include a culture of cooperation and collaboration. Nurses have an active role in the healthcare delivery system and directly impact it. ### CHAPTER OUTLINE

- 3.1 Levels of Care
- 3.2 Organizational Frameworks and Structure
- 3.3 Barriers to Healthcare Access
- 3.4 Culture

**INTRODUCTION** The U.S. healthcare industry is like a vast machine that has been added onto and adjusted over time. The healthcare machine is constantly changing and evolving, adding new ideas, practices, and systems to improve patient care, and slowly removing outdated ideas, practices, and systems that no longer work. Understanding how healthcare systems function can positively impact a new nurse’s ability to adjust to their healthcare environment.

### 3.1 Levels of Care

#### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe primary health care
- Define secondary health care
- Explain tertiary health care

A patient’s **level of care**—primary, secondary, or tertiary—is determined by the complexity and amount of care they receive at any given time (Figure 3.2). Primary care is the most fundamental, and tertiary care is the most complex.

Most individuals move smoothly between levels of care throughout their lifetimes but typically rely mainly on the primary healthcare arena. Individuals with multiple health concerns or complex needs will rely more heavily on the secondary level of care where they can access specialty care. At the same time, those with critical injuries will, at least temporarily, rely on tertiary care.

**FIGURE 3.2** Think about the levels of care like a pyramid with a strong, broad base and small top. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Primary Health Care

The most fundamental access level of health care is **primary health care**. Primary health care focuses on the prevention of illness and the maintenance of health of an individual. As such, it is the “primary” type of healthcare service used by most individuals most of the time. Suppose a patient needs an annual physical, a flu shot, or to have their seasonal allergies treated. In those cases, they will probably see a primary care provider (PCP). If an individual has a new concern or condition, they will also usually begin at the level of primary health care for foundational evaluation and treatment.

Like how the base of a pyramid supports the top, a strong primary healthcare foundation supports the rest of the healthcare system. Studies have consistently shown that patients with a primary healthcare provider have improved health outcomes because changes in health status are identified and managed early (Willis et al., 2021). Patients without a primary healthcare provider often enter the healthcare system at a higher level in the pyramid, which always results in poorer outcomes and higher overall costs.

### Primary Healthcare Goals

The goals of primary health care are health promotion and disease prevention. In other words, to provide preventive care and screening for illness or the development of conditions, primary health care identifies conditions early enough to minimize their impact on a patient’s quality of life and financial resources, treats minor to moderately severe acute and chronic conditions, and coordinates care between higher levels on the pyramid. For example, PCPs order colorectal screening, monitor blood pressure and basic blood work, and manage childhood immunizations (Willis et al., 2021). Primary healthcare goals include the following:

- being a patient’s first contact with the healthcare system (Bodenheimer & Grumbach, 2016);
- supporting current health status (for healthy individuals) (Willis et al., 2021);
- preventing decline in health status, when possible;
- identifying early signs of declining health status;
- treating a wide variety of basic illnesses, conditions, and injuries;
- providing continuity of care over time with the same physician (Bodenheimer & Grumbach, 2016);
- referring patients to secondary or tertiary providers if they need more complex care (Bodenheimer & Grumbach, 2016); and
- functioning as a **medical home**, supplying comprehensive primary care, coordinating care across the other levels of health care, and ensuring patients’ quality of care and safety (Agency for Healthcare Research and Quality [AHRQ], 2022).

## LINK TO LEARNING

The AHRQ offers a set of suggested assessments to be performed on all patients. In [Appendix 4: Adult Health Assessment Sample Questions](#) (<https://openstax.org/r/77AdultHealthQs>) of *Health Assessments in Primary Care*, a checklist of these suggested assessments is offered. Content areas where patients provide affirmative answers can guide primary care visits and assist in identifying patient needs.

### Primary Healthcare Providers

A **primary care provider (PCP)** includes any physician (medical doctor or doctor of osteopathic medicine), nurse practitioner, clinical nursing specialist, or physician assistant. PCPs provide, coordinate, or help patients access a range of healthcare services ([Table 3.1](#)) (Healthcare.gov, n.d.). Primary care providers include family practice physicians, general practitioners, pediatricians, geriatricians, internal medicine physicians, nurse practitioners, physician assistants, registered nurses (RNs), licensed practical nurses (LPNs)/licensed vocational nurses, and a wide variety of assistive personnel.

Provider Type	Total Number in the United States	Number Working in Primary Care
Physicians	730,026	228,936
Nurse practitioners	220,332	94,302
Physician assistants	118,195	42,195

**TABLE 3.1** Percentage of Primary Care Providers Working in the United States (Source: Willis et al., 2021.)

### Primary Healthcare Settings

While most people think “doctor’s office” when they consider seeing a primary care practitioner, primary care occurs in a variety of settings. Primary care can happen in walk-in clinics, urgent care centers, pharmacies, and schools ([Figure 3.3](#)). Any place actively seeking to manage minor illness or injury, to offer preventive care such as vaccinations, or to maintain an individual’s current health offers primary care ([Table 3.2](#)) (Healthcare.gov, n.d.).

**FIGURE 3.3** This PCP obtains a patient’s temperature. (credit: “It takes a village: military medical in East Africa coordinates response to COVID-19” by US Africa Command/Flickr, CC BY 2.0)

Setting/Type	Reason	Scheduling
Primary care office	Annual physical, new complaints, acute illnesses, vaccinations, blood work	Usually scheduled, may be unscheduled
Walk-in clinic/urgent care	Usually freestanding; immunizations, sports or occupational physicals, acute illness, injury care	Usually unscheduled, may be scheduled
Pharmacy	Some testing (such as COVID or flu) and immunizations	Either scheduled or unscheduled
School	Medical care for students who take medications for acute or chronic illnesses or who become ill while at school	Either scheduled or unscheduled
Community settings such as health fairs or community centers	May offer blood pressure screenings, other basic well patient care, and education and encouragement for patients to be mindful of their health	Either scheduled or unscheduled

**TABLE 3.2** Common Primary Healthcare Settings

### Primary Healthcare Procedures and Services

Although the keystone of primary care is preventive care and screening, primary healthcare professionals perform the broadest range of procedures and offer the most services of all levels of care (Hopayian, 2022). At the primary care level, patients may receive laboratory tests, injections, x-rays, minor wound care/procedures, nutritional counseling, and/or referral for additional screening, specialty treatment, or home health care. Primary care procedures also include ordering colorectal screening recommended for all people past a certain age, monitoring blood pressure and basic blood work, and managing childhood immunizations. In addition to preventive care and screening, primary care practitioners offer frontline treatment for common illnesses such as strep throat, flu, or injuries, such as a sprain or a cut needing basic stitches. They also manage many conditions their patients experience that are mild to moderate in severity. For example, in 2019, more people visited their PCP to manage hypertension, diabetes, or asthma than sought secondary care for the same issues (Willis et al., 2021). Finally, and very importantly, PCPs aid patients in accessing higher levels of care by making referrals and ensuring that all patient needs are being met.

## PATIENT CONVERSATIONS

### Referral to a Higher Level of Care

**Scenario:** A 49-year-old male patient recently had x-rays ordered from his PCP related to long-term pain in his back. At the provider's request, the nurse calls the patient to offer the results and next steps. The nurse is polite, introduces herself, states the reason for the call, and ensures the patient can speak with her. She is friendly with the patient and does not make him feel rushed. She establishes a partnership with the patient and provides him with the opportunity to decline care. Finally, she finishes with one topic before she begins another.

**Nurse:** Good afternoon, Mr. Smith. This is Sandy, Dr. Collier's nurse. Dr. Collier asked me to call you about your recent x-ray. Is now a good time to talk?

**Patient:** Sure, Sandy, I've got a few minutes. How are you today?

**Nurse:** I'm doing great. How are you feeling? Did the steroids and medication Dr. Collier prescribed for you help your back?

**Patient:** I've been taking them just like she ordered, and my back does feel better.

**Nurse:** Excellent! That's what we were hoping to hear. The x-ray of your back shows some age-related changes and arthritis like you discussed in the office. Dr. Collier would like to refer you to physical therapy to see if we can get your back stronger and more mobile now that the inflammation is calming down. I think she mentioned this to you at your appointment. Can I make that referral?

**Patient:** That would be great! Thank you.

[In addition to the information the doctor expected to find regarding the patient's back, the doctor also noted an unexpected finding of a large kidney stone on the x-rays. The nurse changes to this new topic and proceeds to discuss next steps with the patient.]

**Nurse:** We will give physical therapy a call to get that first appointment set up for you today. Now, in addition, when the doctor looked at your x-ray, Dr. Collier also noticed a large kidney stone in your left kidney. Are you having any pain in your lower back?

**Patient:** Well, it has been aching back there a lot, but I just assumed it was related to the other issues in my back.

**Nurse:** Dr. Collier would like to refer you to a urologist about that stone. As I mentioned, it is quite large and may give you more problems in the future. May I make that referral?

**Patient:** Yes, please, and thank you. Do I need to worry about surgery?

**Nurse:** It is a possibility, but the urologist has many treatment options, and I am sure that they will work with you to find the best one for you. I will get that referral made today. Do you have any questions for me?

**Scenario follow-up:** The patient is understandably concerned about the potential of surgery related to his kidney stone. The nurse provides him with honesty and reassurance, without providing any treatment information or telling the patient what the urologist will do, which would be outside of her scope of practice. The conversation is closed after asking the patient if he has any other questions.

---

## Secondary Health Care

The second level of the healthcare pyramid is **secondary health care**, sometimes referred to as acute care or hospital care (Hopayian, 2022). Secondary health care encompasses most of the specialties, practices, providers, and settings to which primary care practitioners provide referrals. Secondary care is the next step when a PCP is unable to assist a patient with successfully managing a healthcare problem (Hopayian, 2022). For example, a patient who continues to have severe episodes of asthma despite being on regular medications would probably be referred to a lung specialist (pulmonologist). Patients also access the secondary healthcare system if they go to the emergency department for an acute illness, an injury, or exposure to an environmental toxin (Figure 3.4). Some patients do not have a primary care provider (PCP), so the secondary healthcare level may be where they enter the system. While not ideal, patients can enter the healthcare system at the secondary level for several reasons. Fear, lack of transportation, limited access to primary care appointments, or lack of insurance may cause a delay in seeking care until the situation is urgent. Or having few PCP offices in a rural community may affect if and when a patient seeks health care. Sometimes patients choose to enter the healthcare system at the secondary level when they are self-pay or when their insurance company or payer allows it (Bodenheimer & Grumbach, 2016).

**FIGURE 3.4** When patients go to the emergency room for illness or injury, they enter at a secondary healthcare level. (credit: “Emergency” by Taber Andrew Bain/Flickr, CC BY 2.0)

### Secondary Healthcare Goals

Secondary healthcare goals are to manage an acute problem in order to return a patient to baseline function, to ensure a condition is well controlled, to provide education about the condition in order to decrease the chances of it becoming a problem again, and to return care to the PCP (Bodenheimer & Grumbach, 2016). Often a visit or two may be enough to address an issue; however, with complicated or chronic issues, secondary treatment may last for extended periods.

Consider an example of a primary healthcare service of ordering a patient referral for a routine screening colonoscopy. This screening is recommended by the U.S. Preventive Services Task Force for all adults over the age of 45 years (Centers for Disease Control and Prevention, 2023). The PCP sent that referral to a secondary care provider, probably a **gastroenterologist** (a practitioner who deals specifically with issues involving the digestive tract). The gastroenterologist scheduled and performed the colonoscopy, which was the only time the patient saw that physician because the results were normal. The issue was managed, and the patient returned to baseline. No further secondary care was needed. Primary care resumed responsibility for the patient’s continued care going forward ([Figure 3.5](#)).

**FIGURE 3.5** Primary care providers order recommended screenings, such as colonoscopies and mammograms, from secondary providers. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Sometimes the process of moving from primary to secondary care and back to primary care can be more complicated. For example, a 16-year-old was admitted to an acute psychiatric facility (a secondary setting) with feelings of profound depression and suicidal thoughts. They stay there for one week, begin medication, and attend a few group sessions. After discharge, they are assigned to a psychiatrist (secondary provider) for medication management and a psychotherapist (secondary provider) for talk therapy. They see the psychotherapist weekly for nine months and the psychiatrist every three months until they relocate to attend college. In this case, the patient’s acute problem was managed by a team of secondary healthcare providers over an extended period of time. While this secondary care was occurring, the patient’s PCP managed all the other routine health care needs the patient had. The PCP remained as the patient’s healthcare provider in the long term, while special secondary providers entered and exited as specific problems arose.

## LINK TO LEARNING

Transitions of care, moving between one provider to another, can be very complicated and may even have deadly consequences. The problem is serious enough internationally that the World Health Organization [issued guidance to assist facilities \(https://openstax.org/r/77SafeCareWHO\)](https://openstax.org/r/77SafeCareWHO) in providing safer transitions. Consider how as a new nurse you can ensure safe transitions.

### Secondary Healthcare Providers

A **secondary care provider** falls into one of several groups: medical (physician, nurse practitioner, physician assistant), mental health (psychiatrist, psychologist, counselors), and allied health professionals (physical, occupational, speech therapy, social workers, and case managers) (Hopayian, 2022; MedlinePlus, 2022). Secondary care providers are specialists in their area of expertise and have had additional training to reach that level of expertise. Specialists are chosen for referral based on the scope of their practice. For instance, a **cardiologist** treats disorders of the heart, a **urologist** treats disorders of the urinary tract system, a **pulmonologist** treats conditions of the lungs, and a **dermatologist** treats disorders of the skin.

### Secondary Healthcare Settings

Patients seek secondary health care for a wide variety of reasons, in many locations, and on a scheduled or unscheduled basis. While reading through [Table 3.3](#), consider why it matters if the health care is scheduled or unscheduled (hint: consider the differences between primary and secondary care).

Setting/ Type	Reason	Scheduling
Specialty care office	Meet with a specialist, such as a cardiologist, urologist, physical therapist, or obstetrician, for first or follow-up appointment	Scheduled
Emergency room	Manage an urgent or emergent illness, condition, or injury	Unscheduled
Hospital admission	Manage an urgent or emergent illness, condition, or injury; general surgical procedures (not complex); give birth; receive mental health care after a crisis	Either scheduled or unscheduled
Same-day procedure center	Have a low-risk, basic procedure or surgery, after which discharge is expected the same day, such as colonoscopy or cardiac stress test	Scheduled
Medical imaging center	Receive a wide range of medical imaging services; may be affiliated with an emergency department or hospital or may be freestanding	Either scheduled or unscheduled

**TABLE 3.3** Secondary Healthcare Settings

### Secondary Healthcare Procedures

Secondary healthcare procedures are procedures performed by secondary providers that usually are focused on a specific body part or organ and are noninvasive or minimally invasive (such as requires no more than topical numbing of the skin). Secondary procedures include the following:

- most medical imaging services (i.e., computed tomography [CT] scan or ultrasound);
- therapeutic techniques, such as chiropractic or dry needling (a technique similar to acupuncture that healthcare providers use to manage pain and mobility issues);
- nonsurgical management of fractures, such as setting and casting;
- organ-specific laboratory work, such as cardiac enzymes, liver functioning, or urine osmolality;

- skin and tissue biopsies (sampling); and
- tests, such as cardiac stress test (treadmill test) or pulmonary function test (blow into tube or machine).

## REAL RN STORIES

---

### Secondary Health Care

**Nurse:** Perry, RN

**Clinical setting:** Emergency department

**Years in practice:** 9

**Facility location:** A midsize community hospital in the southern United States

I was working the night shift in the emergency room early in my career. Rodrigo arrived at the emergency department around 2 a.m. He was a 49-year-old man with obesity of African descent, who was a long-haul truck driver. Rodrigo complained of feeling very unwell with the most severe headache of his life. When he walked into the emergency room, his blood pressure was 199/125. He told the doctor that he did not have a primary care physician because of his job and usually only saw a doctor for his yearly department of transportation physical. He admitted that he was aware his blood pressure ran high and that he had used his wife's blood pressure medicines to pass the physical.

Rodrigo received a CT scan of his head, and the radiologist detected a large aneurysm in his brain (a complication of untreated high blood pressure), which appeared to be leaking. Arrangements were at once made to life-flight Rodrigo to a tertiary center for immediate surgery. He was frightened and showed me pictures of his young children to keep his mind off his fear while waiting for the air transport. Unfortunately, his aneurysm ruptured, and he died in flight to the tertiary center.

I still remember Rodrigo today and feel bad for his family. His death was one of the first in my career, and I know it would probably have been completely avoidable if he had sought care from a PCP to manage his blood pressure.

---

### Tertiary Health Care

The top level in the healthcare pyramid is **tertiary health care** (Figure 3.6). When patients have healthcare problems, illnesses, or injuries that cannot be managed by primary or secondary care, they move into the tertiary healthcare level. Tertiary care may involve invasive medical procedures and major surgery. Tertiary health care is offered using specialty tools and medical staff and involves advanced medical treatments and diagnostics (Hopayian, 2022; MBA Healthcare Management, n.d.). Patients may also go to the tertiary healthcare level when they have rare conditions or multiple comorbidities (many conditions occurring at the same time and requiring secondary care) (Hopayian, 2022). There are fewer tertiary healthcare facilities and hospitals than secondary healthcare ones, and severely ill patients are often transported to distant locations to receive tertiary services.

**FIGURE 3.6** Healthcare providers perform surgery, like the surgery shown here, in tertiary healthcare facilities. Shejal Pulivarti/rawpixel, Public Domain)

### Tertiary Healthcare Goals

The goals of tertiary health care are similar to the goals of secondary health care: manage a severe illness, condition, or injury; return a patient to baseline function; ensure a condition is well controlled; and provide all care possible until it is clear that the patient will not survive. Tertiary care is specific and temporary. The patient receives a service, surgery, or supportive treatment and returns to their PCP (Bodenheimer & Grumbach, 2016).

A previous example of primary health care was a referral for a colonoscopy. An example of secondary health care was when the patient received the colonoscopy, and care returned to the primary level when the procedure resulted in normal findings. An example of tertiary care is what happens if the colonoscopy is not clear. Consider Susan from a rural area in the Midwest where she has a long relationship with her local PCP and receives annual physicals consistently. Her PCP orders a colon screening for her when she is 45 years old per national guidelines, and Susan sees a secondary care provider in a nearby midsize town for the test. During the test, polyps are discovered, removed, and sent to pathology for testing. The pathology results reveal that Susan has colon cancer. Her PCP and secondary provider communicate and decide together to refer Susan to a tertiary facility in the closest metropolitan area. The facility is specifically dedicated to treating cancer. Over the next several months, Susan receives tertiary health care that includes a surgical procedure and chemotherapy and radiation therapy. When Susan is deemed to be cancer-free, her care is returned to her secondary provider for intermittent follow-ups and her primary physician for general health care (Figure 3.7).

**FIGURE 3.7** Observe how the flow of care moves from the PCP through the secondary care provider to the tertiary care level and then back to primary and secondary care. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LIFE-STAGE CONTEXT

### Managing Care for Patients with Multiple Chronic Illnesses

Older patients are the population most likely to use tertiary care and/or multiple secondary care providers related to having multiple chronic illnesses. Having a PCP who accepts the responsibility of functioning as a medical home can be most important for these patients. When patients have multiple specialty providers who are each prescribing medications and not communicating with each other, it is very easy for patients to become sicker due to their medications rather than their conditions. Having a medical home allows older patients and those with multiple chronic medical conditions to have higher quality, more efficient care, because it is coordinated through a single location (AHRQ, 2022).

#### Tertiary Healthcare Providers

There is a lot of overlap between secondary and tertiary care providers in terms of the care they provide. The key difference is the level of management (such as surgery) and expertise the provider can offer. A practice group made up mostly of secondary providers will often have a **tertiary care provider** available on staff to manage patients who require more advanced care. [Table 3.4](#) offers a few examples of tertiary care providers.

Secondary Provider		Tertiary Provider	
Cardiologist	Treats cardiac issues	Cardiothoracic surgeon	Treats cardiac issues and performs cardiac surgery
Pulmonologist	Treats lung issues	Pulmonary intensivist	Manages respiratory arrest and life-threatening respiratory conditions in tertiary intensive care unit settings
Radiologist	Reads and diagnoses patients through medical imaging	Interventional radiologist	Uses medical imaging to actively visualize the internal bodily structures while performing surgery

**TABLE 3.4** Examples of Tertiary Care Providers

#### Tertiary Healthcare Settings

Much of the time, tertiary health care happens in large, urban hospitals (such as a level 1 trauma center) or specialty hospitals (such as cancer center hospitals or hospitals for children). However, tertiary care can take place in any medical location where highly specialized treatment and equipment are available ([Table 3.5](#)). For example, in the discussion of secondary health care goals, an example was given of a 16-year-old who was admitted to a psychiatric facility for secondary management of extreme depression and suicidal thoughts. If the patient had gone to an intensive outpatient treatment program after discharge (say five days a week, six- to eight-hour days, for several weeks), they would have been in a tertiary health care setting, working with professionals trained specifically to provide the most effective level of intensive long-term treatment for that age group.

Setting/Type	Reason
Large urban hospitals with critical care specialties	Care and management of rare or complicated illnesses or traumas, including transplants, surgery, burn units, and intensive care units
Specialty hospitals focused on specific diseases or patient groups	Provide intensive management of specific disease processes, such as cancer or spina bifida

**TABLE 3.5** Settings for Different Types of Tertiary Care

Setting/Type	Reason
Specialty medical clinics	Provide intensive treatments for specific disease processes, such as dialysis for kidney disease
Specialty mental health facilities	Provide intensive treatments for mental health, such as intensive outpatient, day treatment, residential treatment for substance abuse, or electroconvulsive therapy

**TABLE 3.5** Settings for Different Types of Tertiary Care

### Tertiary Healthcare Procedures

Tertiary healthcare procedures include any complex procedure or treatment that is performed by highly trained (or group of highly trained) practitioners with specialized equipment to manage complicated conditions (Astron, 2019). Such procedures may include the following:

- major surgeries;
- organ transplants;
- joint replacements;
- long-term care interventions, such as chemotherapy or substance-use treatment; and
- intricate medical services, such as serious burn and wound care, trauma management, and critical care (Hopayian, 2022).

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Take Action: Levels of Prevention versus Levels of Care

Just as there are primary, secondary, and tertiary levels of care, there are also primary, secondary, and tertiary levels of prevention. Unlike levels of care, which reflect the complexity of care a provider delivers, levels of prevention are types of actions that providers engage in to assist their patients to remain healthy:

- Primary prevention includes actions taken to prevent diseases from occurring, such as immunizations or tobacco cessation.
- Secondary prevention includes actions taken to identify diseases early, such as mammogram screenings or colon screenings to detect cancer or blood pressure screenings to detect hypertension.
- Tertiary prevention includes actions taken to mitigate the effects of illnesses once established, such as physical therapy for a patient with fibromyalgia or arthritis or foot care for patients with diabetes.

It is important to remember that the level of prevention and the level of care are not synonymous. A PCP can order or provide tertiary prevention such as physical therapy and diabetic foot care. The key to remember is that prevention levels are always action steps on the part of the provider, the patient, or both (Kisling & Das, 2023).

## 3.2 Organizational Frameworks and Structure

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the organization of healthcare delivery systems
- Recognize the structure of healthcare delivery systems
- Explain the components for integrated healthcare delivery

The way an individual understands and defines healthcare organization, structure, and delivery varies widely based on who they are; where they live; if they are insured, uninsured, or underinsured; and who controls the healthcare system they use. This section covers healthcare delivery system organization, structure, integration, and providers. In the United States, there is fluidity among the levels of care, and physicians may work at several levels based on the needs of their patients (Bodenheimer & Grumbach, 2016). However, in many parts of the world, primary, secondary, and tertiary care are managed by entirely separate practitioners (Bodenheimer & Grumbach, 2016). Yet, the concepts exist universally. In this section, consider how those interactions affect opinions and experiences

within the healthcare system.

Most countries use one of four basic models to structure and organize their healthcare systems (Chung, 2017). By contrast, the United States combines elements of each of these models. [Table 3.6](#) provides a brief introduction to these models.

Model Name	Primary Characteristics	Countries Using
<b>Beveridge model:</b> single-payer national health service	<ul style="list-style-type: none"> <li>• Government alone pays for and controls all medical costs</li> <li>• Paid for with income tax</li> <li>• Medical facilities are public</li> <li>• Universal coverage</li> <li>• Focused on ensuring equal access, reducing disparities, and centralizing decision-making</li> </ul>	<ul style="list-style-type: none"> <li>• United Kingdom, Spain, Cuba, New Zealand</li> <li>• In the United States: Veterans Health Administration, public, and other federal hospitals</li> </ul>
<b>Bismarck model:</b> social health insurance model	<ul style="list-style-type: none"> <li>• If you are employed, you have insurance paid by you and your employer</li> <li>• Prices are controlled by the government</li> <li>• Medical facilities are private</li> </ul>	<ul style="list-style-type: none"> <li>• Germany, France, Japan</li> <li>• In the United States: employer-based healthcare plans are similar, but government does not control prices</li> </ul>
<b>National health insurance:</b> single-payer national health insurance	<ul style="list-style-type: none"> <li>• Government pays for everyone's health care</li> <li>• Medical facilities are private</li> <li>• Patients can contract for private insurance if they choose</li> </ul>	<ul style="list-style-type: none"> <li>• Canada, Taiwan, South Korea</li> <li>• In the United States: Medicare and some Medicaid</li> </ul>
<b>Out-of-pocket model:</b> market-driven health care	<ul style="list-style-type: none"> <li>• Patients pay for their own care</li> <li>• Usually in countries without strong healthcare infrastructure</li> </ul>	<ul style="list-style-type: none"> <li>• Much of Africa and South America, parts of India</li> <li>• In the United States: those who are uninsured or underinsured</li> </ul>

**TABLE 3.6** Basic Models of Health Care (Source: Based on Chung, 2017.)

## LINK TO LEARNING

The American Hospital Association (AHA) offers [Fast Facts on U.S. Hospitals Infographics \(https://openstax.org/r/77USHsptlFacts\)](https://openstax.org/r/77USHsptlFacts) that compare U.S. hospitals using a variety of metrics. Explore some of their visuals comparing different types of hospitals.

## Organization of Healthcare Delivery

A **healthcare delivery organization** is a single facility or group of facilities that provide medical care for some portion of a population. There are three types of healthcare delivery systems in the United States: not-for-profit, for-profit, and state/local government ([Table 3.7](#)) (Yarbrough Landry et al., 2019). To determine which delivery system applies to an organization, three economic questions and one healthcare question can help:

- Where do the funds to operate the organization come from?
- Are **profits** (money left after all bills, including staff salaries, are paid) expected?
- Are **taxes** (money paid to the local, state, or federal government for property and purchase of goods) paid by the organization?
- Is the organization required to function as a **safety-net hospital** (a facility that is required to provide care for a patient no matter their ability to pay)?

	For-Profit	Not-for-Profit	State and Local Government Hospitals
Where do operating funds come from?	Investors	Donors	Government
How are profits managed?	Returned to shareholders	Reinvested in the hospital or in the community	Reinvested in the hospital or in the community
Are taxes paid?	Yes	No	No
Is it a safety-net hospital?	Rarely	Maybe, if it is a university or teaching hospital	Yes

**TABLE 3.7** Comparison of Healthcare Delivery Organizations

**For-Profit Systems**

For-profit hospitals represent 20 percent (1,228) of the hospitals in the United States (see [Figure 3.8](#)) (AHA, 2022). These hospitals are funded by investors who expect to have a return on their investment. In this type of system, an investor is a **stakeholder**, or person with an interest in the success of the organization. While **for-profit** systems serve their communities, they are also under pressure to earn a profit at the end of the year, which is then returned to the investors (Cheney, 2019). As a result, their leadership structures tend to include representatives of their investors and community leaders, which creates a push–pull relationship between patient care and financial outcomes. Further, for-profit facilities must pay local, state, and federal taxes on their facilities, earnings, and purchases.

**FIGURE 3.8** In 2020, there were 6,093 hospitals in the United States divided into several categories. Other hospitals include units within institutions (such as within prisons) and some long-term care facilities (AHA, 2022). (data source: American Hospital Association; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

For-profit facilities are often efficient, supplying high-quality services that are needed in large quantities (such as medical imaging or cardiac stress testing). Yet, they often leave tertiary care to other organizational types due to the expense and lack of profit margin for these types of procedures (Cheney, 2019; Gee & Waldrop, 2021). Some studies have shown that for-profit facilities may choose not to offer unprofitable services even when there is a demonstrated need in the community (Horwitz & Nichols, 2022). Legally, they have more flexibility in what services they provide than their counterparts (Masterson, 2017).

All hospitals are required to treat critically ill patients who come to their emergency departments. However, most for-profit hospitals will stabilize patients who are underinsured or without insurance and transfer them to other facilities (usually either not-for-profit or state/local government–run facilities). Rarely will a for-profit facility function as a safety-net hospital (Moura, 2021).

Often, for-profit hospitals are concentrated into large healthcare systems and/or group their facilities geographically. In 2016, four for-profit hospital groups owned 520 (42 percent) of the for-profit hospitals in the United States (Cheney, 2017). This consolidation of care by the hospital groups can be beneficial for patients. When there are many within one group, there are opportunities for sharing knowledge between facilities. However, there is also evidence that for-profit facilities will leave communities when their facilities no longer create a profit, regardless of the community’s need for a hospital (Masterson, 2017). For example, in 2019, only 10 percent of for-profit hospitals were in rural communities (AHA, 2021).

### Not-for-Profit Systems

A **not-for-profit (NFP)** hospital does not have to pay federal, state, or local taxes but is required to provide **charity care** (free or discounted care) and serve their communities (Gee & Waldrop, 2021). Funding for these facilities comes from private donations, fundraisers, public funding, and payments for their services. Profits are not returned to shareholders but are expected to be turned back into the facility for improvements, salaries or services for employees, or community services. Because they have a mandate to serve their communities and do not have to answer to shareholders, NFP hospitals are more likely to offer services with poor profitability, such as emergency or trauma care, burn units, or obstetrics (Gee & Waldrop, 2021; Horwitz & Nichols, 2022).

NFP hospitals account for 49 percent (2,960) of hospitals in the United States, the largest percentage of any type of hospital system (Figure 3.8) (AHA, 2022). Their focus on community creates an environment of long-term planning and deep attachment to their communities. Most NFP hospitals remain in their communities and are less likely to close if they become unprofitable because they are needed to meet the needs of the community (Cheney, 2019). Unfortunately, some NFP hospital programs have been accused of not providing enough charity care, and there is lack of regulation around the concept of community services. Consequently, regulations vary between states and territories (Ollove, 2020; Rapfogel & Gee, 2022).

As with their for-profit counterparts, NFP hospitals are required to treat critically ill or injured patients, regardless of their ability to pay, until they are stable. Then, many of them will transfer these patients to state and local government institutions. Other NFP hospitals, particularly large university and teaching hospitals, provide safety-net care for patients who are unable to pay (Moura, 2021).

### State and Local Government Institutions

State and local government healthcare institutions are funded entirely or in part with public money (collected taxes) and charitable donations. The institutions are controlled by the state/local government in which they are built (Tikkanen et al., 2020). They include roughly 16 percent of U.S. hospitals (Figure 3.8) (AHA, 2022). These types of hospitals are tax exempt because they are government agencies, and profits are generally unexpected. These institutions do attempt to bill patients and accept insurance; however, they are also safety-net facilities and provide care for the uninsured or underinsured regardless of ability to pay (Moura, 2021).

## LINK TO LEARNING

Explore the informational sections of the following healthcare delivery systems to learn how different hospital structures represent themselves. The “Company Overview” for [Community Health Systems \(https://openstax.org/r/77CommHealthSys\)](https://openstax.org/r/77CommHealthSys) presents details about this large, for-profit health system. The “About” section for [Vanderbilt University Medical Center and Network \(https://openstax.org/r/77VanderbiltMed\)](https://openstax.org/r/77VanderbiltMed) provides details about this large university and teaching NFP hospital and system. The “About Us” section for [Grady Health System \(https://openstax.org/r/77GradyHealth\)](https://openstax.org/r/77GradyHealth) gives more information about this large local government–run hospital in Atlanta, Georgia.

## Structure of Healthcare Delivery

Another way to explore healthcare delivery is based on the concept of public versus private. In health care, an institution is **public** if it is run and largely funded by the government and is for the good of the people it serves. An institution is **private** if it is run and funded by a group other than the government and can be either a for-profit or a NFP institution. However, the differences between the two sectors are much more complex.

### Public Health Institutions

Public health institutions include state and local hospitals. However, **public health institutions** go far beyond hospitals. The federal government's Department of Health and Human Services branch has nine agencies that focus on public health, five of which are the Centers for Disease Control and Prevention (CDC) (Figure 3.9), the Food and Drug Administration, the Administration for Strategic Preparedness and Response, the Agency for Healthcare Research and Quality (AHRQ), and the Centers for Medicare and Medicaid Services (CMS). These agencies set policies and provide governance for all other types of healthcare systems in the United States (both for-profit and NFP systems) and set policy at a **population level** (all individuals within a given population).

**FIGURE 3.9** The Centers for Disease Control and Prevention work closely with state and local health departments to improve population health. (credit: work by Centers for Disease Control and Prevention, Public Domain)

At the local and regional levels, state and local health departments are critical public health institutions. These agencies offer health services such as immunizations and well-baby and family planning services. They also administer programs such as WIC (a food supplement program for women, infants, and children), monitor communicable diseases, and manage testing and reporting of communicable diseases. Additionally, they provide health education programs, are active in regional emergency preparedness activities, and store and provide **vital records** (birth, marriage, divorce, and death certificates) for individuals in their communities. They are also responsible for license certification, verification, and renewal for nurses and other medical health professionals. The programs they offer vary between the states, but they all share the common goal of supporting the overall health and well-being of the citizens of that region.

### Private Health Institutions

Private health institutions include both for-profit and NFP hospitals and facilities, such as doctors' offices, outpatient clinics, pharmacies, same-day surgery centers, and other types of healthcare institutions that are not funded by any government or governed by a public agency and do not set health policy at a population level. Almost 70 percent of U.S. hospitals are **private health institutions**, as are most other types of healthcare providers (Figure 3.8).

## Integrated Delivery Systems

An **integrated delivery system (IDS)** is a network of providers and agencies who collaborate with each other to

provide care to an individual or a community (Figure 3.10) (Yarbrough Landry et al., 2019). They can be large or small and organized and run by a single group or a partnership between groups. They attempt to meet the care needs of their patients at primary, secondary, and tertiary levels. Their goals include sharing information, responsibility, and resources to ensure the best care (Yarbrough Landry et al., 2019). The primary care medical home is one example of the integration of delivery systems.

**FIGURE 3.10** An IDS incorporates all aspects of the individual's health needs. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Nonfederal Hospitals and Systems

Many hospital groups include additional facilities and physician offices that function as IDSs. They provide primary, secondary, and tertiary care for individuals in their communities or networks. They share information through electronic health records that can be pulled up by any provider in the system to improve the quality of care throughout the healthcare process.

One example of a large, well-integrated hospital system is Kaiser Permanente. This large, NFP system includes 39 hospitals and 737 additional medical offices and facilities across nine states plus the District of Columbia (Kaiser Permanente, 2020). Patients can access care at whatever level they need—primary, secondary, or tertiary—through this one system.

### Community Hospitals

Community hospitals include all hospitals that are not federal hospitals and offer both short-term and/or specialty care that is available to the general public (Yarbrough Landry et al., 2019). They can be public or private, for-profit, NFP, or state/local hospitals. While most **community hospitals** are part of IDSs, they may also be stand-alone hospitals without additional affiliated groups.

### Federal Hospitals and Systems

The U.S. federal government does not run public hospitals that can be accessed by any citizen. However, it does run IDSs for several specific populations: the Veterans Health Administration (VHA), the Indian Health Service (IHS), and the U.S. military all have their own IDS structures run by the federal government, and eligible persons can receive any level of care they need within those IDS structures.

### Veterans Health Administration

Established by Abraham Lincoln after the American Civil War, the VHA handles medical care for veterans of the U.S. armed forces. With 171 hospitals and 1,113 outpatient clinics, the VHA is the second largest IDS in the nation and treats nine million veterans every year (Falvey, 2023; VHA, 2023). VA facilities treat veterans and their family members who are covered under the medical plan, including those from all branches of the U.S. armed forces: Army, Navy, Air Force, Marines, and Coast Guard.

### REAL RN STORIES

#### Working for the VHA

**Nurse:** Amalia, RN

**Clinical setting:** Acute care, supervision, and management

**Years in practice:** 24

**Facility location:** A small VHA medical center in the Northeast United States

I would like to share a story about my summer internship at a VA hospital on a medical-surgical unit. I was an older nursing student, in my 30s, with a husband and child. Both of my grandmothers had been nurses, and I was excited to follow in their footsteps. The summer before my final year in my RN program, I had the opportunity for an internship at the local VHA hospital. While I had never considered working at the VHA, it was the most amazing experience of my life. The patients and their families were wonderful, and I learned so much about what it means to be a veteran and have served our country. When I graduated nursing school, I was offered a position with the VHA and took it gladly. The benefits were great, so it was good for my family. Also, both of my grandfathers had served during WWII, and my father had served during the Vietnam War, so I wanted to give back.

Working for the VHA is unlike working for any other healthcare organization. Yes, we provide all the services you would expect from a large hospital group, from primary care to organ transplantation to long-term psychiatric care. But it is more than that. The mission of the VHA is to care for “those who shall have borne the battle.” Being able to work with and provide this particular group of dedicated people with the care and support they need in times of crisis is truly a professional experience I cherish.

### Indian Health Service

The federal government’s involvement in health care for indigenous populations grew from the relationships developed between the U.S. government and tribal populations in the late 1700s. It is based on treaty agreements codified in Article 1, Section 8 of the U.S. Constitution. The IHS consists of 24 federally run and 22 tribally run hospitals, and numerous health centers, clinics, and treatment centers throughout the continental United States and Alaska (Falvey, 2023). It provides comprehensive care for 2.6 million American Indian and Alaskan Native people from 574 federally recognized tribes (IHS, 2020).

### CULTURAL CONTEXT

#### Health Services for Urban American Indian People

Most IHS facilities are on or near reservations populated exclusively by American Indian and Alaskan Native people. But, in 1973, American Indian community leaders living off reservations and in urban areas became concerned about the health needs of American Indian people living in cities. In response, Congress passed a law expanding the IHS into urban environments with large groups of American Indian and Alaskan Native people. The Urban Indian Organizations are funded by the IHS and provide a variety of services including primary care, behavioral health, traditional healing and medicine, and social and community services (IHS, 2022).

### Defense Health Agency

The Defense Health Agency integrates the medical services of the Army, Navy, and Air Force to provide comprehensive health care to members of the U.S. military and their families (spouses and children) all over the world. It includes over 400 hospitals, medical centers, and clinics worldwide. The Defense Health Agency provides

care for over 9.6 million active and retired military members and their families annually (DHA, 2023). [Figure 3.11](#) shows the Landstuhl Regional Medical Center, the largest military hospital outside of the United States.

**FIGURE 3.11** Landstuhl Regional Medical Center in Germany is the largest military hospital outside of the United States and supports military members and their families across Europe, Africa, and the Middle East (Landstuhl Regional Medical Center, 2023). (credit: “Landstuhl Regional Medical Center (2008)” by Landstuhl Regional Medical Center/Wikimedia Commons, Public Domain)

## Providers

Healthcare providers include licensed practitioners who can legally diagnose conditions and prescribe medications, nursing care staff who care for ill or injured patients, and other support personnel. Licensed practitioners include medical doctors, doctors of osteopathic medicine, nurse practitioners, and physician assistants. Nursing staff and various allied health professionals support them (Vorvick, 2022). Like hospitals, licensed practitioners operate in a variety of practice types.

### Independent Practice

An **independent practice**, also known as solo practice, is a medical office owned and run by a single physician who treats patients. The physician may be supported by other providers, such as nurse practitioners or physician assistants, and the office usually includes a small group of nurses and support staff (American College of Physicians [ACP], 2022). While most physician offices were once independent practices, their numbers are rapidly diminishing, down to approximately 20 percent of U.S. physician practices in 2013 (Yarbrough Landry et al., 2019) and down to 14 percent in 2020 (Yegian & Green, 2022). These changes are often due to the entire burden of the practice falling on a single physician as well as complications in arranging agreements with the myriad of health insurance companies (ACP, 2022). Plus, there is a large financial risk in independent practice, particularly when group practices often have better resources and enough physicians to provide on-call assistance for patients. Independent practices are most common in suburban and rural areas where there are fewer choices of providers for patients (ACP, 2022).

### Single-Specialty Practice

A **single-specialty group practice** is currently the most common type of physician practice in the United States (Yarbrough Landry et al., 2019). In 2020, 42.6 percent of physicians in the United States were in this type of practice (Yegian & Green, 2022). In this type of practice, two or more physicians provide patients with the same category of care, such as primary care or specialty care (ACP, 2022). These group practices can be quite large and see much higher numbers of patients than independent practices. They often have multiple nursing and support

staff members. They may be owned by one or more of the physicians within the group or by outside agencies. Single-specialty group practices spread their responsibilities (such as seeing their patients who are hospitalized or responding to patients who need care after business hours) across multiple providers (ACP, 2022).

### Multispecialty Groups

A **multispecialty group practice** includes multiple different specialties within one organization (ACP, 2022). For example, a multispecialty group might include primary care, pulmonology, general surgery, and physical therapy all in one location or in several related locations. Multispecialty groups are common in IDSs. They may be physician owned or owned by outside agencies. Approximately 26 percent of U.S. physicians work in multispecialty groups (Yarbrough Landry et al., 2019; Yegian & Green, 2022).

## 3.3 Barriers to Healthcare Access

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain how lack of access to health care impacts one's health goals
- Identify how cost can be a barrier to obtaining healthcare needs
- Describe how disparities in treatment are a disadvantage to the delivery of health care

Healthcare access is a patient's ability to get healthcare services such as primary, secondary, and tertiary care when and where they are needed. Although a wide range and variety of healthcare systems and facilities are available in the United States, barriers to care may prevent large groups of people from receiving the types of care they need (Agency for Healthcare Research and Quality [AHRQ], 2018a; Center for Health Ethics, n.d.). Recent changes to laws and the creation of new systems, such as the **Patient Protection and Affordable Care Act (ACA)**, have increased access. The goal of the ACA was to improve access to health insurance for Americans, offer subsidies to help pay for health insurance, and make health insurance more affordable. However, millions of Americans still lack necessary health care.

Barriers to health care may develop in a variety of ways. Some patients are unable to access healthcare services, some cannot afford them, and others experience lower quality treatment options. As you read, consider additional barriers to health care—ones that you can imagine or already know about.

### Barriers to Using Healthcare Delivery Systems

Barriers to using healthcare delivery systems are often related to lack of **access**, or the ability to obtain healthcare services when and where patients need them (Huot et al., 2019). These types of barriers include geographical (where people live versus where providers are), timing (when providers are available versus when patients need them), and availability (having enough providers available and in practice for the patients who need them). Even the ability to access transportation can be a substantial barrier to using healthcare delivery systems. Other barriers include sociocultural issues, such as language, religion, and race or ethnicity. Together, these barriers can be as problematic for accessing health care as cost or lack of insurance (Rural Health Information, 2022).

### Rural Areas

Individuals who live in rural areas may experience a variety of barriers to accessing the healthcare delivery system. People who live in rural areas are

- more likely to experience provider shortages;
- less likely to have insurance;
- more likely to have to travel long distances to receive care;
- more likely to work in jobs without paid time off work;
- less likely to trust healthcare professionals to give them quality care or to keep their issues private; and
- more likely to have limited **health literacy** (a patient's ability to understand instructions and education from their providers and be able to actively participate in their care) than other populations (see [Chapter 4 Health, Wellness, and Community-Based Health Care](#)) (Rural Health Information Hub, 2022).

These barriers may be experienced in all locations, but they are often magnified for those living in rural areas. Residents in rural communities may also experience difficulties in unique ways. For instance, recruiting medical personnel is more difficult in rural communities because these areas are far from popular community resources and

attractions. In addition, the rate of closure for rural hospitals is higher than for urban hospitals, particularly in the South. This results in a disproportionate impact on people who are socioeconomically disadvantaged and people of color. People who live in these communities then must travel farther than before for care. Lack of public transportation in rural areas can make the problem even more significant (Rural Health Information Hub, 2022).

## PATIENT CONVERSATIONS

### Assessing Health Literacy

The following is an example of a patient conversation related to health literacy. Note: newspapers are written at an average 8th- to 10th-grade reading level, and news magazines at a 12th-grade level.

**Scenario:** The nurse is trying to quickly assess Mr. Smith’s health literacy and asks him questions about reading, education, and learning habits to know what types of education Mr. Smith will respond to best, and how information should be provided.

**Nurse:** Mr. Smith, can you please read me the information off your prescription bottle?

**Patient:** Diclofenac. It was ordered by my last doctor. It says take for pain twice daily.

**Nurse:** Do you like to read? What kinds of things do you read?

**Patient:** I don’t read much, but I do like the Sunday paper.

**Nurse:** What was the highest level of school that you completed?

**Patient:** I got my GED and then finished a two-year college program in accounting.

**Nurse:** How do you like to learn? By reading about things, discussing them with someone, trying things out, or listening to someone talk to you?

**Patient:** If I am really interested, I’ll look it up on Google or watch a video on YouTube.

**Scenario follow-up:** Identifying a patient’s health literacy is a crucial part of patient assessment and is always the responsibility of the nurse prior to educating. If patients are not provided health information and education in a way that they understand, they will not be able to make informed decisions about their own care. While there are some complicated assessments, there are also some simple techniques such as those the nurse used in this conversation to establish a baseline.

Healthcare providers are more likely to work in urban areas than rural areas. This is most true for specialist providers, such as mental health professionals, surgeons, and/or tertiary care providers, but it is even the case for primary care provider (PCP) (AHRQ, 2018c). [Table 3.8](#) offers a snapshot of the differences between percentages of the U.S. population by location as compared to the percentages of primary care providers. For all areas other than urban centers, there is a lower number of PCPs for areas with smaller populations.

Geography	Percentage of Practicing Primary Care Physicians (%)	Percentage of U.S. Population (%)
Urban (population >50,000)	89	80
Large rural (population 10,000–50,000)	7.1	10

**TABLE 3.8** Primary Care Physicians by Geographic Location (Source: AHRQ, 2018c.)

Geography	Percentage of Practicing Primary Care Physicians (%)	Percentage of U.S. Population (%)
Small rural (population 2,500–9,999)	2.6	5
Remote rural (population <2,500)	1.3	5

**TABLE 3.8 Primary Care Physicians by Geographic Location** (Source: AHRQ, 2018c.)

The problem of supplying access to health care in rural areas is not just a challenge in the United States; it is a worldwide problem. Several reasons account for physicians choosing urban or large rural locations. Access to good school systems, art and cultural activities, and proximity to modern hospital systems are among the many reasons that physicians seem to prefer urban positions. Last, rural areas do not have as many sites for physician residency in the same way that urban areas do (McGrail et al., 2020; Szafran et al., 2020).

### Restricted Daytime Hours

The **restricted hours** (e.g., Monday through Friday, daytime only) at physician offices and clinics are frequently named as a barrier by patients who need to seek care or those who have to have regular treatment visits (Office of Disease Prevention and Health Promotion, Office of the Assistant Secretary for Health [OASH], 2022). Most working adults are at work or children are at school during the same times that physician offices are open. While restricted hours remain a problem, particularly with the ability to receive secondary or tertiary care and in rural areas, the larger medical community is responding with a variety of strategies:

- extended hours (seeing patients after 5 p.m. and/or before 8 a.m.) at doctors' offices, clinics, mental health centers, and providers, such as physical therapy;
- convenience care clinics with weekend or extended hours affiliated with large group practices;
- urgent care clinics unaffiliated with large group practices with extended hours and the ability to provide some primary care as well as acute management of mild to moderate illness and injury; and
- virtual visits where patients can use their smartphones, tablets, or computers to meet with a healthcare provider online.

### Transportation Issues

Lack of transportation or limited transportation is one of the primary reasons (other than cost) that patients miss scheduled appointments or do not seek care until they are very sick (OASH, 2022). Some areas, generally urban ones, have transportation services that assist patients in getting to appointments; however, they may not be able to afford to use them as there can be a substantial cost involved. Additionally, public transportation for patients with disabilities can be quite complicated, particularly when they must walk to a train or bus stop or when they need assistance entering and exiting vehicles. During the COVID-19 pandemic, the regular concerns of patients with disabilities who have to use public transportation were exacerbated by shelter-in-place orders, and they had additional difficulties gaining assistance with getting into and out of transport vehicles, if they could obtain transportation at all (Cochran, 2020). For patients in rural areas, transportation issues can be even more difficult to overcome because public transportation is often unavailable, and they must rely on their own vehicles (if they have them) or the availability of family or friends to assist in getting them to appointments. Also, their appointments may be at a great distance from their home, particularly if they are seeing specialty or tertiary care providers.

### Provider Shortages

Not having enough providers for a given population, or **provider shortage**, is a severe problem throughout the United States. In response to these shortages, the federal government has designated certain "Health Professional Shortage Areas" (HPSA) (Health Resources and Services Administration [HRSA], 2022) based on geographic areas, specific populations (such as people who are migrant workers or who are without homes), or facilities (such as mental health or public hospitals). In 2021, nationwide there were 8,160 federally designated HPSAs needing primary care practitioners; 7,192 HPSAs needing dental health providers; and 6,464 HPSAs needing mental health providers (HRSA, 2022). [Figure 3.12](#) provides a graphic representation of the numbers of HPSAs in the nation and the severity of their need.

**FIGURE 3.12** HPSAs occur all over the United States in both rural and urban communities. The darker the color, the greater is the need for primary care providers. (credit: “HPSAPC” by Health Resources & Services Administration, Public Domain)

## LINK TO LEARNING

The HRSA has [several tools to find shortage areas \(https://openstax.org/r/77HRSAShortTool\)](https://openstax.org/r/77HRSAShortTool) and details about them. Check out your own address to see if shortages exist in your area.

## Barriers Due to Healthcare Costs

Healthcare costs impact both Americans who have health insurance as well as those who do not (Montero et al., 2022). Regardless of their insurance status, almost half of adult Americans report difficulties affording their healthcare costs, and almost 40 percent have either delayed or not gotten needed medical care (Montero et al., 2022). Further, approximately a quarter of adults report not filling prescriptions, taking less than full doses, or skipping doses due to the costs of medications.

Congress enacted the Patient Protection and ACA in 2010 with several goals (Assistant Secretary for Public Affairs [ASPA], 2022):

- Make insurance more affordable for individuals who fall between 100 and 400 percent of the federal poverty level (an income measure determined annually by the government).
- Expand Medicaid insurance to cover all adults below 138 percent of federal poverty level.
- Support overall changes to healthcare delivery which would lower costs while maintaining or improving care.

By 2023, almost 16 million people were using ACA plans nationwide, and as [Figure 3.13](#) shows, there has been a clear decrease in overall healthcare costs (Centers for Medicare and Medicaid Services [CMS], 2023).

# Health, United States Spotlight

## Health Care Utilization & Resources

April 2017

### ABOUT HEALTH, UNITED STATES

*Health, United States* is the annual report on health, produced by the National Center for Health Statistics and submitted by the Secretary of the Dept. of Health and Human Services to the President and Congress.

The report uses data from government sources as well as private and global sources to present an overview of national health trends. This infographic features indicators from the report's Utilization of Health Resources and Health Care Resources sections.

For more information, visit the *Health, United States* website at: <https://www.cdc.gov/nchs/hus.htm>.

### Four Subject Areas of Health, United States

### ACCESS TO NEEDED CARE

#### ABOUT THE DATA

Source: NCHS/National Health Interview Survey (NHIS)

#### Respondents are:

- Civilians
- Not part of Armed Forces active duty
- Noninstitutionalized
- Not living in a long-term care facility
- Not incarcerated

#### Notes:

- Geographic regions are based on U.S. Census Regions.
- Difficulty accessing needed medical care includes experiencing delays or not receiving needed care due to cost.

Difficulty accessing needed medical care due to cost **INCREASED** during the first half of 2005–2015 and then **DECREASED** during the second half for adults across all four regions.

Overall, between 2005 and 2015, difficulty accessing medical care due to cost **decreased** for adults in the South and in the West.

**SOUTH** 12.6%  $-1.6$  → 11.0%

**WEST** 11.1%  $-1.6$  → 9.5%

There was **no significant change** for those in the Northeast or Midwest.

In 2015, about **10 out of every 100 adults aged 18–64** had difficulty accessing needed medical care due to cost, and this varied by region. (See *Health, United States*.)

Adults in the Northeast had the **least difficulty** accessing needed medical care due to cost in 2015.

Meanwhile, adults in the South had the **greatest difficulty** accessing needed medical care due to cost in 2015.

**FIGURE 3.13** The Centers for Disease Control and Prevention is one of the public health agencies active in tracking and improving access to health care nationally. This infographic shows improvements that have been made to access to care over time; however, there is still room for further improvement. Access to care must remain a priority across the United States. (credit: work by Centers for Disease Control and Prevention, Public Domain)

Despite the introduction of the ACA, over 40 percent of people still admit to having **healthcare debt**, in one of several forms:

- past due or unable to pay;
- paying off over time to a provider;
- paying to a bank or collection agency (when the provider has sold old debt);

- paying to a credit card or revolving credit account (with interest, so paying more); or
- paying to a friend or family member from whom the money was borrowed.

Such medical/dental debts can be a financially harmful issue after a critical health event, even for those with insurance, and almost 60 percent of people worry about the effects of unexpected medical bills (Montero et al., 2022).

## LINK TO LEARNING

Dental care is the most common type of medical care for patients to delay due to cost (Montero et al., 2022). However, many patients do not realize how important dental health is to overall health. Explore [the Mayo Clinic's web page on oral health \(https://openstax.org/r/77OrlHealthMayo\)](https://openstax.org/r/77OrlHealthMayo) to see the importance of dental health to overall health and consider why it is concerning that so many people cut costs with their dental health.

### Having Insurance

Simply having insurance is not enough to prevent financial concerns and difficulties accessing health care related to costs. Between one-third and one-half of Americans with insurance worry about whether they can pay for their **premium** (the amount of money they pay each period to subscribe to their insurance) or afford their **deductible** (the amount of money someone with insurance must pay a provider before the insurance begins paying) (Montero et al., 2022). Also, dental and vision insurance are often not provided as part of the medical insurance package, so individuals have to either buy separate plans for dental and/or vision or pay out of pocket for these services.

### Lack of Income for Public Health Insurance

In 2021, 21.7 percent of Americans were on some type of public health plan such as Medicaid, Medicare, military plans, or the Children's Health Insurance Program (Adjaye-Gbewonyo & Boersma, 2022). Unfortunately, these programs may not cover all types of services. For example, Medicare does not cover hearing, dental, or prescription drugs (Montero et al., 2022). Patients are required to either pay out of pocket for supplementary plans that cover what the public health insurance does not cover or pay for the services themselves. For patients who are on fixed incomes (such as those who are retired or on disability), such services may be impossible to afford.

### Uninsured

Since the ACA marketplace for subsidized insurance went into effect in 2013, the uninsured rate has decreased significantly for all age groups and ethnicities in the United States (AHRQ, 2018a). However, in 2021, 13.5 percent (approximately 30 million people) of adults over 18 years old in the United States still did not have health insurance (Adjaye-Gbewonyo & Boersma, 2022). These individuals are less likely than any other group to receive medical care and are more likely to be sicker and die younger (Adjaye-Gbewonyo & Boersma, 2022).

### Barriers Related to Disparities in Treatment

There are also barriers to care that cause **disparities** (differences that negatively impact one group over another) in treatment between groups. Disparities can be caused by factors **intrinsic** (related to personal thoughts, values, and beliefs) to patients and providers or **extrinsic** (related to conditions outside of the individual, systemic issues) to the system as a whole. Intrinsic factors can include patient distrust in healthcare providers, so-called white-coat syndrome, and lack of education about the importance of primary care. Extrinsic factors can include systemic racism and infrastructure.

### Distrust in Healthcare Providers

Distrust in healthcare providers, an intrinsic factor, can arise for many reasons, including previous negative interactions; anxiety about working with a provider of a different race, ethnicity, or gender; and poor health literacy (OASH, 2022). When a person's previous experiences have been poor, it can be difficult to believe that another provider will be any different. Race, ethnicity, and gender concerns may be related to cultural norms, language barriers, or lack of similar life experiences. Poor health literacy can compound all these issues. Individuals with poor health literacy may feel that the provider is being untruthful because they do not understand what the provider is saying.

## LINK TO LEARNING

---

Medical mistrust is a significant barrier to effective healthcare delivery and equitable health outcomes. Among Black Americans, historical and ongoing experiences with systemic racism, unethical medical practices, and inadequate healthcare contribute to a heightened level of mistrust in the medical system. Explore a [comprehensive analysis of medical mistrust among Black Americans \(https://openstax.org/r/77medmistrust\)](https://openstax.org/r/77medmistrust) and strategies for addressing it in this article. Addressing this mistrust is crucial for improving healthcare access, adherence, and overall health outcomes in this community.

---

White-coat syndrome is another example of an intrinsic barrier to effective treatment. White-coat syndrome is when a patient experiences elevated anxiety and mistrust related to working with a healthcare provider. When interacting with a provider, particularly a new one, a patient's vital signs may be altered, such as elevated blood pressure. White-coat syndrome can happen even to healthcare professionals themselves. It speaks to an internalized anxiety or mistrust related to health care of which patients may be unaware.

## REAL RN STORIES

---

### Anxiety Impacting Treatment

**Nurse:** Lashonda, RN

**Clinical setting:** Primary care office

**Years in practice:** 8

**Facility location:** Midwest United States

A few years ago, we had a new 50-year-old male patient come into our primary care office. I felt so badly for Mr. Jones. When he first came to us, he was very anxious. He had a lot of pain that had been getting worse for years, and it greatly impacted his quality of life. I asked him why he had not come in sooner. He said that he never could take time off work and that doctors had addicted his father to pain medicine and then had cut him off and stopped prescribing the pain killers. Shortly after, his father died by suicide because of his pain. Mr. Jones wanted help with the pain, but he was afraid to take opioid pain killers. He did not think that there were any other treatments available to him.

Our provider saw him and did some x-rays. She provided Mr. Jones celecoxib and a round of steroids to help with the inflammation. She recommended physical therapy, and Mr. Jones agreed to go.

When he came back for his follow-up visit, Mr. Jones was like a new man. He was able to stand and move with much less pain. Both the physical therapy and the medication were helping him feel better than he had in years. He told me that if he had just understood, he would have gotten help sooner.

---

### Lack of Education

Moving in tandem with issues of health literacy is lack of education regarding the importance of primary care, preventive screenings, and even acute care needs (OASH, 2022). Once they no longer have annual well-child physicals for immunizations, many individuals (particularly those in their 20s to 40s) do not see a physician unless they are ill or injured. The segment of the population who is in generally good health and/or those with poor health literacy frequently do not recognize the value of seeing a primary care physician. These individuals are often the ones who enter the healthcare system at the secondary or tertiary level when they are struck by an emergency. Additionally, many people are unaware of treatments and services available to them, so they do not seek care (OASH, 2022).

### Racial Disparities

Despite many initiatives to decrease racial disparities in health care throughout the nation, they remain. These extrinsic disparities are deeply embedded in the culture and healthcare system of the nation. For example, in 2013, 14.6 percent of Americans were unable to get care when they needed it because it was unavailable; however, there were significant differences among races (19.8, 19.2, and 13.2 percent of Black, Hispanic, and White persons,

respectively) (AHRQ, 2018a). While the rates of uninsured Americans are decreasing among all three groups due to the ACA, Black and Hispanic persons remain significantly less likely to be insured than White persons (Baumgartner et al., 2023). Also, while over 80 percent of White and Black adults report having a PCP, only 65.7 percent of Hispanic adults have a PCP (Baumgartner et al., 2023). Despite efforts of the Indian Health Service and tribal organizations, American Indian and Alaskan Native people have higher rates of many common conditions (such as diabetes and rheumatoid arthritis) and are more likely to die from them than other Americans (AHRQ, 2018b).

## 3.4 Culture

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the current culture of health care
- Describe how collaborative culture is integrated in health care
- Identify ways to incorporate a culture of safety

A set of values, beliefs, behaviors, language, symbols, and practices shared in common by a group of people is **culture**. A person can be part of multiple cultures (known as a **subculture**) or multiple groups of people with whom they share core ideologies. Cultures can be bound together based on ethnicity, nationalism, regionalism, religion, interests, age, and so on. Consider Lydia, a 20-year-old U.S. college student who lives on campus and is from the Deep South. Lydia is active in women's rugby and tabletop gaming (like *Dungeon and Dragons*), identifies as nonbinary and bisexual, and has autism. Lydia identifies with multiple cultures and shares beliefs, behaviors, values, language, and symbols with other Southerners, college students, members of Generation Z, the LGBTQIA+ community, gamers, rugby players, and people with autism.

Health care has its own culture, and different organizations develop different types of healthcare cultures. Healthcare professionals practice within various healthcare cultures and subcultures which they internalize. The first of these is a professional culture based on the healthcare practitioner's discipline (think physician versus nursing versus physical therapy). This type of healthcare culture acquisition begins in school. For example, someone in a nursing program and reading this textbook is beginning to take on the culture of nursing.

There are several aspects of healthcare culture including general healthcare culture, how organizations express culture at a system level, and some planned and targeted strategies to purposefully develop organizational culture, such as a culture of safety and a culture of collaboration. As you read, visualize yourself as the nurse you want to be and consider how culture might impact your nursing practice.

### Culture of Health Care

Different healthcare professions each have their own culture as do individual healthcare agencies. The beliefs, attitudes, and shared symbols expressed by the agency create a unique internal culture that shapes the behavior of the entire staff from the healthcare professionals to the **ancillary staff** (staff employed by the agency who are not directly responsible for caring for patients, such as housekeepers and administrators). An agency expresses its culture through its mission and vision statements, policies, procedures, and rules (Bayot et al., 2022). The resulting culture provides structure for how various healthcare professionals work together *at that agency* to care for patients and maintain the environment (Bayot et al., 2022). There is an old saying in nursing: if you have worked at one hospital, you only understand how to work at one hospital because they are all different.

### LINK TO LEARNING

The Veterans Health Administration (VHA) is very clear about their core cultural values. The [I CARE core values](https://openstax.org/r/77ICARECore) (<https://openstax.org/r/77ICARECore>) of Integrity, Commitment, Advocacy, Respect, and Excellence offer a clear picture of their organizational culture.

### Organizational Culture

The shared beliefs, thoughts, symbols, and attitudes of an organization shape its **organizational culture**. Healthcare organizations can be further understood as multiple subcultures united by a set of core beliefs and values (Mannion & Davies, 2018). Consider the I CARE core value of Advocacy shared in [Link to Learning](#). The subculture of VHA

intensive care unit nurses may result in their being very actively engaged in advocating for patients who are critically ill and need treatment changes quickly. By contrast, nurses on the acute medicine unit may be more relaxed in their advocacy and follow a chain of command that moves through their charge nurse because they are not performing immediate life and death treatments. Both sets of nurses advocate for their patients but do it in different ways based on the culture of the specific units on which they work.

While organizational cultures can be positive and support high-quality patient care and environments at all levels, they can also become negative (Mannion & Davies, 2018). When agencies do not follow their own mission and vision statements or create environments in which staff cannot perform to the unrealistic expectations of those cultural parameters, staff may become disillusioned. As a result, interdisciplinary (involving more than one discipline, such as medicine and nursing) communication and cooperation may decline, and overall patient care may suffer as a result.

### Patient-Centered Culture

Organizations can make systemic changes that foster positive healthcare cultures, but they must be intentional in these changes to achieve their preferred outcomes for the organization and patients alike. One example of an organizational cultural change is the shift to patient-centered care (PCC) (Figure 3.14). Until the early 2000s, most healthcare culture was very provider driven and disease focused; providers diagnosed problems and told the patient what to do, and the patient was expected to do it or else the fault was the patient's (Bokhour et al., 2018). The patient's own cultural beliefs, abilities, resources, and desires were generally not considered. While this older model remains common, particularly in secondary and tertiary settings, PCC is an alternate model that many agencies follow (Bokhour et al., 2018).

**FIGURE 3.14** In PCC, the patient rather than their disease is at the center of the care activities. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Patient-centered care focuses on relationships and partnerships between providers and patients. Rather than focusing exclusively on a specific disease or condition, in PCC culture, providers engage the patient in a conversation about their health, listen to patient concerns, explain treatment options, make recommendations, and educate the patient so that they can understand the potential outcomes. Then the healthcare provider allows the patient to make decisions that they are most comfortable with based on the patient's beliefs and values, available resources, and abilities (Bokhour et al., 2018; Kamrul et al., 2014). Developing a PCC culture presents a change from traditional medical culture and requires careful attention and planning from the administrative level down to the frontline staff in agencies. However, PCC culture has been proven to positively affect patients' experiences, outcomes, trust, and overall healthcare management (Bokhour et al., 2018).

### Culturally Competent Care

A core part of PCC is **culturally competent care**, ensuring that providers and organizations work with patients in a way that is responsive to cultural differences and adapts to fit a patient's needs (Kamrul et al., 2014). There are eight main principles of culturally competent care:

- critically examining one’s own culture and the values and beliefs they hold;
- recognizing prejudice or racism in agencies and oneself;
- engaging in activities that expand one’s thinking about other cultures;
- learning about the various cultures served by the facility;
- connecting with patients and families to learn more about their culture and culture needs;
- exploring the ways patients and their families understand their conditions and treatment;
- developing relationships with patients and their families based on trust and characterized with openness and willingness to accept their differences; and
- fostering spaces that reflect the diversity of the local community (Kamrul et al., 2014).

Providing access to medically certified interpreters (often via telephone) to ensure that patients who are not native English speakers receive the information they need is an example of a form of cultural competence. Another example of culturally competent care would be allowing a family to bring religious or cultural items or icons to place around a patient’s hospital bed if they do not interfere with necessary medical equipment.

### Collaborative Culture

Once upon a time, “doctor” was synonymous with “god,” nurses did not support one another, and healthcare agency departments vied for resources and did not communicate with each other. There were **silos** (barriers to communication and efficiency) within the medical system and between organizations based on discipline, hierarchy, or ineffective communication (Kelly et al., 2019) (Figure 3.15). Each group focused on their need to do their jobs most effectively without considering other disciplines, the health of the whole patient, or the overall functioning of the agency (JONS, 2017). This can also be described as task-oriented versus patient-centered or holistic health care. Disciplines were divided into silos, such as medicine (doctors), nursing, radiology, dietary services, physical and occupational therapy, and even housekeeping. All struggled to communicate and collaborate with each other. Leadership was also divided into silos with distance and struggle among disciplines. Patients were separated from those who cared for them. The costs—for patients (satisfaction and outcomes), practitioners (morale and resources), and agencies—were steep (Sperling, 2020).

**FIGURE 3.15** Moving from groups separated by discipline, leadership, and location to groups that collaborate regardless of discipline, leadership, or location improves patient care, satisfaction, and outcomes for all participants. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The solution to the problems that healthcare silos generate is the development of a **collaborative culture**, which has become a core measure in evaluating health care (Wei et al., 2019). Arising out of the PCC movement, collaborative culture in health care focuses on bringing disciplines together to work as a team in identifying common

goals, resolving issues, and improving patient-centered care (Goldsberry, 2018). Collaborative culture involves partnering with and communicating with patients to ensure they receive the most effective care when and how they need it. Collaborative culture moves beyond simple teamwork to ensure that different disciplines recognize and acknowledge the skills, abilities, and innovation that other disciplines bring. In that way, everyone's contributions can be maximized to supply efficient, high-quality care (Goldsberry, 2018). The use of technology, such as e-health records and computers, also allows greater communication and collaboration between agencies or practices (Goldsberry, 2018).

### Continuity of Care

An important component of a collaborative culture is **continuity of care**. The principal goal of continuity of care is health care provided in a thoughtful fashion without breakdowns in communication throughout the healthcare experience and regardless of the number of involved practitioners (Bakerjian, 2022). With continuity, patients have the same providers over time and develop relationships with them. When patients are transferring between providers or locations, clear hand-off reporting is performed to ensure the providers taking over the care understand the patient's health, needs, and desires. Continuity of care also encourages patient safety (Rhode Island, Department of Health, 2019).

For nurses, continuity of care is often seen in hospital settings. For example, assigning a nurse to the same group of patients for each shift provides continuity of care. Nurses who have regular interaction with a patient are more likely to develop the relationships needed in a collaborative culture setting. They get to know their patients, can more rapidly identify changes, and are more comfortable providing patient advocacy.

## LINK TO LEARNING

---

Continuity of care is expansive and intrinsically connected to both PCC and primary care. This [short video on continuity of care \(https://openstax.org/r/77ContCare\)](https://openstax.org/r/77ContCare) describes it and how it links to many topics covered in this chapter.

---

### Care Coordination

Another component of collaborative culture that highlights the sharing of information between disciplines to provide orchestrated care to patients is **care coordination**. Care coordination ensures that testing is not repeated between agencies, medications are not duplicated, and treatments are not utilized by one provider that will make a different condition worse (Agency for Healthcare Research and Quality [AHRQ], 2018). A **care transition** (movement among physicians, hospitals, care providers) offers a common place where many patients experience failure in their care. Care transitions are common situations in which care coordination becomes important (AHRQ, 2018).

## LIFE-STAGE CONTEXT

---

### Care Coordination for Older Adults

People age 65 years or older often require higher levels of care coordination than those under 65 years. For example, older adults are 2.5 times as likely to be hospitalized as those between 45 and 64 years old. They are also more likely to experience several chronic illnesses, each requiring its own health provider, to take multiple medications (38 percent of those over age 65 years take more than five medications daily), and to move between care settings, such as physician's office, hospital, and skilled nursing facilities.

The gold standard of care coordination for patients over age 65 years with complex medical, psychological, and/or social needs is a geriatric interdisciplinary team (a group of practitioners who work collaboratively to coordinate care across disciplines and locations). The team may be at a single location (such as a multidisciplinary practice) or communicate electronically between separate locations. The geriatric team ensures safe transfer between practitioners and locations, guarantees the most qualified provider manages each issue, safeguards the patient against duplicated services, and ensures the patient receives comprehensive care. When this type of interdisciplinary team is unavailable, the same group of patients can be managed by strong primary medical homes,

in which their primary practitioner is skilled in geriatric primary care and able to coordinate their services across secondary and tertiary settings.

Patients and caregivers should be involved in group meetings, as appropriate, and asked about their preferences in terms of end-of-life care and pain management, nutritional plans, and treatments. Caregivers should be encouraged to speak openly about their abilities to provide care and their need for resources to do so. Treatment plans should align with those preferences and abilities and demonstrate respect for the patient's culture and ideals (Bakerjian, 2022).

---

## Culture of Safety

Healthcare settings are inherently dangerous for patients. There are many places and circumstances within healthcare systems that can jeopardize the safety of patients and/or staff members (AHRQ, 2019a). Providers can give incorrect diagnoses based on the information they have or symptoms they do not see (such as strokes or heart attacks, particularly for women). Nurses can administer incorrect medications because the medications look alike/sound alike (such as Celebrex versus Celexa) or can give an incorrect dose (such as 1 mg instead of 1 mcg). Communication breakdowns between patients and providers or among providers can result in patients receiving incorrect care.

Historically, making errors resulted in punishment for those who made them and led to a culture of secrecy around reporting errors and taking responsibility for patient safety (AHRQ, 2019a). In the early 2000s, the Institute of Medicine put forth a plan to improve safety in health care through the acknowledgment that errors are going to happen and the recognition that safety can be improved by developing plans to prevent errors and to learn from them when they are made (AHRQ, 2019a). From this new approach to error prevention, the culture of safety was born.

The culture of safety is a planned cultural change that must begin at an organizational level (AHRQ, 2019a). It includes the following:

- shared values and goals between leadership and frontline staff;
- no fear of reprisals for errors (to promote honest reporting);
- in-depth exploration into the reasons for errors in order to develop strategies to prevent them in the future; and
- promoting safety through educating and training.

Nurses play a critical role in a culture of safety and are on the front line of most patient care interactions, even when they are not the primary prescribers of treatment. Nurses should always engage in open communication to promote safe patient care. The culture of safety is one of the backbones of the quality and safety education for nurses on which nursing curricula and licensing examinations are built.

Going hand in hand with the culture of safety is the idea of **just culture**, an organizational principle that fosters open and honest reporting of error and balanced accountability and encourages systemic examination to prevent errors in the future. Use of just culture concepts was endorsed by the American Nurses Association (ANA) in 2010 (Congress on Nursing Practice and Economics, 2010). In a just culture, there are three ways to explain medical errors or potential medical errors (Paradiso & Sweeney, 2019):

- *Human mistakes*: These are legitimate errors—unintentional errors while trying to act in the best interest of the patient. Comfort and coach the individual who made the error and seek additional education if necessary.
- *Risky behaviors*: These are often related to work-arounds to intentionally circumventing rules, but with the intention of providing good care for patients. Provide coaching and systemic investigation into why work-arounds or risky behaviors are perceived by staff as more appropriate than acting per policy. Examine whether the system is also at fault and if the policies should be modified to provide better care.
- *Reckless behavior*: These are actions or behaviors that do not intend to provide or care about providing appropriate care for patients. These types of behaviors may be grounds for serious disciplinary action.

## LINK TO LEARNING

This [video on just culture \(https://openstax.org/r/77JustCulture\)](https://openstax.org/r/77JustCulture) offers an excellent snapshot of the just culture philosophy.

### Quality Improvement

Quality improvement is an important component of a culture of safety. The likelihood that health services will improve patients' health outcomes in a way that is consistent with current knowledge is **healthcare quality** (Centers for Medicare and Medicaid Services [CMS], 2021b). A framework designed to continually improve patient care and outcomes is quality improvement (QI).

Quality improvement is made through a variety of mechanisms, and agencies are continually engaging in quality improvement activities. One common quality improvement tactic is the Plan-Do-Study-Act (PDSA) strategy ([Figure 3.16](#)) (AHRQ, 2020).

**FIGURE 3.16** The PDSA technique for quality improvement can be used in any healthcare setting and is often used for nurse-driven healthcare improvements. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Accountability for Safe, Reliable, Effective Care

In a healthcare environment that encourages a culture of safety and continuous quality improvement, there has been a move toward reliable, consistent care. There are many industries (particularly manufacturing) that function under hazardous conditions (such as aviation or power plants) and still produce products or services in a consistent fashion while keeping higher safety standards than health care. While industrial practices cannot be transferred entirely to health care, the emphasis on process refinement, consistency, and reliability have become components of today's healthcare culture. Effective and safe provision of care is **high-reliability health care** (AHRQ, 2019b). High-reliability organizations (HROs) provide complex health care for long periods of time without serious incidents or poor patient outcomes related to errors (AHRQ, 2019b). HROs are characterized by a strong culture of safety, continuous quality improvement, and hospital leadership that is willing to provide support and resources for safety and quality ([Table 3.9](#)) (AHRQ, 2019b).

Characteristic	Rationale
Heightened focus on failure or near failure	Forces staff to become vigilant, to prevent failures before they occur, and to learn about systemic issues when failures or near failures occur
Refusal to simplify the steps	Health care is complex and dynamic; developing shortcuts in procedures can breed errors
Recognize the larger picture	Recognize how one's work in an area impacts the larger system, for example, taking a patient for imaging without notifying the imaging center or recognizing the imaging center has its own schedule to maintain
Recognize the knowledge of the front line	Understand that the people closest to patients or a given situation have knowledge and insights that are valuable to the larger agency, and those individuals should be involved in quality and safety conversations and improvement
Teach resilience	Recognize that failures are always possible and practice managing and responding to them

**TABLE 3.9** Characteristics of High-Reliability Health Care (Source: Based on AHRQ, 2019b.)

### Pay for Performance

A payment model that ties either bonuses or additional costs to providers based on their performance over several metrics including best practices and patient satisfaction is **pay for performance (P4P)** (NEJM Catalyst, 2018). It contrasts with standard payment, which is **fee for service (FFS)**, payment for each service provided. The goal of P4P is quality over quantity with the hope that practitioners will use best practices to improve health outcomes while reducing overall healthcare costs. While there is some evidence that P4P is working in some places, it is still a fairly new concept, and its real potential has not yet been recognized. There is some evidence that the gains have been minimal, and it may negatively impact poor and marginalized patients because providers have less incentive to treat them. However, P4P is expected to remain important in health care and over time with appropriate adjustments to the structures will improve healthcare quality and outcomes for all patients (NEJM Catalyst, 2018).

### Value-Based Purchasing

The CMS has introduced **value-based purchasing** programs specifically for hospitals and skilled nursing facilities (SNFs) (CMS, 2022). Value-based purchasing looks very much like pay for performance, and some writers speak of them synonymously (NEJM Catalyst, 2018). In the case of SNFs, CMS holds back 2 percent of their Medicare payments until the end of the year. Then they receive up to 60 percent of those payments back as long as their 30-day readmission rate (number of patients who are discharged from the SNF but readmitted for any reason to an acute medicine facility within 30 days) falls below Medicare's threshold (CMS, 2023). The program for hospitals is similar to that for SNFs but includes additional measures including mortality and complications, healthcare-associated infections, patient safety, and patient satisfaction (CMS, 2021a).

## Summary

### 3.1 Levels of Care

Patients move through primary, secondary, and tertiary levels in the healthcare system throughout their lifetimes. Most patients spend most of their lives seeing practitioners at the primary level. At this level, basic preventive and curative care is provided, patients receive regular screening, immunizations, wellness care, and sick care. When a patient needs a higher level of skill, knowledge, or diagnostic capability than what a primary care physician can provide, they move to the secondary health care level. Secondary health care occurs in hospitals, specialty clinics, and therapeutic facilities and is provided by medical, mental health, and allied healthcare professionals who have specialized education beyond the scope of the primary practitioner. When patients have traumatic injuries, require extensive surgeries or treatments, have rare conditions, or are critically ill, they move to tertiary care. Most tertiary care is performed in large hospitals designed to treat and manage severe and unusual conditions and injuries. Some care is performed in smaller specialty clinics such as dialysis or substance abuse treatment centers.

### 3.2 Organizational Frameworks and Structure

Healthcare systems can be arranged and understood in a variety of ways. First, healthcare systems can be described through economics and critical need, in terms of for-profit, NFP, and state/local hospitals. Second, they can be defined based on how they are managed and what their responsibilities include: public versus private health care. Finally, they can be illustrated through the relationships they have with other facilities, physicians, and agencies as systems that provide integrated health care.

### 3.3 Barriers to Healthcare Access

There are many barriers to a patient's ability to access health care. No matter where a patient lives or who they are, at some point in their lives, they may have difficulty with access to varying levels. It is incumbent on the healthcare community to be aware of and work toward taking down these barriers. Geography, time, transportation, and availability of providers all impact patients in ways out of their control. Healthcare costs can be a substantial burden for all people, even those with insurance, but they affect the uninsured most profoundly. There are also disparities related to knowledge, education, racial background, and mistrust of medicine and medical providers that are barriers preventing patients from receiving the care they need.

### 3.4 Culture

Health care has its own culture that has moved from being organized by discipline to being focused on collaboration. Further, it has shifted from being focused on diseases and conditions to being patient centered and holistic. These changes do not happen automatically and are generally due to systemic decisions that encourage improved communication, relationships, and engagement between disciplines and patients. Alongside the movement for PCC has been an increased focus on safety and a shift from a model of blame to a model of planning, management, learning, and continual quality improvement.

## Key Terms

**access** the ability to obtain healthcare services when and where they are needed

**Beveridge model** single-payer national health service

**Bismarck model** social health insurance model

**cardiologist** secondary provider who specializes in heart-related conditions

**charity care** free or discounted healthcare provided to individuals who are uninsured or underinsured

**community hospitals** all hospitals that are not federal hospitals and offer both short-term and/or specialty care available to the general public

**deductible** the amount of money a patient must pay annually before their insurance begins to cover the cost of their care

**dermatologist** secondary provider who specializes in skin-related conditions

**disparities** differences that negatively impact one group over another

**extrinsic** factors external to an individual, such as issues that are political, cultural, or systemic

**for-profit** hospitals and other healthcare organizations that are run as businesses and funded in part by investors who expect to receive a share of the profits from the business in return for the money they invest

- gastroenterologist** secondary provider who specializes in conditions related to the digestive tract
- health literacy** the ability of an individual to locate, comprehend, and use health-related material and make healthcare decisions
- healthcare debt** money owed by patients related to healthcare activities
- healthcare delivery organization** a single facility or group of facilities that provide medical care for some portion of a population
- independent practice** a physician's office, owned and operated by a single physician with a small staff
- integrated delivery system (IDS)** a network of providers and agencies who collaborate with each other to provide care to individuals in a community
- intrinsic** factors internal to an individual, such as beliefs and values
- level of care** amount and complexity of care a patient requires
- medical home** primary care space that functions as a comprehensive primary care deliverer, coordinates care across the other levels, and ensures quality of care and efficiency for the patient
- multispecialty group practice** a group practice that includes providers from multiple specialties
- national health insurance** single-payer national health insurance
- not-for-profit (NFP)** organizations, such as hospitals and other healthcare groups, that are funded in part by donations and do not have to pay local, state, or federal taxes but are required to provide charity care and serve their communities
- out-of-pocket model** market-driven health care
- Patient Protection and Affordable Care Act (ACA)** a law passed by the U.S. Congress designed to improve access to health insurance and health care for all Americans
- population level** all individuals in a group; can be defined by shared demographics like geography, culture, or economic group; for example, U.S. citizens, teenagers, or individuals living below the poverty line
- premium** the fees that individuals pay on a regular basis for their health insurance and that may be taken out of their checks by their employer
- primary care provider (PCP)** any physician or other provider (such as nurse practitioner or physician's assistant) who provides broad, basic health care focused on prevention, screening, and mild to moderate health conditions and coordinates care among levels of the healthcare system
- primary health care** level of care focused on prevention of illness and maintenance of health, includes wellness care, sick care, immunizations, screening, and referral
- private** an institution that is run and funded by a group other than the government and can be either a for-profit or a not-for-profit institution
- private health institutions** organizations run and funded by a group other than the government, including both for-profit and not-for-profit organizations, such as doctors' offices, pharmacies, and same-day surgery centers
- profits** money remaining after all bills, including staff salaries, loans, and taxes, are paid
- provider shortage** not having enough providers for a given population
- public** an institution that is run and largely funded by the government and is for the good of the people it serves
- public health institutions** healthcare organization run and largely funded by the government for the good of the people they serve; provide direct patient care, set healthcare policy for all affiliated organizations, and are actively involved in caring for health at a population level
- pulmonologist** secondary provider who specializes in lung-related conditions
- restricted hours** limited availability of physician offices and healthcare facilities, most commonly Monday through Friday during the day only
- safety-net hospital** a healthcare facility that is required to provide care for an individual regardless of their ability to pay
- secondary care provider** physician, nurse practitioner, physician assistant, mental health professional, or allied health professional with advanced training in a specific organ or system of the body
- secondary health care** (acute or hospital care) when a patient's condition requires specialty care or diagnosis
- single-specialty group practice** a physician practice of two or more physicians in which all providers have the same specialty, such as primary care or urology
- stakeholder** individual with an interest in the success of an organization, such as an investor in a business or a nurse in a hospital
- state and local government healthcare institutions** healthcare organizations funded entirely or in part with

public money (collected taxes) and charitable donations and controlled by the state/local government in which they are built

**state and local health departments** critical public health institutions providing a range of services including immunizations, monitoring of communicable diseases, and provision of health education classes

**taxes** money paid to the local, state, or federal government for property and the purchase of goods

**tertiary care provider** the specialist of the specialists with advanced training in procedures, diagnostics, and treatments

**tertiary health care** level of care focused on treatment of critically ill patients, those with rare or complicated diseases or injuries, or patients requiring advanced tools, diagnostics, or procedures

**urologist** secondary provider who specializes in conditions related to the urinary tract

**vital records** birth, marriage, divorce, and death certificates

## Assessments

### Review Questions

1. A patient is being flown by helicopter to an advanced medical center for emergency surgery after a severe motor vehicle accident. What level of care is this patient going to receive?
  - a. primary
  - b. secondary
  - c. tertiary
  - d. specialized
2. A nursing student is worried about their uncle who has lost some weight and is complaining of discomfort. The student recommends the uncle see his \_\_\_\_\_.
  - a. primary care physician
  - b. family physician
  - c. secondary care physician
  - d. tertiary care physician
3. Occupational therapists, speech therapists, and physical therapists are what type of secondary care practitioners?
  - a. primary care physicians
  - b. mental health providers
  - c. nurse practitioners
  - d. allied health professionals
4. What level of healthcare provider is a patient seeing if they are going to a mental health professional for intermittent visits?
  - a. primary
  - b. secondary
  - c. tertiary
  - d. behavioral health
5. A patient is the spouse of an active-duty military service member. What type of care organization do they probably use?
  - a. federal
  - b. not-for-profit
  - c. public hospital
  - d. private hospital
6. What types of facilities *must* function as safety-net hospitals?
  - a. for-profit hospitals
  - b. not-for-profit hospitals

- c. state/local government hospitals
  - d. community hospitals
7. State and local health departments are responsible for many functions within their geographical areas, including administering federal programs such as WIC, regional emergency preparedness activities, and \_\_\_\_\_.
- a. setting healthcare policy at a national level
  - b. providing vital records for their community members
  - c. providing complete primary, secondary, and tertiary care
  - d. providing care for American Indian and Alaskan Native people
8. A patient's ability to understand and follow physician instructions, engage in their own healthcare decision-making, and understand their condition is related to their \_\_\_\_\_.
- a. health literacy
  - b. health understanding
  - c. education level
  - d. income level
9. Mrs. Simpson, an 82-year-old patient with Medicare who lives on her son's farm, has missed her scheduled appointment. The nurse recognizes she may face which barrier to care?
- a. lack of time
  - b. race
  - c. transportation
  - d. uninsured
10. What is not a goal of the ACA?
- a. make insurance affordable for individuals who fall between 100 and 400 percent of the federal poverty level
  - b. educate enough physicians to cover all physician shortages nationwide
  - c. expand Medicaid to cover all adults below 138 percent of the federal poverty level
  - d. support overall changes to healthcare delivery that will lower costs and improve care
11. During orientation, a new nurse is told by a preceptor that on the unit, staff arrive 10 minutes early for their shift, and report is given by doing "walking rounds" (giving report at the bedside, while using plain language and engaging the patient). The preceptor is teaching the new nurse about the unit's \_\_\_\_\_.
- a. sociology
  - b. structure
  - c. culture
  - d. reliability
12. A patient in which scenario is most likely to have a need for strong care collaboration?
- a. 25-year-old with a fractured ankle, is otherwise healthy, and lives with their spouse
  - b. 75-year-old with a recent hip replacement and multiple other conditions who lives alone
  - c. 35-year-old with an uncomplicated pregnancy who lives with their partner
  - d. 45-year-old with pneumonia who lives alone
13. PDSA is a technique commonly used for \_\_\_\_\_ and stands for \_\_\_\_\_, \_\_\_\_\_, \_\_\_\_\_, and \_\_\_\_\_.
- a. quality improvement; plan; do; study; act
  - b. safety initiatives; plan; do; survey; abandon
  - c. cultural change; plan; do; study; act
  - d. quality improvement; process; do; survey; act

## Check Your Understanding Questions

1. Briefly compare secondary and tertiary levels of care. Include the difference between the two, and provide an example of each type of practitioner, setting, and procedure.
2. Explain the differences between individual, single-specialty group, and multispecialty group practices.
3. In your own words, explain the relationship between health literacy and lack of education regarding primary care.
4. Explain the meaning of culturally competent care.
5. Describe care coordination.
6. Discuss what a culture of safety is.

## Reflection Questions

1. Consider the concept of IDs and your own experiences with health care. What do you think the benefits of IDs are, and how does that reflect your own experiences with the healthcare system?
2. In the introduction to this section, you were asked to consider additional barriers to health care that you have experienced or can imagine. Provide two additional barriers to healthcare access you can think of and how they might impact care.
3. Reflect on the eight main principles of culturally competent care. Which of these principles do you think will be the most difficult for you to integrate into your care and why?
4. Consider working four shifts in a row and being given a very difficult and demanding patient each of those shifts. On the fourth shift, your charge nurse offers to give you a different patient than your demanding one. Do you accept the offer? Why or why not?

## What Should the Nurse Do?

1. Nurse Moa is taking care of Mr. Henley. He has diabetes, asthma, a wound on his left lower leg, a toothache that started last night, and a history of occasional chest pain. While in the hospital, he is upset that he must see so many doctors and nurses. “Why can’t one doctor take care of me? Isn’t that what a hospital is for?” he argues. What should the nurse say?

A new nurse is drawing up a patient’s insulin. The patient needs 4 units of insulin based on their blood glucose level. When their preceptor checks the insulin, they realize that the new nurse has drawn up 4 mL of insulin (400 times the proper dose) in a regular syringe. The preceptor swapped out the insulin for the correct dose, and the patient was administered the correct dose.

2. What kind of situation is this known as?
3. Should the new nurse be punished? Why or why not?
4. What else should the preceptor do with this new nurse?
5. A patient has just requested some as-needed pain medication. It is close to the end of his shift, but the nurse, Bruce, did not want to leave it for the next shift. He went and pulled the pain medication out of the Pyxis, the automated machine that dispenses controlled medications. He drew the medication into a needleless syringe and put the packaging in his pocket. However, he was in a hurry. Rather than scanning the patient’s wristband, then scanning the medication to ensure it was the correct medication, and then giving the medication, he scanned the patient’s wristband and gave the medication, then returned to the computer to scan the medication into the system. When he scanned the medication, it was the wrong dose of pain medication. Instead of giving the patient 2 mg of morphine, Bruce gave the patient 4 mg of morphine. What should the nurse do?

## Competency-Based Assessments

1. You are working in a small community hospital emergency room outside of Chicago, Illinois. You have a patient come into the emergency room after a traumatic motor vehicle accident. The patient will clearly need

multiple orthopedic surgeries for broken bones as well as burn care and perhaps plastic surgery. Conduct internet research and determine which of the following hospitals you would expect to send this patient to.

- Thorek Memorial Hospital Andersonville
  - John H. Stroger, Jr. Hospital of Cook County
  - Kindred Hospital Chicago–North
  - Holy Cross Hospital
2. Conduct internet research and develop a brief 5- to 10-minute presentation about both the positive and negative aspects of one of the three types of federal hospital systems (VHA, IHS, or Defense Health Agency).
  3. Explore the [Healthy People 2030's healthcare access and quality \(https://openstax.org/r/77HealthyPpl\)](https://openstax.org/r/77HealthyPpl) web page. Choose two Related Objectives to examine further. For your chosen objectives, answer the following questions:
    - a. What is the objective?
    - b. What is the current status? Is it improving? What is the percentage difference between baseline, most recent, and target?
    - c. Why is this objective important for healthcare access?
  4. Choose a healthcare facility in your region or a region you wish to work in. Look up the hospital's website and explore their mission and vision statement. Supply the URL and hospital name, describe their mission and vision statement, and explain how you think you would feel about being part of that agency.

## CHAPTER 4

# Health, Wellness, and Community-Based Health Care

**FIGURE 4.1** The nurse's role in community healthcare is to offer the tools and strategies needed for effective illness prevention. (credit: modification of "20141016-DM-LSC-0191" by USDA/Flickr, Public Domain)

### CHAPTER OUTLINE

- 4.1 Defining Health and Wellness
- 4.2 Models of Health
- 4.3 Health Promotion and Illness Prevention
- 4.4 Community-Based Health Care
- 4.5 Community-Based Healthcare Initiatives
- 4.6 Population Health

---

**INTRODUCTION** Health, wellness, and community-based health care are interrelated concepts that are essential for promoting the overall well-being of individuals and communities. Health emphasizes the physical, mental, and social well-being of an individual, while wellness emphasizes the active pursuit of a healthy and balanced lifestyle. Community-based health care can play a critical role in promoting health and wellness by providing individuals access to essential healthcare services, education, and resources to encourage the adoption of healthy lifestyles. In addition, community-based healthcare providers work with local organizations and stakeholders to address broader health issues, such as improving access to healthy food options, promoting physical activity, and addressing environmental health risks. Ultimately, community-based health care can help improve the overall health and well-being of communities by fostering a sense of collective responsibility for promoting health and wellness.

## 4.1 Defining Health and Wellness

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the terms *health* and *wellness*
- Describe the Healthy People 2030 initiative
- Analyze the five social determinants of health

Health and wellness are important concepts related to individuals' physical, mental, and social well-being. Maintaining good health and wellness requires a **holistic approach**, which means addressing the whole patient to assess and treat all facets of the person. This includes regular exercise, a balanced diet, adequate rest, and stress management. In addition to these physical factors, mental and emotional health is also critical to overall well-being. This includes developing healthy coping mechanisms, practicing mindfulness, and seeking help when needed. Prioritizing health and wellness can lead to numerous benefits, including increased energy, improved cognitive function, reduced risk of chronic diseases, and a more optimistic attitude toward life. By adopting healthy habits and focusing on holistic well-being, individuals can improve their quality of life and increase their resilience when faced with challenges. Health and wellness should be viewed as an ongoing journey that requires a long-term commitment to self-care and personal growth.

### Definitions of Health and Wellness

Health and wellness are two different concepts, but they are interrelated. While health is mainly focused on the state of the physical, mental, and social aspects of an individual's life, wellness takes a more holistic approach, which views the person as a whole, considering individual activities, choices, and lifestyle in order to achieve a balanced and fulfilling life.

#### Health

The term health refers to the comprehensive view of physical, mental, emotional, and social well-being. Similarly, health is not simply the absence of disease or illness but a multifaceted concept that encompasses various aspects of a person's life. These aspects should be assessed not only individually but interconnectedly as well.

#### Human Dimensions

The **human dimensions** of health are facets of wellness that interrelate to demonstrate a comprehensive view of health ([Table 4.1](#)). The five dimensions include **emotional health, physical health, social health, intellectual health, and spiritual health** (PDHPE.NET, 2023). All these human dimensions are interrelated and influence one another. Neglecting any aspect of them can have a negative impact on a person's health. For example, if a person's emotional health is neglected, it can impact their physical health. People with depression or anxiety commonly have decreased appetite and decreased physical activity and/or social interactions with others. With deteriorated emotional health and impacted physical/social health, the person's overall health will be affected eventually. Therefore, it is important to take a holistic approach that addresses all aspects of health to achieve overall well-being.

Term	Definition	Example Activities
Physical health	Individual's ability to perform daily activities, maintain healthy body weight, and prevent illness and disease	Exercise, healthy diet, medication compliance (e.g., running, swimming)
Emotional health	Individual's ability to manage and express their emotions, cope with stress, and experience positive emotions	Meditation, mindfulness (e.g., going to yoga class)

**TABLE 4.1** Human Dimensions of Health

Term	Definition	Example Activities
Social health	Individual's ability to participate in social activities, interact with others, and experience a sense of belonging and connection	Social networking (e.g., going to the movies with friends)
Intellectual health	Individual's ability to acquire new skills, think critically, and engage in creative activities	Learning new activities (e.g., taking a painting class or learning a new language)
Spiritual health	Individual's ability to achieve a purposeful and meaningful life	Religious activities or activities that bring peace to the individual (e.g., going to church or a religious celebration, visiting the ocean or mountains, connecting to nature)

**TABLE 4.1** Human Dimensions of Health

### Wellness

The Global Wellness Institute (2023) defines wellness as “the active pursuit of activities, choices, and lifestyles that lead to a state of holistic health” (para. 4). It includes eight mutually codependent dimensions: **physical dimension of wellness, emotional dimension of wellness, social dimension of wellness, occupational dimension of wellness, spiritual dimension of wellness, intellectual dimension of wellness, environmental dimension of wellness, and financial dimension of wellness** (Table 4.2) (Compass Health, 2022). The dimensions of wellness are interrelated and affect each other in various ways. If any one of these dimensions is neglected over time, it will adversely affect one’s health, well-being, and quality of life (QoL). For example, if sleep is neglected, over time this will impact one’s ability to navigate stress and cope with challenging situations. This demonstrates how neglect of the physical dimension can negatively impact the emotional dimension. Similarly, if a patient is unable to access clean air over time, this will negatively impact their respiratory system, thus demonstrating how the environmental dimension can impact the physical dimension. By working to improve each dimension of wellness, individuals can achieve a state of optimal health and well-being.

Term	Definition	Example Activities
Physical dimension of wellness	The actions to maintain an individual's physical health	Nutrition, exercise, sleep, and regular medical checkups
Emotional dimension of wellness	The actions to increase self-awareness and self-regulation to manage emotions in a healthy and constructive way	Activities to cope with stress and adversity and promote positive emotions
Social dimension of wellness	The actions to maintain healthy and positive relationships with others	Activities including utilization of communication skills and social support to achieve a sense of belonging
Occupational dimension of wellness	The actions to achieve job satisfaction, work–life balance, and personal growth and development	Activities to develop personal career goals

**TABLE 4.2** Dimensions of Wellness

Term	Definition	Example Activities
Spiritual dimension of wellness	The actions to achieve personal values	Activities including reinforcement of beliefs and practices that promote inner peace, happiness, and fulfillment
Intellectual dimension of wellness	The actions to acquire new skills and generate new knowledge	Activities to obtain knowledge, such as pursuing certifications, courses, and self-guided learning
Environmental dimension of wellness	The actions to achieve a good relationship with the surrounding environment	Activities including access to clean air and water and a safe and healthy living and working environment
Financial dimension of wellness	The actions to achieve financial stability to meet basic needs and experience a sense of financial security	Income, expenses, debt, savings, and investments

**TABLE 4.2** Dimensions of Wellness

The most well-known model for wellness is Dunn’s Theory of Wellness. Dunn’s Theory of Wellness, also known as the High-Level Wellness Model, defines wellness as an ongoing process of growth and development that encompasses all aspects of an individual’s life. It emphasizes the importance of taking a holistic approach to health and wellness and recognizes that all dimensions of wellness are interrelated and contribute to overall well-being. According to this theory, there are four processes to achieve wellness: being, belonging, becoming, and befitting.

## REAL RN STORIES

### Assessing for Wellness

**Nurse:** Nikolas, APRN

**Clinical setting:** Outpatient Clinic

**Years in practice:** 5

**Facility location:** Ohio

Many years ago, when I was about 29 years old, I took care of an 18-year-old male who really made an impression on me. His name was Rishan. I was working at a clinic doing health assessments for school sports that summer. Rishan came in with his mother. He wanted to play soccer and needed the form filled out before school started. Rishan was in great shape, with no physical limitations and no history of illness. He had good grades and adored his parents. His mother was not comfortable speaking about health care in English. She preferred speaking Gujarati. I asked Rishan to tell her that he was okay and that I would fill out the form. Mrs. Patel shook my hand and left the room. Rishan then admitted that he had told her that I needed to ask him the questions on the sheet alone. I said, “Okay, what’s going on? Are you feeling sick?” Rishan told me that he was completely fine, but ever since school had ended, he just didn’t feel right. He went on to say that he just didn’t feel like doing anything or going anywhere. Plus, there was nothing for him to do; summer camps were for little kids. I sat down and asked him to tell me more. I knew that I had a room full of other patients to see, but I had to take the time to talk to him. Rishan admitted that he just felt sad all the time and that sometimes he didn’t know what day it was. He didn’t want to get out of bed sometimes. I talked to him at length and even completed a suicide assessment. It turned out that Rishan desperately missed going to school. He missed his friends and the structure of school. I connected him and his mom with a counselor and some soccer camps in the area. His mom also agreed to join the local gym so he could play pick-up basketball every day. This was the first time that I realized that even my “healthy” patients might have areas in their lives that are not well. You never know when a simple conversation can really help a patient open up and talk to you.

### Being

In Dunn's Theory of Wellness, **being** is defined as recognizing oneself as an individual and actively working to achieve a state of high-level wellness in all eight dimensions. This includes engaging in regular physical activity, managing stress, developing healthy relationships, pursuing intellectual interests, nurturing spirituality, and finding meaning and purpose in one's work. Individuals who are in a state of high-level wellness are thought to have a strong sense of self-awareness and can make choices that support their overall well-being.

### Belonging

The word **belonging** is defined as the feeling of being accepted, valued, and supported by others, as well as the sense of being part of a larger community or group. Belonging is a key dimension of wellness in Dunn's Theory of Wellness. This dimension focuses on an individual's sense of connectedness to their communities and social networks. The dimension recognizes the importance of social relationships and the impact they can have on an individual's mental and emotional well-being. Individuals who have a strong sense of belonging tend to have higher levels of self-esteem, improved coping skills, and a greater sense of purpose and meaning in life. However, the absence of belonging or social isolation can have negative impacts on an individual's health and well-being, including increased stress, depression, and a higher risk of chronic diseases. Therefore, promoting a sense of belonging and social connection is essential to achieve a state of high-level wellness in Dunn's Theory of Wellness.

### Becoming

The word **becoming** is defined as an individual's pursuit of personal growth and self-improvement, as well as their openness to new experiences and perspectives. Becoming emphasizes the importance of ongoing growth and development. It recognizes that personal growth and development are ongoing processes that require a commitment to lifelong learning and self-reflection. Individuals who prioritize the dimension of becoming are often interested in expanding their knowledge, pursuing new hobbies, and exploring new opportunities for personal and professional growth. This dimension also acknowledges that personal growth can occur through challenges and setbacks, as these experiences can provide opportunities for learning and personal development. In Dunn's Theory of Wellness, becoming is seen as an essential component of overall well-being, as it contributes to a sense of purpose, meaning, and fulfillment in life. By actively pursuing personal growth and development, such as by going back to school to enhance one's education, individuals can enhance their overall well-being and improve their quality of life (QoL).

### Befitting

Taking proactive self-care strategies and personal responsibility to make personal choices to benefit one's well-being is known as **befitting**. It includes taking steps to prevent illness and promote overall health and well-being, such as adopting healthy habits, managing stress, getting regular checkups, and taking care of one's mental and emotional health. By making choices that prioritize long-term well-being, individuals can improve their quality of life and reduce the risk of chronic diseases and other health problems.

## PATIENT CONVERSATIONS

### What Does Your Patient Know About Health and Wellness?

**Scenario:** The patient was admitted to the medical-surgical floor for chest pain. In the morning, the nurse walks into the patient's room.

**Nurse:** Good morning, how are you feeling today?

**Patient:** Hi, I'm feeling much better today. I am trying to stay healthy, and I expect to be discharged soon.

**Nurse:** That's great to hear. Can you tell me what you are doing to try to keep healthy?

**Patient:** Well, I try to eat healthy and exercise regularly.

**Nurse:** Those are definitely important aspects of overall health and wellness. But did you know that being healthy isn't just about physical health?

**Patient:** Really? What else is there?

**Nurse:** Health and wellness encompasses much more than just physical health. It also includes psychological health, a balanced lifestyle, and social well-being. These different aspects work together to make up your overall well-being.

**Patient:** I see. I never really thought about it that way.

**Nurse:** It's a common misconception, but think about it. If you're physically healthy, but you're constantly stressed or not getting enough sleep, it can still take a toll on your overall well-being. That's why it's important to strive for balance in all aspects of your life.

**Patient:** That makes sense. So, how can I work on these other aspects of wellness?

**Nurse:** Well, for psychological health, it's important to take care of your mental and emotional well-being. This can include things like practicing mindfulness, seeking therapy or counseling if needed, and finding ways to manage stress. For a balanced lifestyle, it's important to make time for activities you enjoy, connect with others, and have a good work–life balance. And for social well-being, it's important to build and maintain healthy relationships with friends and family.

**Patient:** I never realized there were so many different aspects of wellness. Thank you for explaining it to me.

**Nurse:** You're welcome. Remember, taking care of your overall well-being can have a positive impact on all areas of your life. Let me know if you have any other questions or concerns.

---

## Healthy People 2030

To improve people's health and well-being over the next decade, the Healthy People 2030 initiative sets a variety of data-driven national objectives. Included in the Healthy People 2030 initiative are 358 core, measurable, and developmental objectives (U.S. Department of Health and Human Services, 2023). These objectives provide a clear and concrete guide to improving the health of the nation, focusing on the most critical challenges and priorities for the public.

### LINK TO LEARNING

The [Healthy People 2030 website \(https://Openstax.org/r/77healthy2030\)](https://Openstax.org/r/77healthy2030) is coordinated by the Office of Disease Prevention and Health Promotion, Office of the Assistant Secretary for Health, Office of the Secretary, and U.S. Department of Health and Human Services. This [Five Social Determinants of Health in Healthy People 2030 video \(https://Openstax.org/r/77healthy2030vd\)](https://Openstax.org/r/77healthy2030vd) gives additional information.

---

### Objectives and Data

The Healthy People 2030 initiative has three types of objectives: core, developmental, and research objectives ([Table 4.3](#)). Five intuitive topics are covered in the Healthy People 2030 objectives: health conditions, health behaviors, populations, settings and systems, and social determinants (Office of Disease Prevention and Health Promotion, 2023a).

More than eighty data systems are used as part of the Healthy People 2030 initiative to track progress toward the achievement of objectives over the course of the decade. These include national censuses of events (e.g., the National Vital Statistics System), nationally representative sample surveys (e.g., the National Health Interview Survey), and other valid and reliable data sources (e.g., the State Tobacco Activities Tracking and Evaluation System).

Objective	Description
Core objectives	Address high-priority public health issues, including evidence-based interventions. The core objectives were developed using valid and reliable data obtained from the nationally representative population. The baseline data for the core objectives were from 2015.
Development objectives	Represent high-priority public health issues that can be addressed with evidence-based interventions but which do not yet have reliable baseline data.
Research objectives	Represent issues of public health with high health and economic burdens or significant disparities between groups of people, but which lack evidence-based interventions.

**TABLE 4.3** Objectives of Healthy People 2030

### Leading Health Indicators

The Healthy People 2030 initiative has twenty-three **leading health indicators** selected from high-priority Healthy People 2030 objectives to inspire action to improve health and well-being and provide a point of measure for success. As a set, leading health indicators encompass all aspects of health. Most leading health indicators focus on factors that contribute to the leading causes of death and disease in the United States, such as cigarette smoking, suicide, exposure to unhealthy air, and so on. These indicators help community and state organizations focus efforts and resources on improving health and well-being. The leading health indicators cover the life span and include objectives across topic areas, such as improved oral health interventions and increasing the proportion of people with health insurance.

### LINK TO LEARNING

The [leading health indicators \(https://Openstax.org/r/77leadhelthind\)](https://Openstax.org/r/77leadhelthind) provide multiple data on the high-priority objectives in the Healthy People 2023 initiative. The data provide information on the trend and progress of fulfilling the objectives, which could help policymakers, researchers, and healthcare providers initiate actions to improve the public's well-being.

### Health Equity

According to the Healthy People 2030 initiative, **health equity** is the attainment of the highest level of health for every person. Achieving health equity means valuing everyone equally with focused and ongoing societal efforts to address avoidable inequalities and historical and contemporary injustices and eliminate health and healthcare disparities (Office of Disease Prevention and Health Promotion, 2023b). It aligns with the overarching goal of the Healthy People 2030 initiative to eliminate health disparities, achieve health equity, and improve health literacy for everyone. Examples of aiming to achieve health equity include providing accessible healthcare services, making medications affordable, promoting health education, addressing language and cultural barriers, expanding health insurance coverage, addressing social determinants of health, conducting research on health disparities, and engaging communities in decision-making processes.

### Health Literacy

The ability to obtain, understand, and use information to make medical decisions is known as health literacy. One of the Healthy People 2030 initiative's overarching goals is to "eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being of all," which demonstrates the importance of this concept (Office of Disease Prevention and Health Promotion, 2023c).

The Healthy People 2030 initiative addresses both personal health literacy and organizational health literacy. While **personal health literacy** focuses on the ability of a single person to comprehend and use health information, **organizational health literacy** focuses on how an organization can help individuals find and use this information for themselves to make decisions about their health and wellness. The Healthy People 2030 initiative recognizes that personal health literacy is context specific, and that health information and service providers have the responsibility to improve personal health literacy. Examples of aiming to improve individuals' health literacy include clearly

communicating, implementing health education programs, providing multimedia tools, and promoting digital literacy.

## PATIENT CONVERSATIONS

---

### Importance of Assessing Health Literacy Levels to Provide Effective Education

**Scenario:** The nurse is educating a newly diagnosed patient with diabetes about making healthy choices. In this scenario, the nurse, Silvia, realizes that her previous teaching efforts were completely misunderstood. Mrs. Harvey has a lower healthcare literacy level than what was assumed.

**Nurse:** Hello, Mrs. Harvey. How are you?

**Patient:** Hello there, Silvia. I am ready to go home.

**Nurse:** Yes ma'am, I hear you. Let's sit, and I'll go over your discharge paperwork with you.

**Patient:** Alright (nodding).

**Nurse:** So, I know you know about your diabetes and how to check your blood sugar. Today I want to talk about your feet.

**Patient:** My feet? What about my feet?

**Nurse:** Well, now that you have diabetes, you will have to have really good foot care. You will have to check your feet every day.

**Patient:** I can do that. I'll do it when I get home.

**Nurse:** Yes, make sure you wear shoes that fit well and aren't tight on your feet.

**Patient:** Okay. I can do that. I will definitely do like you said and check my foot for diabetes every day and see if there is diabetes in my shoes too. Do you think it's in my clothes? I don't want to have to throw my clothes out. That's expensive.

**Nurse:** Oh no, Mrs. Harvey. You are checking your feet for injuries and wounds. Remember, we watched the video on checking to make sure you don't have any injuries that you can't feel on your feet.

**Patient:** Yes, we did watch the video, but if I don't have anything wrong with my feet, why am I checking them? I thought you said to check my blood sugar. Now you want me to check my feet? Just tell the truth, is the diabetes moving down to my feet now?

**Nurse:** You know what, Mrs. Harvey? Why don't I start over and take this step by step with you? I will go over what diabetes is first. Then we can go over what it does to the body, and then I'll explain what we check for and why.

**Patient:** Okay, thank you. And can you teach my granddaughter too? She's coming to see me after lunch today. She's in that fancy college and is very smart. She's studying to be a nurse, you know.

**Nurse:** Yes, I can. I can get everything ready and come back to teach both of you this afternoon.

---

## Social Determinants of Health

The conditions associated with birth, childhood, education, work, play, worship, and aging that impact health, functioning, and quality-of-life outcomes are termed **social determinants of health (SDOH)**. Social determinants of health align with one of the Healthy People 2030's five overarching goals: "Create social, physical, and economic environments that promote attaining the full potential for health and well-being for all" (Office of Disease Prevention and Health Promotion, 2023d). Social determinants of health have a major impact on people's health, well-being, and quality of life. They include five domains: economic stability, healthcare access and quality, education access and quality, neighborhood and built environment, and social and community context. [Figure 4.2](#) outlines the five social determinants of health identified by the HHS.

## Social Determinants of Health

**FIGURE 4.2** Social determinants of health are factors that impact the health and quality of life of all people. (credit: modification of “Healthy People 2030” by U.S. Department of Health and Human Services, Office of Disease Prevention and Health Promotion/health.gov, Public Domain)

### Economic Stability

In the United States, one out of ten people live in poverty, and many cannot afford basic necessities like food, health care, and housing (Semega et al., 2019). As economic stability is a large concern in the United States, one of the Healthy People 2030 goals is to help people earn steady incomes that allow them to meet their health needs. Those who have lower levels of income are less likely to comfortably afford reliable health insurance coverage, preventive care, and resources to support overall health, such as fresh produce. Further, those with lower incomes are more likely to have difficulties paying for expensive treatments or procedures that may be needed.

Steady employment, and thus steady income, can help provide families with financial support for their healthcare needs. A disability, injury, or chronic health condition may make finding or keeping a job difficult for some people, impacting their overall economic stability. To offset these challenges, a variety of employment programs, career counseling, and high-quality childcare services can assist people with finding and keeping jobs. For example, the U.S. Department of Labor supports Job Corps, which provides skills training for those looking for employment. Additionally, programs such as welfare and Head Start help children and families obtain nutrition and medical supplies. Additionally, health, well-being, and poverty can be reduced and improved by policies that help people pay for food, housing, health care, and education.

### Healthcare Access and Quality

Approximately 8 percent of Americans lack health insurance coverage, and many people are unable to receive health care (HHS, 2022). One of the Healthy People 2030 goals is to increase access to comprehensive, high-quality healthcare services.

Patients without insurance may have difficulty accessing health care, and they may be unable to afford medications and healthcare services. Strategies to increase rates of insurance coverage of preventive care and treatment for chronic illnesses are important to help more people to get necessary healthcare services. Other factors, such as lacking a primary care provider and transportation to and from healthcare facilities, may hinder people from getting recommended healthcare services. Interventions to increase access to healthcare services and improve in-person or remote communication can help more people obtain the healthcare services they need. Example initiatives aiming to increase healthcare access and quality include offering universal health coverage (e.g., the Affordable

Care Act), expanding primary care services, utilizing telehealth, reducing wait times, facilitating health information exchange, fostering cultural competence, and addressing health disparities.

## REAL RN STORIES

---

### Resource Management to Facilitate Patient Care

**Nurse:** Patience, Community Health RN

**Clinical setting:** Outpatient Clinic

**Years in practice:** 6

**Facility location:** Dallas, Texas

I was working in a community health clinic for over three years when I met Mrs. Gloria Dennison. She was a retired schoolteacher who lived in an apartment in South Dallas. She was scheduled to come in every month to pick up her medication from our mobile pharmacy and to get her blood pressure checked. Sometimes she would need refills of her asthma medication too. Well, after a year I noticed a change in Mrs. Dennison: she used to come early to every appointment and would chit-chat with me about her years as a teacher. I started to notice that nowadays she was always late and seemed very stressed. She would need to sit for a minute to catch her breath before we took her blood pressure. She would come in long after her medication ran out, and when we assessed her, her blood pressure would be higher than normal. One time she came in, and I could see that she was not breathing well. We had to use a rescue inhaler supplied by the clinic to help her breathe. Finally, I asked her what was going on. Mrs. Dennison broke down and told me that David, her husband of forty years, was very sick and could no longer drive their car. She was now taking the bus everywhere because she didn't have a driver's license. I remember her telling me that they lived across the street from the school where they both worked for all these years. Now that he couldn't drive, she had to take two buses to get to the clinic. And sometimes the buses were late, or she would just miss her connection by a few minutes. Since the trip was so stressful, she waited till she felt like she needed the medications before she came in. I sat her down and told her that the clinic could help her with this. We had transportation vouchers from our community partners that could be used to pay for her transportation to and from the clinic. She was so happy and held on to my hand for a long time. I told her to please let us know if she needed anything else because even if we couldn't help her with a problem, we might have community resource partners who could. Then I told her that we could find her a ride home today. She was overjoyed. That was the day I decided to keep working in community health and to educate myself about available resources that might help my patients.

---

### Education Access and Quality

People who have higher education levels are more likely to be healthier and live longer (Raghupathi & Raghupathi, 2020). Adult education, especially post-secondary education, is the most important factor influencing life expectancy and infant mortality (Raghupathi & Raghupathi, 2020). One of the Healthy People 2030 goals is to increase educational opportunities and help children and adolescents do well in school. This foundation for learning will then help those children and adolescents as they move into adulthood.

Numerous families are unable to finance the expense of their children's college education. Some children reside in areas with underperforming schools. The stress of living in poverty can impact children's brain development and make it hard for them to do well in school. Interventions that can help children and adolescents do well in school can have long-term health benefits.

### Neighborhood and Built Environment

The neighborhoods people live in have a huge impact on their health and well-being. One of the Healthy People 2030 goals is to create neighborhoods and environments that promote health and safety. Example initiatives to create healthy neighborhoods and built environments include creating multiple green spaces (open spaces designated for grass or trees) or parks for residents, allocating food markets and fresh produce markets near residential areas, and providing accessible resources to the community. With healthy neighborhoods and environments, residents can overcome barriers such as transportation or lack of resources. The initiatives can help to promote residents' health and quality of life (QoL).

Many individuals in the United States reside in neighborhoods with elevated levels of danger, such as high rates of

violence or poor-quality air and water. Racial/ethnic minorities and people with low incomes are particularly prone to living in such areas. Moreover, certain individuals are exposed to environmental risk factors that could negatively impact their well-being, including exposure to secondhand smoke or loud noises. To address these issues and promote good health, interventions at the local, state, and national levels are crucial. For example, incorporating bike lanes and sidewalks in community designs can improve safety, promote physical activity, and boost the overall quality of life.

### Social and Community Context

Individuals' relationships and interactions with family, friends, coworkers, and community members can have a major impact on their health and well-being. One of the Healthy People 2030 goals is to increase social and community support.

Individuals sometimes encounter challenges, such as discrimination, financial instability, and living in unsafe areas, which can adversely affect their health and safety. Having positive relationships within one's family, workplace, and community can help alleviate these negative impacts. However, there are certain groups, such as children with incarcerated parents and bullied adolescents, who lack such support. Bullying can lead to profound psychological distress, social isolation, and compromised physical and mental health outcomes for affected adolescents. Interventions aimed at providing social and community support are essential to improve the overall health and well-being of individuals. Targeted interventions, such as counseling services, mentorship programs, community support groups, and educational initiatives, are needed to provide support and resources for these at-risk populations. Examples of such support and resource services include the Centers for Disease Control and Prevention, the American Psychiatric Association, the Crisis Text Line, and local health departments.

## 4.2 Models of Health

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the different nursing models used in patient care
- Describe medical models used by nurses when providing patient care
- Identify examples of models for health and illness

The **models of health** are conceptual frameworks that guide healthcare providers to understand and promote health. They encompass various theories and approaches that aim to explain the complex relationships among individuals, environment, and health outcomes. By understanding multiple factors that contribute to health, healthcare providers can develop comprehensive care plans that address the unique needs of the patients. Models of health are continuously evolving and remain a critical aspect of healthcare practice and research ([Table 4.4](#)).

Types of Models	Description	Examples
Nursing models	Guide nursing practices that emphasize comprehensive care to patients	Health Belief Model, Health Promotion Model, Holistic Health Model, Maslow's hierarchy of needs
Medical models	Provide approaches to understanding and treating illness	Religious Model, Humanistic Model, Transpersonal Model
Models for health and illness	Used to understand and explain the complex interactions between biological, psychological, social, and environmental factors that contribute to a person's health status	Biomedical Model, Psychosomatic Model, Existential Model

**TABLE 4.4** Models of Health

## Nursing Models

The **nursing models** of health draw from various frameworks, such as the Health Belief Model, the Health Promotion Model, the Holistic Health Model, and Maslow's hierarchy of needs, to guide nursing practice and provide comprehensive care to patients. These models emphasize the importance of considering the whole person and taking a holistic approach to health and wellness. Nursing models of health recognize the importance of personal and environmental factors in shaping health behaviors and outcomes. By incorporating these models into the practice, nurses can provide patient-centered care (PCC) and promote optimal health outcomes for the patients. Patient-centered care focuses on the individual and that individual's specific healthcare needs, while encouraging the individual's active participation in their own medical plan.

### Health Belief Model

The **Health Belief Model (HBM)** (Figure 4.3) is a widely recognized model of health that emphasizes the importance of an individual's beliefs and attitudes in shaping health behaviors. It includes six concepts: perceived susceptibility, perceived severity, perceived benefits, perceived barriers, self-efficacy, and cues to action (Rural Health Information Hub, 2023). The HBM recognizes that individuals are more likely to engage in healthy behaviors when they perceive a threat to their health and believe that taking action will be beneficial in reducing that threat. An example of this behavior is when people quit smoking because they believe it will improve their health. The model also takes into account an individual's perceived barriers to taking action and their self-efficacy or confidence in their ability to make changes. The HBM is frequently used in health promotion and disease prevention programs to help individuals understand the importance of taking action to protect and promote their health. By focusing on an individual's beliefs and attitudes, the HBM can help nurses tailor interventions to meet the specific needs and concerns of each patient.

**FIGURE 4.3** The Health Belief Model says that a patient's personal assumptions will influence their health interventions and their actions regarding their health plans. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LINK TO LEARNING

The Health Belief Model is one of the most used models. It addresses health behavior change, health promotion, and disease prevention. Some [other theories and models used for health behavior change, health promotion, and disease prevention programs \(https://openstax.org/r/77healthbehav\)](https://openstax.org/r/77healthbehav) include Ecological Models, the Stages of Change Model (Transtheoretical Model), Social Cognitive Theory, and the Theory of Reasoned Action/Planned Behavior.

### Health Promotion Model

The **Health Promotion Model** (HPM) (Figure 4.4) is another widely recognized model of health that takes a holistic approach to health and wellness. It focuses on three areas: individual characteristics and experiences, behavior-specific cognitions and affect, and behavioral outcomes (Chen & Hsieh, 2021). This model emphasizes the importance of personal and environmental factors in shaping health behaviors and outcomes. The HPM recognizes that individuals are more likely to engage in healthy behaviors when they feel empowered to take control of their health and have access to supportive environments that promote health. The model also highlights the importance of ongoing education and skill building to promote long-term behavior change. The HPM is frequently used in health promotion and disease prevention programs such as lung cancer screening programs and mammogram screening programs to help individuals understand the importance of making healthy choices and to provide them with the tools and resources they need to make those choices. By taking a holistic approach to health promotion, the HPM can help individuals achieve optimal health and well-being.

**FIGURE 4.4** The Health Promotion Model states that individuals' health-promoting behaviors are impacted by their characteristics and experiences, as well as their behavior-specific cognitions and affect. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Holistic Health Model

The **Holistic Health Model** is a comprehensive model of health that takes into account the physical, emotional, social, and spiritual aspects of health and wellness (Schoon & Krumwiede, 2022). This model recognizes that health is more than just the absence of disease—it is a state of balance and harmony within the body, mind, and spirit. The Holistic Health Model emphasizes the importance of promoting health and preventing disease by addressing the root causes of imbalances in the body, such as poor nutrition, lack of exercise, stress, and environmental toxins. This model also recognizes the interconnectedness of all aspects of health and wellness and encourages individuals to take a proactive approach to their own health by making informed choices that support their overall well-being. By taking a holistic approach to health, the Holistic Health Model can help individuals achieve optimal health and well-being in all areas of their lives.

### Maslow's Hierarchy of Needs

Maslow's **hierarchy of needs** (Figure 4.5) is a well-known model of health that describes human needs and motivations. It is a pyramid-shaped model that includes five levels of needs: physiological needs, safety needs, love and belonging needs, esteem needs, and self-actualization needs (Hayre-Kwan et al., 2021). The model suggests that individuals must satisfy their lower-level needs before they can move on to meet higher-level needs (Hayre-Kwan et al., 2021). By understanding the hierarchy of needs, nurses can identify the needs of their patients, provide care that meets those needs, and support their patients' overall well-being.

**FIGURE 4.5** Maslow's hierarchy of needs suggests that individuals' physiological needs should be satisfied before their security, social, esteem, and self-actualization needs are met. (credit: modification of work from *Psychology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Medical Models

The **medical models** of health and wellness are approaches to understanding and treating illness. Medical models view health as the absence of disease or illness and focus on identifying and treating physical symptoms and underlying medical conditions through medical interventions, such as medications, surgeries, and other medical procedures. Medical models also emphasize the importance of preventive measures, such as vaccinations, regular health screenings, and lifestyle modifications, to maintain and promote optimal physical health.

### Religious Model

A **religious model** refers to a framework or system of beliefs that serves as a guide for individuals or communities to understand and relate to a higher power or spiritual reality. The religious model of health views health as a state of complete physical, mental, and spiritual well-being that is attained through a relationship with a higher power or divine being. It emphasizes the importance of spirituality and religious practices in maintaining and promoting health and often incorporates prayer, meditation, fasting, and other religious practices into health care (Hvidt et al., 2020). It often includes a set of practices, rituals, and traditions that help people cultivate a sense of connection and meaning in their lives. The religious model of health can provide individuals with a sense of purpose and meaning as well as a support system through a faith community, which can contribute to overall health and well-being. However, religious models can vary widely depending on the specific traditions, doctrines, and interpretations that people follow. Some of the most well-known religions include Christianity, Islam, Hinduism, Buddhism, and Judaism, but there are countless other religious models practiced around the world.

### Humanistic Model

The **humanistic model** focuses on the importance of the individual and their personal experience and emphasizes the need for PCC that recognizes the unique needs and values of each patient. The humanistic model of health views health as a holistic state of well-being that encompasses physical, emotional, social, and spiritual aspects of life. This model places emphasis on the individual's self-awareness, personal growth, and ability to make choices that lead to a fulfilling life. It recognizes that each individual has unique experiences, beliefs, and values that shape their perspective on health and well-being. The humanistic model of health promotes a patient-centered approach to health care, where the focus is on the whole person and not just their symptoms or illness. It encourages the development of a positive and supportive relationship between the patient and healthcare provider, with an emphasis on open communication, empathy, and mutual respect. The humanistic model of health places a strong

emphasis on the importance of preventive care and healthy lifestyle choices as well as the promotion of social justice and equality (Werder, 2019).

### Transpersonal Model

The **transpersonal model** of health proposes that beyond the adult ego, there are developmental stages that involve experiences of connectedness with phenomena considered outside the boundaries of the ego (Watson Caring Science Institute, 2024). It views health as a state of consciousness that transcends the individual self and connects us to a larger universal reality. This model emphasizes the importance of personal growth in achieving optimal health and well-being. It recognizes that the human experience includes the spiritual and mystical dimensions of life. This model also acknowledges the role of interconnectedness and community in promoting health and well-being, as individuals are seen as part of a larger whole. The transpersonal model of health offers a holistic approach to health care that incorporates a broader range of experiences and practices beyond the traditional biomedical model, providing a framework for individuals to explore their spiritual and mystical dimensions in the pursuit of optimal health and well-being.

### Models of Health and Illness

Models of health and illness are frameworks used to understand and explain the complex interactions between biological, psychological, social, and environmental factors that contribute to a person's health status. They are useful in understanding the complexities of how health is defined, maintained, and influenced by different factors and are essential for guiding research, clinical practice, and public health interventions. Some of the most commonly used models of health and illness include the biomedical model, psychosomatic model, and existential model.

The **biomedical model** is a traditional approach to health care that focuses on diagnosing and treating specific physical diseases or disorders using medical interventions such as drugs or surgery. The **psychosomatic model** stands on the idea that psychological factors, such as emotions, beliefs, and personality traits, can have a direct impact on physical health. The **existential model** is a philosophical and psychological approach that emphasizes the subjective experience of individual existence and the search for meaning in life. These models, summarized in [Table 4.5](#), provide different lenses through which to understand and approach health and illness. Understanding their different perspectives can help individuals, nurses, and policymakers better understand the complex nature of health and illness and develop more effective strategies for promoting health and preventing disease.

Model	Description	Example
Biomedical model	<ul style="list-style-type: none"> <li>• Body is viewed in individual pieces, similar to a machine that can be fixed by fixing independent parts</li> <li>• Strong emphasis placed on biological and physiological factors</li> <li>• Criticized for neglecting the psychological and social aspects of health and illness, which limits its use in chronic or complex disease states</li> </ul>	Disease-specific causes of death: Cigarette smoking is linked to death from lung cancer.
Psychosomatic model	<ul style="list-style-type: none"> <li>• According to this model, emotional or psychological distress can manifest as physical symptoms or illnesses, without a clear underlying physical cause (Meares, 1975).</li> <li>• Supports the interconnectedness of the mind and body, demonstrating the effect mental and emotional health has on physical health</li> </ul>	The placebo effect: The patients in a drug trial may unknowingly be given a “fake” drug or placebo as a control group. Some of these patients will have such a strong belief that they received the real drug that they will actually have an improvement in their symptoms. Another example is of a cancer patient in severe pain who believes that a blessing they received from a religious leader has caused relief from their pain.
Existential model	<ul style="list-style-type: none"> <li>• The existential model highlights the importance of personal responsibility, authenticity, and self-awareness in the search for meaning, and recognizes the potential for individuals to experience feelings of anxiety, despair, and isolation in the face of life's uncertainties (Cohn, 1984).</li> <li>• According to this model, individuals are confronted with the realities of existence (e.g., death, freedom, and choice).</li> </ul>	A patient who has a terminal illness: The patient, who believes in nature and nontraditional medicines, may choose to only use herbs, exercise, and dietary changes to combat their illness. They may see their illness as a part of the cycle of life and choose to make peace with the diagnosis instead of utilizing more aggressive treatment options.

**TABLE 4.5** Models of Health and Illness

## 4.3 Health Promotion and Illness Prevention

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the global strategies for health promotion
- Discuss levels of prevention and application to patient care
- Compare factors influencing a patient's risk of illness
- Explain the impact illness has on health promotion

Health promotion is an essential aspect of nursing practice, and it involves the integration of global strategies, the application of prevention levels, and the consideration of factors that influence the risk of illness in patients. Health promotion aims to improve the overall well-being and health of individuals, families, and communities through a range of interventions and programs. Nurses play a vital role in health promotion, and they use a variety of strategies to prevent and manage illnesses and promote healthy behaviors. In this context, it is important to understand the levels of prevention and their application in patient care, the factors that contribute to illness, and the impact of illness on health promotion. This knowledge equips nurses to provide effective care and support to patients, enabling patients to make informed decisions about their health and well-being.

### Strategies for Health Promotion

Global strategies for health promotion are comprehensive and coordinated efforts to improve health and wellness worldwide. The World Health Organization (WHO) has developed several global strategies for health promotion which focus on a variety of approaches, including improving access to healthcare services, promoting healthy lifestyles, addressing social determinants of health (SDOH), and advocating for policies and systems that support health and wellness. The goal of these strategies is to promote health equity, reduce health disparities, and empower individuals and communities to take an active role in their own health and well-being. The global strategies for health promotion include several key components, including governance for health, health literacy, and healthy cities. Overall, these global strategies for health promotion are aimed at creating supportive environments that enable individuals and communities to lead healthy and fulfilling lives. They emphasize the importance of collaboration and partnership among governments, organizations, and communities, as well as the need for a comprehensive and coordinated approach to promoting health and wellness worldwide. A recent example is the Healthy People 2030 initiative discussed earlier in this chapter.

#### Governance for Health

The process of developing and implementing policies, strategies, and actions that support and promote the health and well-being of individuals and communities is referred to as **governance for health**. Effective governance for health requires collaboration and coordination across various sectors and stakeholders, including government, civil society, and the private sector (WHO, 2023c). It emphasizes the importance of policies, laws, and regulations that support health and wellness. The role of governance in health promotion involves creating environments that support healthy behaviors, reducing health inequalities, and ensuring equitable access to health services. Good governance practices such as transparency, accountability, and participation are crucial to achieve these goals. Examples of actions that promote health and well-being include public service announcements and mass media campaigns, which provide communication to raise awareness. By prioritizing governance for health, policymakers and leaders can create the conditions necessary for individuals and communities to achieve optimal health and well-being.

#### Health Literacy

The ability of individuals to obtain, process, and understand basic health information and services needed to make informed decisions about their health is referred to as health literacy. It focuses on promoting knowledge and understanding of health and wellness among individuals and communities, which includes providing access to reliable health information, improving communication and decision-making skills, and promoting healthy behaviors and lifestyles (Centers for Disease Control and Prevention [CDC], 2023). In the context of health promotion, improving health literacy is essential to enable individuals to take an active role in their own health and well-being. People with low health literacy may have difficulty navigating the healthcare system, accessing appropriate health services, and making informed decisions about their health.

## LINK TO LEARNING

---

Understanding health literacy is imperative for effective health promotion. The U.S. Department of Health and Human Services presents [five facts to know about health literacy \(https://Openstax.org/r/77healthlit\)](https://Openstax.org/r/77healthlit) to improve health goals.

---

To improve health literacy, health promotion efforts should focus on providing clear, accurate, and accessible health information and services, using plain language and visual aids, breaking down information into small concrete steps, providing written information at or below sixth-grade reading level, limiting the objectives of a visit to three key points or tasks, and assessing for comprehension using the teach-back method (CDC, 2023). Community-based health education programs, health coaching, and digital health tools can also be used to support health literacy and empower individuals to take control of their health. By improving health literacy, individuals and communities can become more knowledgeable and engaged in making informed decisions about their health and well-being.

### Healthy Cities

**Healthy Cities** is a strategy that focuses on creating environments that support the health and well-being of their residents. This includes designing cities and communities that promote physical activity, access to healthy food, clean air and water, and safe and affordable housing (WHO, 2023a). Healthy Cities recognizes that health is influenced by a range of factors, including the built environment, SDOH, and individual behavior. It prioritizes creating safe and accessible green spaces, promoting physical activity, and encouraging healthy eating habits (WHO, 2023a).

The Healthy Cities project was launched by the WHO in 1978. The goal was to promote public health and well-being as a result of the action of local government. The plan was to recognize the many determinants of health and to work collaboratively across all sectors to prioritize public health so that local governments work to improve public health. There are over seventy flagship cities that have expanded to form a national and global network. The WHO has created a resource for any city leader to utilize to improve health determinants specific to their locale or to work toward joining the Healthy City Network. By prioritizing health in their development and policies, healthy cities have the potential to improve the health and well-being of the residents and create a more sustainable future (WHO, 2023a). For example, in a healthy city, walking and biking are encouraged through the availability of pedestrian and cycling infrastructure. Residents have access to nutritious and affordable food options, and the city promotes local food production and farmers' markets. The design of buildings and public spaces is inclusive and encourages social interaction, reducing isolation and promoting mental health.

### Levels of Prevention

Different stages or approaches that can be taken to prevent the occurrence of a health condition or disease are referred to as **levels of prevention**. There are three levels of prevention: primary, secondary, and tertiary ([Table 4.6](#)). Understanding the different levels of prevention is essential to implementing effective and efficient healthcare strategies that can prevent the occurrence or progression of health conditions.

Level of Prevention	Intent	Example
Primary prevention	First level of prevention that aims to prevent the onset of a disease or health condition before it occurs	Encourage exercise and healthy eating to prevent obesity
Secondary prevention	Second level of prevention that aims to detect and treat a disease or health condition in its early stages to prevent complications and progression	Check body mass index at wellness checkups to identify any changes to weight and potential for obesity
Tertiary prevention	Third level of prevention that aims to manage and treat the complications of a disease or health condition to prevent disability or death	Help patient who is obese to lose weight to prevent more severe consequences

**TABLE 4.6** Levels of Prevention

### Primary Prevention

The first level of prevention is **primary prevention**. It aims to prevent the onset of a disease or health condition before it occurs (Kisling & Das, 2023). This approach involves promoting healthy behaviors and lifestyles as well as implementing vaccination programs (Baumann & Ylinen, 2020). Examples of primary prevention include regular exercise, healthy diet, avoiding tobacco and alcohol use, and practicing safe sex to prevent sexually transmitted infections. Vaccinations are also a vital part of primary prevention, such as immunizations for infectious diseases like measles, mumps, rubella, hepatitis B, and human papillomavirus. Additionally, community-based programs that promote healthy behaviors and lifestyles, such as antismoking campaigns or nutrition education programs, are also effective primary prevention strategies. By implementing primary prevention strategies, individuals can take proactive steps to reduce their risk of developing health conditions and improve their overall health and well-being.

### Secondary Prevention

The second level of prevention is **secondary prevention**. It aims to detect and treat a disease or health condition in its early stages to prevent complications and progression (Kisling & Das, 2023). This approach involves implementing screening programs and early detection initiatives to identify the disease before the symptoms appear (Baumann & Ylinen, 2020). Examples of secondary prevention include regular health checkups, cancer screenings, mammograms, colonoscopies, and Pap smears. These screenings can detect the early signs of diseases like diabetes, heart disease, and cancer. Early detection allows for prompt treatment, which can prevent the progression of the disease, reduce the severity of symptoms, and improve outcomes. By implementing secondary prevention strategies, individuals can detect diseases early, which improves their chances of successful treatment and recovery.

### Tertiary Prevention

The third level of prevention is **tertiary prevention**. It aims to manage and treat the complications of a disease or health condition to prevent disability or death (Kisling & Das, 2023). This approach involves implementing rehabilitation and chronic disease management programs to help individuals manage and cope with the consequences of the disease (Baumann & Ylinen, 2020). Examples of tertiary prevention include physical therapy, occupational therapy, and speech therapy for individuals who have experienced a stroke or a traumatic injury. Chronic disease management programs, such as diabetes management programs and cardiac rehabilitation programs, can help individuals manage the complications of their chronic condition and prevent further health issues. By implementing tertiary prevention strategies, individuals can improve their quality of life (QoL), manage their symptoms, and prevent complications associated with their disease.

## Factors Influencing Risk of Illness

The risk of illness can be influenced by a range of factors, including inherent factors, lifestyle factors, and environmental factors (WHO, 2023b). Factors a patient cannot change or modify are **inherent factors**, also called nonmodifiable factors, such as age, gender, race, genetics, and family history. Factors the patient can change are lifestyle factors, also called modifiable factors, such as tobacco use, alcohol consumption, diet, and activity level.

These can affect an individual's risk of developing certain health conditions. Exposure to pollution, toxins, and infectious agents in the air, water, or surrounding environment are some of the **environmental factors** that can also increase the risk of illness (Rojas-Rueda et al., 2021). Understanding the various factors that influence the risk of illness can help individuals and healthcare professionals develop effective prevention and management strategies to reduce the risk of illness and promote optimal health and well-being (Table 4.7).

Factor	Description	Examples
Inherent factors	Individual nonmodifiable characteristics that can influence the risk of illness	Genetics, age, and sex
Lifestyle factors	Individual modifiable behaviors and habits that can influence the risk of illness	Tobacco and alcohol use, diet, physical activity, and stress level
Environmental factors	Physical, chemical, biological, and social factors that affect the quality of air, water, food, and the general environment, which can eventually influence the risk of illness	Pollutants, sanitation, climate change, and access to health care

**TABLE 4.7** Factors Influencing Risk of Illness

### Inherent Factors

Inherent factors are the individual nonmodifiable characteristics that can influence the risk of illness, which include genetics, age, and sex. Genetic factors can make an individual more susceptible to certain health conditions, such as cancer, heart disease, and diabetes (Johansson et al., 2021). Age is also an important inherent factor, as the risk of many diseases increases with age due to physiological changes and accumulated exposure to risk factors. For example, the risk of dementia, osteoporosis, and many types of cancer increases with age. Additionally, sex can also influence the risk of illness as females and males have different biological characteristics that make them more susceptible to certain conditions. For example, females are at a higher risk of developing breast cancer and osteoporosis, while males are more likely to develop prostate cancer. Understanding inherent factors that influence the risk of illness can help individuals and healthcare professionals develop personalized prevention and management strategies that address the unique risk factors of each individual.

### Lifestyle Factors

Lifestyle factors, which include tobacco and alcohol use, diet, physical activity, and stress level, are individual modifiable behaviors and habits that can influence the risk of illness (Zaman et al., 2019).

## CULTURAL CONTEXT

### Cultural Considerations About Health

While assessing and discussing lifestyle factors with a patient, it is important for the nurse to consider cultural norms and expectations. For example, some cultures place great value on large meals to celebrate a lifestyle milestone and/or mourn a loss. While the food options at these events may be high in sodium, fat, and/or carbohydrates, thus making them not ideal for a patient struggling with obesity or diabetes mellitus type II, it is important to consider the social and familial factors in the decision to engage in these meals. The nurse should consider mental and emotional health and work with the patient to make a plan for engaging with and enjoying cultural traditions while keeping healthy choices in mind.

Tobacco use is a major lifestyle factor that increases the risk of respiratory illnesses, heart disease, and cancer. Alcohol consumption can also increase the risk of liver disease, cancer, and mental health disorders. Diet that is high in saturated fats, sugar, and salt can increase the risk of obesity, type 2 diabetes, and heart disease. Physical inactivity can increase the risk of obesity, heart disease, and stroke. Chronic stress can also affect the immune system and increase the risk of mental health disorders such as anxiety and depression. Adopting healthy lifestyle habits, such as regular exercise, a balanced diet, avoiding tobacco and excessive alcohol consumption, and

managing stress, can help individuals reduce their risk of illness and promote optimal health and well-being (Zaman et al., 2019).

## PATIENT CONVERSATIONS

---

### Discussing Lifestyle Changes to Improve Health

**Scenario:** This is a conversation between Nurse Luis DeSilva and Mr. Travis Butler, a 44-year-old male who was born and raised in the South. He has obesity and has high cholesterol and high blood pressure. Read what happens when Nurse Luis discusses lifestyle changes with Mr. Butler.

**Nurse:** Mr. Butler, the last time you were here, we talked about the changes you needed to make to improve your health.

**Patient:** Luis, I know we did, but I don't know if I can do it. I was born in Texas and raised in Louisiana and Mississippi. Frying food is a part of who I am. I honestly don't know if I can give that up.

**Nurse:** I understand that fried food is a part of your Southern culture. I do. My culture is Mexican, and we fry a lot of foods too. I get it. But when I became a nurse and learned about health and nutrition, I started trying ways to improve my traditional foods.

**Patient:** What do you mean? Like what?

**Nurse:** Well, for one thing, I use an air fryer now. So, I can still get the crispy coating on my food, but I don't have to use all that oil.

**Patient:** An air fryer? I see them on TV sometimes. I've never tried it though. I always wonder if the food is actually crispy or if it's fake for TV.

**Nurse:** It actually is. So, this is how I recommend you do this. Make gradual changes to your diet and exercise. Take small steps like trying your regular recipes in the air fryer instead of deep frying them. Do that first. Then we can try cutting back on your salt and increasing your fresh seasoning or even low sodium sauces and marinades. The key is to make small changes that will slowly improve your health without you having to abandon your traditional meals.

**Patient:** Ahhh, I see what you mean. I get it now. I don't have to eat rabbit food. You know what, I think I'll ask my daughter to lend me her air fryer this weekend. It'll be cheaper without having to buy all that oil.

---

### Environmental Factors

Environmental factors can significantly impact the risk of illness in individuals and populations. These factors can include physical, chemical, biological, and social factors that affect the quality of air, water, food, and the general environment (WHO, 2023b). Exposure to pollutants, such as particulate matter, formaldehyde, lead, and other toxic chemicals, can lead to respiratory problems, cancer, and other health problems. Poor sanitation, lack of access to clean water, and inadequate waste disposal can also increase the risk of infectious diseases. Climate change can worsen air quality, increase the frequency and intensity of extreme weather events, and lead to the spread of vector-borne diseases (WHO, 2023b). SDOH, such as poverty, education, and access to health care, can also influence the risk of illness. Understanding and addressing these environmental factors is critical in preventing and controlling illness and promoting public health.

### Impact of Illness on Health Promotion

The impact of illness on health promotion can be significant, as an individual's ability to engage in healthy behaviors may be hindered by their health condition. When someone is dealing with an illness, they may experience physical limitations, pain, fatigue, and emotional distress, which can make it difficult to adopt healthy habits such as exercise, eating a balanced diet, and managing stress. In addition, some medical treatments may also have side effects, such as dizziness, nausea, and vomiting, that can further impact an individual's ability to engage in healthy behaviors. It is important for healthcare providers to take these factors into consideration and work with patients to create realistic and achievable health goals that take their illness and limitations into account. By working together to develop a personalized health plan, patients can still engage in health promotion activities that are appropriate

for their condition and improve their overall well-being.

### Emotions and Behavior

Illness can have a significant impact on a person's emotions and behaviors (Levenson, 2019). Physical symptoms and limitations can lead to frustration, anxiety, and depression. Pain, fatigue, and discomfort can also make it difficult for individuals to engage in daily activities, leading to feelings of helplessness or hopelessness. These emotional states can further impact a person's behavior, potentially leading to social withdrawal, decreased motivation, and changes in eating or sleeping habits. Additionally, illness can disrupt daily routines and responsibilities, leading to feelings of guilt or inadequacy (Levenson, 2019). It is important for healthcare providers to recognize and address the emotional and behavioral impact of illness on their patients. This may include providing emotional support, counseling, or referring patients to mental health specialists who can assist with the psychological and behavioral effects of illness.

### Body Image and Self-Concept

Illness can have a significant impact on body image and self-concept. Physical changes resulting from illness or its treatment, such as hair loss, weight changes, and scars, can lead to negative body image and self-esteem issues (Cleveland Clinic, 2020). In addition, illness can disrupt daily routines and activities, which can affect a person's sense of identity and purpose. This can be particularly challenging for those who have previously identified with their physical abilities or appearance. Illness can also lead to social isolation and decreased social support, which can further exacerbate feelings of low self-esteem and poor body image. Examples of how a change in body image can lead to social isolation can be found in the cases of amputees, burn patients, and patients with a colostomy bag. These patients have undergone medical procedures to save and improve their lives. When the body change is visible, as in the case of a burn victim or an amputee, the patient might retreat from social gatherings to avoid being gawked at or having to explain "what happened to me." Therefore, healthcare providers should be aware of the potential impact of illness on body image and self-concept and provide support and resources to help patients cope and adjust to changes in their physical and emotional well-being.

### Impact on the Family

The health of one family member can have a significant impact on the rest of the family. For example, if a family member is dealing with a chronic illness, it can be emotionally and physically taxing on everyone involved. Caregiving responsibilities can fall on other family members, which can add stress and strain to their lives. Additionally, if the ill family member requires frequent medical appointments or hospital stays, it can disrupt daily routines and create financial burdens. Furthermore, if the illness is genetic, other family members may be at a higher risk of developing the same condition, which can create anxiety and uncertainty. Overall, the health of one family member can have a ripple effect on the entire family unit.

## 4.4 Community-Based Health Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the nurse's role in community-based health care
- Identify different competencies used by the nurse in community-based health care
- Recognize different at-risk populations within community-based health care

The nurse's role in community-based health care involves being an educator, caregiver, change agent, collaborator, counselor, and patient advocate. To promote health, prevent disease, and manage chronic conditions, nurses work in collaboration with other healthcare professionals and community members to provide care to individuals, families, and communities in a variety of settings, including clinics, schools, and homes. Some of the key competencies used by nurses in community-based health care include promoting healthy lifestyles, preventing disease and health problems, educating the community, and evaluating the community. Nurses must have strong skills to effectively engage with diverse populations and communicate health information in a way that is easy to understand. There are several at-risk populations within community-based health care, including patients with disabilities, pediatric patients, older adults, individuals from underrepresented groups, people who are under- or uninsured, and patients with low socioeconomic status. Nurses play a critical role in addressing the unique health needs of these populations, such as providing access to healthcare services, education on self-management of chronic conditions, and support for social determinants of health (SDOH). Nurses also work to address health

disparities within these populations and promote health equity.

### Nurse's Role in Community-Based Health Care

Nurses play a vital role in community-based health care. They provide a wide range of services to individuals and families in the communities as the first point of contact for patients. Nurses in community-based healthcare settings educate individuals and communities on healthy behaviors, provide disease prevention and screening services, and connect patients with appropriate resources and services. They also work closely with other healthcare professionals to coordinate care and ensure patients receive the support they need to achieve optimal health outcomes. Overall, nurses in community-based healthcare settings are critical members of the healthcare team, working tirelessly to improve the health and well-being of individuals and communities.

Community-based healthcare settings may include outpatient clinics, mobile clinics, home health, and healthcare centers. They can be located in a free-standing building, in a multipurpose room, or even in the basement of a building. The National Association of Community Health Centers provides information on how a community clinic can provide primary health care to patient populations who might otherwise have limited access to care. These patients may not have insurance, may not be able to afford the service, or may have barriers because of distance and language.

#### Types of Nursing Roles

Nursing roles can be diverse and multifaceted. Nurses serve as educators, teaching patients and families about disease prevention, medication management, and healthy lifestyle choices. Caregiving is also a fundamental nursing role, involving providing direct patient care, monitoring vital signs, administering medications, and supporting patients and families emotionally. As change agents, nurses are responsible for identifying areas of improvement in patient care and developing and implementing strategies to improve patient outcomes (Ten Ham-Baloyi, 2022). Collaboration is also essential for nurses, as they often work as part of a team with physicians, other healthcare professionals, and community organizations to ensure that patients receive coordinated and comprehensive care. Nurses serve as counselors, providing emotional support and guidance to patients and families facing health challenges. Finally, nurses act as patient advocates, ensuring that patients' needs and preferences are prioritized, and advocating for their rights to receive appropriate care. All the nursing roles are interconnected and critical to ensuring that patients receive the best possible care and that their health needs are met holistically. For example, nursing as a counselor also involves providing education and resources to patients and families (educator) to help them better understand their health conditions and make informed decisions about their care. Nurses as counselors also work with other healthcare professionals (collaborator), such as social workers and psychologists, to provide comprehensive support to patients and families ([Table 4.8](#)).

Role	Description	Example
Educator	Educating patients and their families about disease prevention, treatment options, medication management, and healthy lifestyle choices; providing education to their colleagues, sharing their expertise and knowledge to improve the quality of patient care; providing health education to schools, churches, and community organizations	A nurse leading a health education workshop about healthy lifestyles for patients
Caregiver	Providing direct patient care, monitoring patients' vital signs, administering medications, and performing various medical procedures; providing emotional support and comfort to patients and their families	A nurse providing the postsurgical care for a patient who has just had a gastrectomy

**TABLE 4.8** Types of Nursing Roles

Role	Description	Example
Change agent	Identifying areas for improvement in patient care, developing strategies and implementing actions to bring positive change	A nurse leading a quality improvement project about preventing falls
Collaborator	Working as part of a team with other healthcare professionals to provide coordinated and comprehensive care to patients	A nurse working with the physician to implement a care plan for a patient with multiple organ failure
Counselor	Providing emotional support and guidance to patients and their families who are experiencing health challenges	A nurse providing diabetic foot care consultant service to a patient with diabetes
Patient advocate	Ensuring that patients' needs and preferences are prioritized and that they receive appropriate care	A nurse suggesting that the physician should talk to a patient who has some questions about his treatment

**TABLE 4.8** Types of Nursing Roles

### Educator

One of the key nursing roles is that of an educator, which refers to their critical role in educating patients and their families about disease prevention, treatment options, medication management, and healthy lifestyle choices. This education helps patients better understand their health conditions and empowers them to make informed decisions about their care (National League for Nursing, 2022). Nurses also provide education to their colleagues, sharing their expertise and knowledge to improve the quality of patient care. Additionally, nurses may serve as educators in community settings, providing health education to schools, churches, and community organizations. Nursing as an educator is essential to ensure that patients and their families have the information needed to manage their health and make informed decisions about their care.

### Caregiver

The nursing role as caregiver is fundamental to patient care, where nurses provide direct patient care, monitoring patients' vital signs, administering medications, and performing various medical procedures. Caregiving also involves providing emotional support and comfort to patients and their families. Nurses spend a significant amount of time with their patients, developing a rapport and building trust. They play a crucial role in assessing patients' needs and ensuring that they receive individualized care that meets their physical, emotional, and spiritual needs. In addition to caring for their patients, nurses work to prevent complications and promote healing. They monitor patients' progress and collaborate with other healthcare professionals to develop and implement treatment plans. Nursing as a caregiver is essential to provide high-quality patient care and promote positive health outcomes.

### Change Agent

The nursing role as **change agent** involves identifying areas for improvement in patient care, developing strategies and implementing actions to bring positive change. Nurses are often at the forefront of healthcare delivery and have a unique perspective on the challenges and opportunities for improvement in the healthcare system (Swanson et al., 2020). They play a critical role in implementing evidence-based practice and innovative solutions to improve patient outcomes (Ten Ham-Baloyi, 2022). As change agents, nurses collaborate with other healthcare professionals,

patients, and families to identify opportunities for improvement, develop goals and objectives, implement actions, and evaluate interventions (Ten Ham-Baloyi, 2022). They are also responsible for advocating for policy changes that promote high-quality patient care and patient safety. Nursing as a change agent is essential to improving patient outcomes and transforming the healthcare system to meet the evolving needs of patients and families.

### **Collaborator**

The nursing role as a **collaborator** involves working as part of a team with other healthcare professionals to provide coordinated and comprehensive care to patients (Swanson et al., 2020). Nurses collaborate with physicians, social workers, physical therapists, and other healthcare professionals to develop and implement patient care plans (Swanson et al., 2020). They work together to ensure that patients receive the most appropriate and effective treatments and care that is delivered in a timely and efficient manner (Ten Ham-Baloyi, 2022). Collaboration also involves sharing knowledge and expertise, working together to identify areas for improvement, developing strategies and implementing actions to improve patient outcomes (Ten Ham-Baloyi, 2022). Nurses as collaborators also work with community organizations and other stakeholders to address the SDOH and promote health equity (Swanson et al., 2020). For example, nurses may work as collaborators to identify grants used to provide transportation to health services. To achieve this, nurses may partner with city governments, and public, private, and religious organizations to fund back-to-school initiatives (e.g., dental and vision clinics). They may collaborate with local branches of organizations like Mothers Against Drunk Driving, Alcoholics Anonymous, or the Department of Housing and Urban Development to raise funding or create community outreach programs. Overall, nursing as a collaboration is essential to providing high-quality patient care and promoting positive health outcomes for individuals and communities.

### **Counselor**

The nursing role as a **counselor** involves providing emotional support and guidance to patients and their families who are experiencing health challenges. Nurses serve as trusted advisors and advocates, providing a listening ear, offering practical advice, and helping patients and families cope with the stress and anxiety that can accompany illness and treatment (Swanson et al., 2020). Overall, nursing as a counselor is essential to promoting patients' emotional well-being and supporting their overall health and recovery.

### **Patient Advocate**

The nursing role as a **patient advocate** involves ensuring that patients' needs and preferences are prioritized and that they receive appropriate care. Nurses serve as the primary liaison between patients and the healthcare system, advocating for patients' rights to receive high-quality care that meets their individual needs (Abbasinia et al., 2020). Patient advocacy involves supporting patients in decision-making, providing information and resources, and helping patients and families navigate complex healthcare systems (Abbasinia et al., 2020). Nurses as patient advocates also work to identify and address barriers to care, such as financial, cultural, or linguistic barriers (Nsiah et al., 2019). They work collaboratively with other healthcare professionals and community organizations to promote health equity and ensure that all patients receive the care they need to achieve optimal health outcomes (Nsiah et al., 2019). Overall, nursing as a patient advocate is essential to promoting PCC and ensuring that patients' voices are heard and that their needs are met.

## **LINK TO LEARNING**

Review [the story of Florence Nightingale \(https://Openstax.org/r/77flnighingale\)](https://Openstax.org/r/77flnighingale) who is a role model for nurses today. In her life, she worked as an educator, caregiver, change agent, collaborator, counselor, and patient advocate.

## **Competencies Utilized in Community-Based Health Care**

Nurses who work in diverse community-based healthcare settings must possess a unique set of competencies to effectively care for patients. These competencies include the competencies for promoting healthy lifestyles, preventing diseases and health problems, educating the community, and evaluating the community. Nurses who possess these competencies are essential to providing high-quality care in community-based healthcare settings.

## LINK TO LEARNING

---

This article describes [critical thinking skills \(https://Openstax.org/r/77critthink\)](https://Openstax.org/r/77critthink) that are necessary for community-based nursing.

---

### Promoting Healthy Lifestyles

Nurses play a vital role in promoting healthy lifestyles and preventing disease. To effectively promote healthy lifestyles, nurses must possess a range of competencies, including knowledge of health promotion and disease prevention, communication skills, assessment skills, and counseling skills. Nurses must be knowledgeable about healthy lifestyle practices, such as proper nutrition, exercise, and stress management, and be able to communicate this knowledge effectively to patients and communities (Kris-Etherton et al., 2021). Assessment skills allow nurses to identify patients' health needs and develop individualized plans of care that promote healthy behaviors (Kris-Etherton et al., 2021). Counseling skills enable nurses to effectively motivate and support patients to make positive health choices and change unhealthy behaviors. Nurses must also possess skills in behavior change theories and motivational interviewing techniques to effectively support patients in making lasting behavior changes. Overall, nurses who possess competencies in promoting healthy lifestyles are essential to improving the overall health and wellness of individuals and communities.

### Preventing Disease and Health Problems

Nurses play a crucial role in preventing disease and health problems. To effectively prevent disease, nurses must possess competencies in health promotion and disease prevention, assessment, communication, and education (Frenn & Whitehead, 2021). Nurses must have a strong understanding of the risk factors for various diseases and the strategies to reduce those risks. They must also be able to assess patients' needs and develop tailored plans to prevent or manage diseases (Frenn & Whitehead, 2021). Communication and education are essential competencies for nurses to teach patients about healthy lifestyles, provide information on screening tests and vaccinations, and explain the importance of medication adherence (Greiner & Knebel, 2003). Nurses must also have knowledge of infection control and be able to identify and respond to outbreaks or other public health emergencies.

### Educating the Community

Nurses play a vital role in educating the community on a range of health-related topics. To effectively educate the community, nurses must possess communication, cultural, and community outreach competencies. Nurses must be able to communicate health information in a clear and understandable manner and use appropriate teaching methods to reach diverse audiences. The ability to respect and understand one's own beliefs and values as well as how these values and beliefs may differ between cultures is cultural competence. This is essential in health care, as nurses must understand the unique cultural beliefs and values of the community to effectively communicate health information to best provide care and educate accordingly (Nair & Adetayo, 2019). Community outreach is another essential competency, as nurses must be able to establish and maintain relationships with community organizations, government agencies, and other healthcare providers to effectively reach and educate the community. Overall, health education competencies or skills enable nurses to develop and implement community health programs that promote healthy lifestyles and disease prevention. Nurses who possess competencies in community health education are essential to improving the overall health and well-being of communities.

### Evaluating the Community

Nurses play a crucial role in evaluating the health status and needs of communities. To effectively evaluate communities, nurses must possess competencies in data collection, analysis, assessment, and program evaluation. Nurses must be able to collect and analyze data on the health status and needs of the community to identify health disparities and areas for improvement. Assessment skills allow nurses to identify the specific health needs of the community, and program evaluation skills enable nurses to assess the effectiveness of community health programs and interventions. Nurses must also possess knowledge of health policy and be able to advocate for policies that address the health needs of the community. Effective collaboration and communication skills are also essential, as nurses must work with community members, healthcare providers, and other stakeholders to develop, implement, and evaluate community health programs. Overall, nurses who possess competencies in community health assessment and program evaluation are essential to improving the health and well-being of communities.

## At-Risk Populations Within Community-Based Health Care

Nurses play a critical role in caring for at-risk populations within community-based healthcare. An at-risk population includes individuals who face barriers to accessing healthcare services, have limited access to health care, or are marginalized. These populations include patients with disabilities, pediatric patients, older adults, individuals from underrepresented groups, people who are under- or uninsured, individuals with low incomes, immigrants, people experiencing housing insecurity, sexual and gender minority groups, and those with mental health or substance use disorders. Nurses must be able to identify and address SDOH, such as poverty and housing instability, which contribute to poor health outcomes among at-risk populations. Overall, nurses who possess competencies in caring for at-risk populations are essential to improving the health and well-being of marginalized communities.

### PATIENT CONVERSATIONS

---

#### Identification of Patient Needs

**Scenario:** Nurse Barbara Rosencrantz works at a homeless shelter and has a patient named Delroy Barnes. Mr. Barnes is 29-years-old and has recently immigrated from Jamaica and is staying with his older brother. He is Rastafarian and wears a cloth wrap over his hair.

**Nurse:** Hello, Mr. Barnes. How are you?

**Patient:** Hello, Nurse. Please call me Delroy.

**Nurse:** Okay, Delroy. I was told that you wanted to speak to me. Are you looking for a bed for the night?

**Patient:** No, ma'am. The pastor at my sisters' church sent me here.

**Nurse:** Okay (nodding gently).

**Patient:** I'm not homeless, but I need information about work and other things.

**Nurse:** I see. I can definitely help you with that, but I need more information about exactly what your needs are.

**Patient:** Well, it's like this. I want to work, but every time I look for work, I have to do some paperwork. And I can't do the paperwork.

**Nurse:** I see. Delroy, in order to help you, I need to ask you some questions. I'm not trying to be intrusive, but I need some detailed information about you. Are you okay with that?

**Patient:** Go ahead, ma'am.

**Nurse:** Can you read and write, Delroy?

**Patient:** Oh yes, I can read and write. That's not the problem (laughing and nodding). The problem is that it's a lot of paperwork with fine print. Back home when I looked for work, I didn't have to do all this paperwork. Now I have to fill out these packets (raises his hands to show two packets of paper), and I can't read them.

**Nurse:** But Delroy, you just told me that you can read. Can you try to read one page for me?

**Patient:** That's the problem. I can read, but I can't read these papers because I can't see the words. It's too small, and my glasses don't work on these.

**Nurse:** Oh, I see. You need an eye exam from our eye clinic. So, Delroy, at this shelter we have a vision clinic every Tuesday and a dental clinic on Wednesdays. The service is free, and we provide glasses too.

**Patient:** Okay, I need to come on Tuesdays and Wednesdays then. Because I need glasses, and I need my teeth looked at. Can you tell me what else you have here? I don't have insurance, and I don't want to be a problem to my brother, you know.

**Nurse:** Definitely. I understand. So let me tell you about our schedule. We are a homeless shelter at night, but during the day we do the vision and dental clinics. We also do regular doctor visits like checkups. Dr. Martin will prescribe medications too if needed. Most of the medications are free or at a reduced price because the city and the

department of health help support this program financially. We have job fairs twice a month to support employment opportunities.

**Patient:** Thank you so much, Ms. Barbara. I will come back tomorrow for the eye clinic then. Thank you!

---

### Patients With Disabilities

Nurses play an important role in caring for patients with disabilities, ensuring that they receive the highest quality care possible. According to the Americans with Disabilities Act (ADA), an individual with a disability is defined as “a person who has a physical or mental impairment that substantially limits one or more major life activities, a person who has a history or record of such an impairment, or a person who is perceived by others as having such an impairment” (ADA, 2020, para. 3). Caring for patients with disabilities requires nurses to possess competencies in PCC (Bezyak et al., 2020). Patient-centered care involves recognizing and respecting the unique needs and preferences of each patient and ensuring that their care is tailored to those needs. Nurses must be knowledgeable about the various types of disabilities and their impact on a patient’s physical and mental health, as well as any accommodation that may be needed to provide optimal care (Bezyak et al., 2020). Some disabilities are invisible, meaning they are not immediately apparent or visible. Nurses must be aware of such disabilities and create an environment where patients can share about these disabilities. Nurses must respect visible and invisible disabilities and should work to support these patients in their healthcare and lifestyle needs. Nurses must also be able to educate patients with disabilities and their families on self-care management and promote the patient’s independence and autonomy. Overall, nurses who possess competencies in caring for patients with disabilities are essential to ensuring that patients receive the highest quality care possible and achieve the best possible health outcomes.

## PATIENT CONVERSATIONS

---

### Discharging a Patient With a Disability

**Scenario:** Mr. Smith, a 38-year-old, has just had an amputation after a car accident. He is going to be discharged later today. The morning shift nurse walks into his room and begins their conversation.

**Nurse:** Good morning, Mr. Smith. How are you feeling today?

**Patient:** Hi, I’m feeling okay. I’m just a bit frustrated with my amputated leg.

**Nurse:** I understand that it can be frustrating at times. As your nurse, I want to make sure that I’m supporting you in the best way possible. How can I assist you today?

**Patient:** Well, since I am going to discharge today, I have some concerns that I want to discuss with you. I have been having some trouble with my mobility since the surgery, and I’m not sure what I can do to improve it. I feel like I’m not getting the same level of care as someone without a disability.

**Nurse:** I hear your concerns, and you’re right that people with disabilities can face unique challenges. However, as your nurse, I’m here to make sure that you receive the best possible care regardless of your disability. I can work with you to come up with a care plan that takes into account your specific needs and limitations.

**Patient:** That sounds good. What can we do to start?

**Nurse:** Well, first, let’s talk about your mobility concerns. Are there any particular activities that you’re having trouble with?

**Patient:** Yeah, I’m having trouble with walking longer distances, and I’m worried that I won’t be able to get the exercise I need to stay healthy.

**Nurse:** I understand. One thing we can do is to work with a physical therapist to develop an exercise plan that is tailored to your specific needs and abilities. We can also explore assistive devices like wheelchairs to help you move around more easily.

**Patient:** That sounds like it could help. But what about when I come to the clinic for appointments? I feel like I

struggle to get around the clinic, and it can be challenging for me to get into the exam room.

**Nurse:** I can help with that too. We can make sure that your appointments are scheduled in an accessible exam room that is easy for you to get into. We can also work with you to make any necessary accommodations, such as providing a wheelchair or a helper.

**Patient:** Thank you. That would be really helpful. I appreciate that you're taking my disability into consideration.

**Nurse:** Of course. It's my job to make sure that you receive the best possible care. If you have any other concerns or questions, please don't hesitate to ask. I'm here to support you.

---

### Pediatric Patients

Nurses play a vital role in caring for pediatric patients, from newborns to adolescents. Caring for pediatric patients requires nurses to possess competencies in PCC, family-centered care, communication, and developmental assessment. As noted earlier in this chapter, patient-centered care involves recognizing and respecting the unique needs and preferences of each pediatric patient. This remains true in the pediatric population, where developmental stage and current needs underscore each decision made for the patient. Furthermore, in the pediatric population, family-centered care is most effective to meet the needs of the patient and family. This **family-centered care** involves recognizing and respecting the role of the family in the pediatric patient's care, including their preferences and priorities for their health decisions (Cincinnati Children's Hospital Medical Center, 2023). Effective communication skills are essential for nurses to communicate with pediatric patients and their families effectively, especially when providing education or discussing complex medical information. Developmental assessment skills allow nurses to evaluate and monitor the physical, cognitive, and emotional development of pediatric patients and intervene appropriately when necessary.

## LIFE-STAGE CONTEXT

---

### Considering Developmental Age in Pediatric Patients

While considering developmental level for all patients is important, it is foundational for success in pediatric nursing. Age often does not link directly to the developmental level of the patient, so the nurse must be able to assess each patient individually and cater care accordingly. For example, pain assessment will look different for each patient and may vary for the patient at different moments in time. While the numeric pain scale of 0 to 10 is generally approved for anyone over six years old, there are many patients over six years old who would benefit from an alternative pain assessment. Children who are nonverbal or are not able to understand the numeric system may utilize a visual scale system (such as the Wong-Baker FACES Pain Scale) instead. Additionally, the nurse can assess pain via vital signs and physiological changes in the patient.

---

Nurses must also be knowledgeable about pediatric illnesses and their management, including medication administration, pain management, and psychosocial support. Overall, nurses who possess competencies in caring for pediatric patients are essential to providing high-quality care and achieving positive health outcomes for children and their families.

### Older Adults

Nurses play a critical role in caring for older patients, who require specialized care to address the unique physical, cognitive, and social needs that come with aging (Kim & Oh, 2020). Caring for older patients requires nurses to possess competencies in geriatric assessment. Geriatric assessment skills allow nurses to evaluate and monitor the physical, cognitive, and social function of older patients and intervene appropriately when necessary, such as addressing fall risk or managing chronic diseases like dementia or diabetes. Nurses must be knowledgeable about age-related changes in health and medication metabolism, as well as common geriatric syndromes such as delirium and frailty. Nurses must also communicate effectively with older patients and their families, especially when providing education or discussing complex medical information (Kim & Oh, 2020). Overall, nurses who possess competencies in caring for older patients are essential to ensuring that older patients receive high-quality care and achieve the best possible health outcomes in their later years.

### Individuals From Underrepresented Groups

Nurses play a crucial role in caring for individuals from underrepresented groups, who may experience disparities in health outcomes due to SDOH, including racism, poverty, and inadequate access to health care. Nurses who work with individuals from underrepresented groups must engage with the community to understand the community's health needs and work collaboratively with other healthcare providers to promote health equity. They must provide patient education that is culturally appropriate and address any barriers to accessing care, such as language or transportation barriers (Joo & Liu, 2020). Nurses must also advocate for policies and programs that address health disparities and ensure access to high-quality care for all patients, regardless of their race or ethnicity (Joo & Liu, 2020). Overall, nurses who possess competencies in caring for individuals from underrepresented groups are essential to reducing health disparities and promoting health equity for all patients.

### Underinsured/Uninsured

Nurses play a critical role in caring for people who are under- or uninsured, who may lack access to adequate health care due to financial barriers. Caring for these groups requires nurses to possess competencies in PCC, resource management, and advocacy. Patient-centered care involves working with persons who are under- or uninsured to develop affordable care plans that meet their needs. Resource management skills are essential for nurses to help patients access resources, such as medication assistance programs, community health clinics, and financial assistance programs. Nurses must also advocate for policies and programs that address healthcare access and affordability for all patients, regardless of their insurance status. Nurses can refer patients to appropriate and cost-effective resources for their care, focusing on preventive care. They must work collaboratively with other healthcare providers, social workers, and community organizations to ensure that patients receive comprehensive care that addresses their physical, emotional, and social needs. Nurses must also provide patient education that is tailored to the patient's insurance status and address any barriers to accessing care (e.g., a transportation barrier). Overall, nurses who possess competencies in caring for patients who are under- or uninsured are essential to promoting access to high-quality care and improving health outcomes for at-risk patients.

### Socioeconomic Status

Nurses play a crucial role in caring for people with lower incomes, who may experience health disparities due to SDOH, such as poverty, lack of education, and inadequate access to health care. Nurses must consider the financial situation of people with lower incomes and help them access affordable resources, such as financial assistance programs, community health clinics, and social services, to promote health equity. They must work collaboratively with other healthcare providers, social workers, and community organizations to ensure that patients receive comprehensive care that addresses their needs. Nurses must also provide culturally appropriate patient education that is tailored to the patient's socioeconomic status. For example, nurses should never assume patients can safely afford prescribed medication or treatment tools. Instead, they should outline what will be needed, help assess any barriers for the patient to obtain or maintain access to these items, and work with the interdisciplinary team to develop solutions. Overall, nurses who possess competencies in caring for people with lower incomes are essential to promoting health equity and improving health outcomes for at-risk patients.

## 4.5 Community-Based Healthcare Initiatives

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the guidelines for implementation of community-based health initiatives
- Discuss the process for conducting a community health needs assessment
- Describe the nurse's role in education for community-based health care

Community-based health initiatives are important for improving the health and well-being of individuals and populations. Guidelines for implementation of such initiatives typically include a comprehensive community health needs assessment, stakeholder engagement, goal setting, and an action plan. Knowing the characteristics of community-based programs is an essential step before conducting the community-based health initiative. The elements of quality, respect, and empowerment related to the characteristics of community-based programs need to be considered to ensure the community-based health initiatives are effective and sustainable. Conducting a community health needs assessment is a crucial first step in identifying the health issues and priorities of the community and informing the development of relevant initiatives. Evidence-based tools, such as the Vulnerable

Populations Footprint (Center for Applied Research and Engagement Systems, University of Missouri Extension), can be used for the community health needs assessment. Nurses play a vital role in resource management, advocating for the implementation of evidence-based practices that address the identified health needs and educating the community about health care and promoting healthy behaviors. The steps for nurses planning education in the community-based health initiatives include prioritizing identified problems, setting goals and objectives, developing strategies, implementation, and evaluation. By working collaboratively with other healthcare professionals, community organizations, and local leaders, nurses can help to ensure the success of community-based health initiatives and contribute to the overall health of the community.

### Guidelines for Implementation of Community-Based Health Initiatives

The implementation of community-based health initiatives requires a well-thought-out plan that takes into consideration the unique needs and characteristics of the community. Guidelines for implementation of such initiatives typically include a comprehensive needs assessment, stakeholder engagement, goal setting, and an action plan. A community health needs assessment should involve the identification of health priorities, existing health resources, and gaps in the provision of health services. Stakeholder engagement is important in identifying potential collaborators, understanding community values and beliefs, and building trust. Goal setting should be based on the identified needs and should be specific, measurable, achievable, relevant, and time bound. An action plan should outline the steps needed to achieve the goals, including timelines, resource allocation, and monitoring and evaluation strategies. Ongoing community involvement and partnerships are key to the successful implementation of community-based health initiatives.

#### LINK TO LEARNING

This link provides [resources about planning strategies for accelerating health equity \(https://Openstax.org/r/77healthequity\)](https://Openstax.org/r/77healthequity) and information on different perspectives on the guidelines.

#### Characteristics of Community-Based Programs

Community-based programs are characterized by their focus on addressing the specific needs and challenges of a particular community. They are typically developed and implemented by local organizations or stakeholders who have a deep understanding of the community's culture, values, and resources. Community-based programs are characterized by several important elements, including quality, respect, and empowerment. By embodying these characteristics, community-based programs can create a culture of trust, engagement, and empowerment that leads to more effective and sustainable interventions ([Table 4.9](#)).

Characteristic	Description	Example
Quality	Providing evidence-based interventions and services that are effective, efficient, and responsive to the needs of the community	Use trained professionals who can deliver interventions with fidelity; use regular monitoring and evaluation to ensure that interventions are meeting intended outcomes
Respect	Acknowledging and valuing the perspectives, needs, and experiences of the community members who are being served	Create a culture of trust and engagement that values the contributions of community members
Empowerment	Giving community members a voice and agency in the program's decision-making processes	Involve community members in leadership roles, provide education and training opportunities, and create opportunities for community members to advocate for themselves and their needs

**TABLE 4.9** Characteristics of Community-Based Programs

### Quality

The term **quality** refers to the provision of evidence-based interventions and services that are effective, efficient, and responsive to the needs of the community. This involves ensuring that the program is staffed by trained professionals, that the interventions are based on best practices, and that there is a continuous cycle of monitoring and evaluation to ensure quality improvement. To achieve high-quality community-based programs, it is essential to prioritize evidence-based interventions that are grounded in best practices and have been demonstrated to be effective in similar contexts. This requires the use of trained professionals who can deliver interventions with fidelity, as well as regular monitoring and evaluation to ensure that interventions are meeting their intended outcomes. Quality can also be ensured using culturally appropriate interventions that are sensitive to the community's culture, values, and beliefs. Community involvement in program design and implementation is also key to ensuring quality, as it provides valuable feedback on the relevance and effectiveness of interventions. Ultimately, the quality of community-based programs is a function of ongoing collaboration, monitoring, and evaluation, as well as a commitment to providing effective, efficient, and culturally appropriate services to the community.

### Respect

An important aspect of community-based programs is **respect**, acknowledging and valuing the perspectives, needs, and experiences of the community members who are being served. This involves creating a culture of respect within the program, actively listening to feedback from community members, incorporating their input into program design and implementation, and involving them in leadership roles and decision-making processes. Respect is a fundamental principle of community-based programs. To ensure that community-based programs are respectful, it is essential to create a culture of trust and engagement that values the contributions of community members. Respect can also be demonstrated by ensuring that interventions are culturally appropriate and sensitive to the community's values and beliefs. By prioritizing respect, community-based programs can establish strong relationships with the community and create a safe and supportive environment that promotes positive health outcomes.

### Empowerment

Another key element of community-based programs is **empowerment**, giving community members a voice and agency in the program's decision-making processes. This includes involving community members in leadership roles, providing education and training opportunities, and creating opportunities for community members to advocate for themselves and their needs. Empowerment also involves creating a culture of trust and collaboration, where community members feel valued and supported in their efforts to improve their health and well-being. By prioritizing empowerment, community-based programs can promote a sense of ownership and investment in the program among community members, leading to more sustainable and effective interventions. Additionally, empowering community members can help to build individual and collective capacity within the community, allowing them to better address health disparities and other social determinants of health (SDOH).

## Community Health Needs Assessment

The **Community Health Needs Assessment (CHNA)** is a systematic process of identifying the health needs and priorities of a specific community (Figure 4.6). This process involves the collection and analysis of various data sources such as demographic data, health outcomes, and health behaviors (CDC, 2022).

**FIGURE 4.6** The CHNA process is a stepped approach that can help nurses identify the needs of a community and prioritize those needs to develop interventions. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The CHNA helps to identify health disparities and gaps in health services in the community. Community engagement is a critical component of the CHNA process, as it ensures that community members' perspectives and needs are incorporated into the assessment. This involvement can take many forms, including community forums, focus groups, and surveys. The results of the CHNA are then used to develop strategies and interventions to address the identified health needs and improve health outcomes in the community (Rayan-Gharra et al., 2022). The CHNA is an essential process for promoting community-based interventions that are tailored to the specific needs and characteristics of the community.

## LINK TO LEARNING

The Community Health Assessment and Group Evaluation (CHANGE) tool includes five steps: commitment, assessment, planning, implementation, and evaluation. More information about the [Community Health Assessment \(https://Openstax.org/r/77commhealth\)](https://Openstax.org/r/77commhealth) can be found on the CDC website.

### Evidence-Based Tools Used for Needs Assessment

There are several evidence-based tools used for CHNA, which can be tailored to the specific needs and characteristics of the community being served (Table 4.10). One such tool is the Community Assessment for Public Health Emergency Response (CASPER), which is designed to rapidly assess the health needs of a community following a disaster or emergency (CDC, 2020). The Mobilizing for Action through Planning and Partnerships (MAPP) framework is another evidence-based planning tool that involves a comprehensive and collaborative approach to CHNA. By using evidence-based tools for CHNA, stakeholders can gain more comprehensive understandings of the health needs and priorities of the community that can inform the development of tailored interventions and strategies to address these needs (Ravaghi et al., 2023).

Tool or Technique	Description
Community Health Assessment and Group Evaluation (CHANGE) tool	The <a href="https://Openstax.org/r/77changetool">CHANGE tool (https://Openstax.org/r/77changetool)</a> is a data-collection tool and planning resource to help make communities healthier.
Community Assessment for Public Health Emergency Response (CASPER)	The <a href="https://Openstax.org/r/77CASPER">Community Assessment for Public Health Emergency Response (CASPER) (https://Openstax.org/r/77CASPER)</a> is an epidemiological technique designed to provide public health leaders and emergency managers with household-based information about a community.

**TABLE 4.10** Community Health Assessment Tools

## LINK TO LEARNING

Information about the [Mobilizing for Action through Planning and Partnership \(MAPP\) tool \(https://Openstax.org/r/77mobforaction\)](https://Openstax.org/r/77mobforaction) and some other models to guide collaborative planning for communities (e.g., the Planned Approach to Community Health, the Community Health Improvement Process) can be found in the article “Models for Collaborative Planning in Communities.”

### Vulnerable Populations Footprint

The **Vulnerable Populations Footprint (VPF)** is a tool that can be used for CHNA, specifically to identify the most at-risk populations within a community. This tool uses data from the U.S. Census Bureau and other sources to assess factors that contribute to vulnerability, such as poverty, housing insecurity, limited English proficiency, and lack of transportation. The VPF provides a visual representation of vulnerability within a community by creating a map that highlights areas with high concentrations of at-risk populations. This tool can be used to target

interventions to the areas of greatest need and to ensure that at-risk populations receive equitable access to health services and resources. By using the VPF for CHNA, stakeholders can better understand the SDOH that impact at-risk populations and develop interventions that address the root causes of health disparities (Ravaghi et al., 2023).

## LINK TO LEARNING

---

The [Vulnerable Populations Footprint \(https://Openstax.org/r/77vulnerablepop\)](https://Openstax.org/r/77vulnerablepop) is a mapping and report tool identifying locations with overlaps in high concentrations of populations living in poverty and populations living without a high school diploma.

---

## Nurse's Role in Education for Community-Based Health Care

Nurses play a critical role in education for community-based health care. As frontline healthcare providers, nurses are uniquely positioned to educate and empower individuals, families, and communities to take an active role in their health and well-being. Nurses can provide education on a range of topics, including disease prevention, health promotion, medication management, and self-care. In community-based health care, nurses may work in a variety of settings, including clinics, schools, and community centers, and they may provide education through individual counseling, group sessions, or community outreach programs. Additionally, nurses can collaborate with other healthcare providers and community stakeholders to develop and implement educational programs that are tailored to the specific needs and characteristics of the community. By providing education and promoting health literacy, nurses can help to improve health outcomes, reduce health disparities, and promote community engagement and empowerment.

### Verification of Identified Problems

In community-based health care, nurses play a crucial role in verifying identified problems and developing solutions to address these issues (Mathieson et al., 2019). Nurses can use a range of assessment tools and techniques to identify health problems and risk factors within a community, such as community health needs assessments, health screenings, and environmental assessments. Once these problems have been identified, nurses can collaborate with other healthcare providers and community stakeholders to develop and implement evidence-based interventions that address the root causes of these issues (Mathieson et al., 2019). Nurses can also monitor the effectiveness of these interventions and adjust as needed to ensure that they are achieving their desired outcomes. Additionally, nurses can provide ongoing education and support to individuals and communities to help them maintain their health and prevent future health problems. By playing an active role in verifying identified problems and implementing solutions, nurses can help to improve health outcomes and promote community empowerment and resilience.

### Resource Management

Nurses play an important role in resource management for community-based health care. Resource management involves the allocation and optimization of resources, including personnel, equipment, and funding, to achieve the best possible health outcomes for individuals and communities. Nurses can play a key role in managing resources by ensuring that resources are allocated equitably, efficiently, and effectively to meet the needs of the community. They can also work with other healthcare providers and community stakeholders to identify and secure additional resources, such as grants or donations, to support community-based healthcare initiatives. Nurses can also use their expertise in clinical decision-making and evidence-based practice to make informed resource allocation decisions and ensure that resources are being used to support interventions and programs that have been shown to be effective in improving health outcomes. By playing an active role in resource management, nurses can help to ensure that limited resources are being used in the most effective and efficient manner to improve the health and well-being of individuals and communities.

### Steps of Planning Education

The planning of education for community-based health care involves several important steps. The first step is to identify the target audience, assess their educational needs and preferences, and prioritize identified problems (Cutilli, 2020). This can be done through community needs assessments, surveys, and focus groups. The next step is to set clear goals and objectives that are measurable and achievable. These objectives should be based on the

identified educational needs and should be specific, measurable, attainable, relevant, and time bound. Once learning objectives have been established, the next step is to develop appropriate educational strategies and resources that are tailored to the needs and characteristics of the target audience. This may include written materials, audiovisual resources, interactive workshops, and community outreach programs. After implementing the interventions, the final step is to evaluate the effectiveness of the educational program through feedback from participants, pre- and posttests, and other evaluation methods (Cutilli, 2020). By following these steps, nurses and other healthcare providers can develop and implement educational programs that are tailored to the specific needs of the community and that promote health literacy and community engagement ([Table 4.11](#)) (Cutilli, 2020).

Step	Description
1) Prioritizing identified problems	<ul style="list-style-type: none"> <li>Review identified community needs and/or problems to determine how to best help at this time.</li> <li>Prioritize problems, and choose a focus point.</li> </ul>
2) Setting goals and objectives	<ul style="list-style-type: none"> <li>Set goals by determining the ideal outcome for the intervention.</li> <li>Set objectives by identifying measurable actions to achieve the overall goal.</li> </ul>
3) Developing strategies	<ul style="list-style-type: none"> <li>Based on the community, select education strategies.</li> <li>Brainstorm multiple strategies, and select the best strategies for the current problem and population.</li> </ul>
4) Implementation	<ul style="list-style-type: none"> <li>Implement outlined strategies based on the designed plan.</li> </ul>
5) Evaluation	<ul style="list-style-type: none"> <li>Review the education process from start to finish. This includes each step of the planning and implementation process. During this step, goals and objectives will be measured for success.</li> <li>After reviewing, determine if the intervention was effective and/or how things may need to change moving forward.</li> </ul>

**TABLE 4.11** Steps for Nurses Planning Education in Community-Based Health Initiatives

### Prioritize Identified Problems

Prioritizing identified problems is a crucial step in the planning of education for community-based health care. Not all health problems identified through community needs assessments or other assessment tools can be addressed at once, and resources are often limited. Therefore, it is essential to prioritize the identified problems based on their severity, impact on the community, and feasibility of intervention, to make sure that limited resources are being used in the most effective and efficient manner. The prioritization process should involve input from community members, healthcare providers, and other stakeholders to ensure that the identified priorities are relevant and appropriate to the needs and characteristics of the community. Once priorities have been established, goals and objectives can be set up, and educational strategies and resources can be developed and implemented to address these issues.

### Set Goals and Objectives

Setting goals and objectives is a critical step in planning education for community-based health care. Goals provide a broad and overarching vision for what the educational program aims to achieve, while objectives are specific, measurable, attainable, relevant, and timely steps that will lead to the attainment of these goals ([Figure 4.7](#)) (Bailey, 2019). When setting goals and objectives, it is essential to consider the identified health needs and characteristics of the community as well as the resources available for education and intervention. Goals and objectives should be

relevant, attainable, and aligned with evidence-based practices to ensure that they are achievable and effective in improving health outcomes. The process of setting goals and objectives should involve input from stakeholders to ensure that they are relevant and appropriate to the needs and characteristics of the community. By setting clear and measurable goals and objectives, healthcare providers can develop and implement educational programs that are focused and effective in addressing the identified health needs of the community.

**FIGURE 4.7** The acronym SMART can be used for setting goals when planning education for community-based health care. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Develop Strategies

Developing strategies is a crucial step in planning education for community-based health care. Once the goals and objectives have been established, healthcare providers must identify and develop appropriate educational strategies that are tailored to the needs and characteristics of the target audience (National Collaborating Centre for Methods and Tools, 2023). This may include a range of strategies, such as workshops, community outreach programs, written materials, and audiovisual resources. When selecting strategies, it is essential to consider the health literacy, cultural and linguistic diversity, and other characteristics of the target audience to ensure that the strategies are effective in engaging and educating them. The strategies should also be evidence based, feasible, and aligned with the goals and objectives of the educational program, and they should involve input from stakeholders. Additionally, behavioral change theories and models, such as the Health Belief Model, the Transtheoretical Model/ Stages of Change, and the Theory of Planned Behavior, could be utilized to develop appropriate educational materials. By developing and implementing tailored strategies, healthcare providers can promote health literacy and community engagement, and improve health outcomes in the community.

## LIFE-STAGE CONTEXT

### Developing Strategies Based on Age for Community-Based Health Initiatives

When planning education for community-based health initiatives, nurses must consider age-related matters to ensure the effectiveness of their interventions. Age-related factors, such as developmental stages, cognitive abilities, and health literacy levels, can affect how individuals perceive and respond to health information. Nurses

must adapt their teaching strategies and materials to meet the needs of different age groups, from children to older adults. For example, when nurses plan a community-based health initiative for older adults, they should consider the changing functions and needs of older people. Using a larger font in visual materials, giving brief and concise instructions, and repeating key information can help older people better obtain, understand, and remember information. By prioritizing these age-related matters in their planning, nurses can ensure that their education efforts are relevant, accessible, and meaningful to the community they serve.

---

### Implementation

Implementation is a critical step in the planning of education for community-based health care. Implementation involves putting the plan into action, which may include scheduling and conducting workshops, developing and distributing written materials, conducting outreach programs, and delivering other educational resources (Cutilli, 2020). Healthcare providers must ensure that the educational program is implemented with fidelity to the strategies and objectives developed in the planning phase. This may involve monitoring and evaluating the implementation process to identify any barriers or challenges that may need to be addressed to ensure the program's success. The implementation process should involve stakeholders to ensure that the educational program is culturally appropriate and relevant to the needs of the community. By effectively implementing the educational program, healthcare providers can promote health literacy and community engagement and improve health outcomes in the community.

### Evaluation

Evaluation is a crucial step in the planning of education for community-based health care. After implementing the educational program, healthcare providers must evaluate its effectiveness to determine whether the program's goals and objectives have been achieved. Evaluation involves measuring and analyzing the outcomes of the program and assessing whether the strategies used were effective in achieving the desired outcomes (Cutilli, 2020). Healthcare providers should use quantitative and qualitative data to evaluate the program's impact on the community's health outcomes, health behaviors, and health literacy. The evaluation process should involve stakeholders to ensure that their input is included in the assessment. This feedback can help healthcare providers make any necessary adjustments to the educational program, improve its effectiveness, and promote sustainability. By evaluating the educational program, healthcare providers ensure that they are providing quality education and resources that address the community's health needs and lead to improved health outcomes.

## 4.6 Population Health

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the divisions of population health
- Recognize the goals of population health management
- Discuss the nurse's role in population health management

The health outcomes of a group of individuals including the distribution of those outcomes within the group is called **population health** (Silberberg et al., 2019). It takes into account the social determinants of health (SDOH) and the environmental factors that affect the health of the population. Population health is different from community health. The concept of population health is broader, compared to the concept of community health. Population health includes data representing the health condition of a specific group, while community health includes data representing the health condition of the residents in a community. The goals of population health management are to improve clinical care outcomes, integrate care across the delivery system, and address chronic and complex issues. To achieve these goals, nurses play an important role in population health management. As a primary care partner, nurses provide care for individuals and families while also working to improve population health outcomes. As a care coordinator, nurses help coordinate care for patients with complex medical needs. As a community-based facilitator, nurses work to improve health outcomes by engaging with community organizations and stakeholders. Finally, as an informatics specialist, nurses use technology and data to manage population health and improve patient outcomes.

### Divisions of Population Health

Population health is a broad approach to health care that focuses on improving the health of entire populations,

rather than just treating individual patients. The four main divisions of population health are population involvement, improved health outcomes, patterns of health determinants, and policy revision (Silberberg et al., 2019). Each division plays a crucial role in ensuring the health and well-being of populations, and together, they form a comprehensive approach to population health. Population involvement means engaging with populations to understand the health needs and priorities of the population. Improved health outcomes focus on developing interventions and strategies to improve the health of the population (Silberberg et al., 2019). Patterns of health determinants involve understanding the factors that contribute to health outcomes, such as social, economic, and environmental factors (Silberberg et al., 2019). Policy revision focuses on advocating for policies that support population health.

### Population Involvement

A critical component of population health is **population involvement**, which refers to the active engagement of populations in the design, implementation, and evaluation of programs and policies that affect their health and well-being. Population involvement can take many forms, such as population-based participatory research, patient engagement in healthcare decision-making, and involvement in public health campaigns. By involving populations in the process of addressing their health needs, the resulting solutions are more likely to be culturally appropriate, effective, and sustainable. Additionally, population involvement can promote health equity by addressing underlying SDOH and empowering populations to advocate for their own health and well-being. Overall, population involvement is essential for creating a truly comprehensive and effective approach to population health.

### Improved Health Outcomes

Improved health outcomes are the ultimate goal of population health. Measurable improvements in the health status of individuals and populations are referred to as health outcomes. Population health seeks to improve health outcomes by addressing underlying determinants of health and promoting evidence-based interventions (Silberberg et al., 2019). By improving access to healthcare services, promoting healthy behaviors, addressing SDOH, and implementing policies that promote health equity, population health initiatives can lead to improved health outcomes, such as increased life expectancy, reduced rates of chronic diseases, and improved quality of life (QoL). Improving health outcomes is not only beneficial for populations but also has significant economic and social benefits. Overall, improving health outcomes is a critical component of population health and requires a collaborative effort among individuals, healthcare providers, policymakers, and communities.

### Patterns of Health Determinants

Patterns of health determinants are the underlying factors that influence health outcomes of populations (Silberberg et al., 2019). Health determinants can be broadly categorized into social, economic, and environmental factors. Social determinants of health include factors such as education, income, and social support networks. Economic determinants of health include factors such as employment, income, and access to affordable housing. Environmental determinants of health include factors such as air and water quality, housing conditions, and access to green spaces. These determinants interact with each other to influence health outcomes, with some populations experiencing greater exposure to negative health determinants and fewer resources to address them. Understanding the patterns of health determinants is critical for developing effective population health strategies that address the underlying factors that contribute to health disparities. By identifying and addressing the root causes of poor health outcomes, population health initiatives can work to improve the health and well-being of all populations.

### Policy Revision

Policy revision is a crucial component of population health as policies play a significant role in shaping the social, economic, and environmental factors that influence health outcomes. Policy revision involves reevaluating existing policies and developing new policies that better address the needs and priorities of populations (Centers for Disease Control and Prevention, 2021). This can include changes to healthcare policies, social welfare policies, environmental policies, and other policies that impact the health and well-being of populations. Policy revision requires a collaborative effort among policymakers, healthcare providers, community organizations, and other stakeholders to identify areas for improvement, gather input from affected populations, and implement evidence-based interventions. By revising policies to better reflect the needs and priorities of populations, population health initiatives can help to address health disparities and promote health equity. Overall, policy revision is an essential component of population health, as it can help to create supportive environments that enable populations to lead

healthy lives.

## Goals of Population Health Management

The goals of population health management are to improve clinical care outcomes, integrate care across the delivery system, and address chronic and complex issues. Population health management is a proactive approach to health care that focuses on the health of entire populations rather than just individuals. The goals of population health management are achieved through a combination of strategies, including risk stratification, care coordination, patient engagement, and population health analytics. Risk stratification categorizes patients by health risk level to help determine allocation of resources. This process works seamlessly with care coordination, population health analytics, and patient engagement. By identifying and addressing the underlying determinants of poor health outcomes, population health management initiatives can help to prevent chronic diseases, reduce hospital readmissions and healthcare costs, and improve overall health outcomes and quality of care (World Health Organization, 2023).

### Improving Clinical Care Outcomes

Improving clinical care outcomes is an important goal of population health management. This involves implementing evidence-based practices and strategies to improve the quality of clinical care delivered to patients (National Collaboration Centre for Methods and Tools, 2023). This can include implementing care coordination strategies, enhancing patient engagement, promoting preventive care, and optimizing the use of healthcare technologies. By improving clinical care outcomes, population health management initiatives can help to prevent the progression of chronic diseases, reduce hospital readmissions, and improve overall health outcomes. Additionally, improving clinical care outcomes can lead to increased patient satisfaction, which is an important component of quality care.

### Integrating Care Across the Delivery System

Integrating care across the delivery system is a crucial goal of population health management. This approach involves connecting different components of healthcare services, including primary care, specialty care, behavioral health, and social services, to ensure that patients receive comprehensive and coordinated care (Farmanova et al., 2019). By integrating care, healthcare providers can more effectively manage patients' health needs, prevent duplicate services, and minimize unnecessary costs (Farmanova et al., 2019). This approach also enables healthcare providers to work collaboratively with patients and their families to develop personalized care plans that address their unique needs and preferences (Farmanova et al., 2019). Ultimately, integrating care across the delivery system is essential for improving the overall health outcomes of populations and reducing healthcare disparities.

### Addressing Chronic and Complex Issues

Addressing chronic and complex issues is a significant goal of population health management. Chronic conditions, such as diabetes, heart disease, and obesity, are among the leading causes of morbidity and mortality worldwide. These conditions require long-term management and support, making them a significant challenge for healthcare providers and patients. Complex issues, such as mental health disorders and substance use, also require comprehensive approaches to improve outcomes. Population health management addresses these challenges by promoting proactive and preventive measures, promoting patient engagement and education, and providing coordinated and integrated care. The goal is to improve health outcomes, enhance patient experiences, and reduce costs by addressing the root causes of chronic and complex issues through a population health lens.

## Nurse's Role in Population Management

Nurses play a crucial role in population health management. As the primary care partner, care coordinator, community-based facilitator, and informatics implementor, nurses have extensive interactions with patients and their families, making them well-positioned to identify health concerns and provide patient education and support. Nurses' involvement in population health management can help improve health outcomes, enhance patient experiences, and reduce healthcare costs by promoting preventive measures and proactive management of chronic conditions (Table 4.12).

Role	Responsibilities	Examples
Primary care partner	Collaborate with physicians, nurse practitioners, and other healthcare providers to provide comprehensive, patient-centered care to individuals and populations	Perform assessments, manage chronic conditions, provide patient education, and coordinate care with specialists and other healthcare providers
Care coordinator	Work with healthcare providers, patients, and their families to coordinate and manage patient care across multiple settings and providers	Assess patient needs, develop care plans, and communicate with providers to ensure that patients receive appropriate and timely care
Community-based facilitator	Work with community organizations and other healthcare providers to address social determinants of health that impact patient outcomes	Collaborate with community members and leaders to identify health concerns and develop strategies to promote health and prevent disease
Informatics implementor	Use electronic health records and other health information technology tools to manage patient data, monitor patient outcomes, and identify opportunities to improve care	Analyze population health data to identify trends

**TABLE 4.12** Nurse's Role in Population Management

### Primary Care Partner

Nurses can serve as primary care partners in population health management. As a primary care partner, nurses collaborate with physicians, nurse practitioners, and other healthcare providers to provide comprehensive, patient-centered care to individuals and populations. Nurses can take on a variety of roles in primary care, including performing assessments, managing chronic conditions, providing patient education, and coordinating care with specialists and other healthcare providers. They can also facilitate access to community resources and social services that address SDOH.

### Care Coordinator

Nurses can also serve as care coordinators in population health management (Swanson et al., 2020). As care coordinators, nurses work with healthcare providers, patients, and their families to coordinate and manage patient care across multiple settings and providers (Duncan, 2019). They assess patient needs, develop care plans, and communicate with providers to ensure that patients receive appropriate and timely care (Duncan, 2019). Nurses also promote patient engagement and education, providing resources and support to help patients manage their health conditions effectively (Duncan, 2019).

## PATIENT CONVERSATIONS

### Nurses as Care Coordinators

**Scenario:** A conversation between Nurse Mita Kapoor and her patient Mrs. Rhonda White Feather.

**Patient:** Hello again, Mita.

**Nurse:** Good afternoon, Mrs. White Feather. How are you today?

**Patient:** Mita, I'm afraid that I'm not doing so good (sits down at the desk).

**Nurse:** Oh, no. I'm so sorry to hear that. Well, you are in the right place. How can I help you?

**Patient:** Well (pauses and dabs away a tear), I want you to cancel my doctor appointments for next month (wipes another tear). With Ron, my husband, working so much and teaching so many classes, it's too much for me.

**Nurse:** Okay (nodding). I am hearing that you are feeling overwhelmed. Is that how you feel?

**Patient:** It's just too much. I can't keep these doctors straight . . . who wants me to do what and go where . . . it's just too much for an old lady like me.

**Nurse:** Well, Mrs. White Feather, I can tell that you are overwhelmed and very stressed. I don't want you to feel like that at all. It is a lot of appointments and information. Ron and I worked together to keep it all straight. Now that he is helping more at the school, he cannot help as much. However, I am still here, and now that I know about this, I can help you to keep it all straight.

**Patient:** Oh, Mita, that would be wonderful.

**Nurse:** Awesome. I already spoke with your cardiologist, your nephrologist, and your neurologist. But now that I know what's going on, I can work more closely with you.

**Patient:** Mita, I forget who is who and what I'm supposed to tell them.

**Nurse:** That is a lot to remember. I want to help you with this. I always speak to them every Monday. We go over your weekly lab values and then make adjustments to your plan of care. Now I will call you after I speak with them and go over any changes we need to make. I will also tell you if you have to come in for labs in that week.

**Patient:** That would be great, Mita. Last week I came in when I didn't have to. I felt like such a fool (shakes her head).

**Nurse:** Oh, no! You made that trip for nothing. I don't want that to happen again.

**Patient:** Ron was annoyed, but he loves me too much to be upset with me.

**Nurse:** Well, we are going to work together to make sure that it never happens again. I'm going to make sure you know when to come in and where to go. I will also make sure that all your medications are safe to be taken together.

**Patient:** (laughing) I remember when you had the pharmacy change my night medicine to liquid because it was easier for me to take. Ron said I was a baby. But that big pill made me throw up.

**Nurse:** Mrs. White Feather, that is what I am here for. I am here to make sure all your doctors are kept up to date and know what is going on with you. And I'm here to make sure you understand what is happening, when, and why.

**Patient:** Ron and I joke that you are the best gossip we know (laughing)!

**Nurse:** (laughing) I am kind of a busybody. But that's okay as long as you are safe and everybody knows what's going on with your health.

---

### Community-Based Facilitator

Nurses can also serve as community-based facilitator in population health management. In this role, nurses work with community organizations and other healthcare providers to address SDOH that impact patient outcomes. They collaborate with community members and leaders to identify health concerns and develop strategies to promote health and prevent disease (Swanson et al., 2020). Nurses can also provide health education, screening, and counseling services to community members and facilitate access to community resources that address SDOH, such as food insecurity, housing instability, and access to transportation (Swanson et al., 2020). For example, nurses can connect their patients with food banks, local charities, or facilities where they can receive free or discounted care. Nurses can work with other team members, such as social workers, to link patients with resources that can help them and their family.

### Informatics Implementor

Nurses can also serve as **informatics implementor** on population health management. In this role, nurses use electronic health records (EHRs) and other health information technology (HIT) tools to manage patient data, monitor patient outcomes, and identify opportunities to improve care. Nurses also work with healthcare providers to develop and implement clinical decision support systems that provide real-time alerts and recommendations to clinicians based on patient data (Swanson et al., 2020). Nurses in this role can also analyze population health data to identify trends, track outcomes, and develop strategies to improve health and prevent disease (Swanson et al.,

2020).

## Summary

### 4.1 Defining Health and Wellness

Health and wellness are vital components of overall well-being. Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity. Wellness is the active pursuit of activities, choices, and lifestyles that lead to a state of holistic health. Human dimensions of health include five aspects, encompassing physical, emotional, social, intellectual, and spiritual health. Wellness includes eight mutually codependent dimensions: physical, emotional, social, occupational, spiritual, intellectual, environmental, and financial wellness. The most used model for wellness is Dunn's Theory of Wellness, including four processes: being, belonging, becoming, and befitting. The Healthy People 2030 initiative is a nationwide endeavor in the United States that aims to improve public health and prevent diseases by setting core, developmental, and research objectives concerning different health areas. The SDOH, including economic stability, healthcare access and quality, education access and quality, neighborhood and built environment, and social and community context, are significant factors that influence health outcomes and inequalities. By analyzing these determinants, the root causes of health disparities can be identified, and policies can be formulated to promote health equity. To achieve optimal health outcomes for individuals and communities, it is crucial to comprehend the interdependence of health, wellness, and community-based health care. The Healthy People 2030 initiative highlights the most critical needs of the nation and outlines concrete objectives on how to achieve health goals.

### 4.2 Models of Health

Models of health are conceptual frameworks that guide healthcare providers to understand and promote health. Various nursing models used in patient care include the HBM, HPM, Holistic Health Model, and Maslow's hierarchy of needs model. These models assist in assessing patient needs, developing care plans, and evaluating patient outcomes. These models guide nursing practices that emphasize providing comprehensive care to patients. Medical models used by nurses when providing patient care include the religious model, humanistic model, and transpersonal model. These models provide approaches to understanding and treating illness. Models for health and illness, such as the biomedical model, psychosomatic model, and existential model, explain the factors that influence health behaviors and can guide interventions to improve health outcomes. Models help healthcare providers understand and explain the complex interactions between the biological, psychological, social, and environmental factors that contribute to a person's health status. Understanding these various models can help nurses provide holistic care to patients, addressing the physical, psychological, and social aspects of health.

### 4.3 Health Promotion and Illness Prevention

Global strategies for health promotion include implementing policies and programs that promote healthy lifestyles, creating supportive environments for healthy behaviors, strengthening community action for health, and developing personal skills for health. These strategies involve effective governance for health, improving health literacy, and building or creating healthy cities, which improve health and prevent illness at the population level. The levels of prevention include primary, secondary, and tertiary prevention. Primary prevention aims to prevent the onset of disease through interventions that target risk factors and promote healthy behaviors. Secondary prevention focuses on early detection and treatment of disease to prevent complications and further progression. Tertiary prevention aims to reduce the impact of disease and disability through rehabilitation and management. The application of these strategies and levels of prevention to patient care involves identifying individual risk factors and addressing them through targeted interventions. This may include lifestyle modifications, such as increasing physical activity and improving diet, as well as screening for early signs of disease and medication management. Factors influencing a patient's risk of illness include inherent factors, lifestyle factors, and environmental factors. Understanding these factors can help healthcare providers develop personalized prevention and treatment plans for each patient. The impact illness has on health promotion can vary depending on the stage and severity of the disease. Illness can have a negative impact on a patient's emotion and behaviors, lead to further body image and self-concept problems, and add stress and strain to the family members. However, effective management and treatment of illness can be a key component of health promotion, improving overall health and preventing further complications.

### 4.4 Community-Based Health Care

Nurses play a crucial role in community-based health care as educator, caregiver, change agent, collaborator,

counselor, and patient advocate. They must have a variety of competencies to provide high-quality care, including promoting healthy lifestyles, preventing disease and health problems, educating the community, and evaluating the community. Nurses also work with diverse populations, including at-risk populations such as patients with disabilities, pediatric patients, older adults, individuals from underrepresented groups, people who are under- or uninsured, and patients with low socioeconomic status. Nurses in community-based healthcare settings are essential in improving health outcomes and addressing health disparities among at-risk populations.

#### 4.5 Community-Based Healthcare Initiatives

Community-based health initiatives are essential for improving the health and well-being of communities, and their implementation requires adherence to guidelines that include community involvement, stakeholder engagement, and sustainability planning. Successful community-based programs are characterized by quality, respect, and empowerment, with a focus on addressing the specific health needs and priorities of the community. Conducting a CHNA is a critical step in identifying these health issues and informing the development of relevant initiatives. Tools such as evidence-based tools, the CDC CHSI, and the VPF can be used to assess community health needs. Nurses play a vital role in educating the community about health care and promoting healthy behaviors as well as managing resources and advocating for the implementation of evidence-based practices that address the identified health needs. To effectively plan education for community-based health initiatives, nurses must prioritize identified problems, set goals and objectives, develop strategies, implement interventions, and evaluate outcomes. By following these guidelines and steps, nurses can ensure that their education efforts are relevant, accessible, and meaningful to the community they serve.

#### 4.6 Population Health

Population health is divided into four divisions, including population involvement, improved health outcomes, patterns of health determinants, and policy revision. The goals of population health management include improving clinical care outcomes, integrating care across the delivery system, and addressing chronic and complex issues. Nurses play an essential role in population health management, taking on different roles such as a primary care partner, care coordinator, community-based facilitator, and informatics specialist. These roles involve working with patients, families, healthcare providers, and community organizations to improve health outcomes and address the SDOH. Nurses can use their skills and knowledge to promote health equity, facilitate access to care, and provide support for populations to manage chronic and complex health issues.

### Key Terms

- at-risk population** includes individuals who face barriers to accessing healthcare services, have limited access to health care, or are marginalized (e.g., patients with disabilities, pediatric patients, older adults, individuals from underrepresented groups, people who are under- or uninsured, individuals with low incomes, immigrants, people experiencing housing insecurity, and those with mental health or substance use disorders)
- becoming** an individual's pursuit of personal growth and self-improvement, as well as their openness to new experiences and perspectives
- befitting** taking proactive self-care strategies and personal responsibility to make personal choices to benefit one's well-being
- being** recognizing oneself as an individual and actively working to achieve a state of high-level wellness in all eight dimensions
- belonging** the feeling of being accepted, valued, and supported by others, as well as the sense of belonging to a larger community or group
- biomedical model** model of health that focuses on diagnosing and treating specific physical diseases or disorders using medical interventions such as drugs or surgery
- change agent** nursing role that involves identifying areas for improvement in patient care and developing and implementing strategies to bring about positive change
- collaborator** nursing role that involves working as part of a team with other healthcare professionals to provide coordinated and comprehensive care to patients
- Community Health Needs Assessment (CHNA)** a systematic process of identifying the health needs and priorities of a specific community
- counselor** nursing role that involves providing emotional support and guidance to patients and their families who

are experiencing health challenges

**Dunn's Theory of Wellness** also known as High-Level Wellness Model, defines wellness as an ongoing process of growth and development that encompasses all aspects of an individual's life

**emotional dimension of wellness** actions to increase self-awareness and self-regulation to manage emotions in a healthy and constructive way, including strategies to cope with stress and adversity and promote positive emotions

**emotional health** an individual's ability to manage and express their emotions, cope with stress, and experience positive emotions

**empowerment** giving community members a voice and agency in a program's decision-making processes

**environmental dimension of wellness** actions to achieve a good relationship with the surrounding environment, including access to clean air and water and a safe and healthy living and working environment

**environmental factors** physical, chemical, biological, and social factors that affect the quality of air, water, food, and the general environment

**existential model** model of health that emphasizes the subjective experience of individual existence and the search for meaning in life

**family-centered care** recognizing and respecting the role of the family in the pediatric patient's care, including their preferences and priorities for their health decisions

**financial dimension of wellness** actions to achieve financial stability to meet basic needs and experience a sense of financial security

**governance for health** the process of developing and implementing policies, strategies, and actions that support and promote the health and well-being of individuals and communities

**Health Belief Model** model of health that emphasizes the importance of an individual's beliefs and attitudes in shaping health behaviors

**health equity** when everyone has a fair opportunity to obtain optimal health

**health outcomes** the measurable improvements in the health status of individuals and populations

**Health Promotion Model** model of health that takes a holistic approach to health and wellness

**Healthy Cities** a strategy that focuses on creating environments that support the health and well-being of their residents

**hierarchy of needs** created by Abraham Maslow, a pyramid-shaped model that includes five levels of needs: physiological needs, safety needs, love and belonging needs, esteem needs, and self-actualization needs

**holistic approach** addressing the whole patient to assess and treat all facets of the person

**Holistic Health Model** comprehensive model of health that takes into account the physical, emotional, social, and spiritual aspects of health and wellness

**human dimensions** facets of wellness that interrelate to demonstrate a comprehensive view of health; include emotional, physical, social, intellectual, and spiritual aspects of illness and wellness

**humanistic model** model of health that focuses on the importance of the individual and their personal experience and emphasizes the need for patient-centered care that recognizes the unique needs and values of each patient

**informatics implementor** a nurse who uses electronic health records (EHRs) and other health information technology (HIT) tools to manage patient data, monitor patient outcomes, and identify opportunities to improve care

**inherent factors** the individual, nonmodifiable characteristics that can influence the risk of illness, which include genetics, age, and sex

**intellectual dimension of wellness** actions to acquire new skills and generate new knowledge

**intellectual health** individuals' ability to acquire new skills, think critically, and engage in creative activities

**leading health indicators** cohesive set of indicators of health and well-being across the life span, encompassing all aspects of health

**levels of prevention** different stages or approaches that can be taken to prevent the occurrence of a health condition or disease

**lifestyle factors** individual behaviors and habits that can influence the risk of illness, which include tobacco and alcohol use, poor diet, physical inactivity, and stress

**medical models** approaches to understand and treat illness; view health as the absence of disease or illness and focus on identifying and treating physical symptoms and underlying medical conditions through medical interventions, such as medications, surgeries, and other medical procedures

- models of health** conceptual frameworks that guide healthcare providers to understand and promote health
- nursing models** conceptual frameworks that draw from other frameworks to guide nursing practice and provide comprehensive care to patients, emphasizing the importance of considering the whole person and taking a holistic approach to health and wellness
- occupational dimension of wellness** actions to achieve job satisfaction, work–life balance, and personal growth and development
- organizational health literacy** focuses on how an organization can help individuals find and use health information for themselves to make decisions about their health and wellness
- patient advocate** nursing role that involves ensuring that patients’ needs and preferences are prioritized and that they receive appropriate care
- personal health literacy** focuses on the ability of a single person to comprehend and use health information
- physical dimension of wellness** actions to maintain individual’s physical health, including nutrition, exercise, sleep, and regular medical checkups
- physical health** individual’s ability to perform daily activities, maintain healthy body weight, and prevent illness and disease
- population health** the health outcomes of a group of individuals, including the distribution of those outcomes within the group
- population involvement** the active engagement of communities and individuals in the design, implementation, and evaluation of programs and policies that affect their health and well-being
- primary prevention** the first level of prevention that aims to avert the onset of a disease or health condition before it occurs
- psychosomatic model** model of health that stands on the idea that psychological factors, such as emotions, beliefs, and personality traits, can have a direct impact on physical health
- quality** the provision of evidence-based interventions and services that are effective, efficient, and responsive to the needs of the community
- religious model** framework or system of beliefs that serves as a guide for individuals or communities to understand and relate to a higher power or spiritual reality
- respect** acknowledging and valuing the perspectives, needs, and experiences of the community members who are being served
- secondary prevention** the second level of prevention that aims to detect and treat a disease or health condition in its early stages to prevent complications and progression
- social determinants of health (SDOH)** conditions associated with birth, childhood, education, work, play, worship, and aging that impact health, functioning, and quality-of-life outcomes
- social dimension of wellness** actions to maintain healthy and positive relationships with others, including utilization of communication skills and social support to achieve a sense of belonging
- social health** individuals’ ability to participate in social activities, interact with others, and experience a sense of belonging and connection
- spiritual dimension of wellness** actions to achieve personal values, including reinforcement of beliefs and practices that promote inner peace, happiness, and fulfillment
- spiritual health** individuals’ ability to achieve personal values
- tertiary prevention** the third level of prevention that aims to manage and treat the complications of a disease or health condition to prevent disability or death
- transpersonal model** model of health that proposes that beyond the adult ego, there are developmental stages that involve experiences of connectedness with phenomena considered outside the boundaries of the ego
- Vulnerable Populations Footprint (VPF)** a tool that can be used for community health needs assessment, specifically to identify the most at-risk populations within a community

## Assessments

### Review Questions

1. John is a public health professional who is passionate about promoting health and preventing disease. He is interested in learning about the Healthy People 2030 initiative. What is the goal of this initiative?
  - a. to increase the prevalence of chronic diseases in the population

- b. to decrease the number of people with access to health care
  - c. to improve the health and well-being of all individuals and communities
  - d. to decrease the use of evidence-based practices in health care
2. Sarah is a community health worker who is working with a family struggling with poverty. Which SDOH is likely to have the greatest impact on the family's health outcomes?
- a. healthcare access and quality
  - b. education access and quality
  - c. neighborhood and built environment
  - d. economic stability
3. The nurse is discussing foundational concepts of community-based nursing care. Which concept is the nurse describing when stating, "this concept refers to the comprehensive view of physical, mental, emotional, and social well-being and not simply the absence of disease or illness"?
- a. wellness
  - b. health
  - c. cultural competence
  - d. befitting
4. What is an example of an intervention that a nurse can use to address the perceived barriers to a patient's health behavior, as outlined in the HBM?
- a. providing educational resources on the relationship between healthy behaviors and diseases
  - b. offering financial incentives for behavior change
  - c. helping the patient identify available social support networks
  - d. scheduling follow-up appointments to monitor progress
5. Mr. Brown, a 68-year-old male, is diagnosed with type 2 diabetes. He is currently taking medication to manage his blood glucose levels. He asks the nurse, "What more can I do to manage my diabetes?" If a nurse were responding to this question in a way that reflected the limitations of the biomedical model of care, what might she say?
- a. "It's important to keep taking your medication and incorporating some exercise to manage your diabetes."
  - b. "There's not much more you can do beyond taking your medication. Your compliance to the medication is the only way you can manage your diabetes."
  - c. "We can focus on managing your symptoms and preventing complications of diabetes, such heart and kidney diseases."
  - d. "Let's explore some lifestyle changes you can make, such as improving your diet, to better manage your diabetes."
6. A nurse would like to use a medical model of health when planning a care plan. The nurse selects a model that emphasizes the importance of personal growth in achieving optimal health and well-being, involving development beyond the adult ego. Which model has the nurse selected?
- a. transpersonal model
  - b. religious model
  - c. humanistic model
  - d. Holistic Health Model
7. A 55-year-old male patient visits the clinic for his annual checkup. He reports having a family history of cardiovascular disease and is concerned about his risk of developing heart disease. Which level of disease prevention would be most appropriate for this patient?
- a. primary prevention
  - b. secondary prevention
  - c. tertiary prevention

- d. quaternary prevention
8. A patient with chronic obstructive pulmonary disease (COPD) expresses concern about the impact the illness has on his ability to engage in health-promoting activities. What would be the best response from the nurse?
- a. “It’s understandable that you’re feeling discouraged, but you should still try to engage in some form of exercise.”
  - b. “It’s important to listen to your body and not push yourself too hard, but there are still ways you can promote your health.”
  - c. “With COPD, there’s not much you can do to promote your health. You just have to focus on managing your symptoms.”
  - d. “You should avoid any physical activity that makes you short of breath. Just take it easy and rest.”
9. What is the nurse’s role as a patient advocate?
- a. to make medical decisions for the patient
  - b. to ensure the patient’s wishes are respected and their rights are upheld
  - c. to prioritize the needs of the healthcare facility over the patient’s needs
  - d. withhold information from the patient in the interest of their well-being
10. What strategy can nurses use to provide culturally sensitive care to patients from underrepresented groups?
- a. engage in self-reflection and education to become aware of their own biases
  - b. avoid discussing cultural beliefs or practices with patients to avoid causing offense
  - c. use standardized treatment protocols that are not tailored to individual patient needs
  - d. focus on evidence-based practice and ignore the patients’ cultural beliefs
11. What is a characteristic of successful community-based programs?
- a. quality
  - b. cost-effectiveness
  - c. efficiency
  - d. effectiveness
12. Which tool is commonly used for conducting a community health needs assessment?
- a. CASPER
  - b. Health Impact Assessment (HIA)
  - c. Rapid Assessment and Response (RAR)
  - d. Participatory Action Research (PAR)
13. The nurse is developing an educational plan regarding community-based initiatives. Problems within the community have been identified, and one specific program has been prioritized for this education plan. What is the next step in the planning process?
- a. developing strategies
  - b. setting goals
  - c. implementing interventions
  - d. evaluating
14. Which is not a division of population health that nurses should be familiar with?
- a. population involvement
  - b. patterns of health determinants and risk factors
  - c. policy revision
  - d. access to healthcare services
15. Which statement shows the nurse has a wrong understanding about the goals of population health management?
- a. “Improving patient care outcomes is very important in population health management.”

- b. “We should enhance patient engagement in their own care, which is one of our population health management goals.”
- c. “Chronic and complex health issues are something we need to work on in population health management.”
- d. “Integrating care across the delivery system should always be considered.”

### Check Your Understanding Questions

1. Describe how you can incorporate the five SDOH into your daily clinical setting.
2. Compare and contrast the different models for health and illness.
3. Describe how you can incorporate the three levels of prevention into your daily clinical settings when you take care of your patients.
4. Outline global health strategies for health promotion. Identify one example of a global health strategy you have witnessed or experienced.
5. Describe the concept of family-centered care. How can it be used in your future nursing practice?
6. Based on your understanding and experience, describe the nurse’s role in education for community-based health care.
7. How would the nurse’s role in addressing chronic and complex patient concerns differ in a community-based setting versus providing individualized patient care?

### Reflection Questions

1. What nursing model might you consider incorporating into your daily nursing care activities? How do you incorporate it into your daily nursing care activities?
2. Consider yourself as a patient, and write three inherent factors, three lifestyle factors, and three environmental factors that are either influencing your health currently or have impacted your health in the past. Are there any changes you wish to make currently or changes you made in the past regarding these factors to improve health?
3. Reflect on what competencies you may lack or want to improve when you engage in community-based health care. Describe how you could improve these competencies.
4. Review the types of nursing roles in community-based health care. Which roles do you feel you would enjoy, and which do you feel may take more practice to refine? Explain.
5. How can you incorporate the goals of population health management into your daily practice to better serve the health needs of your patients and your community?

### What Should the Nurse Do?

Sofia is a 48-year-old Latina who lives in a neighborhood with people with low incomes. She has recently been diagnosed with type 2 diabetes and has struggled to manage her blood sugar levels due to a lack of access to healthy food options and limited physical activity opportunities. She has also experienced discrimination and language barriers when seeking healthcare services. Based on the case, please answer the following questions.

1. How do economic stability, healthcare access and quality, neighborhood and built environment, and social and community context impact Sofia’s ability to manage her diabetes effectively?
2. What are some potential strategies to improve Sofia’s access to healthy food options and increase her opportunities for physical activity?
3. How might Sofia’s experiences with discrimination and language barriers affect her willingness to seek healthcare services and adhere to her treatment plan?
4. How can healthcare providers work to address the SDOH that impact Sofia’s health outcomes and disparities?
5. How might Sofia’s experiences with discrimination and language barriers impact her mental health and well-being, and what interventions could healthcare providers implement to address these factors?
6. What should the nurse do if a patient expresses a desire to improve their physical health but is resistant to

making any lifestyle changes or following through with the nurse's recommendations?

7. What should the nurse do if a patient expresses worry about the impact of their illness on their emotions and behaviors, body image and self-concept, and family members' lives?
8. What should the nurse do if they encounter at-risk populations within community-based health care?

### Competency-Based Assessments

1. Form a group of peers (recommended: two to five people) and develop a patient's case, write the plan of care focusing on one of the five SDOH each, and discuss the topic further.
2. Based on a medical model described in this chapter, develop a nursing care plan to promote the health of a patient.
3. Based on the steps of planning education, develop and deliver a ten-minute PowerPoint presentation about your plan for providing a health education workshop for a community.
4. Form a group of peers (recommended: two to five people), and discuss how you would demonstrate your competency as a nurse in fulfilling the role of a care coordinator in population health management.

## CHAPTER 5

# Cultural Competence

**FIGURE 5.1** A culturally diverse community finds its strengths in its differences. (credit: “School diversity many hands held together,” by “Wonder woman0731”/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

- 5.1 Understanding Cultural Differences
- 5.2 Ethical Practice in Culture and Diversity
- 5.3 Cultural Practice in Nursing
- 5.4 Diversity, Equity, and Inclusion

**INTRODUCTION** Every person in the world belongs to a culture. Culture shapes one’s personal identity, influences social relationships, and contributes to the overall richness of human societies. Basic elements of culture include language, symbols, societal norms and customs, beliefs, values, and cognitive elements (such as learning to cope, managing difficult situations, and qualities taught to children). Culture plays a significant role in health and wellness, as it can affect what types of medicines and treatments to use, who is allowed to provide care, and beliefs about what causes illness and injury.

The United States has long had a reputation as a multicultural nation, and according to the United States Census Bureau (2020), it continues to grow even more racially and ethnically diverse every year (Jensen, 2022) ([Figure 5.2](#)). Nurses will interact with patients who belong to diverse cultures, both distinct from each other and distinct from the nurses’ own cultural background. It is crucial for nurses to understand and accommodate cultural differences, ensuring the delivery of the best possible care to all patients, regardless of their cultural background. This chapter discusses how to gain a better understanding of cultural differences among the patients who nurses serve as well as ethical and cultural practices in nursing and how to incorporate diversity and inclusion as best practice standards.

# A More Diverse Nation

## Distribution of Race and Hispanic Origin by Age Groups

## 5.1 Understanding Cultural Differences

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify cultural influences on beliefs of health and illness
- Recognize health disparities among different cultures
- Describe different healers among cultural variations
- Explain how to counteract unconscious bias

Nurses encounter patients from a variety of backgrounds; therefore, it is essential they are able to provide culturally competent care. A lifelong process of applying evidence-based nursing in agreement with the cultural values, beliefs, worldview, and practices of patients to produce improved patient outcomes is known as **cultural competence**. It is a way of providing patient-centered, holistic nursing care.

A nurse who provides holistic care to patients will focus on healing the person as a whole rather than on one specific problem. In holistic nursing care, the interconnected aspects of a person's life, including their physical, cognitive, social, emotional, and spiritual health, are taken into account. In **culturally competent care**, an individual's cultural beliefs are integrated into their health care. Culturally competent care is required for a trusting, effective relationship with the patient.

### Cultural Influences on Health and Illness

The United States is a nation characterized by a multitude of ethnic and cultural groups, with its diversity steadily increasing each day. A set of beliefs, attitudes, and practices shared by a group of people or community which is accepted, followed, and passed down to other members of the group is known as **culture**. Some groups of people have cultural beliefs that explain what causes illness, how illnesses are treated or cured, and who should be involved in the healing process. Culture also affects how people communicate with healthcare team members in terms of language or eye contact, or what can be discussed in terms of the person's body, health, or illness. A person's culture affects everything from how they think and feel about health and illness, to how receptive they are to treatment recommendations, to how, when, and from whom they receive care.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety and Procedure: Patient-Centered Care

**Definition:** Recognize the patient as a full partner in control of all decisions when providing compassionate and coordinated care based on respect for the patient's preferences, values, and needs.

**Knowledge:** Describe how diverse cultural, ethnic, and social backgrounds function as sources of patient, family, and community values.

**Skill:** Communicate patient values, preferences, and expressed needs to other members of the healthcare team.

**Attitude:** Respect and encourage individual expression of patient values, preferences, and expressed needs.

Best practice standards include the nurse providing competent, effective care with each patient interaction. Conducting a cultural assessment is one way to ensure the patient's preferences and cultural needs are met.

### Physiological Differences

Some ethnic and cultural groups have a higher likelihood of experiencing specific diseases, particularly those with genetic conditions associated with their ancestry. Individuals belonging to these ancestral ethnicities are more prone to carrying recessive genes responsible for these illnesses. See [Table 5.1](#) for a list of various ethnic groups along with some of the prevalent genetic diseases associated with each. For instance, there is potential susceptibility to certain cancers and rapid disease progression due to certain physiological diversity such as body structure, skin color, hair type, and metabolism (Perreira et al., 2019).

Ethnic Group(s)	Associated Hereditary Conditions
African	Sickle cell anemia, cystic fibrosis, thalassemia
Ashkenazi Jewish	Tay-Sachs disease, cystic fibrosis, Gaucher disease
Asian	Thalassemia
French Canadian, Cajun	Tay-Sachs disease
Mediterranean	Sickle cell anemia, thalassemia

**TABLE 5.1** Ethnicities and Associated Hereditary Conditions

### Psychological Differences

One main psychological distinction between cultures that affects how people think and make decisions is **individualism** versus **collectivism**. People from individualistic cultures focus on the individual. They are encouraged to make choices for their own benefit with an emphasis on independence and self-reliance, and health care tends to be viewed as a personal responsibility. Most Western countries, such as the United States, United Kingdom, and other parts of Western Europe are considered to have individualistic cultures (Fatehi et al., 2020).

In contrast, people from collectivistic cultures place an emphasis on community and cooperation. Decisions are made for the benefit of the collective. These cultures believe that it is best for society when everyone works together as a group, and the needs of the individual come secondary to the needs of the greater good. A patient from a collectivistic culture might entrust decisions about their treatment to their family, for example, reflecting the communal approach to decision-making and the importance of considering the broader impact on the group. Some countries that practice cultural collectivism include China, Japan, Indonesia, and some other Eastern countries.

### Cultural Influences on Pain

Pain management can be a challenging task and can be made more complex by the cultural considerations particular to each patient (IASP, n.d.). Pain is perceived differently across diverse cultures, including how to express it, how to treat it, and what it means. While pain is a universal physical sensation, its emotional and behavioral aspects are influenced by the cultural perspective of the individual (Givler & Bhatt, 2022). While each patient is an individual, and their response to pain should not be assumed based on their background, there are some broad tendencies in pain perception based on ethnicity. For instance, some research has shown that Black, Japanese, Hispanic, and East Asian cultures tend to be stoic about pain and may keep an unresponsive facial expression or believe that requesting pain medication is a sign of weakness (Hollingshead et al., 2016; Pieper, 2020). Others, such as those part of Muslim or Christian communities, can view pain as part of God's plan. Chinese patients may view pain as an imbalance between yin and yang (Perreira et al., 2019). This does not mean that these groups do not experience pain. Avoiding misunderstandings related to cultural differences in perceptions of pain is crucial in preventing either overtreating or undertreating the patient's pain.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Take Action: Culturally Sensitive Nursing Interventions for Pain

Even though the ways in which patients experience and express pain are influenced by their cultural background, pain is an individual experience. It is important for the nurse to be aware of cultural differences so they can treat the individual in a way that best suits their pain. Culturally sensitive nursing interventions for pain include the following (Givler & Bhatt, 2022):

- Providing an interpreter for patients with limited verbal or written English skills.
- Asking the patient about their ideas and understanding of the concept of pain. Their beliefs may be representative of their cultural background, or they may not—be careful not to generalize without listening to the patient.
- Providing thorough education to the patient on pain assessment and the importance of reporting pain. Self-reported assessments allow for a more accurate understanding of the patient's pain, taking into account their personal perception and experience.
- Assessing both observable behaviors and self-reported assessments to formulate a comprehensive approach to pain management. While observable behaviors can provide valuable insights into a patient's condition, they may not capture the full range of pain experiences. Some individuals may not express pain through observable behaviors, while others may exaggerate their discomfort.
- Being sensitive to traditional healing remedies, such as prayer or use of certain foods. Allow the patient to incorporate traditional remedies whenever possible. Make sure to gather a thorough history of all medicines, herbs, plants, and foods to avoid any possible interactions.
- Assuring the patient that the healthcare team is there to help treat their pain in a way that is the most appropriate and suitable for them.
- Adjusting the patient's care plan to reflect their cultural needs.

## UNFOLDING CASE STUDY

### Unfolding Case Study #1: Part 4

Refer back to [Chapter 2 Communication](#) for Unfolding Case Study Parts 1-3 to review the patient data. The medical-surgical nurse is providing care to a 28-year-old female patient who arrived to the hospital one hour ago from a walk-in medical clinic. The patient speaks Spanish and is accompanied by her bilingual 10-year-old son.

Past Medical History	<p>Patient is a mother of one, who cares for her child and older mother in a small apartment. The patient's mother is not able to leave home and is not present at the hospital. Patient engages in house cleaning to financially support her family; however, the income is inconsistent. Patient has an eighth-grade education, is a native Spanish speaker, and does not speak English. Medical history includes seasonal allergies, sinusitis, and two episodes of COVID-19 in the past two years.</p> <p><b>Family history:</b> Patient's father is deceased, and patient's mother has stage 2 Alzheimer disease. Patient's son is in good health, talkative, and attentive to his mother.</p> <p><b>Social history:</b> Patient is primary caregiver for mother and adolescent. No other support systems available. Patient has difficulty shopping and making doctor's appointments due to lack of care for her mother. Patient has difficulty communicating in English, so the son translates for his mother.</p> <p><b>No current medications and no known allergies.</b></p>
Nursing Notes	<p><b>2310: Assessment</b></p> <p>History and assessment is difficult to obtain because patient does not speak English. Son reports that patient was seen at the clinic for a cough and was diagnosed with pneumonia and started on medication to treat it. Patient remains on 2 L oxygen via nasal cannula, breathing pattern appears normal without distress.</p>
Flow Chart	<p><b>2310: Assessment</b></p> <p>Blood pressure: 135/75 mm Hg          Heart rate: 97 beats/minute          Respiratory rate: 22 breaths/minute          Temperature: 100.1°F (37.8°C)          Oxygen saturation: 97 percent on 2 L nasal cannula          Pain: 9/10 (ear)</p>
Lab Results	None
Diagnostic Tests/ Imaging Results	<p>Chest x-ray: Bilateral infiltrates indicative of pneumonia.          Sputum culture pending.</p>
Provider's Orders	<p><b>2330: New orders</b></p> <p>Close observation.          Continue antibiotics.          Wean off oxygen as tolerated.</p>

1. Recognize cues: Which finding from the information provided is the highest priority at this time?
  - a. patient does not speak English
  - b. oxygen saturation 97 percent

- c. heart rate 97 beats/minute
  - d. sputum culture results
2. Analyze cues: The patient is reporting a 9/10 pain in the ear but does not show any other signs of being in pain such as grimacing or holding the ear. Which is the most likely rationale for this?
- a. The patient is lying about their pain level.
  - b. The patient's pain has improved since getting to the hospital.
  - c. The patient's culture may dictate how they show and process pain.
  - d. The son stated the patient's pain was a 9/10 so she would get pain medicine more quickly.

## Health Disparities Related to Cultural Differences

The **social determinants of health (SDOH)** are the economic, social, and environmental factors that influence an individual's health and well-being. The term **health disparity** describes the differences in health outcomes that result from SDOH. Various factors contribute to health disparities among various cultural groups. Socioeconomic status, race, educational level, and physical proximity to healthcare facilities are all factors related to health disparities. Black and American Indian populations have higher rates of obesity, diabetes, hypertension, and heart disease when compared to White populations (Perreira et al., 2019; National Academies of Sciences, Engineering, and Medicine, 2017a). Distrust of mainstream Western medicine in Black and American Indian communities due to a long history of systemic discrimination can further health disparities by preventing community members from seeking preventative care. This is another example of why it is important for the nurse to provide culturally sensitive care to all groups and foster a trusting relationship with the patient.

### UNFOLDING CASE STUDY

#### Unfolding Case Study #1: Part 5

Refer back to [Unfolding Case Study #1: Part 4](#) to review the patient data.

Nursing Notes	<b>0100: Assessment</b> Patient given one dose of acetaminophen and reports that ear pain is now 4/10. Interpreter has arrived and plans to stay on the unit until morning rounds so they can translate when the provider comes in. Patient resting comfortably, son sleeping on couch at the bedside.
---------------	---

- 3. Prioritize hypotheses: Based on the information provided in the patient's social history, the nurse is concerned that the patient may be experiencing health disparities. How are the social determinants of health linked to an increased risk of health disparities?
- 4. Generate solutions: What actions can the nurse take to address the social determinants of health that are contributing to the health disparities being experienced by the patient?

## Healer Variations Among Different Cultures

Every culture develops its own ways of dealing with health and illness. The various medicines and healing practices around the world that differ from the modern, Western healthcare system are referred to as **traditional healing** (World Health Organization, n.d.) ([Table 5.2](#)). The term encompasses a vast range of traditions and practices that differ across diverse regions and cultures.

Traditional healing has long been used to promote health and fight disease and is still used today by many people around the world because traditional healers tend to be accessible, affordable, and knowledgeable of the language and culture. Some people rely on traditional healers instead of Western medicine, while others may choose to incorporate traditional healing practices into Western medical care.

Healing Tradition	Chief Characteristics
Traditional Chinese Medicine (TCM)	Belief in the idea of balance as the root of health; based in concepts of Qi and yin and yang; practices include acupuncture, cupping, herbs, tai chi
Ayurveda	Hindu form of medicine from India, based on idea that disease is caused by imbalance; seeks to cure imbalances using Ayurvedic medicine including diet, herbal medicines, yoga, and meditation
African Traditional Healing	Extremely diverse and varies by tribe; some many believe that ancestral spirits are closely involved in the lives of the living; offer spiritual education and care, and function as counselors and social workers
American Indian Traditions	Belief in spiritual and physical health as intertwined; the healer's role is to help the individual as they help themselves; ritual and ceremony have key roles in healing
Hispanic Traditions	Curanderismo is a holistic practice rooted in beliefs that health is achieved through the right balance of mind, body, and spirit; healers focus not only on the individual's physical health but also on their mental health, diet, personal relationships, and more; use various healing methods including prayer, oils, herbs, special diets, and other spiritual rituals
Western European Traditions	Role of patient at the center of the patient-healer relationship is crucial; strong foundation in using medicines created from natural elements, including herbs, plants, minerals, and animals

**TABLE 5.2** Healing Traditions

### Asian Traditions

Asian healing traditions are rooted in the concept of balance. Two of the more well-known traditions are Traditional Chinese Medicine and Ayurveda. Both Traditional Chinese Medicine and Ayurveda have become increasingly popular in recent years as complementary therapies to Western medicine.

**Traditional Chinese Medicine (TCM)** is an ancient practice based on the ideas of Qi and yin and yang. Qi is the life force that runs through one's body; yin and yang are the qualities of Qi that must be in balance for optimal health (Johns Hopkins Medicine, 2019b). TCM consists of such practices as acupuncture, acupressure, cupping, herbs, tai chi, and others (Figure 5.3). The Accreditation Commission for Acupuncture and Oriental Medicine is a federally recognized organization that accredits schools in the United States that teach acupuncture and TCM.

**FIGURE 5.3** Various herbs shown here are used in Traditional Chinese Medicine. (credit: “Chinese prescription,” by Tim Wilson/Flickr, CC BY 2.0)

**Ayurveda** is a traditional Hindu form of medicine from India that is based on the idea that disease is caused by an imbalance in the body. Ayurvedic medicine seeks to cure this imbalance through a combination of diet, herbal medicines, yoga, and meditation. In India, Ayurvedic medicine is considered equivalent to conventional Western medicine, and providers receive formal training; however, there is no licensing process for Ayurvedic practitioners in the United States (Johns Hopkins Medicine, 2019a). Ayurvedic medicine consists of herbs, spices, minerals, and other substances that can interfere with conventional drugs (medications that are widely accepted and commonly used in mainstream medical practice); a thorough list of all medicines and supplements is an important part of the nursing assessment for this reason.

### African Traditions

African healing traditions have their foundations in practices dating back thousands of years. Although specific religious traditions vary by tribe, traditional African healing is rooted in the idea that ancestral spirits are closely involved in the lives of the living and act as “mediators” between the living and God (Mokgobi, 2014). As Christianity and Islam began to spread across the continent, many people converted from traditional religions. However, they often retained traditional practices alongside embracing Westernized health care.

Healers vary among tribes; for example, the Bapedi tribe has diviners (*Ngaka ya ditaola*), Sanusi (or *Sedupe*), traditional surgeons, and traditional birth attendants. Diviners and Sanusi can diagnose and prescribe treatment for mental, physical, and spiritual afflictions (Zuma et al., 2016). Surgeons have been trained to perform circumcisions, along with the duties of diviners and Sanusi. Older women who have experience assisting with births over many years become traditional birth attendants. However, African traditional healers do more than help with physical illness and injury. They also offer spiritual education and care and have special knowledge of traditional culture, which allows them to function as counselors and social workers (Zuma et al., 2016).

### American Indian Traditions

In American Indian and Alaska Native cultures, physical and spiritual health are interconnected. The belief is that in order for the body to heal, the soul must heal as well. American Indian healers believe the individual is the source of most of the healing and is responsible for their own health, wellness, and behavior. The healer's role is to help the individual as they heal themselves, although the individual's family and community play an important part as well (National Institutes of Health [NIH], n.d.).

Ritual and ceremony hold a key role in traditional American Indian healing. Purifying and cleansing the body, whether through sweating or purging, is an important practice in some American Indian healing rituals. Smudging is another practice that involves cleansing a place or person with the smoke of certain sacred plants. Some healing ceremonies can involve whole communities. These ceremonies can include music, painting bodies, dancing, exorcisms, sand paintings, stories, and use of mind-altering substances. These ceremonies are a way to seek spiritual assistance and physical healing (NIH, n.d.).

Members of the Native American Church are legally allowed to use peyote, a hallucinogen, during religious ceremonies. It can cause hallucinations and alterations in perceptions of space, time, and self. Physical symptoms include nausea, vomiting, dilated pupils, increased heart rate, elevated blood pressure, perspiration, headaches, muscle weakness, and impaired motor coordination. In rare cases, large doses have been reported to cause bradycardia, hypotension, and respiratory depression (Department of Justice, 2020). Peyote has been used for centuries by American Indians and is considered a sacred plant.

### LINK TO LEARNING

This video from the Harvard Divinity School features a [discussion with Native American Church leaders about the Sacrament of Peyote \(https://openstax.org/r/77peyote\)](https://openstax.org/r/77peyote) and its history in the Indigenous medicine world.

### Hispanic Traditions

Traditional Hispanic medicine is known as *curanderismo*, with the healers called *curandera* (women) or *curandero* (men). The holistic practice of **curanderismo** is rooted in beliefs that health is achieved through the right balance of mind, body, and spirit. A *curandero* focuses not only on the individual's physical health but also on their mental health, diet, personal relationships, and more. *Curanderos* use various healing methods including prayer, oils, herbs, special diets, and other spiritual rituals. They also act as counselors and social workers, listening to individuals talk about their problems and helping them build an emotional support network (Cruz et al., 2022).

### Western European Traditions

The central role of the patient in the healer/patient relationship is foundational to modern Western European healing culture. There is also a strong emphasis on technology and scientific evidence of healing practices.

Traditional European medicine has a strong foundation in using medicines created from natural elements, including herbs, plants, minerals, and animals (Firenzuoli & Gori, 2007; Hosseinzadeh et al., 2015). Homeopathy (an alternative medicine system based on the principle of "like cures like," utilizing highly diluted substances to treat similar symptoms) and naturopathy (focusing on the body's self-healing abilities through holistic approaches like dietary changes, herbal medicine, and lifestyle counseling) both have roots in European tradition. Individuals who rely on herbal and plant-based remedies tend to either use them in conjunction with conventional Western medicine or view them as alternatives to harsher methods of treatment. Examples of these remedies are discussed later in this chapter, in [5.3 Cultural Practice in Nursing](#). Nurses should provide quality education to their patients about clinical evidence of the effectiveness of these complementary and alternative therapies (Leonti & Verpoorte, 2017).

### Counteracting Implicit Bias

Everyone holds biases that reflect their own personal belief systems. An **explicit bias** is a consciously held set of beliefs about a person, situation, or group based on certain characteristics (Sabin, 2022). Explicit bias is what we typically think of when we see or hear the word *bias*. A person might be openly biased against someone due to their age, gender, race, sexuality, or another reason. An overtly racist comment is an example of explicit bias (Sabin, 2022).

In comparison, **implicit bias** refers to all our unconscious biases. Implicit bias is an automatic reaction toward a person, situation, or group involving subconscious feelings, perceptions, attitudes, and stereotypes. You may hold conscious beliefs about equality and fairness while still having unconscious, implicit biases that contradict these beliefs.

Bias negatively affects the patient-provider relationship, leading to poorer quality care and worse outcomes for certain groups. For example, research studies have shown that implicit bias regularly leads to the undertreatment of pain in Black patients (Sabin, 2022). Implicit bias can be difficult to change because it operates at an unconscious level, making individuals often unaware of these biases. The first step in overcoming implicit biases is to become aware of them; training in diversity and inclusiveness can also help identify problematic feelings, thoughts, and behaviors.

## 5.2 Ethical Practice in Culture and Diversity

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify ways to accommodate different cultural practices
- Explain ethical ways to engage in cultural diversity practices
- Define how nurses can be responsive to diversity and inclusion

As discussed in [5.1 Understanding Cultural Differences](#), the concept of culturally competent care, which involves integrating an individual's cultural beliefs into their health care, is an important foundation of cultural competence. Providing culturally competent care requires attention to diversity and inclusion and a willingness to understand and accommodate the cultural differences of others. According to the American Psychological Association (APA) (n.d.), cultural diversity is “the existence of societies, communities, or subcultures that differ substantially from one another.” And, **inclusion** is “the practice of creating an environment in which individuals of all backgrounds feel respected, valued, and supported.”

According to the Centers for Disease Control and Prevention (CDC) (2021), there are eight principles of cultural competence:

1. Define culture broadly.
2. Value patients' cultural beliefs.
3. Recognize complexity in language interpretation.
4. Facilitate learning between providers and communities.
5. Involve the community in defining and addressing service needs.
6. Collaborate with other agencies.
7. Professionalize staff hiring and training.
8. Institutionalize cultural competence.

Note that it is the responsibility of the healthcare professional to seek out, understand, and integrate the patient's beliefs into their care. Ultimately, the goal is to build cultural competence into the permanent framework of health care.

### Accommodating Cultural Practices

According to the American Nurses Association (ANA) Code of Ethics (2015), nurses must practice with cultural humility and inclusiveness. Culture is constantly evolving, so true cultural competence requires a lifetime of learning with these changes. The ANA defines **cultural humility** as “a humble and respectful attitude toward individuals of other cultures that pushes one to challenge their own cultural biases, realize they cannot know everything about other cultures, and approach learning about other cultures as a life-long goal and process.”

There are both intrapersonal and interpersonal components to cultural humility ([Table 5.3](#)) (Hughes et al., 2020).

The **intrapersonal** component consists of a personal awareness of one's own limited knowledge of the patient's culture. The **interpersonal** component involves respect for the patient's culture and openness to their beliefs and experiences. By focusing on developing partnerships with patients, the nurse can create a space that encourages learning and appreciation for diverse cultures. It is a patient-centered way of providing culturally sensitive care.

Interpersonal Skills	Intrapersonal Skills
Involves relations between people	Occurs within the individual mind or self
Two or more parties involved	No external parties involved
Feedback comes from the parties involved	Feedback comes in the form of self-analysis
Important to building and maintaining relationships; must develop self-awareness	Continuous flow of thought; ones' own thoughts, views, opinions, and attitudes are developed

**TABLE 5.3** Interpersonal versus Intrapersonal Skills

### Avoid Forcing Change

Cultural humility involves inclusion. Inclusion means considering the patient's own cultural preferences and involving the patient and caregivers in the process as much as possible. Forcing a patient to accept a treatment plan that conflicts with their cultural practices and beliefs is rarely effective and can damage the relationship of trust between the nurse and the patient. A **cultural negotiation** is a process by which the patient and nurse seek a mutually acceptable way to deal with competing interests of nursing care, prescribed medical care, and the patient's cultural needs. Cultural negotiation is reciprocal and collaborative. When the patient's cultural needs do not significantly or adversely affect their treatment plan, the cultural needs can and should be accommodated.

### Seek Cultural Assistance

Having respectful, curious, in-depth conversations with patients is the best way to learn about their individual cultural practices. When seeking ways to accommodate diverse cultural practices, approach patients with cultural humility to learn how best to care for the patient. Cultural guides from various local communities may also be available for cultural dialogue (Substance Abuse and Mental Health Services Administration [SAMHSA], 2014). Collaboration between patients from diverse cultures and nurses is an excellent way to produce culturally sensitive, patient-centered care plans (Hughes et al., 2020). Examples of seeking cultural assistance include exploring programs and initiatives that may be offered by various organizations, discovering available resources, or developing initiatives for unit-based councils.

### Engagement in Cultural Diversity

As a nurse, it is necessary to actively engage with the patient and their culture to foster cultural competence, build trust, and tailor healthcare services to individual needs. This approach ensures a patient-centered, inclusive, and holistic approach to health care. Cultural negotiation is mutual; the nurse and the patient must gain an understanding of each other's perspective. There are many ways a nurse can actively participate in learning about various cultures to best serve diverse patient populations. Some examples include encouraging the patient to bring food from home and involving the family in medical decision-making.

### Active Learning

One of the first steps in engaging in cultural diversity is to get to know your community—what ethnic groups are most prevalent, what languages are most widely spoken, what religions are most popular? Use sources such as newspapers, journal or book articles, and cultural training seminars or courses to research cultural issues that are relevant to your area. However, it is important to remember not to stereotype or generalize patients. Make sure to ask each patient about their personal preferences when it comes to their cultural background and beliefs (Stubbe, 2020).

Learning about cultural diversity also includes becoming aware of your own practices and implicit biases. There are various implicit bias tests available to help you identify unconsciously held beliefs. Journaling is another way to help

identify and reflect on personal thoughts and feelings toward working with diverse groups.

Awareness of your own practices can help identify and address issues with practices observed in the workplace. For example, your area may have a large Arabic-speaking population, but your clinic does not have consent forms in Arabic. You decide to advocate for your patients and ask the clinic to provide consent forms in Arabic. Another example would be your clinic hosts educational workshops so employees can actively learn about the populations they serve. Learning about the culture of your patient population leads to better patient outcomes and often greater job satisfaction.

### Exploring

Immersing yourself in diverse cultural communities can be an engaging and fun way to learn more about cultural diversity. Attending local cultural events such as festivals and dances, exploring art and music scenes, and even joining religious ceremonies (special permission may be needed) are all ways to experience cultural practices firsthand ([Figure 5.4](#)).

**FIGURE 5.4** Attending cultural festivals, like the annual Carnival celebration of Mardi Gras in Louisiana, is an excellent way to gain firsthand exposure to diverse cultural practices. (credit: “Fat Tuesday\_Mardi Gras Indians\_4,” by Derek Bridges/Flickr, CC BY 2.0)

### Responsiveness to Cultural Diversity

Learning about diverse cultures is only one step toward providing culturally competent care. How one responds to cultural diversity is what directly affects the nurse-patient relationship and outcomes. According to the U.S. Department of Health and Human Services (HHS, n.d.), “being culturally responsive requires having the ability to understand cultural differences, recognize potential biases, and look beyond differences to work productively with children, families, and communities whose cultural contexts are different from one’s own.” Being responsive to cultural diversity involves taking what you have learned about other cultures from conversations, experiences, and research and integrating the knowledge into your practice. It also involves advocating for diversity and inclusion at a structural and institutional level.

### Willingness to Change

Approach the process of learning about diverse cultures with cultural humility. To understand various cultures, one must engage in self-reflection and remain open to new ideas, beliefs, and behaviors. It is normal to encounter beliefs and practices that are different from your own. They may be in direct conflict with your own cultural background and may even make you uncomfortable, sad, angry, or confused. It is not expected that you will completely change all your thoughts and feelings, but a *willingness* to change is key to accepting others and putting cultural competence into action.

## REAL RN STORIES

---

### Recognition of Cultural Biases

**Nurse:** Jenny, RN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 2

**Facility location:** Southern California

At 28 years old, I relocated from Florida to southern California. I am White, and until this point, I had spent my entire life living in Florida. I had been practicing nursing for two years and had just started a new job on a medical-surgical floor at a local hospital. The hospital was located in a community that was known for its large Vietnamese population. Most of the nurses, providers, and patients at the hospital were either Vietnamese immigrants or of Vietnamese descent.

One day I took report on a new patient, a 53-year-old Vietnamese female with a diagnosis of terminal brain cancer. The patient was not expected to survive; however she remained a full code, and the family was refusing hospice (end-of-life care focused on increasing comfort and managing pain). I wondered why the patient and family would refuse hospice care.

As I went to assess the patient, I found her lying in bed and moaning while clutching her head in her hands. She was nonverbal and nonresponsive to my stimuli. I noticed she had an order for pain medication, so I administered it as ordered.

Upon reassessing her, I noticed the medication did not seem to make much difference in the observable behaviors. The patient was still clutching her head in her hands and moaning. The doctor refused to increase the dose at my suggestion and seemed to brush me off when I recommended talking to the family again about comfort measures. I found myself growing increasingly frustrated on behalf of my patient, and I felt she might be suffering unnecessarily at the end of her life.

At lunch, I called the patient's daughter, Viv, and requested she come to the hospital to visit her mother. Upon the daughter's arrival, I had just given the patient some IV pain medication, but the patient was not responding or showing signs of relief. Viv stated, "The pain medication does not seem to be making much of a difference the last couple of days." I asked her if she had considered hospice for her mother and explained that I had found hospice very helpful when my own grandmother was at the end of her life. Viv told me that she had discussed hospice with the physicians but decided against it. "Hospice is not an option for us. In our culture, we believe in fighting with everything we have down to the last minute," she stated. She explained that she and her family viewed the use of medication at end-of-life in hospice care as hastening death.

After having this conversation with Viv, I had a new understanding of why the family was refusing hospice and comfort measures. I now understood how important it was to the patient and the patient's family that their own views on end-of-life care be respected. This conversation allowed me to reexamine my own cultural biases and be more culturally respectful of the patients I was now serving.

---

## 5.3 Cultural Practice in Nursing

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the guidelines for nursing care of different cultural practices
- Explain the importance of cultural competency in nursing
- Recognize factors that can affect diversity and inclusion in nursing

The importance of cultural competence cannot be understated. Cultural competence enables a nurse to deliver the highest quality, safest, and most patient-centered care possible. Establishing a culturally sensitive environment is the first step in providing culturally competent care to patients. An accurate and thorough cultural assessment allows for the gathering of patient-specific cultural information. The pursuit of culturally competent care also requires recognizing the various factors that can affect diversity and inclusion in nursing.

## Guidelines for Nursing Care

Providing culturally competent care integrates an individual's cultural beliefs into their health care. Begin by conveying cultural sensitivity to patients and their family members with these suggestions:

- Set the stage by introducing yourself by name and role when meeting the patient and their family for the first time. Until you know differently, address the patient formally by using their title and last name. Ask the patient how they wish to be addressed and record this in the patient's chart. Respectfully acknowledge any family members and visitors at the patient's bedside.
- Begin by standing or sitting at least arm's length from the patient.
- Observe the patient and family members in regard to eye contact, space orientation, touch, and other nonverbal communication behaviors and follow their lead.
- Make note of the language the patient prefers to use and record this in the patient's chart. If English is not the patient's primary language, determine if a medical interpreter is required before proceeding with interview questions.
- Use inclusive language that is culturally sensitive and appropriate. For example, do not refer to someone as "wheelchair bound"; instead say "a person who uses a wheelchair."
- Be open and honest about the extent of your knowledge of their culture. It is acceptable to politely ask questions about their beliefs and seek clarification to avoid misunderstandings.
- Adopt a nonjudgmental approach and show respect for the patient's cultural beliefs, values, and practices. It is possible that you may not agree with a patient's cultural expressions, but it is imperative that the patient's rights are upheld. As long as the expressions are not unsafe for the patient or others, the nurse should attempt to integrate them into their care.
- Assure the patient that their cultural considerations are a priority of their care.

### Cultural Assessment

After establishing a culturally sensitive environment, nurses should incorporate a cultural assessment when caring for all patients. There are many assessment guides used for patient interviews that are adaptable to a variety of healthcare settings and are designed to facilitate understanding and communication.

The Four Cs of Culture model is an example of a quick cultural assessment tool that asks questions about what the patient **C**onsiders to be a problem, the **C**ause of the problem, how they are **C**oping with the problem, and how **C**oncerned they are about the problem. Use these questions based on the Four Cs model in nurse-patient conversations to conduct a cultural assessment:

1. What do you think is wrong? What is worrying you? (In other words, discover what the patient **C**onsiders to be the problem and what they call it.)
  - Example: A patient with a diagnosis of a sinus infection believes their body is "unbalanced."
2. What do you think **C**aused this problem? How did this happen?
  - Example: The patient believes this illness is a punishment for a misdeed.
3. What are you doing to **C**ope with this problem? How are you taking care of yourself?
  - Example: The patient avoids eating certain foods to treat the illness while also using home remedies such as herbal tea.
4. How serious is this problem for you? How **C**oncerned are you?
  - Example: A patient views the illness as being "God's will" and states, "It's in God's hands."

## PATIENT CONVERSATIONS

### How Do You Perform a Brief Cultural Assessment?

**Scenario:** The nurse enters the patient's room to perform a cultural assessment. The patient is a woman from China who is visiting family in the area and prefers to speak Mandarin. The nurse sets up the video translator to begin the conversation and introduces the translator to the patient.

**Nurse:** Hi, I'm Travis, and I'm going to be your nurse today. Can you please tell me your name and date of birth?

**Patient:** Mei Wang, January 2, 1947.

**Nurse:** What would like for me to call you?

**Patient:** Mrs. Wang is fine.

**Nurse:** Mrs. Wang, I'm here to do a cultural assessment, which involves asking you a few questions. It should take less than 15 minutes. Is that okay?

**Patient:** Yes, that is fine.

**Nurse:** What do you think is wrong? What is worrying you?

**Patient:** The doctors are telling me that I have an infection in my lungs. I haven't been feeling well, and I believe it is because my body is not in balance.

**Nurse:** What do you think caused this problem? How did this happen?

**Patient:** My husband died four months ago, and I left China to live with my son and his family here in the United States. I miss my husband, and everything here is so different compared to what I'm used to.

**Nurse:** Have you been trying things at home to make yourself feel better? How have you been coping?

**Patient:** I've been making some special food. A lot of soup, and other foods with ginger, onion, garlic to help with the phlegm.

**Nurse:** How serious is this problem for you? How concerned are you?

**Patient:** I've never been in the hospital before, so I'm worried, but I think the doctors are good here and will get me home. I want to make sure that my family can bring me food from home, though. I don't like the hospital food, my food from home is much better for me.

**Nurse:** I'll check with your doctor to see if your family can bring your food from home; I'll tell them how much better you like it, okay? My assessment is done for now, do you have any other questions for me?

**Patient:** Not right now, thank you for talking to me.

---

Another, more comprehensive cultural assessment tool, inspired by R. E. Spector's Heritage Assessment Interview, is called the Sample Cultural Assessment Interview and includes these additional questions:

- Where were you born? Where were your parents born?
- What pronoun do you use (he, she, they)?
- In what language are you most comfortable speaking and reading?
- Did you grow up in a city or a town or a rural setting?

### UNFOLDING CASE STUDY

#### Unfolding Case Study #1: Part 6

Refer back to [Unfolding Case Study #1: Part 4](#) to review the patient data.

Nursing Notes	<b>0700: Assessment</b> Patient is awake and alert and reports feeling “much better.” Patient reports anxiety about finances and is worried about being able to feed her family. She states that she makes enough each month to get by, but her mother is getting older and beginning to require more care and medications.
Flow Chart	<b>0700: Assessment</b> Blood pressure: 128/72 mm Hg Heart rate: 87 beats/minute Respiratory rate: 18 breaths/minute Temperature: 99.1°F (37.3°C) Oxygen saturation: 97 percent on room air
Provider's Orders	<b>0745: New orders</b> Discharge after meeting with social worker.

5. Take action: As part of the assessment, the nurse also conducts a cultural assessment. How would the nurse use the Four Cs of Culture model to conduct the assessment on this patient?

6. Evaluate outcomes: How would you determine that the patient's social needs have been addressed sufficiently before discharge home?

### Cultural Knowledge

Acquiring cultural knowledge is another important step toward becoming a culturally competent nurse. The term cultural knowledge refers to seeking information about cultural health beliefs, history, customs, and values to understand patients' worldviews. To acquire cultural knowledge, the nurse actively seeks information about other cultures, including common practices, beliefs, values, and customs, particularly for those cultures that are prevalent within the communities they serve. Cultural knowledge also includes understanding the historical backgrounds of culturally diverse groups in society, as well as physiological variations and the incidence of certain health conditions in culturally diverse groups. Cultural knowledge is best obtained through cultural encounters with patients from diverse backgrounds to learn about individual variations that occur within cultural groups and to prevent stereotyping.

### Standards of Practice

The Transcultural Nursing Society has developed Standards of Practice for Culturally Competent Nursing Care (Douglas et al., 2011). These twelve standards are intended to serve as a universally applicable guide for nurses in all aspects of culturally competent nursing care:

1. Social justice: Nurses must promote and advocate for social justice for all.
2. Critical reflection: Nurses must engage in ongoing, personal, critical reflection of how their cultural beliefs and practices affect their nursing care.
3. Knowledge of cultures: Nurses must understand diverse cultures and factors that affect health and well-being.
4. Culturally competent practice: Nurses must use cross-cultural knowledge and skills in implementing culturally competent nursing care.
5. Cultural competence in healthcare systems and organizations: Healthcare institutions must provide the structure and resources necessary to meet the needs of their culturally diverse patients.
6. Patient advocacy and empowerment: Nurses must empower their patients to navigate the healthcare system and advocate for inclusion of the patient's cultural beliefs in their health care.
7. Multicultural workforce: Nurses must actively work toward having a multicultural workforce in healthcare settings.
8. Education and training in culturally competent care: Nurses must be educationally prepared to promote and provide culturally congruent health care through formal education, clinical training, and continuing education for practicing nurses.

9. Cross-cultural communication: Nurses must use culturally competent communication skills when providing patient care.
10. Cross-cultural leadership: Nurses must strive to influence others to achieve culturally competent care for diverse groups.
11. Policy development: Nurses must work to establish policies and standards for culturally competent care.
12. Evidence-based practice and research: Nurses must base their practice on interventions that have been shown to be effective through evidence-based practice.

### Complementary and Alternative Therapies

Nonmainstream approaches to health that are used alongside conventional Western medical care are called **complementary therapies**. When nonmainstream approaches are used in place of conventional Western medical care, they are called **alternative therapies** (U.S. Department of Health and Human Services [HHS], n.d.a). Conventional therapies are more common than alternative therapies in the United States. Examples of therapies that may be used for complementary or alternative purposes include the use of melatonin for insomnia or acupuncture for muscle pain. It is important for the nurse to perform a thorough medication reconciliation so that complementary or alternative therapies are not missed. Patients may not consider these supplements as “medicines” or “drugs.”

### Nutritional/Supplemental Therapies

Nutritional and supplemental therapies involve the use of dietary approaches and supplements to enhance well-being and address health issues. Dietary supplements, such as vitamins and minerals, are taken to supplement the diet and ensure adequate nutrient intake. Herbal supplements, derived from plants, are believed to have medicinal properties. Probiotics, which are beneficial bacteria that promote gut health, are commonly used as supplements. Fish oil supplements, rich in omega-3 fatty acids, are believed to have cardiovascular benefits. It is crucial for individuals considering these approaches to consult with healthcare professionals to ensure they align with their specific health needs and do not interfere with any existing medical treatments. As these products can interact with drugs, it is important to get a comprehensive list from the patient of all supplements they are taking. For example, St. John’s Wort, a common supplement, is known to interact with numerous different common medications including selective serotonin reuptake inhibitors, certain contraceptives, and digoxin (Mayo Foundation, 2021).

### Physical and Psychological Therapies

Physical and psychological therapies include a wide range of modalities, such as acupuncture, massage therapy, meditation, reiki (a Japanese healing technique that involves the transfer of energy through the practitioner’s hands to promote physical and emotional healing), and qigong (a Chinese practice that combines breath control, gentle movement, and meditation to cultivate and balance the body’s vital energy). Cupping, coining (a traditional East Asian healing technique that involves scraping the skin with a smooth-edged tool, such as a coin or spoon, to promote blood flow and release tension), yoga, art, music, and dance also fall into this category. Acupuncture and cupping are two of the more popular alternative and complementary physical therapy modalities. Acupuncture is used to treat pain and multiple other conditions; it is performed by inserting needles at special points in the body. Acupuncture is intended to restore balance and is thought to work by releasing endorphins, the body’s natural painkillers. Cupping is another traditional therapy where cups are placed on the skin to increase blood flow with the aim of helping with stress or muscle aches and pains (see [Figure 5.5](#)).

**FIGURE 5.5** Blood marks such as these are a normal finding on someone after a cupping session. (credit: “Cupping,” by Renato Ganoza/ Flickr, CC BY 2.0)

### Other Complementary Therapies

There are other complementary therapies that do not fit in either category. These include traditional healers, Ayurvedic medicine, TCM, naturopathy, and homeopathy. Derived from eighteenth- and nineteenth-century European natural healing systems, naturopathy involves a combination of therapies including herbal medicine, diet, acupuncture, and psychotherapy (HHS, 2017). In homeopathy, natural products are used in highly diluted doses to treat illness. Examples include *Arnica montana*, often used for muscle soreness and injuries, or chamomilla, often used for colic, teething, and childhood irritability. Homeopathic products can still include ingredients that can cause significant drug interactions, so they must be noted on the patient’s chart (HHS, n.d.b).

### Cultural Competency

The freedom to express one’s cultural beliefs is a fundamental right of all people. Nurses realize that people speak, behave, and act in many different ways due to the influential role that culture plays in their lives and their view of the world. Cultural competence is a lifelong process of applying evidence-based nursing in agreement with the cultural values, beliefs, worldview, and practices of patients to produce improved patient outcomes.

Culturally competent care requires nurses to combine their knowledge and skills with awareness, curiosity, and sensitivity about their patients’ cultural beliefs. It takes motivation, time, and practice to develop cultural competence, and it will evolve throughout your nursing career. Culturally competent nurses have the power to improve the quality of care leading to better health outcomes for culturally diverse patients. Nurses who accept and uphold the cultural values and beliefs of their patients are more likely to develop supportive and trusting relationships with their patients. In turn, this opens the way for optimal disease and injury prevention and leads toward positive health outcomes for all patients.

### LINK TO LEARNING

A unique and inspiring [discussion about becoming a culturally competent nurse \(https://openstax.org/r/77cultcomp\)](https://openstax.org/r/77cultcomp) is presented in this video.

### Transcultural Nursing

The roots of providing culturally competent care are based on the original transcultural nursing concept developed by nurse and anthropologist, Madeleine Leininger. In **transcultural nursing**, care incorporates the cultural beliefs and practices of individuals to help them maintain and regain health or face death in a meaningful way. It forms the basis of all culturally competent care.

### Theory of Cultural Care Diversity

Leininger’s Theory of Culture Care: Diversity and Universality is also known as the **Culture Care Theory (CCT)**. It

provides the framework for transcultural nursing and the development and practice of culturally competent nursing care (McFarland & Wehbe-Alamah, 2019). Leininger states that health care cannot be effectively provided without considering the patient's cultural background. The theory emphasizes the importance of understanding the cultural values, beliefs, and practices of patients in order to provide appropriate care. According to Leininger, culture is a fundamental component of human life and influences an individual's perception of health, illness, and health care (McFarland & Wehbe-Alamah, 2019). Therefore, healthcare providers must approach each patient with cultural sensitivity and strive to deliver care that is respectful and tailored to the patient's cultural needs. The CCT is an important framework for promoting culturally competent care and achieving health equity for all individuals. Using the CCT as a framework, nurses can guide research of discovery and translational research projects for evidenced-based nursing practice. Educational programs can develop nursing courses and curricula to prepare culturally competent nurses. Hospitals and medical facilities can use the framework to guide future culturally competent administrative and leadership policies and procedures.

### Factors Affecting Diversity and Inclusion in Nursing

The ANA recognizes specific factors that negatively affect diversity and inclusion in nursing. Explicit bias in the form of discrimination due to gender identity, race, ethnicity, sexual orientation, or socioeconomic status negatively impacts the health status of various populations. Implicit bias affects the relationship between healthcare providers and patients, as well as outcomes, even though it is unintentional (Jolley & Peck, 2022). Awareness of one's biases is always the first step in combating them.

#### Cultural Self-Awareness

A person's understanding of their own culture and its impact on self is referred to as **cultural self-awareness**. Understanding self is a crucial step in forming a broader understanding and acceptance of other cultures (Lu & Wan, 2018). To develop cultural awareness, people can educate themselves about diverse cultures, learn to recognize and avoid stereotypes, and engage in cross-cultural communication and interaction. It is important to note that cultural awareness is not a one-time achievement but an ongoing process that requires continuous learning and adaptation. Cultural self-awareness can help us understand what shapes our own values and beliefs and recognize our place in a larger multicultural society.

#### Ethnocentrism

The belief that one's culture (or race, ethnicity, or country) is better than and preferable to another's culture is termed **ethnocentrism**. An example would be a nurse telling a patient that conventional Western medical treatments are better than traditional healing remedies. Appropriate cultural self-awareness can help the nurse avoid ethnocentrism. Designing interventions that are relevant to and respectful of the patient's culture is one way to avoid ethnocentrism. Other ways to avoid ethnocentrism include avoiding generalizations or stereotypes about diverse cultures. Approach cultural differences with an open mind, a readiness to learn and understand, and a willingness to consistently engage in each patient interaction with cultural humility and active-listening.

#### Six Cultural Phenomena

There are other cultural considerations that can affect efforts to increase diversity and inclusion in nursing, which Giger and Davidhizar identify in their Transcultural Assessment Model (2002). The Transcultural Assessment Model was developed as a way for nurses to assess and provide care for culturally diverse patients. This model states that each individual is unique and should be assessed according to six cultural phenomena:

- **Communication:** This includes the language, tone, and nonverbal cues used by the individual and the healthcare provider. Communication styles can vary across cultures and can impact the effectiveness of healthcare interactions.
- **Personal space:** All communication occurs in the context of space. There are four distinct zones of interpersonal space intimate, personal, social/consultative, and public ([Figure 5.6](#)) (Hall, 1966). This includes the physical and emotional distance between the individual and the healthcare provider. Cultural norms around personal space and touch can vary across cultures.

**FIGURE 5.6** There are four zones of interpersonal space that vary depending on cultural norms. How much space is acceptable varies across cultures. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

- **Social organization:** This includes the individual's cultural values and beliefs related to family, community, and social roles. Cultural expectations around family involvement in healthcare decisions, for example, can vary across cultures. Another example is local, state, or government agencies that all share the same values, beliefs, and interests.
- **Time orientation:** Time is an important aspect of interpersonal communication. This includes the individual's cultural beliefs and practices related to time, such as punctuality and the perception of time as linear or cyclical. For example, the past, present, and future have different meanings and value to different cultures.
- **Environmental control:** This includes the individual's cultural beliefs and practices related to controlling their environment, such as beliefs around the causes of illness and how it is directly impacted by one's environment.
- **Biologic variations:** This includes the individual's cultural beliefs and practices related to biology, such as beliefs around the causes of illness and the use of alternative therapies. Cultural beliefs around pain management and the use of medication can also vary across cultures.

## CULTURAL CONTEXT

### Patients and Personal Space

The amount of space that a person surrounds themselves with to feel comfortable is influenced by culture. For example, for some people, it would feel awkward to stand four inches away from another person while holding a social conversation, but for others a small personal space is expected when conversing with another. There are times when a nurse must enter a patient's personal space, which can cause emotional distress for some patients. The nurse should always ask for permission before entering a patient's personal space and explain why and what is about to happen.

Patients may also be concerned about their modesty or being exposed. A patient may deal with the violation of their space by removing themselves from the situation, pulling away, or closing their eyes. The nurse should recognize these cues for what they are, an expression of cultural preference, and allow the patient to assume a position or distance that is comfortable for them.

Similar to cultural influences on personal space, touch is also culturally determined. This has implications for nurses because it may be inappropriate for a male nurse to provide care for a female patient and vice versa. In some cultures, it is also considered rude to touch a person's head without permission.

## 5.4 Diversity, Equity, and Inclusion

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define important considerations related to providing equal, diverse, and inclusive nursing care
- Identify factors that can prevent diversity and inclusion
- Explain how barriers to communication affect diversity and inclusion

Diversity and inclusion create an environment that encourages different ideas, cultures, backgrounds, and experiences. This type of environment allows nurses to provide more comprehensive and effective care to their patients. Diversity, equality, and inclusion foster a culture of mutual respect, understanding, and support which can lead to improved patient outcomes. Additionally, diversity and inclusion can help to reduce health disparities which can improve healthcare access and quality for communities that are traditionally underserved. Ultimately, diversity and inclusion are critical components of successful nursing practice that can help to ensure that all patients receive the best possible care.

### Equality

The principle of ensuring that all individuals, regardless of their background or socioeconomic status, have equal access to healthcare resources and opportunities is called **health equality** (CDC, 2022b). When everyone has a fair opportunity to obtain optimal health, **health equity** is achieved (CDC, 2022a). Both equity and equality are important considerations when providing inclusive nursing care (Figure 5.7).

**FIGURE 5.7** Health equality is providing the same resources and opportunities to all individuals, while health equity is ensuring that everyone has access to the resources they need to attain the same level of health, addressing systemic disparities and promoting fairness. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

A standard linked to fairness for all in society is **justice**, a principle and moral obligation to act on the basis of equality and equity. The ANA states this obligation guarantees not only basic rights (respect, human dignity, autonomy, security, and safety) but also fairness in all operations of societal structures. This includes care being delivered with fairness, rightness, correctness, unbiasedness, and inclusiveness while being based on well-founded reason and evidence.

The CDC (2022a) discusses diversity and inclusion as important factors in health equity considerations. Diversity refers to the existence of societies, communities, or subcultures that differ substantially from one another. Cultural competence means respecting and appreciating these similarities and differences. Inclusion is the practice of creating an environment in which individuals of all backgrounds feel respected, valued, and supported (CDC, 2022b). There are numerous factors that can prevent diversity, inclusion, and justice. These can in turn create health disparities that limit access to care and decrease outcomes for certain groups.

### Race/Ethnic Heritage

Race is a socially constructed idea because there are no true scientifically or biologically distinct races. Humans are not biologically different from each other. However, race and ethnicity have an undeniable effect on healthcare access and outcomes. In **racism**, it is presumed that races are distinct from one another and that there is a

hierarchy to race, implying that races are unequal. As healthcare providers, nurses have an obligation to recognize the impact of racism on their patients and the communities they serve. In the United States, race and ethnic background have long played a role in health disparities among different populations.

Most underrepresented populations experience higher rates of chronic disease and premature death compared to the rates among White populations; however, some individuals from underrepresented groups, such as Asian and Hispanic immigrants, experience lower rates (National Academies of Sciences, Engineering, and Medicine, 2017a). American Indian, Alaska Native, and Black populations experience the highest infant mortality rates, while Asian and Pacific Islander populations experience the lowest (Figure 5.8). Black people are more likely than White people to die prematurely from heart disease, and Black men are twice as likely as White men to die prematurely from stroke.

**FIGURE 5.8** Infant mortality rates by race and ethnicity for the United States illustrate discrepancies between groups. (data source: Center for Disease Control and Prevention; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Implicit bias related to race and ethnicity has been repeatedly shown in research to negatively affect patient care and outcomes. Nurses should also be sensitive to the fact that individuals from certain ethnicities may be distrusting of healthcare professionals due to cultural history and other factors.

### Religion

Throughout human history, spirituality and health have often gone hand-in-hand. In many healing traditions, healers also serve as religious leaders (Figure 5.9). Many people consult and rely on their religious and spiritual beliefs when making medical decisions. For instance, Jehovah's Witnesses do not accept whole blood, plasma, and platelets because they believe that this might interfere with eternal salvation; they believe it is against God's will to accept blood products and will therefore not allow blood transfusions. A person's religious beliefs can affect their diet, what medications they will take, and approaches to death and dying. Healthcare providers must be prepared to take patients' religious and spiritual preferences into account as an important part of the treatment plan (Swihart et al., 2022). A thorough cultural assessment should include information on a patient's religious or spiritual beliefs that might affect their care.

**FIGURE 5.9** Religion and health are closely intertwined for many people. (credit: “Guatemalan Clergymen Lead Sunday Mass Aboard USNS Comfort” by Navy Medicine/Flickr, Public Domain)

### Age

Older adults struggle with some limitations in their care related to their age. Studies have shown that healthcare providers are more likely to assume that older patients’ conditions, such as cognitive decline, are due to their age and to deny them certain treatments as compared to younger patients (Hughes et al., 2020). Older patients also tend to be undertreated for pain and depression. Older adults are more likely to live in poverty and have limited access to transportation, which can make it difficult to get to medical appointments.

### Gender Identity and Sexual Orientation

A person’s inner sensibility that they are a man, a woman, or perhaps neither is **gender identity**. The term **cisgender** is used to describe a person whose identity matches their sex assigned at birth. To the extent that a person’s gender identity does not conform with the sex assigned to them at birth, they may identify as transgender or as gender nonbinary. The term transgender refers to someone whose gender identity or expression differs from traditional cultural gender roles for one’s sex assigned at birth. Transgender people, like cisgender people, may be sexually oriented toward men, women, both sexes, or neither sex. Gender expression refers to a person’s outward demonstration of gender in relation to societal norms, such as in style of dress, hairstyle, or other mannerisms. Sharing pronouns as part of a basic introduction to a patient can assist a transgender patient to feel secure sharing their pronouns in a healthcare setting. Asking a patient for their pronoun (he, she, they, ze) is considered part of a nursing assessment.

There is a strong body of research showing a history of gender bias in health care (Hughes et al., 2020). Providers are more likely to believe that the health complaints of women result from emotional instead of physical causes compared to men. There is also a demonstrated history of underdiagnosis and undertreatment of cardiovascular disease in women when compared to men.

A person’s physical and emotional interest or desire for others is their sexual orientation. Sexual orientation is on a continuum and is manifested in one’s self-identity and behaviors. The acronym LGBTQIA+ stands for lesbian, gay, bisexual, transgender, queer or questioning, intersex, or asexual in reference to sexual orientation. (The “+” is sometimes added after LGBTQIA+ to capture additional orientations.) Historically, individuals within the LGBTQIA+ community have experienced discrimination and prejudice from healthcare providers and avoided or delayed health care due to these negative experiences. Despite increased recognition of this group of people in recent years, members of the LGBTQIA+ community continue to experience significant health disparities.

### Disability

Disabilities can be present from birth or acquired later in life. They can be physical, cognitive, or mental health related. Adults with disabilities are more likely than adults with no disabilities to report poor health, including higher

rates of obesity, diabetes, smoking, lack of physical activity, and cardiovascular disease. Adults with disabilities are also more likely to live in poverty, and even those with health insurance are less likely than adults without disabilities to seek care. Adults with disabilities also cite common stereotypes, bias, and beliefs among providers as barriers to care (VanPuymbrouck et al., 2020). Examples include lack of appropriate equipment to transfer patients with disabilities, or a healthcare provider's assumption that the patient is unhealthy or fragile simply because they have disabilities.

### Education Level

Differences in educational levels can affect how people access healthcare services and understand health information to make informed decisions. The higher a person's level of education, the higher is their life expectancy and the more likely they are to access preventative and screening services (Viinikainen et al., 2022). People with lower education levels are more likely to have higher weight and to engage in risky activities such as smoking and heavy drinking (Viinikainen et al., 2022). In the United States, the health disparities between the most educated and least educated people have been increasing over the last forty years, leading to an increasing discrepancy in morbidity and mortality rates among these groups (Viinikainen et al., 2022).

### Physical Characteristics

Certain physical characteristics have the potential to create barriers to care. Patients who are deaf or blind may need accommodations to ensure that communication is clear and accurate. American Sign Language interpreters can be sought for patients who are deaf. Educational materials and consent forms printed in Braille can assist blind populations.

### Socioeconomic Status

In the United States, socioeconomic status is a major determinant of health status. Individuals from low socioeconomic groups, including those experiencing homelessness or living in poverty, are prone to higher rates of diseases like heart disease, diabetes, stroke, and obesity (Baggett et al., 2013; Fazel et al., 2014; National Academies of Sciences, Engineering, and Medicine, 2017b). This is attributed to their limited opportunities for early prevention and a lack of resources to adhere to standard treatment plans (Baggett et al., 2013; Fazel et al., 2014; National Academies of Sciences, Engineering, and Medicine, 2017b). For instance, someone experiencing homelessness is unable to perform clean dressing changes daily without adequate access to water. They also have higher rates of infant mortality, substance misuse, and shorter life expectancies. Additionally, they may report avoiding care because they feel discrimination from healthcare workers (Hughes et al., 2020).

In 2021, the majority of Americans relied on privately purchased insurance for their health care. Most of this insurance is made available through employers. About 35 percent of the population holds a public form of insurance in the form of Medicaid or Medicare. Medicare is for those who have been determined to need special care such as older people or those who experience certain disabilities. Medicaid is for those who need aid in receiving care, such as people who meet certain low-income guidelines (Keisler-Starkey & Bunch, 2022).

### Veteran Status

Military veterans often have complex needs due to physical and psychological trauma sustained during military service and socioeconomic issues that arise after discharge ([Figure 5.10](#)). Many veterans struggle with a lack of access to healthcare benefits, sometimes based on residing in rural locations that do not have veteran-specific healthcare facilities. The Veterans Administration offers free health care to veterans who meet certain low-income guidelines, allowing these patients to be seen at any facility.

**FIGURE 5.10** Veterans are an especially at-risk population who often have complex needs. (credit: “210512-N-QB805-0110” by Navy Medicine/Flickr, Public Domain)

### Factors Preventing Sensitivity to Diversity

Sensitivity to diversity can be hindered by several factors that are related to a person’s experiences, attitudes, and knowledge. One significant factor is a lack of exposure to diverse individuals and cultures. Limited exposure can lead to a lack of understanding and appreciation for diversity. Stereotyping and prejudice can also contribute to insensitivity, as preconceived notions or stereotypes about certain groups can lead to discrimination and bias. Personal biases can influence perceptions and attitudes toward different groups, leading to insensitivity. Additionally, a lack of education or awareness about different cultures and backgrounds can lead to misunderstandings. Overcoming these barriers requires ongoing education, open-mindedness, and a willingness to learn about and appreciate different cultures and backgrounds. It also requires actively challenging one’s biases and seeking out opportunities for exposure to diversity.

#### Stereotyping

The assumption that a person has the attributes, traits, beliefs, and values of a cultural group because they are a member of that group is termed **stereotyping**. Engaging in stereotyping prevents the ability to identify people’s needs on an individual level. One common stereotype is the assumption that all older patients are forgetful or have memory problems. This stereotype can lead to medical professionals overlooking or dismissing legitimate concerns or symptoms of older patients, attributing them solely to age-related memory decline, which can in turn lead to misdiagnosis or delayed treatment. Stereotypes can be harmful to patients and must be avoided. Culturally competent care extends beyond general knowledge of a cultural group to knowledge of the individual themselves.

#### Cultural Imposition

The imposition of one’s own values, beliefs, and practices upon another person or group is **cultural imposition**. Cultural imposition runs counter to cultural humility and can manifest in various ways. Examples include disregarding a patient’s cultural practices, beliefs, and values when making medical decisions, or imposing Western medical practices on non-Western cultures without consideration for their unique cultural beliefs and practices. For instance, healthcare providers may fail to consider a patient’s traditional healing practices or the role of family members in healthcare decisions, which can lead to a breakdown in communication and a lack of trust between patients and healthcare providers. Cultural awareness can help the nurse recognize their own biases and avoid

cultural imposition.

### Cultural Blindness

The belief that all cultural groups are the same and share identical experiences is **cultural blindness** (Bhattacharya et al., 2019). Different cultural groups can have vastly different experiences within the healthcare system. Cultural blindness might lead a nurse to conclude that all treatment services are adequate for all patients, contributing to the continuation of policies that prevent diversity and inclusion. For instance, a hospital might stock consent forms available in English and Spanish exclusively. However, despite a significant local Vietnamese population, the nurse consistently faces difficulty in locating consent forms in Vietnamese for these patients. This is a result of system-wide cultural blindness. Once the nurse identifies the issue, they can escalate it and have the issue addressed by having adequate Vietnamese-language consent forms available for the patient population.

To address cultural blindness in health care, providers should receive regular cultural competency training and actively work to understand and respect the diverse backgrounds of their patients. This includes learning about cultural beliefs and practices related to health and illness, as well as developing effective communication strategies that bridge language and cultural barriers.

### Culture Conflict

A **culture conflict** occurs when there is tension or opposition between different cultures. Often, the dominant culture weakens the cultural practices of the minority group as a result (APA, n.d.b). Culture conflict can arise in many ways, such as when a patient's cultural beliefs around illness and healing differ from those of the healthcare provider, or when a patient's cultural practices conflict with medical protocols. For example, a patient who refuses to receive a blood transfusion due to religious beliefs may have conflict with the nurse who sees this treatment as medically necessary.

Culture conflict can also arise when healthcare providers make assumptions or judgments about patients based on their cultural background, leading to biases and discrimination. This can result in disparities in healthcare access and outcomes for patients from diverse backgrounds. Nurses should approach such conflicts with cultural humility to ensure they are resolved without damage to the nurse-patient relationship.

### Barriers to Communication

It is necessary to overcome communication barriers to maximize the patients' opportunities for the highest quality care. According to the Agency for Healthcare Research and Quality (2020), approximately three out of 100 people in the United States have a hearing disability, and two out of 100 have a visual disability to the extent that they are blind or have trouble seeing even with corrective vision wear. Various strategies can help improve the communication process for these patients.

For patients with hearing barriers, offer print materials, text telephones (TTYs), or videos with captioning. Sign language interpreters use American Sign Language or Signed English; there are also oral and cued-speech interpreters who use articulation and gestures. When having conversations, make sure the television or other sources of background noise are silenced and the surrounding environment is free of distracting noise.

For patients with sight barriers, make sure that the lighting is at their comfort level. Whenever possible, provide assistance in the form of audio recordings, large-print materials, and screen magnifiers. Text-to-speech or Braille output screen reading software is also available.

### Linguistic Competence

According to a recent study, nine percent of the U.S. population has limited English proficiency (Agency for Healthcare Research and Quality [AHRQ], 2020). Linguistically competent care aims to help reduce these discrepancies. The AHRQ defines linguistic competence as "providing readily available, culturally appropriate oral and written language services to limited English proficiency members through such means as bilingual/bicultural staff, trained medical interpreters, and qualified translators" (AHRQ, 2019).

Educational materials, instructions, and consent forms should be offered in the patient's preferred language and written using simple language. When caring for a patient whose primary language is not English and they have a limited ability to speak, read, write, or understand the English language, seek the services of a trained medical interpreter. Healthcare facilities are mandated by The Joint Commission to provide qualified medical interpreters.

Use of a trained medical interpreter is linked to fewer communication errors, shorter hospital stays, reduced thirty-day readmission rates, and improved patient satisfaction.

Refrain from asking a family member to act as an interpreter. The patient may withhold sensitive information from them, or family members may possibly edit or change the information provided. Unfamiliarity with medical terminology can also cause misunderstanding and errors.

Medical interpreters may be on-site or available by videoconferencing or telephone. The nurse should also consider coordinating patient and family member conversations with other healthcare team members to streamline communication, while being aware of cultural implications such as who can discuss what healthcare topics and who makes the decisions. When possible, obtain a medical interpreter of the same gender as the patient to prevent potential embarrassment if a sensitive matter is being discussed.

Some additional guidelines for working with a medical interpreter are as follows:

- Allow extra time for the interview or conversation with the patient.
- Whenever possible, meet with the interpreter beforehand to provide background.
- Document the name of the medical interpreter in the progress note.
- Always face and address the patient directly, using a normal tone of voice. Do not direct questions or conversation to the interpreter.
- Speak in the first person (using “I”).
- Avoid using idioms, such as, “Are you feeling under the weather today?” Avoid abbreviations, slang, jokes, and jargon.
- Speak in short paragraphs or sentences. Ask only one question at a time. Allow sufficient time for the interpreter to finish interpreting before beginning another statement or topic.
- Ask the patient to repeat any instructions and explanations given to verify that they understood.

## Summary

### 5.1 Understanding Cultural Differences

Culture is a set of beliefs, attitudes, and practices shared by a group of people or community that is accepted, followed, and passed down to other members of the group. An individual's cultural background influences their beliefs, feelings, and attitudes toward health care. Their culture informs how they view health and illness, how they view healthcare providers, and how receptive they are to treatment plans. Culture also determines who receives care and the quality of their care. Certain cultures experience higher rates of disease due to genetics or health disparities caused by socioeconomic factors. Various cultures have their own traditional healing practices and beliefs, and many people still use these practices either alongside or in place of Western medicine. Nurses often care for patients from cultures different than their own, with different beliefs and practices. Respecting individual differences and staying mindful of both explicit (conscious) and implicit (unconscious) biases are crucial to counteract such biases and ensure the delivery of optimal care.

### 5.2 Ethical Practice in Culture and Diversity

Accommodating diverse cultural practices begins with the practice of cultural humility. By seeking cultural assistance from appropriate sources and practicing cultural negotiation, the nurse can demonstrate respect for diverse cultures. Engaging in cultural diversity practices can range from one-on-one conversations with patients, to researching written history, to actively participating in different cultural activities and experiences. Being responsive to cultural diversity involves understanding cultural differences and being willing to overcome personal biases to accommodate the cultural preferences of a patient in order to provide the most culturally competent care.

### 5.3 Cultural Practice in Nursing

When providing care for patients from diverse cultural practices, it is necessary to perform a thorough cultural assessment to gain information on patient-specific details. The Transcultural Nursing Society developed Standards of Practice for Culturally Competent Nursing Care, which serve as universally applicable guidelines for nurses in all aspects of culturally competent nursing care. Cultural competency is important because it has the power to improve the quality and safety of care and lead to better health outcomes for culturally diverse patients. Various factors can impact diversity and inclusion in nursing, including the six cultural phenomena: communication, space, social organization, time, environmental control, and biological variations. The best way to counteract this is to identify biases and change practices going forward.

### 5.4 Diversity, Equity, and Inclusion

Important considerations related to providing equal, diverse, and inclusive nursing care include health equity and health disparities. The nurse should be aware of possible disparities in the patient population and strive to foster a culture of mutual respect, understanding, and support, which can lead to improved patient outcomes. Factors that can prevent diversity and inclusion include stereotyping, cultural imposition, cultural blindness, and culture conflict. Barriers to communication can affect diversity and inclusion by causing barriers to inclusion related to language, literacy, and accessibility for all patients, not just deaf and blind patients.

## Key Terms

**alternative therapies** nonmainstream approaches that are used in place of conventional Western medical care

**Ayurveda** a traditional Hindu form of medicine from India that is based on the idea that disease is caused by an imbalance in the body

**cisgender** relating to or being an individual whose gender identity aligns with the biological sex they were assigned at birth

**collectivism** when a culture emphasizes the importance of the community over the individual

**complementary therapies** nonmainstream approaches to health that are used alongside conventional Western medical care

**cultural blindness** the belief that all cultural groups are the same and share identical experiences

**cultural competence** ability to respect and understand one's own beliefs and values as well as how these values and beliefs may differ between cultures

**cultural humility** a humble and respectful attitude toward individuals of other cultures that pushes one to

challenge their own cultural biases, realize they cannot know everything about other cultures, and approach learning about other cultures as a lifelong goal and process

**cultural imposition** the imposition of one's own values, beliefs, and practices upon another person or group

**cultural knowledge** seeking information about cultural health beliefs and values to understand patients' worldviews

**cultural negotiation** a process by which the patient and nurse seek a mutually acceptable way to deal with competing interests of nursing care, prescribed medical care, and the patient's cultural needs

**cultural self-awareness** a person's understanding of their own culture and its impact on themselves

**culturally competent care** health care that incorporates and values a patient's culture when caring for the patient

**culture** the common beliefs, values, symbols, language, behaviors, and practices that unite a group

**Culture Care Theory (CCT)** (also known as Theory of Culture Care: Diversity and Universality) framework for transcultural nursing and the development and practice of culturally competent nursing care

**culture conflict** tension or opposition between different cultures

**curanderismo** a holistic practice rooted in beliefs that health is achieved through the right balance of mind, body, and spirit

**ethnocentrism** the belief that one's culture (or race, ethnicity, country) is better than and preferable to another's

**explicit bias** a consciously held set of beliefs about a particular person, situation, or group of people based on characteristics

**gender identity** a person's deeply felt, internal and individual experience of gender, which may or may not correspond to the person's physiology of designated sex at birth

**health disparity** differences in health outcomes that result from social determinants of health

**health equality** the principle of ensuring all individuals, regardless of their background or socioeconomic status, have equal access to healthcare resources and opportunities

**health equity** when everyone has a fair opportunity to obtain optimal health

**implicit bias** an automatic reaction toward a person, situation, or group of people involving subconscious feelings, perceptions, attitudes, and stereotypes

**inclusion** the practice of creating an environment in which individuals of all backgrounds feel respected, valued, and supported

**individualism** when a culture focuses on the importance of the individual over community

**interpersonal** component of cultural humility that involves respect for the patient's culture and openness to their beliefs and experiences

**intrapersonal** component of cultural humility that consists of a personal awareness of one's own limited knowledge of the patient's culture

**justice** a principle and moral obligation to act on the basis of equality and equity

**racism** the belief that races are distinct from one another and that there is a hierarchy to race, implying that races are unequal

**social determinants of health (SDOH)** economic, social, and environmental factors that influence an individual's health and well-being

**stereotyping** the assumption that a person has the attributes, traits, beliefs, and values of a cultural group because they are a member of that group

**Traditional Chinese Medicine (TCM)** an ancient practice based on the ideas of Qi and yin and yang

**traditional healing** various medicines and healing practices around the world that differ from the modern, Western healthcare system

**transcultural nursing** nursing that incorporates cultural beliefs and practices of individuals to help them maintain and regain health or to face death in a meaningful way

## Assessments

### Review Questions

1. What is the term used to refer to the integration of an individual's cultural beliefs into their health care?
  - a. cultural integrity
  - b. culturally competent care
  - c. holistic care

- d. integrative care
2. A patient is admitted to the medical-surgical floor for uncontrolled hypertension. He is a seventy-five-year-old Hispanic man who speaks fluent English. He tells the nurse that he has been seeing a curandero, or traditional healer, for his health issues for the last several years. What is the best initial response from the nurse?
    - a. Ask the patient for a list of all herbs, plants, and special diets that he is currently taking.
    - b. Educate the patient on why adherence to a Western medical treatment plan is better for his health.
    - c. Inform the patient that the treatment he has been receiving from the curandero is not evidence based.
    - d. Tell the patient he is welcome to continue whatever traditional treatments he likes while he is in the hospital.
  3. You are a nurse and have just finished taking a course on identifying implicit bias. You decide to journal after one of your shifts to reflect on any possible instances of implicit bias in your workday. What might an interaction reflecting implicit bias look like?
    - a. You are frustrated when you learn during report that one of your patients is an 82-year-old male with dementia who is forgetful, difficult to redirect, and often agitated.
    - b. You learn that one of your patients went to another high school in your hometown. You rush through your medication pass so you can spend some extra time talking to this patient.
    - c. One of your patients is a 59-year-old female from Syria. During report, the patient's previous nurse explains to you that the patient's husband is at the bedside and that when the patient is questioned, he usually answers the questions for her. The nurse states "I think it's really sexist, but they are from the Middle East."
    - d. You enter the room of your patient who is a 23-year-old Black female with a history of alcohol misuse. She is on alcohol withdrawal protocol and has orders for frequent vital signs. She shares with you her drinking history and how difficult it is for her to stop. You empathize with her and tell her you are supportive of her efforts to get sober.
  4. What is the term used to describe nonmedical factors that influence health outcomes, including conditions in which people are born, grow, work, live, and age, and the wider sets of forces and systems shaping the conditions of daily life?
    - a. environmental influences
    - b. life circumstances
    - c. situational occurrences
    - d. social determinants of health
  5. A process where the patient and nurse seek a mutually acceptable way to deal with competing interests of nursing care, prescribed medical care, and the patient's cultural needs is known as cultural negotiation. What would be an example that demonstrates cultural negotiation?
    - a. a nurse insisting the patient shave his facial hair
    - b. a nurse demanding daily medication be taken at 0900, when the patient wakes daily at 0500
    - c. a nurse planning to keep the patient's hijab in place for a surgical procedure
    - d. a nurse requesting a special religious healer visit the patient after admission
  6. While learning about Chinese culture and attending local presentations on culturally competent care, you discover a local event happening in your area. You decide to ask a group of coworkers to join you in attending a local Chinese New Year parade. This is an example of engaging in what type of cultural diversity practice?
    - a. active learning
    - b. interpersonal awareness
    - c. intrapersonal awareness
    - d. willingness to change
  7. What is an example that illustrates being culturally competent?

- a. attending an Indian dance night at a local community center
  - b. educating the patient on your own cultural practices
  - c. implementing a system to improve cardiovascular health screening procedures for Black women at your hospital
  - d. insisting a patient answer your questions instead of her husband answering
- 8.** What is an example of cultural humility?
- a. a nurse allowing a non-English-speaking patient's son to translate for them
  - b. a nurse listening to a patient who is pregnant explain why they want a traditional midwife from their own culture present in the room while they are delivering their baby
  - c. a nurse administering a new medication to a patient with limited English, even though the translator is late, so that it can be given on schedule
  - d. a nurse giving the patient discharge paperwork printed in their preferred language because they do not have time to verbally discuss discharge instructions with the patient
- 9.** What is the purpose of the Theory of Culture Care: Diversity and Universality?
- a. to provide a framework for transcultural nursing and the development and practice of culturally competent nursing care
  - b. to explain the many cultural differences that exist among communities
  - c. to shape the beliefs of nurses regarding certain health- and wellness-related customs among historically marginalized communities
  - d. to provide patients with a way to address health disparities and systemic inequality in the healthcare system
- 10.** Taking a test to examine your own implicit biases is an example of which of the twelve standards of practice for culturally competent nursing care?
- a. critical reflection
  - b. culturally competent practice
  - c. knowledge of cultures
  - d. social justice
- 11.** According to Giger and Davidhizar's Six Cultural Phenomena, all communication exists in the context of which factor?
- a. biology
  - b. environment
  - c. space
  - d. time
- 12.** What is one important purpose of cultural competency?
- a. to improve the quality of care leading to better health outcomes for culturally diverse patients
  - b. to ensure that the predominant cultural voices in a community are the ones who shape healthcare practices
  - c. to prevent unscientific beliefs from influencing important medical decisions
  - d. to provide education to cultural communities on how they can best adapt their practices to suit the modern healthcare system
- 13.** What term describes the state in which everyone has a fair and just opportunity to obtain their highest level of health?
- a. health equality
  - b. health equity
  - c. fairness
  - d. justice

14. You receive report from another nurse who tells you that your patient is an 82-year-old Chinese female. You know that you will have a good day with this patient as older Asian women are usually very polite, easy to get along with, and compliant with your requests. What prevents you from recognizing diversity and inclusion?
  - a. cultural application
  - b. cultural blindness
  - c. ethnocentrism
  - d. stereotyping
  
15. You have a patient who is Spanish-speaking only, and you are required to obtain their signature on a consent form. The patient requests that their family member interpret for them. What is the most appropriate response?
  - a. Ask the family member to leave the room and use an official translator.
  - b. Find an official translator to assist with the conversation along with the patient and family member.
  - c. Proceed with allowing the family member to interpret.
  - d. Tell the patient that you are only allowed to use official translators or interpreters.

### Check Your Understanding Questions

1. Describe ways in which a nurse can provide culturally sensitive nursing interventions for a patient in pain.
2. Describe how a nurse can overcome implicit bias.
3. List some specific ways in which to engage in cultural diversity practices.
4. What are some ways to demonstrate responsiveness to diversity and inclusion?
5. Describe the steps to beginning a culturally sensitive nursing assessment.
6. List five different types of alternative and complementary therapies.
7. Why do you think the Transcultural Nursing Society included Multicultural Workforce as one of their Twelve Standards of Practice for culturally competent care?
8. Describe the guidelines for working with a medical interpreter.

### Reflection Questions

1. Why is it important for nurses to be aware of the health practices associated with various cultures?
2. Why is cultural humility such an important part of cultural competence?
3. The concept of cultural blindness is the belief that all cultural groups are the same and share identical experiences. How would experiencing cultural blindness be a barrier to diversity and inclusion?

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #1: Part 4](#).  
How would you react if the patient requested to perform a traditional healing method including prayer, candles, and herbs during their stay in the hospital?
2. Refer to [Unfolding Case Study #1: Part 6](#).  
What are some ways the nurse could display cultural competence when caring for the patient?

### What Should the Nurse Do?

1. Francine, a new graduate nurse, was offered a full-time position on the dialysis floor of an acute care hospital. The new hire process includes a six-week training program that allows the new hire to observe and work closely with a seasoned employee. On Francine's first shift, she realizes that she has been assigned to shadow Muhammad. Muhammad has been an employee for over ten years and was awarded Nurse of the Year two years ago. Francine notices that with each patient interaction, he educates the patient on both conventional Western medical treatments and traditional healing remedies. Francine is very confused; she

thought that Western medicine was superior to that of traditional healing practices. She decides to confront Muhammad. If you were Muhammad, how would you explain to Francine that her thought process is impacting diversity and inclusion?

2. The nurse is assigned to care for a patient whose background differs from their own and wants to make sure to identify factors that can prevent diversity and inclusion when assessing the needs for this patient and family. What factors should the nurse consider?
3. A new graduate nurse takes a job with a travel company and for the first time leaves her southern state. She is stationed in an area that primarily serves a Jewish-based population. She has never cared for this population but wants to learn as much as possible while on this assignment. After analyzing content from this chapter, apply some factors that can prevent the nurse from achieving diversity and inclusion in her new setting. How would the nurse achieve incorporating these factors?

### Competency-Based Assessments

1. Use various sources to research diverse cultural communities in your region. Note important cultural factors such as language, race/ethnicity, and religion. Discuss how these cultural factors might impact the abilities of these diverse communities to access health care.
2. Identify a diverse cultural event in your community in which you can actively participate, such as a meal, dance, or festival. Attend the event and write a journal entry about your experience. What did you learn about diversity at this event? Did it help you to identify any implicit biases? What lessons will you take with you as you begin your nursing practice?
3. Have you ever experienced or witnessed an interaction where there was a lack of cultural competency? What factors caused the lack of cultural competency? Discuss how you can use your experiences to ensure better diversity and inclusion in nursing.
4. Develop a fifteen-minute presentation on an alternative or complementary therapy.

## CHAPTER 6

# Promoting Individualized Care

**FIGURE 6.1** Healthcare workers and patients work together to provide patient-centered, holistic, and person-centered care. (credit: “Patient Walking With Nurses” by NIH Clinical Center/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

- 6.1 Patient-Centered and Holistic Health Care
- 6.2 Foundations for Providing Person-Centered Care

**INTRODUCTION** In the 1970s, psychiatrist George Engel developed the biopsychosocial model of illness. Engel used Carl Rogers’s theory of person-centered therapy as his foundational framework. Engel’s theory was a different medical model than what was trending at the time; it focused on how disease and illness affected multiple dimensions of a person. Engel believed for a person to be fully healed, the mind, body, and soul must be treated equally. His approach was that illness affects multiple parts of a person at once. He believed regardless of which bodily processes were affected, a person’s psychosocial aspect would be affected at the same time. For instance, a person diagnosed with a mental disorder experiences changes in brain chemistry (bodily process), but they will also experience difficulties interacting with other people (psychosocial). While Engel’s biopsychosocial model wasn’t very popular at the time of its development, it is what inspired the current model for patient-centered care (PCC) used in today’s health care.

## 6.1 Patient-Centered and Holistic Health Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain patient-centered nursing care
- Recognize how providing patient-centered care increases interaction among stakeholders
- Describe interventions nurses can include in the care plan to promote holistic nursing care

The term **patient-centered care (PCC)** is a healthcare delivery model that aims to ensure the patient is an equal partner in their health care. Patient-centered care can be described as the framework for providing care to individuals. Relatedly, **holistic care** is aimed at healing all parts of the body, mind, and spirit. Holistic nursing strives to care for all the needs of the body, mind, and spirit. Holistic care is a philosophy for nursing linked as far back as the beginning of the profession. Florence Nightingale, the founder and first theorist of nursing, developed the Nightingale theory still incorporated in nursing today. See [Chapter 1 Introduction to the Nursing Profession: Evolution, Theories, and Practice](#) for details regarding nursing theories. Nightingale believed a person's health was directly tied to their physical environment, and healing the whole person was the nurse's goal. She encouraged the addition of clean air, clean environment, and sunlight in order to care for a person. This could be accomplished by opening a window to let in sunlight and fresh air. This simple task not only removed germs from the environment but also increased the patient's feeling of happiness when they felt the warmth of the sun. She believed in providing a bath to a patient to reduce germs and increase feelings of worthiness and cleanliness.

### Patient-Centered Care

Patient-centered care aims to empower patients to become active participants in their care, with the hope of giving them self-management in the process. Healthcare providers are patient advocates who strive to provide safe, efficient, cost-effective care. Patient-centered care requires improved communication among healthcare professionals and patients. For example, when a patient visits a doctor's office, they are allowed to focus on describing how they are feeling and functioning versus just discussing the progression of a diagnosed disease. Another example of improved communication is when patients are encouraged to use electronic patient portals to review upcoming appointments and suggested treatment plans. Empowering patients to get involved in their care increases the probability of compliance.

Nurses are tasked with providing patient-centered care to focus on the whole person. As part of the nurse–patient relationship, nurses are primed to understand and incorporate more patient-centered care during healthcare delivery than other healthcare providers. For instance, consider a patient who reports overall pain and sleepiness. While the physician may diagnose the patient with depression, the nurse may uncover that the patient's close friend died recently and the patient is spending more time in bed. The nurse was able to spend more time discovering why the patient had the complaints, and these contributing factors could add to why the patient is complaining of overall pain. The nurse might also question the patient about their daily routine and eating habits to provide more clues for better patient-centered care. The nurse looks at the whole patient, not just the diagnosis or complaint, to get a better understanding of the situation. The nurse can collaborate with the physician and act as a liaison between the physician and patient to improve care and outcomes.

Patient-centered care models emerged as best practice standards in nursing and can be achieved through care coordination and integration of care. For example, nurses demonstrate respect for patients' values, preferences, and expressed needs. Nurses can provide patients with information and education related to disease development and progression. They provide patients with both physical and emotional support, while attempting to alleviate patients' fear and anxiety. Patient-centered care also includes the involvement of family and friends.

### Benefits of Patient-Centered Care

There are multiple benefits of patient-centered care. Patients who receive patient-centered care report more satisfaction with care received, higher rates of patient engagement, and better healthcare outcomes. The benefits can translate into faster recovery and lower emergency room visits or readmission rates, all of which affect the total cost of patient care. Positively affecting the total cost of patient care allows for healthcare providers to meet benchmarks set by health insurance companies, which lowers population-wide healthcare costs.

### LINK TO LEARNING

The [American Medical Association \(AMA\) website \(https://openstax.org/r/77AMAwebsite\)](https://openstax.org/r/77AMAwebsite) discussed trends in healthcare spending along with policy research perspectives.

### Care Coordination

The term care coordination is the specific coordination among team members to organize healthcare activities. Care

coordination is an important factor in providing effective, efficient, and safe patient-centered care. High-quality, high-value care is delivered as the best care possible with efficient resources achieving optimal results for each patient. Consider a patient receiving a timely referral or quick turnaround time getting an appointment with physical therapy. High-value examples include multiple specialties within one practice, such as physical therapy, occupational therapy, and speech therapy available in one practice. Care coordination goals for the nurse should include the delivery of high-quality, high-value health care.

Care coordination also provides a foundation for improving patient care outcomes, which benefits the patient, providers, and the healthcare system. Care coordination can be as simple as establishing accountability and agreeing upon responsibility within the healthcare team. For example, creating a care plan for an individual with diabetes would include podiatry, endocrinology, ophthalmology, diabetes education, and nutrition services. Another example might be coordinating pediatric care for a child with juvenile arthritis.

Care coordination also involves linking the patient with community resources and aligning community resources with population needs. For example, when facilities utilize integrated electronic health records across specialties, it allows healthcare providers real-time access to accurate patient information such as screenings, laboratory tests, and prescriptions. With this integrated access, duplicating laboratory tests does not occur, which controls overall costs.

## LINK TO LEARNING

---

The Agency for Healthcare Research and Quality's [Care Coordination Quality Measure for Primary Care \(CCQM-PC\)](https://openstax.org/r/77CCQM-PCsurvey) (<https://openstax.org/r/77CCQM-PCsurvey>) is a free downloadable survey in the public domain that assesses adult patient experiences with care coordination in primary care settings.

---

### Transparency in Care

When establishing trust in a patient–healthcare provider relationship, it is important to have transparency. Transparency gives the patient protection and greater control over the care they receive. Many healthcare providers utilize electronic health records so patients can see the results of their own laboratory tests and exams, providing transparency with the test results. When providers review with patients the necessity for why certain diagnostics are ordered, such as a magnetic resonance imaging (MRI) scan versus a computerized tomography (CT) scan, this is another example of transparency.

Transparency can include data and interoperable systems as well. For instance, hospital outcomes data are publicly available so that healthcare consumers can choose where they receive care. Data transparency provides patients with the information to make smart decisions about the quality of the health care and receive the best value for their healthcare dollars. Transparency in health care promotes care coordination and the concept of high-quality, high-value care. As patients are more aware of the costs, able to make better choices for care, and participate in programs that promote care coordination, better health outcomes should occur. Transparency also increases accountability and competition among healthcare organizations.

From the Agency for Healthcare Research and Quality, the [TeamSTEPPS 3.0 Pocket Guide](https://openstax.org/r/77STEPPSPockGui) (<https://openstax.org/r/77STEPPSPockGui>) is a quick reference tool for communication among healthcare providers. Download the app and use it during patient care.

---

### Increased Interaction

Increased interaction is an important tenet of PCC. Patient-centered care increases interaction among the patient and the healthcare providers and can include other stakeholders in the patient's care, such as the patient's family and the interdisciplinary healthcare providers. As part of the interdisciplinary healthcare team, nurses are responsible for improving communication during rapidly changing medical conditions. One way a nurse can improve communication is by implementing more frequent patient room checks. Increased interaction and improved

communication, such as following up with patients after surgical procedures, with test results, or after new medications are started, has positive effects on patient satisfaction, length of stay, and adverse events (Wang et al., 2018).

### Patient Involvement in Decision-Making

Patient-centered care promotes the patient to be an active team member in their own care plan. Increased interaction among team members means the patient is involved in all aspects of the decision-making process. Research suggests that patients who participate in decision-making not only have better healthcare outcomes, improved satisfaction with health care, and reduction of healthcare costs, but also can reduce their mortality from chronic disease (Paterick et al., 2017). A patient who is involved in self-managing their chronic conditions has a better prognosis and longer quality of life than patients who are not involved in self-management (Delaney, 2018).

### Family Involvement in Decision-Making

When families are involved in the decision-making process, patients are more prone to following through with the care plan because the family can provide additional resources for the patient. Many times, patients rely on a loved one or significant other to provide support and guidance. Making sure all parties understand ensures compliance with the assigned healthcare tasks. If a patient is under 18 years of age or is not capable of making decisions for themselves, then a family member is typically assigned as the **medical power of attorney**, or the person in charge of making medical decisions for the patient. Patients can deem someone as medical power of attorney in charge of making medical decisions for them if they are unable to. Regardless of the scenario, to achieve care coordination, the patient's family should be involved in the decision-making process to achieve better outcomes.

### Support for Self-Management

Increased patient interaction also means supporting the patient in self-management of their own healthcare needs. One way to achieve this goal is when the nurse empowers the patient through education. Nurses should help patients realize they are in control of their own health; health care is not a passive process in which only the healthcare provider tells them what to do. A patient's health is self-managed based on the decisions they make throughout the day, week, months, or years. For example, if a patient has diabetes and chooses to eat a high-sugar, high-carbohydrate snack, that action will have a negative effect on their health. The nurse can provide education on snacks with a low glycemic index and empower the patient to make health-conscious decisions.

It is also the nurse's responsibility to inform the patient that they have options for their care. Patients should be encouraged to explore different treatment options if they feel another plan is more reasonable. Interacting with the patient as a key team member in their care plan enables support of self-management.

## PATIENT CONVERSATIONS

---

### How Nurses Can Empower Patients with Information

**Scenario:** Nurse walks into the room in the healthcare provider's outpatient office to complete an assessment. The nurse starts by taking the patient's blood pressure.

**Nurse:** Hi, my name is Alice, and I am going to be your nurse today. Is it okay if I take your blood pressure?

**Patient:** Yes.

**Nurse:** Your blood pressure is 144/86.

**Patient:** Is that normal?

**Nurse:** Your blood pressure is a little high. We consider a normal blood pressure around 120/80.

**Patient:** Should I be worried? What do the numbers mean?

**Nurse:** There are two numbers for blood pressure: a top number and a bottom number. The top number is the amount of pressure your heart must exert against your blood vessels when your heart is at work. It is called the systolic number. The bottom number is the amount of pressure your heart must exert against the blood vessels when your heart is at rest. It is called the diastolic number. High blood pressure increases your risk for stroke, heart

attack, kidney disease, and eye disease.

**Patient:** I thought my blood pressure was high. That is why I came here today. What can I do to lower my blood pressure?

**Nurse:** There are many things you can do to lower your blood pressure, such as decrease your salt intake, exercise, stop smoking, drink less alcohol, maintain a reasonable weight, and avoid stress. Do you think there are some behaviors that I just listed that you could work on?

**Patient:** Yes, I can decrease my salt intake and exercise more. Thank you for talking to me about high blood pressure.

**Nurse:** I will get some educational pamphlets regarding ways to lower your blood pressure for you to take home today just in case you need to look back over them later. I also suggest you get an at-home blood pressure monitor, so you can start recording your blood pressure daily. Bring your recording log into the office next time you come in so we can see how your changes are helping to improve your blood pressure.

(Based on Funnell, 2000.)

---

### Thoughtful Practice

Practicing care in a way that reflects compassion and incorporates empathy for a patient's unique situation is known as **thoughtful practice**. The patient remains the nurse's center of attention, which promotes the patient's overall well-being. Thoughtful practice allows for reflection upon everyday situations and finding ways to make improvements. Tasks, such as delegation and decision-making, are founded on thoughtful practice. Nurses who incorporate thoughtful practice strive to develop therapeutic nurse-patient relationships to provide a more patient-centered approach to meeting healthcare needs.

### Self-Knowledge

Nursing is a life-long learning process. Increasing self-knowledge, the understanding of one's own motives and character, is an important aspect of being a nurse. Nurses should participate in ongoing education. Nurses have a responsibility to their profession and to their patients to keep up to date on current research. Researching the most current evidence gives the nurse a way to incorporate knowledge into their practice. To provide effective, quality PCC, the nurse needs to be as knowledgeable as possible in the patient's individual healthcare needs. Nurses join relevant nursing societies or participate in statewide nursing organizations, which provide nurses with current data and research to increase self-knowledge.

### Providing Holistic Nursing Care

Holistic nursing care encompasses treating the patient's mind, body, and spirit as one. The American Holistic Nurses Association (AHNA) is a specialty nursing association that was developed to help nurses practice health more holistically through advocacy, research, and education. Nurses can join the AHNA and be linked with resources for practicing nursing more holistically.

### LINK TO LEARNING

The [American Holistic Nurses Association \(https://openstax.org/r/77AHNAwebsite\)](https://openstax.org/r/77AHNAwebsite) is where nurses can find resources for practicing health care more holistically. Click on the resource tab at the bottom of the page and complete one of the self-care modalities.

---

### Interdisciplinary Holistic Healthcare Providers

Interdisciplinary holistic healthcare providers include traditional treatments along with complementary and alternative treatments to provide overall health and well-being. Complex health problems that require a team approach or coordination of palliative care are two examples where interdisciplinary holistic healthcare providers would be utilized. For example, a patient on palliative care might require their spiritual, psychological, and physical needs to be met. When a team of interdisciplinary holistic healthcare providers convene to work with the patient to manage an illness, the patient is more likely to meet positive health outcomes. For example, a patient in the

intensive care unit (ICU) who was in a motor vehicle accident with fractures of the jaw and leg, a collapsed lung, and head contusions would require many different disciplines to care for them including orthopedic specialists, physical therapy, occupational therapy, neurologists, neurosurgeons, pulmonologists, nutrition specialists, and pharmacists. All the team members work together to provide a quicker recovery process for the patient.

### Common Holistic Treatments

There are many holistic treatments for patients. Some holistic treatments are provided by interdisciplinary healthcare providers and require certifications. For instance, acupuncture should only be performed by a certified acupuncturist. However, there are several holistic treatments that can be completed by nurses. Examples include aromatherapy, massage, touch, and hot/cold application. Nurses should attempt to incorporate holistic interventions into their patients' care plans only after confirming with the rest of the clinical team that the treatments are safe and will not interfere with the medical plan. Some holistic interventions, such as aromatherapy, guided imagery, hydrotherapy, massage, and progressive relaxation, do not require special prescriptions or extensive training, meaning the patient can also complete the tasks independently.

#### Aromatherapy

The use of essential oils via inhalation or diluted application to the skin is known as **aromatherapy**. An **essential oil** is an oil extracted from the flower, bark, leaves, or fruit of plants. Many essential oils are thought to have properties that provide symptom relief. When the essential oil is inhaled, the olfactory nerve is activated, which then stimulates the activation of the **amygdala**, the emotional center of the brain. This stimulation can boost mood and may help with anxiety, depression, or insomnia. Aromatherapy can be used to treat nausea, decreased appetite, or dry mouth. For example, ginger, peppermint, and licorice have all been shown to alleviate nausea. Nurses should educate patients about the possible benefits of aromatherapy, as well as how to properly use essential oils by advising patients not to consume them and to avoid drug interactions or possible allergies.

#### Guided Imagery

A holistic treatment used to reduce anxiety is guided imagery. In guided imagery, the nurse directs the patient to close their eyes and picture a scene that makes them comfortable and relaxed or provides a feeling of peacefulness, such as a beach. The nurse would encourage the patient to notice everything about the scene, such as the way the sun feels on the skin, the color of the water, the sounds of the surf, the scents of the breeze, and the taste of the foods eaten. Patients can be educated to do guided imagery on their own when they are feeling stressed, anxious, or depressed. Guided imagery has been used as pain management therapy for patients suffering from chronic pain and for women in labor.

#### Hydrotherapy

The use of water to reduce pain, swelling, and sore muscles is called **hydrotherapy**. It can be administered with hydromassage blankets or in swimming pools, whirlpools, hot tubs, and physiotherapy tanks. Hydrotherapy allows the muscles to relax and can ease joint pain. The warmth of the water stimulates dilation of the blood vessels, promoting blood circulation and reducing fluid accumulation in interstitial cells ([Figure 6.2](#)). Caution must be taken to avoid too much time in the water as negative effects can occur such as maceration of the skin.

**FIGURE 6.2** Hydrotherapy can help to reduce pain and swelling, as well as increase strength and range of motion. Hydrotherapy pools, such as the one seen here, are designed to help prevent and rehabilitate injuries. (credit: modification of work by U.S Navy Mass Communication Specialist 3rd Class Robyn Gerstenslager/Wikimedia Commons, Public Domain)

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Recognize Cues: Asking Subjective Questions about Patient Cues

Before recognizing cues, nurses must make sure they have enough data about a patient's situation to interpret the information. For example, consider an adult patient who reports weeping from the lower extremities. The nurse does not have enough information to determine the patient's needs and may ask a series of questions such as "Have you ever experienced weeping in your legs before? When did you first notice the weeping? Have you done anything at home that made it better or worse?" The patient's responses provide the nurse detailed information from which to form an educated hypothesis and start determining what actions to take for the patient. The nurse should recognize, based on the provided cues and clinical judgement measurement model, that this patient would not be a good candidate for hydrotherapy as they already have emaciated skin in the lower extremities.

#### Massage

Massage is widely used as a holistic treatment for pain, muscle soreness, and stress reduction. Massage can be done at the bedside by a nurse, a physical therapist, or a massage therapist who is specifically trained in massage techniques. There are several types of massage, including aromatherapy, chair, deep tissue, hot stone, lymphatic, prenatal, shiatsu, sports, and Swedish massage. Some types of massage are beneficial to a certain part of the body. Lymphatic massage, for example, is used for the lymph system to promote less lymphedema and can be used in patients who have had lymph nodes removed (Figure 6.3). The benefits of all types of massage are lowering heart rate, improving immune function and circulation, and increasing relaxation. Nurses should educate patients not to massage lower extremities if they are diagnosed with or are expected to have deep vein thrombosis (DVT), or blood clots in the lower extremities, as the massage could accidentally dislodge the DVT and elicit negative outcomes, such as stroke.

**FIGURE 6.3** Facial lymphatic massage can help to reduce swelling and lymphedema. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Progressive Relaxation

Another holistic technique that nurses can administer is **progressive relaxation**. During progressive relaxation, the nurse guides the patient to get comfortable and encourages the patient to start with a muscle group such as the feet or toes. The nurse instructs the patient to contract and then relax that body part and then move up to the next set of muscles. Working in a systemic order, when finished, the patient should have contracted and released all the major muscle groups. This progressive relaxation of all the muscles can bring a sense of calmness. Progressive relaxation can help lower blood pressure, ease muscle tension, and increase a patient's perception of overall well-being.

### Holistic Care across the Life Span

Holistic care across the life span includes maternal/newborn, pediatric, and geriatric populations ([Table 6.1](#)). A nurse can meet the holistic needs of the maternal and newborn population by encouraging healthy pregnancies. Healthcare providers educate women about ways to maintain a healthy pregnancy by avoiding stress and unhealthy behaviors such as smoking. Newborn holistic care includes education for the parents such as bath safety and car seat safety. Nurses can provide holistic care for the pediatric population by involving the family throughout the care process. For the geriatric population, the interdisciplinary team should be included along with the patient's family so that all the patient's needs can be met.

Developmental Stage	Physical Needs	Psychological Needs	Spiritual Needs
Maternal/newborn	Discuss healthy diet	Provide education about postpartum depression	Refer to counseling if fetal demise occurs
Pediatric	Provide age-appropriate anticipatory guidance	Discuss with parents how to support a child's self-esteem needs	Encourage parents to connect with the child daily
Geriatric	Discuss vaccines such as pneumonia and shingles	Encourage service in community, such as volunteering	Suggest sharing stories and memories with loved ones

**TABLE 6.1** Holistic Nursing Care across the Life Span

## 6.2 Foundations for Providing Person-Centered Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe physical considerations involved in providing person-centered care
- Identify emotional considerations involved in providing person-centered care
- Recognize spiritual considerations involved in providing person-centered care

In the 1940s, psychologist Carl Rogers developed the theory of person-centered therapy, which suggests a person can understand themselves and focus on their self-worth. Rogers believed that the person and the therapist could work together toward personal growth, achieving self-management. The humanistic approach to psychotherapy was founded on Rogers's theory and included shared decision-making between the person and the therapist. The development of person-centered therapy provided the foundation for person-centered care within health care.

Person-centered, patient-centered, and holistic care are terms that are intertwined; however, they have separate definitions and should not be interchanged. The **person-centered care** focuses on disease management with the personal, social, and religious beliefs of the person incorporated into the care. Person-centered care includes integrated healthcare services that allow goals, values, and preferences of an individual to be included in the development of a care plan with the healthcare provider. An example of an integrated healthcare service is the Veterans Health Administration (VHA), a federal agency that provides veterans with hospital and long-term health care. An integrated healthcare plan includes informed decision-making about treatment options, well-being considerations for the patient, and an understanding of their comprehensive needs ([Figure 6.4](#)).

**FIGURE 6.4** Person-centered care, as defined by the American Association of Colleges of Nursing, shows the person as the center surrounded by the six tenets of person-centered care. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Shared decision-making and self-management support are part of the six tenets for current practices of person-centered care. When the patient and healthcare provider work together to develop a healthcare plan that meets the goals set by the patient, this is known as **shared decision-making (SDM)**. Support for self-management gives patients with chronic conditions the ability to manage their health and take an active role in their health care. Through the implementation of person-centered care, healthcare providers deliver tools and resources assisting the person to reach their own individual health goals.

When caring for patients, nurses use a framework to help prioritize care. While most patients have multiple needs, the nurse can only address one need at a time. The most recognized framework for prioritizing patient's needs is Maslow's hierarchy of needs, which includes physiological needs as the basis of the hierarchy, meaning those needs must be met at least minimally to sustain life and before moving onto the needs above those (Figure 6.5). Examples of physiological needs include oxygen, nutrition, hydration, elimination, thermoregulation, sexuality, activity, and rest. The nurse cannot address other needs for the patient if these basic needs are not being met first. Security, social, esteem, and self-actualization complete Maslow's hierarchy. A patient cannot have needs met in the social category if the needs below it (physiological and security) are not being met. Maslow's hierarchy provides the nurse with a framework for prioritizing a patient's needs while providing person-centered care, which focuses on three considerations: physical, emotional, and spiritual.

**FIGURE 6.5** Maslow's hierarchy of needs is used as a framework to prioritize the needs of a patient. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Physical Considerations

The nurse should address a patient's physical considerations when providing person-centered care. For most patients, the physical considerations that are reported as important are pain management, assistance with activities of daily living, and short-term care facility environments. Patients may want assistance with dressing and personal hygiene and express a desire for a clean facility in which to heal. Meeting a patient's physical needs ensures the nurse is providing person-centered care. For instance, if a patient does not receive timely pain management after surgery, the negative impact on the patient's overall experience can be significant. For example, if physical pain is not managed well, safety, security, and emotional well-being are affected. The patient may not want to return to the healthcare facility if they received poor pain management after surgery.

### Physiological Needs

A person's physical needs and **physiological** needs can be intertwined. Physiological needs refer to the functions of the body while physical needs refer to the care of the physical body. A patient is having stomach pains (physical

need) and they could also be stating that they have not had a bowel movement in a week (physiological need). The nurse can provide person-centered care by caring for both the patient's physical and physiological needs. Often, resolving one issue will inadvertently resolve the other. [Table 6.2](#) examines examples of physical and physiological need links.

Physical Needs	Physiological Needs
Stomach pain	Bowel movement
Chest pain	Disruption in cardiac circulation
Headache	Decreased blood flow to the brain
Shortness of breath	Decreased oxygenation of blood from lungs

**TABLE 6.2** Physical and Physiological Needs

## REAL RN STORIES

### Early Recognition of Physiological Needs

**Nurse:** Jose, RN

**Clinical setting:** Emergency department

**Years in practice:** 8

**Facility location:** Fort Wayne, Indiana

I had been working in an acute care emergency department in the suburbs of Indiana for more than eight years. Most nights were busy and seemed to run together. One shift I had a patient come in named Mark. Mark was a 45-year-old White male who presented with no previous medical history. Mark entered the triage room clutching his chest and had rapid respirations. He rated his chest pain at 10/10 and was actively vomiting into an emesis basin. I immediately assessed his vital signs (blood pressure of 167/104, heart rate of 112, a respiratory rate of 28, and an oxygen saturation of 92 percent on room air). I also noted his skin had a dusky pale appearance, and his nail beds were pale and bluish in color. Per our facility protocol, I administered oxygen 4 L via nasal cannula and started to obtain an electrocardiogram (EKG). A thorough assessment revealed Mark's physical need was chest pain, but his physiological need was a disruption in cardiac circulation and oxygenated blood flow to the body, and once the cardiac circulation was restored, the physical need of chest pain resolved.

### Safety and Security Needs

The safety and security needs of a person can include a range of topics, such as personal security, employment, resources, health, and property. For example, being unemployed, underemployed, or not having health insurance should never affect a patient's ability to obtain care when needed. A person should have their safety and security needs addressed early in the assessment process to avoid missing opportunities for care later as their needs increase. For example, taking a thorough health and social history can allow the nurse to identify specific actions to improve a patient's security. Another example of addressing a patient's safety needs might be making sure they have resources to contact if their environment is not secure or safe.

Age and developmental considerations also fall under safety and security. A patient might not be able to care for themselves, placing their safety at risk. For instance, safety and security needs for an infant include providing a secure environment and safe sleep position. An infant feels secure when they are swaddled and held. Safety and security needs for a toddler include preventing drowning and injuries and using car seat safety. Toddlers should be allowed to explore but need to be provided with structure and reassurance. The nurse must fully assess each individual patient's situation when considering safety and security and connect the patient to appropriate interdisciplinary professionals, who each have their own set of resources to provide assistance.

## LIFE-STAGE CONTEXT

---

### Financial Status of Older Adults

More than fifteen million Americans are economically insecure and living at or below the federal poverty level. People 65 years old and older often struggle with healthcare costs, and one major adverse life event such as a stroke can change their ability to pay for health care (National Council on Aging, 2022). Nurses should ask questions regarding current financial status and refer patients and their family to additional services, such as Medicaid and facility financial assistance programs.

---

### Emotional Considerations

Emotional considerations for patients include addressing emotions such as fear, happiness, loneliness, sadness, and self-acceptance. The nurse should address emotional needs early in the care process. For instance, if a patient is fearful of having an MRI scan, the nurse needs to address those fears before the patient is scheduled for the test. An MRI scan requires the patient to lie completely still for an extended period, and a patient who is claustrophobic will have difficulty lying still and possibly not be able to complete the exam. If the patient discusses their fears with the nurse, a solution to address these fears can be achieved. Another example might be a patient who is depressed because of the loss of a loved one. If not fully assessed, the patient can easily sink further into an unhealthy state of mind. The nurse needs to be aware of each individual patient's emotional needs to provide comprehensive person-centered care.

#### Love and Belonging Needs

One aspect of emotional considerations is a patient's love and belonging needs. These needs can include friendship, intimacy, family, and sense of connection. Having a relationship with friends, family, or a significant other can provide the support needed for a patient to heal and recover. For instance, consider a patient who has inguinal hernia repair with a mesh support. The post-op instructions state that they are unable to drive or lift more than five pounds for six weeks. This patient has a partner that can be responsible for the day-to-day activities of the household. The patient relies on the mutual benefit aspect of a partnership to help achieve good outcomes after surgery. If the patient did not have a partner or someone they could rely on, a different outcome may be the result because the patient would still have the need for belonging. A patient who didn't have a partner might try to lift more than five pounds, causing complications with the mesh support and a reoccurrence of the hernia. Love and belonging needs can also be met by providing feelings of self-worth. If someone feels loved, needed, and wanted, they often feel more positive about their own role in life and have more positive self-esteem.

#### Self-Esteem Needs

The term self-esteem can be defined as confidence in one's own worth or abilities. Self-esteem is based on the patient's own opinions and beliefs about themselves, which is sometimes hard to change once negativity is associated. Sometimes self-esteem can be developed based on what others have said, which the person can internalize as fact. For example, a person who has been told as a child that they are ugly, fat, or dumb may internalize those words, linking their self-esteem with those negative words. As this child moves through adolescence and enters the stage when other's opinions are important, their negative feelings may take over and cause unhealthy coping. However, the opposite is also true; if a child has been told they are worthy and important based on their actions and not appearance, the child is less likely to give in to negative feelings about themselves as they mature. A positive self-image is the foundation for healthy mental health, which aids in managing life's stressors. A nurse who considers a person's self-esteem needs is better prepared for helping the patient achieve optimal health outcomes.

Watch [this video by Psych Hub about eating disorders \(https://openstax.org/r/77PsychHubVidED\)](https://openstax.org/r/77PsychHubVidED) to find out more about the complex relationship these disorders have with self-esteem.

---

### Self-Actualization Needs

The realization of one's potential is called **self-actualization**. A person who is self-actualized can be described as someone who accepts and appreciates themselves and their accomplishments in life. Self-actualization can be achieved through reflecting on one's own values and beliefs. A patient who has accomplished self-actualization will be more accepting of their current state of health and may be more willing to participate in the care plan. For example, a patient diagnosed with inoperable cancer may recognize they have led a fulfilling life. The patient focuses on the life journey, not the diagnosis of inoperable cancer. The patient would be considered to have met their self-actualization needs and would be better prepared mentally to handle the notion of death because the patient feels they have met all their life goals.

### Spiritual Considerations

Another aspect of providing PCC is taking into consideration the patient's spiritual needs and caring for the patient's spirituality. Spiritual care in healthcare facilities includes recognizing and providing care that takes religious customs into account. Spiritual care is mandated by both The Joint Commission and the National Consensus Project for Quality Palliative Care. Nurses are responsible for identifying and understanding a patient's spiritual needs, assisting the patient in developing the care plan, involving the appropriate healthcare/spiritual professionals, and evaluating the patient's spiritual care. The nurse should work closely with the patient and healthcare providers to make sure the patient's spiritual needs are being met. Resources available in the healthcare organization, such as a chaplain, clergy, or nondenominational advisor, are helpful in assisting the nurse to meet the spiritual needs of a patient. Nurses must not be judgmental or biased; they should be open minded to better meet the spiritual needs of the patient. The nurse providing spiritual care for patients should also understand their own spiritual views.

### LINK TO LEARNING

---

Nurses can visit [the HealthCare Chaplaincy Network \(HCCN\) \(https://openstax.org/r/77HCCNwebsite\)](https://openstax.org/r/77HCCNwebsite) to find additional information about meeting a patient's spiritual needs. HCCN is a nonprofit organization that offers spiritual care-related information and resources.

---

### Concepts Related to Spiritual Health

Spiritual health can be related to achieving self-actualization. Spiritual health care can be described as helping a patient meet their psychological needs and develop a meaningful life. Spiritual health concepts include faith, religion, hope, and love. Faith, religion, and spirituality can be intertwined ideas; however, each has its own meaning. Sometimes nurses equate spiritual health with religious affiliation. However, in today's world, spiritual health means embracing and understanding whatever the patient considers spiritual. Some people find spiritual peace in tasks such as meditation or yoga ([Figure 6.6](#)).

**FIGURE 6.6** Healthcare providers can benefit from workplace yoga classes, helping to provide spiritual health at the workplace. (credit: “Yoga: A quiet escape for healthcare professionals” by Master Sgt. Cohen A. Young/U.S. Air Force, Public Domain)

### Faith

An absolute trust or belief in something or someone is called faith. A patient can have faith that the nurse will treat them fairly and equitably. They can also have faith in a higher power or entity. Faith does not imply religious affiliation; some patients have a strong faith but do not follow an organized religion.

### Religion

The term religion refers to the actual practice of worship within an organized culture or group of like-minded individuals. There are many forms of religion in the world. Some examples include Buddhism, Christianity, and Judaism. Nurses should refrain from making assumptions about the values and beliefs of any religious affiliation. Asking the patient questions about their religious practices will develop a therapeutic nurse–patient relationship, which is needed to provide person-centered care. For instance, if the patient, because of religious beliefs, shuns away from a certain medical practice, such as the administration of blood or blood products, or has specific dietary practices, such as eating only kosher foods, the nurse needs to know this. The nurse should respectfully honor the patient’s wishes and provide resources on alternative treatments or notify nutritional services. Understanding the patient’s religious beliefs ensures PCC is being given.

## PATIENT CONVERSATIONS

### Completing a Spiritual Assessment

**Scenario:** Indy, an RN for six years, has been assigned to admit Mr. Denzel Bernstein, a new patient to the hospice unit. The patient has end-stage glioblastoma and his significant other and adult children are present at admission. Hospice is focused on comfort, care, and quality of life for someone approaching the end of their life.

**Nurse:** Hello, my name is Indy, and I am going to be your nurse today. Do you mind verifying your name and date of birth for me?

**Patient:** My name is Denzel Bernstein and my birthday is July 26, 1965.

**Nurse:** Hello, Mr. Bernstein, I am here to admit you and would like to ask you some questions about your religious

preferences? Is that okay?

**Patient:** It is okay, but I am tired. Would you please ask my wife, Chava?

**Nurse:** Sure. Mrs. Bernstein, is it okay if I ask you these questions about your religious preferences?

**Patient's wife:** Yes, it is okay.

**Nurse:** What are your and Denzel's religious or spiritual preferences?

**Patient's wife:** We are lapsed Methodists; we have not attended church in a few years.

**Nurse:** Do you have any dietary preferences related to your religious or spiritual beliefs?

**Patient's wife:** No, we do not.

**Nurse:** How have your beliefs influenced your behavior during your illness?

**Patient's wife:** Denzel was diagnosed two years ago with glioblastoma, and at the time it did not change anything about our beliefs. However, as he is being admitted to hospice and facing his impending death, we have started talking about religion and spirituality again. We have always had a belief in God, and we hope Denzel goes to heaven to see his parents.

**Nurse:** Would you like me to call the Methodist clergy to come visit with you?

**Patient's wife:** Not right now, but maybe tomorrow once Denzel has rested.

**Nurse:** I would be happy to arrange for a chaplain to visit you and your family. I understand what a hard time this is. I am willing to help you in any way I can during your time here. If there is anything I have not addressed at this time or anything else that comes up later, please do not hesitate to reach out to me.

---

## Hope

The term hope can be defined as how the person views their future. It can be an attitude, an inspiration, or an overall sense that a person feels. As the nurse develops a therapeutic relationship with the patient, hope can be explored. For example, if the patient was diagnosed with an infection that requires long-term antibiotics, the nurse can explore the patient's hope for recovery. Nurses can also foster hope in families with transparent communication. Incorporating the patient's wishes ensures the spiritual considerations of a person-centered approach are being met.

## Love

Love is discussed as part of Maslow's hierarchy of needs and allows for a sense of belonging. Love can also be spiritual in nature. Spiritual love can help patients find meaning and purpose in their lives and create kindness and acceptance of themselves and others. When a patient describes spiritual love, it can feel like an intense connection with someone or something. This intense connection can help the patient see and understand things in the world around them differently. A patient who has a deep spiritual love with their significant other may not be bothered when separated from the significant other, knowing the love will sustain the relationship during the separation, such as during a hospitalization.

## Aspects Influencing Spiritual Health

Spiritual health includes critical attributes such as transcendence, purposefulness, mindfulness, faithfulness, harmonious interconnectedness, integrative power, multidimensionality, and holistic being (Table 6.3). These terms describe a sense of completeness between one's mind, body, and spirit. When spiritual health has been disturbed, physical and emotional health can also be affected. Connection with others remains key to the influence of spiritual health.

Term	Definition	Example
Transcendence	The state of existing or extending beyond the physical being	Meditating
Purposefulness	The state of having a useful purpose	Giving to a charity
Mindfulness	The state of being present in the moment	Living in the moment
Faithfulness	The act of being faithful	Being loyal to relationships
Harmonious interconnectedness	The connection between mind, body, and spirit	Feeling that everyone and everything means something
Integrative power	The capacity to obtain what one needs and wants while maintaining human connection	Feeling love
Multidimensionality	The state of having connection with people from different parts of one's life	Having a neighbor who works with your family member and is also your friend
Holistic being	The act of being authentic to one's self in all aspects of life	Looking at everything as whole and connected

**TABLE 6.3** Spiritual Health Attributes

### Developmental Considerations

To provide person-centered care, the nurse must assess the patient's developmental and spiritual needs. The nurse should assess a patient's knowledge level, communication ability, cognition status, and ability, all of which may affect their spiritual needs. For example, a 4-year-old child will have different spiritual needs than a 74-year-old patient with dementia. The nurse should involve the patient's family in the healthcare decision-making when it is determined that the patient cannot make spiritual decisions for themselves.

### Family Influences

Many patients value their families' thoughts and beliefs when considering healthcare options. Often, patients will not make any healthcare decisions until they have consulted their family. The nurse should include the family in all aspects of the patient's care. The nurse should provide the family with opportunities to weigh in on decisions and plans. Scheduling patient meetings with all interdisciplinary team members when the family can attend is one way to ensure PCC is provided.

It is important to remember not every patient will have the same value placed on family opinion. Occasionally a patient will not have a good trusting relationship with their family and not *want* to consider what they think. In this case, the nurse needs to respect that decision and not push for family opinions. It is vital the nurse respects the patient's decision regarding privacy and does not discuss private information with other family members without the patient's permission. It is a patient's right not to discuss their medical condition or prognosis with loved ones.

Other times the perception of family can mean different things to different people, and genetics may not have anything to do with a person's perception of family. Some people consider friends their family, rather than actual blood relatives. Regardless of the situation, best practice standards are for the nurse to always respect a patient's decision regarding who receives their private health information.

## REAL RN STORIES

---

### A Veteran and His Family

**Nurse:** Willow, RN

**Clinical setting:** VA clinic unit

**Years in practice:** 11

**Facility location:** San Antonio, Texas

I had been working as a nurse for eleven years in a Veterans Health Administration (VHA) clinic in Texas when I encountered a patient named Jorge. He was a 32-year-old male, airman in the U.S. military, home on leave from active duty. Jorge was being evaluated in the clinic for trouble sleeping, nightmares, flashbacks, and anxiety. He had previously tried cognitive behavioral therapy and counseling without any relief. After a complete assessment, the healthcare provider suggested prescribing Sertraline 50 mg by mouth daily. I explained to Jorge this medication was used to help minimize post-traumatic stress disorder (PTSD) symptoms and would provide him with some relief. Jorge was very concerned with the stigma that was associated with mental health and military members, and he said he really wanted to think about it before starting a medication. Jorge informed the provider and me that he wanted to talk to his “family,” which was a group of veterans who had served with him for many years in the military before proceeding with the recommended care plan. I discussed the concept of family with Jorge and encouraged the benefit of a good support system. Later that afternoon, Jorge called the clinic and said he was willing to try the new medication.

---

### Previous Beliefs

Previous beliefs affect how a patient perceives their current state of health. A nurse should ask the patient about their beliefs and past experiences. This is especially true if the patient and/or family had a previous negative experience. For instance, if a patient had a family member experience a negative outcome from a particular medical procedure, the patient’s perception of that medical procedure could forever be altered. The nurse should understand and incorporate the patient’s previous beliefs into the current care plan. The nurse can use therapeutic communication techniques and education about the procedure to alleviate fears and clarify any misinformation. The healthcare provider should explain the risks associated with the procedure and openly and honestly answer any questions the patient has before the patient has the procedure. The nurse is responsible for reinforcing what the healthcare provider has taught the patient and addressing the patient’s anxiety. The nurse also has a responsibility to ensure that the patient understands what they are being told/taught. Nurses often are also the patient’s voice—advocating for patients.

### Life Events

Some patients experience life events that require additional consideration when developing a care plan as those life events may impact the patient’s ability to heal. For example, a female patient who was previously sexually assaulted by a male authoritative figure and is seeking treatment for an unrelated medical issue may request a nurse of the same gender due to the trauma associated with her previous life event. The previous trauma may affect how the patient responds to treatment and can disrupt the ability to meet health goals. Loss of a loved one is another life event that impacts a person’s ability to heal and recover. When a nurse cares for a patient who has lost a loved one, that patient should be provided additional resources for grief support, as the previously experienced grief may bring up emotions that affect their ability to cope and heal.

### Parish Nursing

Sometimes called faith community nursing, **parish nursing** is a specialty that focuses on the care of people in a faith community, church, or parish. Parish nurses help their communities by mobilizing volunteers in the faith community to support members in need. Parish nurses could be responsible for organizing volunteers to visit the sick and older people of the faith community. Parish nurses could coordinate blood drives or blood pressure screenings for the members of the faith community. Parish nursing is recognized nationally and internationally. Nurses who wish to practice parish nursing must follow their state’s Nurse Practice Act and the American Nurses Association (ANA) Faith Community Nursing: Scope and Standards of Practice.

## UNFOLDING CASE STUDY

### Unfolding Case Study #1: Part 7

Refer back to [Chapter 2 Communication](#) and [Chapter 5 Cultural Competence](#) for Unfolding Case Study Parts 1–6 to review the patient data. The medical-surgical nurse is providing care to a 28-year-old patient who arrived to the hospital one hour ago from a walk-in medical clinic. The patient speaks Spanish and is accompanied by her bilingual 10-year-old son. She has been admitted to the medical-surgical unit for observation.

Nursing Notes	<p><b>2310: Assessment</b> History and assessment is difficult to obtain because patient does not speak English. Son reports patient was seen at the clinic for a cough, was diagnosed with pneumonia, and was started on a medication to treat it. Patient remains on 2 L oxygen via nasal cannula, breathing pattern appears normal without distress.</p>
Flow Chart	<p><b>2310: Assessment</b> Blood pressure: 135/75 mmHg Heart rate: 97 beats/minute Respiratory rate: 22 breaths/minute Temperature: 100.1°F (37.8°C) Oxygen saturation: 97 percent on 2 L nasal cannula Pain: 9/10 (ear)</p>
Nursing Notes	<p><b>0100:</b> Patient given one dose of acetaminophen and reports ear pain is now 4/10. Interpreter has arrived and plans to stay on the unit until morning rounds so they can translate when the provider comes in. Patient resting comfortably, son sleeping on couch at the bedside.</p>
Nursing Notes	<p><b>0700: Assessment</b> Patient is awake and alert and reports feeling “much better.” Patient reports anxiety about finances and is worried about being able to feed her family. She states that she makes enough each month to get by, but her mother is getting older and beginning to require more care and medications.</p>
Flow Chart	<p><b>0700: Assessment</b> Blood pressure: 128/72 mmHg Heart rate: 87 beats/minute Respiratory rate: 18 breaths/minute Temperature: 99.1°F (37.3°C) Oxygen saturation: 97 percent on room air</p>
Provider's Orders	<p><b>0745: New Orders</b> Discharge after meeting with social worker.</p>

1. Recognize cues: Based on the information provided in the case study and your knowledge of Maslow's hierarchy of needs, what is the patient's priority need at this time?
2. Analyze cues: What other information should the nurse gather from the patient regarding her security concerns and needs?
3. Prioritize hypotheses: Based on the information presented in the case study, what emotional considerations should the nurse address with this patient?
4. Generate solutions: What actions can the nurse take to address the patient's concerns before discharge?
5. Take action: In addition to addressing the patient's security and financial concerns, the nurse decides to

conduct a spiritual assessment. How would the nurse go about this?

6. Evaluate outcomes: How would you determine that the patient's social needs have been addressed sufficiently before discharge home?

## Summary

### 6.1 Patient-Centered and Holistic Health Care

Nurses have the privilege of providing patient-centered care (PCC) in every setting. Patient-centered care includes working with the patient to ensure they are an equal partner in the healthcare process. Nurses should recognize that providing patient-centered care increases the patient's interaction among other team members, such as specialists and social workers. When healthcare providers work together to develop common goals, improved patient care outcomes are the result. When incorporating a more patient-centered approach, interaction among providers is resourced in a more cost-effective, efficient manner. Thoughtful practice is providing care in a way that reflects compassion and incorporates empathy for a patient's unique situation. Nurses can foster open, therapeutic nurse–patient relationships with thoughtful practice. Nurses can provide multiple holistic interventions into patient care, such as aromatherapy, guided imagery, hydrotherapy, massage, and progressive relaxation. Nurses also have the opportunity to assess and educate patients throughout the life span, accommodating for the patient's mind, body, and spiritual needs.

### 6.2 Foundations for Providing Person-Centered Care

Nurses are responsible for providing person-centered, patient-centered, and holistic care in every healthcare setting, from parish/faith communities to acute care settings. It is the nurse's responsibility to assess the patient's needs—physical, emotional, and spiritual—before assisting the patient in developing a care plan. The nurse should address the physical considerations involved in providing person-centered care, such as the patient's need for safety during care. The nurse should include emotional considerations involved in providing person-centered care, such as including the patient's family when planning care with the patient, and recognizing the patient's need for love and belonging. Finally, the nurse should recognize spiritual considerations involved in providing person-centered care by not only including spirituality of the patient in the care plan but also reviewing their own spirituality.

## Key Terms

**amygdala** the emotional center of the brain

**aromatherapy** the use of essential oils via inhalation or diluted application to the skin

**essential oil** an oil extracted from the flower, bark, leaves, or fruit of plants

**holistic care** a care approach that considers the whole entity, encompassing the physical, psychological, emotional, and spiritual dimensions of an individual patient

**hydrotherapy** a holistic treatment that uses water to treat pain, swelling, and sore muscles

**medical power of attorney** a person deemed in charge of medical decisions when the patient is unable or unwilling

**parish nursing (also, faith community nursing)** a specialty that focuses on the care of people in a faith community, church, or parish

**patient-centered care (PCC)** the healthcare delivery model that aims to ensure the person is an equal partner in their health care; a framework for providing care to individuals

**person-centered care** a focus on disease management with personal, social, and religious beliefs of a person incorporated into the care

**physiological** relating to the functions of the body

**progressive relaxation** a holistic technique in which each part of the body is contracted and relaxed

**self-actualization** the realization of one's potential

**shared decision-making** the practice of empowering patients to make healthcare decisions and state their needs and limitations

**thoughtful practice** care that reflects compassion and incorporates empathy for a patient's unique situation

**transparency** in health care, allows the patient to see the information about their care, such as electronic health records and laboratory results the patient can access

## Assessments

### Review Questions

1. An adult patient is admitted to the emergency department with chronic kidney failure. The patient states they did not go to their dialysis appointments this week. Which aspect of health care is most important for the nurse to include in the assessment?
  - a. transparency of care
  - b. emotional well-being
  - c. understanding of aromatherapy
  - d. self-management of disease
2. Which factor about a patient's health status is essential to consider while providing holistic care?
  - a. ability to drive
  - b. social media presence
  - c. athletic ability
  - d. developmental age
3. A healthcare team is working together with a patient to establish a care plan based on the patient's goals. Which outcome is likely to be the result for this type of collaboration?
  - a. increased healthcare costs
  - b. decreased adherence with the care plan
  - c. less satisfaction with care received
  - d. improved recovery phase
4. A patient is complaining of anxiety before a surgical procedure. Which holistic treatment should the nurse recommend first to the patient?
  - a. exercise
  - b. hydromassage
  - c. progressive relaxation
  - d. spiritual counseling
5. A nurse is developing a care plan for a patient diagnosed with spiritual distress. Which question would be most appropriate for the nurse to ask to assess spiritual distress?
  - a. What is your relationship status?
  - b. Do you have health insurance?
  - c. Do you feel like you have accomplished all you wanted to accomplish in life?
  - d. Do you feel like you have had a peak experience in your life?
6. A patient who is hospitalized with end-stage breast cancer states that they want to see the Grand Canyon. What spiritual consideration would the nurse attribute to this statement?
  - a. hope
  - b. faith
  - c. religion
  - d. spiritual love
7. A nurse is taking care of a patient who says they have no family or friends to help care for them. Which level of Maslow's hierarchy of needs is the patient possibly lacking based on this information?
  - a. love and belonging
  - b. safety and security
  - c. self-esteem
  - d. self-actualization
8. A nurse is addressing a patient's physical needs. Which physical needs should the nurse anticipate?

- a. a visit from the hospital clergy
  - b. assistance with putting on socks after knee replacement surgery
  - c. receiving last rites at end of life
  - d. verifying next of kin was notified of visitation hours
9. A nurse has accepted the role of parish nursing in their faith community. Which tasks should the nurse be prepared to oversee?
- a. scheduling volunteers for the annual blood drive
  - b. attending healthcare provider visits with individual faith community members
  - c. arranging for daily meal delivery for members who are housebound
  - d. caring for older members

### Check Your Understanding Questions

1. Describe ways nurses can provide a more holistic approach to patient-centered care.
2. Describe how a nurse could assess if a patient has reached self-actualization.

### Reflection Questions

1. What information might a nurse need to include when educating a patient about the use of aromatherapy?
2. What information might a nurse need to include when educating a patient about massage therapy?
3. What information might a nurse need when assessing the spiritual needs of a patient?

### Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #1: Part 7](#).  
How would you assess the patient's love and belonging needs?

### What Should the Nurse Do?

1. A nurse is assigned to a patient who has end-stage bone cancer and wants to enter hospice. The patient expresses concern that all the people taking care of them are not talking to each other. The nurse notices some disjointed care from the other healthcare providers; some of the team is prescribing palliative measures while others are continuing to treat issues. What should the nurse do to resolve this issue?
2. A 78-year-old patient presents to the emergency room with a swollen knee for one week. Patient states the knee is painful and limits mobility; pain is 5 on a scale of 1–10. Vital signs: temperature, 98.8°F (37.1°C); respiratory rate, 18 breaths/minute; heart rate, 88 beats/minute; blood pressure, 98/60 mmHg. Patient's height is 4 ft 10 in (147.3 cm) and weight is 98 lbs. (44.4 kg). The patient states the knee aches with weather changes, has sustained no injury to provoke swelling. Pulses are palpable 2 + bilaterally, no injury noted to right knee, 1 + nonpitting edema noted on top of knee. The patient is accompanied by a significant other. The patient acknowledges practicing the Jewish religion. What needs (physical, emotional, spiritual) are a priority? Why?
3. A 27-year-old patient is admitted to a mental healthcare facility with depression and suicidality after telling a family member about a suicide plan. The patient states they have considered suicide for a few weeks and have developed a plan on how to complete the act. Vital signs: temperature 98.6°F (37.0°C); respiratory rate, 16 breaths/minute; heart rate, 80 beats/minute; blood pressure, 128/78 mmHg. Patient's height is 5 ft 7 in (170 cm) and weight is 190 lbs (86.2 kg). The patient has no complaints of pain or previous medical history. The patient is accompanied by a significant other. The patient acknowledges practicing no religion. What needs (physical, emotional, spiritual) are a priority? Why?
4. The nurse is assigned to care for a patient who is actively dying. Which needs should the nurse address for this patient and family?

## Competency-Based Assessments

1. Develop a two-minute presentation defining the nurse's role in holistic care and its contribution to quality patient care.
2. Develop a five-minute presentation defining the nurse's role in spiritual health and its contribution to patient-centered care.

## CHAPTER 7

# Vital Signs

**FIGURE 7.1** Measurement of blood pressure is done by a trained medical professional using a stethoscope and sphygmomanometer, or with an automated blood pressure machine. Accurately performing, effectively analyzing, and routinely monitoring a patient's vital signs are key components of nursing care. (credit: "Blood Pressure Monitoring" by NIH Clinical Center/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

- 7.1 Indicators of Physiologic Functioning
- 7.2 How to Perform Vital Signs
- 7.3 Teaching Patients to Perform Vital Signs

**INTRODUCTION** Vital signs are gathered during an initial encounter with a patient to establish a baseline, and routinely thereafter, according to condition, to assess disease progression or resolution. When vital signs are abnormal, a patient's plan of care is typically altered. When vital signs are taken routinely, the healthcare team can analyze them to observe the response to treatments or disease progression. The combination of multiple vital sign measurements over a period of time also provides the typical and normal range for an individual patient. These individualized ranges are called vital sign trends. Vital signs provide a snapshot of the circulatory, respiratory, and neurological status of the patient.

At the same time, vital signs are only one piece of the patient's health. While there is a normal and abnormal range for each vital sign, there is some variability between individual peoples' baseline vital signs. For example, an athletic patient with a heart rate of 58 beats per minute and a blood pressure of 90/54 mm Hg may be numerically concerning; however, the reading may be normal for that patient, since the cardiovascular system of an athlete is more efficient than that of a person who is not as physically active. Conversely, a patient who lives a largely sedentary life who presents with this heart rate and blood pressure may not have as efficient a cardiovascular system and may feel symptomatic (presenting with dizziness, lightheadedness, weakness, and/or confusion); therefore, the lower numbers must be addressed.

This chapter discusses each vital sign and its relationship to the overall homeostatic balance of our bodies, how to measure each vital sign accurately, and how to identify ways to teach patients to assess and analyze their own vital signs.

## 7.1 Indicators of Physiologic Functioning

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify how vital signs represent the body's homeostatic functioning
- Recognize how body temperature reflects a person's health status
- Describe how the pulse reflects a person's health status
- Understand how respiratory status reflects a person's health status
- Recognize how oxygen saturation reflects a person's health status
- Analyze how blood pressure reflects a person's health status

The process of self-regulation that bodies maintain through multiple, interdependent physiological processes is called **homeostasis**. Vital signs are the measurement of these interdependent processes and are the metrics used to determine when this self-regulation is out of balance. The markers of physiological homeostasis are called **vital sign**, and they are essential in the analysis of monitoring patient progress. They include body temperature, pulse, respiratory rate, blood pressure, and saturation of peripheral oxygen. Changes such as fever, increased heart rate, or a drop in blood pressure are signs that the body is no longer in balance. Sometimes these changes are part of the body's attempt to regulate itself and get back into balance; other times they are signals that the body is unable to properly regulate itself, and further intervention is required. Understanding these signs can help prevent a life-threatening emergency.

### Vital Signs

The five vital signs are temperature (T), pulse (also known as heart rate [HR]), blood pressure (BP), respiratory rate (RR), and saturation of peripheral oxygen (SpO<sub>2</sub>). These vital signs are interrelated; for example, an increase in respiratory rate often correlates with an increase in heart rate, while a decrease in oxygen saturation may correspond with a decrease in blood pressure. Pain is often regarded as the sixth vital sign, and changes in a patient's pain can affect all five other vital signs. Thus, it is often assessed along with vital signs. Vital signs provide the necessary information needed to guide healthcare providers in making care decisions.

Vital signs have established normal and abnormal ranges, but variations occur. Besides an individual's personal baseline, vital sign parameters can also vary across the life span and change as a person gets older. What is considered normal for an infant or a toddler can be abnormal or problematic in an adult, and vice versa.

#### Age-Related Variations in Normal Vital Signs

One potential age-related change to vital signs that many people may already be familiar with is high blood pressure, or hypertension. As people grow older, the risk for hypertension increases, as does the risk for other heart problems such as tachycardia (fast heart rate), **bradycardia** (slow heart rate), or **arrhythmia** (abnormal heart rhythm). Environmental and lifestyle influences also play a part in the development of diseases like hypertension. Factors such as smoking, drinking, and dietary choices have direct effects on the cardiovascular system and therefore heart rate and blood pressure.

Heart rate is inversely proportional to age; rates are faster at a younger age and get progressively slower as we get older (Ostchega et al., 2011). This can be due to arrhythmias, like tachycardia; comorbidities, like hypertension or atherosclerosis; or may be naturally occurring from the aging process. A resting heart rate of 120 bpm in a newborn is acceptable; however, a resting heart rate this fast is problematic in an adolescent or adult. Knowing these age-related variations is key for the nurse to recognize what heart rate is appropriate for their patient and identify the correct course of action if not appropriate. See [Table 7.1](#) for a general range of normal vital sign measurements across the life span.

Age (Years Old)	Temperature	Heart Rate (Beats per Minute [bpm])	Systolic Blood Pressure (mm Hg)	Respiratory Rate (Breaths per Minute)
Neonate	97.7°F to 99.5°F (36.5°C–37.5°C) (rectal)	100 to 205	67 to 84 systolic; 35 to 53 diastolic	30 to 60
Infancy (1–12 months)	97.5°F to 99.5°F (36.4°C–37.5°C) (rectal or tympanic)	100 to 180	70 at birth to 90 at 1 year	30 to 53
Toddler (12–36 months)	97.5°F to 99.5°F (36.4°C–37.5°C) (rectal, axillary, or tympanic)	98 to 140	86 to 106 systolic; 42 to 63 diastolic	22 to 37
Preschool age (3–5 years)	97.5°F to 99.5°F (36.4°C–37.5°C) (oral)	80 to 120	89 to 112 systolic; 46 to 72 diastolic	20 to 28
School-age children (6–9 years)	97.5°F to 99.5°F (36.4°C–37.5°C) (oral)	75 to 118	97 to 115 systolic; 57 to 76 diastolic	18 to 25
Preadolescent (10–12 years)	97.5°F to 99.5°F (36.4°C–37.5°C) (oral)	75 to 118	102 to 120 systolic; 61 to 80 diastolic	18 to 25
Adolescence (12–17 years)	97.5°F to 99.5°F (36.4°C–37.5°C) (oral)	60 to 100	110 to 131 systolic; 64 to 83 diastolic	12 to 20
Adulthood (18–64 years)	97.5°F to 99.5°F (36.4°C–37.5°C) (oral)	60 to 100	90 to 120 systolic; 60 to 80 diastolic	12 to 20
Late adulthood (65 years and older)	96.4°F to 98.5°F (35.8°C–36.9°C) (oral)	60 to 100	90 to 120 systolic; 60 to 80 diastolic	12 to 20

**TABLE 7.1 Age Variations in Vital Signs** (Sources: American Heart Association, 2023; Cleveland Clinic, 2023; Sapra et al., 2023; Topjian et al., 2020.)

While the range of normal temperatures generally stays the same throughout the life span, it does become harder for the body to regulate temperature as it ages. Loss (or gain) of body fat and hormonal changes can affect how comfortably warm or cool the body may feel, resulting in the need to adjust clothing layers or environmental temperature when possible.

Knowing normal age-related variations as well as a patient’s medical history and aspects of their family history can help give the nurse a better understanding of their patients’ vital signs and changes that may occur through the course of their care for them.

### When to Assess Vital Signs

In general, healthcare facilities set their own guidelines as to when vital sign should be measured, and these guidelines depend on the acuity of the patients in the facility. Acute care facilities, such as hospitals, usually have a

regular schedule of assessing vital signs every four to eight hours, whereas critical care units within the hospital tend to measure vital signs every hour or even every fifteen to thirty minutes depending on patient acuity. Patients who are postsurgical, postprocedure, or clinically unstable will also have their vital signs checked frequently; some of these critical patients will have equipment that provides a constant monitoring of their vital signs to the nurse and medical providers. In contrast, ambulatory facilities, such as clinics and urgent care centers, or outpatient departments, such as physical and occupational therapy, will usually measure vital signs at the start of a patient visit. Assisted living facilities, such as nursing homes, with patients who live there for extended periods of time, may measure vital signs once every twenty-four hours or as necessary.

In addition to assessing vital signs as per facility guidelines, the nurse is empowered to take vital signs when necessary. For instance, if a patient says they are short of breath and they appear pale and sweaty, or complain of a racing heart or a pounding headache, the nurse can recheck the patient's vital signs on the spot. The information gained from the reported change in patient status and correlated in vital sign measurements is invaluable in deciding the next steps of action and treatment decisions.

In acute care facilities and long-term care centers, such as hospitals and nursing homes, the measurement of vital signs is often delegated to unlicensed assistive personnel, such as nurse's aides or patient care technicians. Regardless of who takes the vital signs, the registered nurse is ultimately responsible for taking action should there be any issues.

## Temperature

Targeted temperature management follows an average overall scale with normal fluctuations, which can range between 97.7°F and 99.5°F (36.5°C and 37.5°C) (Sapra et al., 2023). The targeted range for body temperature is referred to as **normothermia**. Fluctuations occur within normothermia due to circadian rhythm, metabolism, and hormones. For instance, circadian rhythm refers to the body's natural ability to lose heat in the extremities due to naturally occurring vasodilatation of the cutaneous vasculature during sleep-wake cycles. Changes in body temperature naturally drop between the hours of 3 and 5 a.m. and again between 1 and 4 p.m. Times of high metabolic activity increase temperature because of the increase in chemical reactions producing heat within the body. Exercise, infection, and hyperthyroidism are all examples of increased metabolic needs. Fluctuations of the thyroid hormone affect metabolic activity as well, meaning that an increase in thyroid hormone will increase the temperature.

The body's ability to maintain its temperature within normal ranges is termed **thermoregulation**. The hypothalamus is responsible for thermoregulation and is an endogenous, or internal, mechanism of heat regulation. For example, if the body's temperature is increasing, the hypothalamus will detect this change and increase blood flow to the body's surface, which in turn activates the sweat glands, inducing perspiration. If the body's temperature is decreasing, the hypothalamus will induce shivering to create more heat ([Figure 7.2](#)).

**FIGURE 7.2** The hypothalamus is the structure in the brain that is responsible for regulating temperature, also known as thermoregulation. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

When temperatures are markedly outside of normal ranges, they are considered either hyperthermia or hypothermia. When the core body temperature is more than 105.8°F (41°C), **hyperthermia** occurs. When the core body temperature is less than 95°F (35°C), it is known as **hypothermia**. These conditions are the result of exogenous factors (variables outside the body's control), such as exposure to cold water or extreme temperatures, not the result of the hypothalamus.

### Mechanisms of Heat Transfer

Heat is transferred from areas of higher temperatures to lower temperatures. The body utilizes four types of heat transfer to cool the body when necessary. These mechanisms are evaporation, radiation, convection, and conduction (Osilla, 2023). The transfer of heat through dissipation of sweat from the skin, thus cooling the body, is called **evaporation**. The loss of heat through indirect contact with cooler nearby surfaces or objects, such as when walking outside during the winter without a coat, is called **radiation**. When cooler air surrounds the body, such as when entering a room with air-conditioning, and the body cools, **convection** occurs. When skin encounters a cooler object (such as an ice pack), thus lowering its temperature, **conduction** occurs. On the other hand, shivering and teeth chattering when the body's temperature is lower than normal is an attempt by the hypothalamus to generate heat.

### Factors Affecting Temperature

Sometimes internal or external factors will overrule the body's homeostatic mechanisms, and the body cannot regulate its temperature enough on its own. This can cause abnormal body temperature. A body temperature greater than 100.4°F (38°C) is called **pyrexia**, or fever (Cleveland Clinic, 2023). A patient with a fever is considered **febrile**. When the patient's body temperature returns to normal after a fever, the patient is considered **afebrile**, or without fever.

Factors that affect temperature include the following:

- **Age.** Studies have shown that older adults tend to have lower baseline body temperatures. This can be due to natural age-related changes in the body, such as loss of insulating muscle mass and/or body fat.
- **Environment.** Changes in the environment can affect a patient's temperature, especially if they are older and cannot thermoregulate as well anymore due to reduced muscle mass and body fat.
- **Hormones.** Recent research has shown that the hormonal changes that accompany menopause can cause a reduction of core body temperature (Neff et al., 2016). The decreased levels of estrogen in the body cause the hypothalamus to become more sensitive to minor changes in body temperature. When the hypothalamus "thinks" the body is too warm, it sends messages to thermoregulate, which is why menopausal women often shiver after a hot flash.
- **Disease states.** The body's immune system response is frequently responsible for increases in core body temperature. Research has shown that the systemic inflammation often accompanying a fever is an evolutionary response to infection (Evans et al., 2015). A fever is a sign the body is out of its homeostatic balance and that the normal methods of thermoregulation are unable to return the body to its afebrile state. The resulting inflammation is the body's attempt to fight what is likely an invading pathogen, and this process raises the body's core temperature. From an evolutionary perspective, a fever also indicates a person should let their body heal and regain homeostasis. When we run a fever, often our instinct is to rest or sleep.

Of course, these factors are not definitive. Body temperature provides information at a specific moment, and the nurse should consider all factors when assessing a patient. The nurse should always look at the whole patient, think critically, and avoid jumping to conclusions based on temperature alone.

### Pulse

A **pulse** is the palpable way to assess each time the heart beats, while **heart rate** is the number of times the heart beats in one minute; these two terms are often used interchangeably. Measuring a patient's pulse is an accurate and rapid method of assessing their heart rate; in an emergent situation, the ability to assess a patient's pulse quickly and accurately helps providers make necessary care decisions.

### Physiology of the Pulse

During a normal heartbeat, blood flows from the right atrium into the right ventricle, then is pushed out to the lungs' vasculature where it is oxygenated by the pulmonary system. The newly oxygenated blood returns to the heart via the left atrium. It progresses into the left ventricle and from there is pushed out to the rest of the body. When the heart is relaxed, it allows blood to fill into it, and when it contracts, it pushes blood into the next chamber from the atrium to the ventricles, and from the ventricles out into the arteries. The right ventricle pushes blood into the pulmonary artery and toward the lungs to be oxygenated, and the left ventricle pushes blood into the aorta that then distributes it throughout the rest of the body.

Pulse refers to the pressure wave that expands and recoils arteries when the left ventricle of the heart contracts. It

is palpated at many points throughout the body. The most common locations to assess pulses as part of vital sign measurement include radial, brachial, carotid, and apical areas ([Figure 7.14](#)).

### Factors Affecting Pulse

There are factors that can affect a patient's pulse. These factors can affect the pulse rhythm, pulse rate, pulse force, and pulse equality. It is important to include these characteristics in the assessment documentation.

A normal pulse has a regular rhythm, meaning the frequency of the pulsation felt by your fingers is an even tempo with equal intervals between pulsations. For example, if you compare the palpation of pulses to listening to music, it follows a constant beat at the same tempo that does not speed up or slow down. Some cardiovascular conditions, such as atrial fibrillation, cause an irregular heart rhythm.

The **pulse force** is the strength of the pulsation felt on palpation. Pulse force can range from absent to bounding. The volume of blood, the heart's functioning, and the arteries' elastic properties affect a person's pulse force. Pulse force is documented using a four-point scale:

- 3+: full, bounding
- 2+: normal/strong
- 1+: weak, diminished, thready
- 0: absent/nonpalpable

A comparison of the pulse forces on both sides of the body is referred to as **pulse equality**. For example, a nurse often palpates the radial pulse on a patient's right and left wrists at the same time and compares if the pulse forces are equal. However, the carotid pulses should never be palpated at the same time because this can decrease blood flow to the brain. Pulse equality provides data about medical conditions such as peripheral vascular disease and arterial obstruction.

### Respiratory Status

The action of breathing is termed **respiration**. There are two types of respiration: external and internal ([Figure 7.3](#)). The act of breathing in oxygen (O<sub>2</sub>) and breathing out carbon dioxide (CO<sub>2</sub>) is called **external respiration**. The exchange of oxygen for carbon dioxide that occurs within the cells is called **internal respiration**.

**FIGURE 7.3** Understanding the relationship between internal and external respiration is a key part of understanding how gas exchange occurs in the lungs: (a) internal respiration occurring in the cells and (b) the body during external respiration. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Physiologically, when the body completes the processes of external respiration, the thoracic muscles in the chest and abdomen go to work. During **inspiration** (inhaling/breathing in), the diaphragm moves down as the lungs expand and fill with air, bringing oxygen into the body. This expansion increases the volume of space and air in the chest and enables air to flow inward. During **expiration** (exhaling/breathing out), the lungs naturally recoil as the air is expelled from the lungs, and the diaphragm moves back to its original position. A complete respiratory cycle of one sequence of inspiration and expiration is considered one breath while measuring a patient's respiratory rate.

Other things to consider when assessing respirations are the quality, rhythm, and rate of respirations. The quality of a person's breathing is normally relaxed and silent. However, loud breathing, nasal flaring, or the use of accessory muscles in the neck, chest, or intercostal spaces indicate respiratory distress. Respirations normally have a regular rhythm in children and adults who are awake. A regular rhythm means that the frequency of the respiration follows an even tempo with equal intervals between each respiration. It is also important to consider factors such as sleep cycle, presence of pain, and crying when assessing a patient's respiratory rate.

### Factors Affecting Respiratory Status

Many factors can affect the quality, rhythm, and rate of respirations. The quality of a patient's respirations can be affected by acid-base imbalances, low oxygen levels, carbon dioxide levels, or damage to any component of the respiratory system. The following are common factors that can affect respiratory status:

- **Age.** Lungs become less elastic with age, decreasing respiratory strength and room in the lungs for gas exchange. This can increase the work of breathing and prevent a person from having a strong, productive cough for airway clearance.
- **Activity level.** Physical activity and exercise make the lungs more adept at expanding and recoiling. A person who exercises frequently or regularly meditates and does deep breathing develops lungs that constantly stretch and contract. Their lungs are conditioned to this frequent expansion and contraction and become more efficient. Conversely, a person who is mostly sedentary does not have lungs that are conditioned to take the deep breaths required with strenuous physical activity, which is why a sedentary person is out of breath after strenuous physical activity.
- **Disease states.** Diseases that specifically affect the lungs include chronic obstructive pulmonary disease (COPD), asthma, pneumonia, and COVID-19, among others. The course and severity of these diseases varies greatly from person to person. Because of this, it is always important to consider how a patient's current or past medical histories can affect respiratory function.
- **Environment.** Factors in a person's surroundings can affect their respiratory status. For example, visiting places at high altitudes, such as Colorado or Peru, can affect respiratory function due to the thinner atmosphere and less available oxygen. This can negatively affect a person's oxygenation status and respirations, as the body attempts to maintain homeostasis. Pollution is another environmental factor that can negatively affect a person's oxygenation and respirations. Some jobs with poor air quality (mining, factories, military, construction) can also have deleterious harmful effects on the lungs, which can affect a person's respiratory status.
- **Lifestyle.** Damaging lifestyles and behaviors such as smoking or vaping introduce harmful toxins and pollutants into the lungs that have been proven to negatively affect a person's respiratory health. Multiple research studies have ascertained that smoking and vaping cause significant health risks due to the chemicals brought into the body, such as acetaldehyde, formaldehyde, and acrolein (American Lung Association, 2023).
- **Emotions.** Pain, anxiety, excitement, fear, and other emotions can affect a person's respiratory status. A heightened emotional state can cause a person to hyperventilate or breathe rapidly or deeply. Hyperventilation causes low levels of CO<sub>2</sub> in the blood and can make a person feel lightheaded, dizzy, short of breath, or even faint. This is not uncommon and often resolves once the person begins to breathe normally.

## REAL RN STORIES

### Effects of Anxiety on Respiration

**Nurse:** Sarah, RN

**Years in practice:** 7

**Clinical setting:** Veterans Administration medical center

**Facility location:** A large metropolitan city in Texas

I had a patient once who was very anxious about leaving the hospital. He had a history of generalized anxiety disorder and occasional panic attacks. He had been admitted for a minor procedure that had gone very well, but when we started preparing him for discharge, he started getting anxious and agitated. He kept telling us something was wrong and that he should stay longer. I did my best to reassure him. I retook his vital signs and even did another entire physical assessment. The patient's vital signs were beginning to change in accordance with his anxiety—his heart rate was slightly elevated at 110 bpm, but his blood pressure and respirations were within his normal range of 110/70 mm Hg and 18 breaths a minute. As I was talking with him, however, I observed him beginning to breathe faster and faster. He was getting really agitated; his heart rate increased up to 120 bpm, and then 125 bpm, and I could see his respirations were at 25 breaths per minute. I knew that if my patient continued to hyperventilate, he could pass out. Using what I had available, I quickly grabbed a paper bag that was in the room. I instructed the patient to breathe in and out of the bag. By doing so, the patient would bring some CO<sub>2</sub> back into his body and

restore the balance the hyperventilation was threatening to destabilize. While the patient was breathing slowly into the bag, I spoke with him calmly, trying to soothe and de-escalate his anxiety. When he seemed a bit calmer, I called the doctor to come talk to the patient about his concerns.

---

## Oxygen Saturation

The measure of arterial oxyhemoglobin saturation ( $\text{SpO}_2$ ) of arterial blood is called **oxygen saturation**. The reported result is a ratio, expressed as a percentage, between the actual oxygen content of the hemoglobin and the potential maximum oxygen-carrying capacity of the hemoglobin. A range of 95 to 100 percent is considered normal  $\text{SpO}_2$ ; values less than 95 percent are considered abnormal, indicating that oxygenation to the tissues is inadequate and should be investigated for potential hypoxia or technical error (Hafen & Sharma, 2022).

Oxygen saturation is determined using a **pulse oximeter** and is a noninvasive test that measures  $\text{SpO}_2$ . The pulse oximeter has LED lights and a photodetector that measures the amount of oxygenated hemoglobin that passes through a vascular bed, such as the fingertip, earlobe, or forehead (Hafen & Sharma, 2022). Desaturation, or decreased levels of  $\text{SpO}_2$ , indicates gas exchange abnormalities. Oxygen desaturation is considered a late sign of respiratory compromise in patients with reduced rate and depth of breathing.

### Factors Affecting Oxygen Saturation

Oxygenation is affected by many factors that are interconnected with other vital signs; thus, anything that affects one of the other vital signs can also affect oxygen saturation. Lung diseases such as COPD and asthma will affect oxygen saturation; pain and anxiety can affect it as well. If heart rate or respirations are abnormal, oxygen saturation may be affected as well.

Cold limbs, poor circulation from peripheral vascular disease, and certain blood disorders, such as sickle cell disease, can give a falsely low reading. A patient can also have a falsely low oxygen saturation reading if the oxygen probe is incorrectly placed or there is fingernail polish on the finger being used.

---

## LIFE-STAGE CONTEXT

### Obtaining Oxygen Saturations in Older Adults

Extremities in older adults can be much cooler than those of a younger patient; if this is the case, recheck the  $\text{SpO}_2$  in a warmer place (perhaps the other hand or the forehead), or give the patient a hot pack to hold to vasodilate the blood vessels and recheck. Research shows that older adults cannot adjust to temperature changes as quickly as younger people; reasons for this vary from medications to comorbidities and other chronic illnesses to age-related changes, such as loss of body fat (Centers for Disease Control and Prevention, 2021).

---

## Blood Pressure

The pressure of blood pushing against the walls of the arteries is termed **blood pressure**, and it is one of the most important vital signs because of its direct correlation to heart rate and oxygenation. A person needs a certain level of blood pressure to maintain perfusion, or adequate blood flow, to their organs to stay alive. A person's blood pressure must be enough to maintain perfusion to oxygenate and nourish the brain, the kidneys, the liver, the intestines, along with all other areas. A lack of perfusion results in a lack of oxygen, which ultimately results in organ failure and death.

### Physiology of Blood Pressure

When systemic arterial blood pressure is measured, it is recorded as a ratio of two numbers expressed as systolic pressure over diastolic blood pressure (e.g., 120/80, which is a normal adult blood pressure). The **systolic blood pressure** is the higher value (typically around 120 mmHg) and reflects the arterial pressure resulting from the ejection of blood during ventricular contraction, or systole. The **diastolic blood pressure** is the lower value (usually about 80 mmHg) and represents the arterial pressure of blood during ventricular relaxation, or diastole ([Figure 7.4](#)). Because of the physiology of the heart, the systolic pressure will never be lower than the diastolic pressure.

**FIGURE 7.4** The combination of cardiac muscle contraction and relaxation results in (a) systolic and (b) diastolic blood pressure, which is the metric healthcare providers use called blood pressure. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The difference between the systolic pressure and the diastolic pressure is the **pulse pressure**. For example, an individual with a systolic pressure of 120 mm Hg and a diastolic pressure of 80 mm Hg would have a pulse pressure of 40 mm Hg. Generally, a pulse pressure should be at least 25 percent of the systolic pressure.

The **mean arterial pressure (MAP)** represents the “average” pressure of blood in the arteries, that is, the average force driving blood into vessels that serve the tissues. A mean is a statistical concept (also known as an average) and is calculated by taking the sum of the values divided by the number of values. Although MAP can be complicated to measure directly and calculate accurately, it can be approximated by adding the diastolic pressure to one-third of the pulse pressure, or systolic pressure minus the diastolic pressure. See this calculation:

$$\text{MAP} = \text{diastolic BP} + \frac{(\text{systolic} - \text{diastolic BP})}{3}$$

Normally, MAP falls within the range of 70 to 110 mm Hg. If the value falls below 60 mm Hg for an extended time, blood pressure will not be high enough to ensure circulation to and through the tissues, which results in ischemia, or insufficient blood flow.

### Factors Affecting Blood Pressure

There are many factors that affect a person’s blood pressure, and the mechanics of these factors as they relate to blood pressure and the heart are discussed in [Chapter 19 Oxygenation and Perfusion](#). This discussion focuses on the various internal and external factors that can affect blood pressure readings:

- Emotional states. Heightened emotions such as anger, sadness, fear, and anxiety can increase a person’s heart rate, which will accordingly increase their blood pressure. In situations such as this, relieving the emotional distress can often alleviate the high blood pressure.
- Disease states. Obesity, high cholesterol, coronary artery disease, and diabetes all affect the cardiovascular system and therefore will also affect blood pressure readings. Sometimes, chronic kidney disease or lupus can alter blood pressure and perfusion.
- Social and dietary habits. Smoking, excessive alcohol, caffeine, and sodium consumption can all increase the

risk of hypertension.

- Medications. Patients who have heart arrhythmias, such as persistent tachycardia, at baseline can be put on a medication called a beta blocker, which slows their heart rate; this will also affect their blood pressure.

A low pulse pressure may occur, for example, in patients with a low stroke volume, which may be seen in congestive heart failure, stenosis of the aortic valve, or significant blood loss following trauma. In contrast, a high or wide pulse pressure is common in healthy people following strenuous exercise, when their resting pulse pressure of 30 to 40 mm Hg may increase temporarily to 100 mm Hg as stroke volume increases. A persistently high pulse pressure at or above 100 mm Hg may indicate excessive resistance in the arteries and can be caused by a variety of disorders. Chronic high resting pulse pressures can degrade the heart, brain, and kidneys and warrant medical treatment.

A condition called hypoxia, inadequate oxygenation of tissues, commonly accompanies ischemia. The term *hypoxemia* refers to low levels of oxygen in systemic arterial blood. Neurons are especially sensitive to hypoxia and may die or be damaged if blood flow and oxygen supplies are not quickly restored.

## 7.2 How to Perform Vital Signs

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify how to assess a patient's temperature
- Understand how to assess a patient's pulse rate
- Recall how to assess a patient's respiratory status
- Demonstrate how to assess a patient's oxygenation saturation
- Analyze how to assess a patient's blood pressure

The consistent and accurate measurement of vital signs is a fundamental skill that healthcare providers in all facilities and settings should be able to deliver. Nurses must have the technical skill to take vital signs correctly, the ability to recognize changes in those vital signs from the patient's baseline, and the ability to obtain additional data, if necessary, in order to better analyze the reasons for the change in vital signs. This section discusses the proper technique to measure each of the five vital signs: temperature, pulse, respirations, blood pressure, and oxygen saturation.

### Assessing Temperature

Accurate temperature measurements provide information about a patient's health status and guide clinical decisions. Methods of measuring body temperature vary based on the patient's developmental age, cognitive functioning, level of consciousness, and health status, as well as agency policy. Two main scales are used to measure temperature: Fahrenheit and Celsius. Often these two scales are used interchangeably in the healthcare setting; most thermometers available for temperature measurement are digital and can be manually programmed to show one scale or the other (Figure 7.5).

**FIGURE 7.5** It is important for nurses and other healthcare providers to recognize hypothermia, normal temperature, and hyperthermia on both Fahrenheit and Celsius temperature scales. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Sites and Methods

Common methods of temperature measurement in the hospital setting include oral, tympanic membrane, axillary, and rectal routes. It is important to document the route used to obtain a patient's temperature because of normal variations in temperature in different locations of the body.

Selecting the correct method to take a temperature is also important ([Table 7.2](#)). For children 5 years of age and under, the most accurate choice for taking a temperature is rectally; however, as most children do not like to have their temperature taken this way, it can also be done via tympanic or axillary routes. Tympanic temperatures are the most accurate after rectal/core temperatures. Since oral temperatures require cooperation from the patient, they are usually indicated for patients over 5 years of age.

Age	Recommended Method
Newborn to 3 months	Rectal
3 months to 3 years	Rectal, axillary, tympanic
4 to 5 years	Rectal, oral, axillary, tympanic
5 years and older	Oral, axillary, tympanic

**TABLE 7.2** Recommended Methods for Temperature Measurement  
(Source: Sapra et al., 2023.)

### Oral Temperature

To take an oral temperature, obtain an oral thermometer. These come in many designs and sizes, depending on your practice location ([Figure 7.6](#)). Oral temperature is reliable when it is obtained close to the sublingual artery.

(a)

(b)

**FIGURE 7.6** (a) Oral thermometers come in many shapes and sizes, depending on your practice location. (b) Devices can have blue coloring, indicating it is an oral or axillary thermometer, as opposed to a rectal thermometer that has red coloring. (credit (a): Digital Medical Thermometer, Adoric Rectal and Oral Thermometer for Adults and Babies, Thermometer for Fever - Accurate and Fast Readings with Fever Indicator" by Jefferson William/Flickr, CC BY 2.0) (credit (b): "Oral Thermometer" by Chippewa Valley Technical College, CC BY 4.0)

Follow these steps to take an oral temperature:

1. Wash your hands before any patient interaction, and ensure use of proper personal protective equipment (PPE) as required. Gloves are the standard when working with patients; however, if the patient requires additional PPE, such as masks or gowns, don the additional appropriate PPE as required. Ensure there is a probe cover for the oral thermometer if the thermometer is reusable.
2. Ask the patient to open their mouth and place the thermometer in the posterior sublingual pocket under the tongue, slightly off-center ([Figure 7.7](#)).

3. Ask the patient to keep the thermometer under their tongue with their mouth closed and refrain from moving it around. Leave the thermometer in place for as long as is indicated by the device manufacturer. The thermometer typically beeps within a few seconds when the temperature has been taken.

**FIGURE 7.7** Improperly placing a thermometer in a patient's mouth can result in inaccurate temperature measurements. By placing an oral thermometer in one of the "hot pockets" under the tongue, you can obtain a more accurate reading. (credit: "Frenulum linguae" by Wikimedia Commons, CC BY 3.0)

4. Remove the thermometer, and read the digital display of the results. Discard the probe cover in the garbage (without touching the cover), clean the device according to facility policy, and place the probe back into the device, if appropriate.

## PATIENT CONVERSATIONS

### Assessing Temperature

**Scenario:** Corrine is a nurse on a medical-surgical floor, and she is preparing to discharge her 45-year-old adult patient, Anna. While she is preparing the paperwork, Anna puts on her call light. Corrine goes to the room.

**Patient:** I'm suddenly freezing cold, and I'm shivering! What is the temperature in here?

**Nurse:** [checks thermostat] It's 73°F (22.8°C) in here, but it has been that way as long as you have been here. How are you feeling?

**Patient:** I don't know. Besides cold, I guess I just don't feel good. Just kind of icky.

**Nurse:** Let me take your temperature. [Gets the oral thermometer, sees that the temperature is 104°F (40°C). Corrine looks at her patient and sees she looks a bit more flushed than usual, but she also knows the patient would have many other symptoms if this was a true temperature, so she determines further assessment is needed.] Have you had anything to eat or drink since I was last in here?

**Patient:** Not really. Well, when I started feeling cold, I drank some of my hot tea to try and warm up. I'm still really cold though.

**Nurse:** Ah okay. Your oral temperature was quite high, but that's probably because of the tea. Let me take your temperature from a different site. [She gets the tympanic thermometer and checks Anna's temperature in her ear.] Ah. Your temperature is 101.3°F (38.5°C), so it looks like you may have a bit of a fever. Let me grab you a warm blanket, and then I will call your provider.

**Scenario follow-up:** Corrine knows that while tympanic temperatures are not as accurate as oral or core temperatures, the fact Anna has a fever correlates with her feeling chilled; thus, even though the oral temperature was inaccurate, she knows an intervention is still required. She provides the blanket for patient comfort while contacting the doctor.

Some factors can cause an inaccurate measurement using the oral route. For example, if the patient recently consumed a hot or cold food or beverage, chewed gum, or smoked prior to measurement, a falsely elevated or decreased reading may be obtained. Oral temperature should be taken fifteen to twenty-five minutes following

consumption of a hot or cold beverage or food, or five minutes after chewing gum or smoking.

### Tympanic Temperature

The tympanic temperature is typically 32.5°F to 33.1°F (0.3°C–0.6°C) higher than an oral temperature. It is an accurate measurement because the tympanic membrane shares the same vascular artery that perfuses the hypothalamus (the part of the brain that regulates the body's temperature). The tympanic method should not be used if the patient has a suspected ear infection.

Obtain the appropriate thermometer to take tympanic (ear) temperature. These thermometers also come in many shapes and sizes, depending on your practice location ([Figure 7.8](#)).

**FIGURE 7.8** Tympanic thermometers can be used for adult patients and pediatric patients 2 years of age and older. (credit: “Tympanic thermometer” by BCcampus, CC BY 4.0)

Follow these steps to obtain a tympanic temperature:

1. Wash your hands before any patient interaction. Don appropriate PPE.
2. Remove the tympanic thermometer from its holder, and place a probe cover on the thermometer tip without touching the probe cover with your hands. Turn the device on.
3. Ask the patient to keep their head still. For an adult or older child, gently pull the helix (outer ear) up and back to visualize the ear canal. For an infant or child under age 3 years, gently pull the helix down. Insert the probe just inside the ear canal, but never force the thermometer into the ear. The device will beep within a few seconds after the temperature is measured ([Figure 7.9](#)).

**FIGURE 7.9** Taking a tympanic temperature accurately entails gently using the pinna of the ear to open the ear canal, thus getting a better read on the tympanic membrane. (credit: modification of “Taking tympanic temperature” by BCCampus, CC BY 4.0)

4. Remove the thermometer, and read the results displayed. Discard the probe cover in the garbage (without touching the cover), clean the device according to facility policy, and then place the device back into the holder.

### **Axillary Temperature**

The axillary method is a minimally invasive way to measure temperature and is commonly used in children. It uses the same electronic device as an oral thermometer (with blue coloring). However, the axillary temperature can be as much as 33.8°F (1°C) lower than the oral temperature.

Obtain the appropriate thermometer, and if necessary, ensure it is calibrated to take axillary temperature.

Follow these steps to take an axillary temperature:

1. Wash your hands before any patient interaction, and don gloves. Ensure use of any additional appropriate PPE as required.
2. Remove the probe from the device and place a probe cover on the thermometer without touching the cover with your hands.
3. Ask the patient to raise their arm and place the thermometer probe in their armpit on bare skin as high up into the axilla as possible. The probe should be facing behind the patient. Ask the patient to lower their arm and leave the device in place until it beeps, usually about 10 to 20 seconds ([Figure 7.10](#)). If the patient is a child or is confused, gently assist them to keep the thermometer in place.

**FIGURE 7.10** The nurse is taking an axillary temperature with the patient, while assisting with keeping the thermometer probe in place. (credit: “Axillary temperature being taken” by BCCampus, CC BY 4.0)

4. Hold the thermometer in place until it beeps, indicating the temperature reading has been recorded.
5. Remove thermometer, clean according to facility policy, and place the probe back into the device.

### Rectal Temperature

Measuring rectal temperature is an invasive method. Some sources suggest its use only when other methods are not appropriate. However, when measuring infant temperature, it is considered a gold standard because of its accuracy. The rectal temperature is usually 33.8°F (1°C) higher than the oral temperature. A rectal thermometer has red coloring to distinguish it from an oral or axillary thermometer (Figure 7.11). Thermometers that are specified for rectal use only should not be used to take any other type of temperature.

**FIGURE 7.11** Thermometers specified for rectal use only are generally colored red and/or labeled for rectal use only. (attribution: Copyright

Rice University, OpenStax, under CC BY 4.0 license)

Follow these steps to take a rectal temperature:

1. Before taking a rectal temperature, ensure the patient's privacy. Wash your hands and put on gloves and any other PPE as necessary.
2. For infants, place them in a supine position and raise their legs upward toward their chest. Parents may also be encouraged to hold the infant across their lap, face down, to decrease movement and provide a sense of safety (Figure 7.12).

**FIGURE 7.12** Rectal temperatures can be taken in either of these positions for an infant or child under the age of 2 years. (a) In this position, the infant is placed on their back with the nurse holding their legs up. (b) Alternatively, the infant can be placed stomach down on the nurse's lap. Rectal thermometers should be clearly marked that they are for rectal use only and should not be used for any other route. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

3. When taking a rectal temperature in older children and adults, assist them into a side-lying position (Figure 7.13) and explain the procedure.

**FIGURE 7.13** When taking a rectal temperature in adults, bending one or both of the knees better exposes the anus and anatomically aligns the rectum for ease of inserting the temperature probe. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

4. Remove the probe from the device and place a probe cover on the thermometer. Lubricate the cover with a water-based lubricant, and then gently insert the probe  $\frac{1}{2}$  to 1 in (1.3 to 2.5 cm) inside the anus, depending on the patient's size. Remove the probe when the device beeps.
5. Read the result and then discard the probe cover in the trash can without touching it. Assist the patient with redressing/covering up, as appropriate. Disinfect the device as indicated by facility policy. Remove your gloves, wash your hands, and store the thermometer in a designated place to ensure it will be only for rectal

use.

Taking rectal temperatures may not be the standard of practice in acute care or inpatient settings. In general, a specific order is required in inpatient/acute care settings for measuring rectal temperatures. Rectal temperatures are contraindicated in many patient situations, ranging from disease states, such as leukemia, to whether the patient is on certain medications such as blood thinners. Moreover, if the patient cannot be positioned in such a way to take a rectal temperature, this method is contraindicated as well.

### Normal Temperature Ranges

Normal temperature ranges can vary across the life span and can vary among individuals. When working in an inpatient or acute care facility, be sure to check facility policy for specific parameters on what defines a fever. See [Table 7.3](#) for normal temperature ranges for various routes.

Method	Normal Range
Oral	96.4°F to 99.1°F (35.8°C–37.3°C)
Axillary	94.7°F to 97.3°F (34.8°C–36.3°C)
Tympanic	97°F to 100.2°F (36.1°C–37.9°C)
Rectal	98.2°F to 100.4°F (36.8°C–38°C)

**TABLE 7.3** Normal Temperature Ranges

### Assessing Pulse

Pulse refers to the pressure wave that expands and recoils arteries when the left ventricle of the heart contracts. It is palpated at many points throughout the body. The most common locations to assess peripheral pulse are the radial, brachial, posterior tibial, dorsalis pedis, and popliteal arteries. Other sites are listed in [Figure 7.14](#).

**FIGURE 7.14** A patient's pulse is most readily measured at the radial artery but can be measured at any of the pulse points shown. (credit: modification of work from *Anatomy and Physiology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The **pulse rate** is measured in beats per minute, counted with the first beat detected. It is considered best practice to assess a patient's pulse for a full sixty seconds, especially if there is an irregularity to the rhythm. Every nurse must determine the most appropriate site to assess a patient's pulse. This is especially important if the patient is bleeding, unconscious, or has experienced trauma that might compromise a pulse site. In an emergency, the body will shunt blood away from the body's periphery (arms or legs) in favor of the core (torso and head). In this situation, the nurse should check pulses that are more centrally located, such as the carotid or femoral pulses, and then check more peripheral pulses, such as radial or brachial pulses, only if necessary.

## REAL RN STORIES

### The Necessity of Strong Assessment Skills

**Nurse:** Ahmad, RN

**Years in practice:** 4

**Clinical setting:** Cardiovascular Intensive Care Unit (CICU)

**Facility location:** Large hospital in Milwaukee, Wisconsin

It was three years into my nursing career, and at the end of my first year in the intensive care unit. I loved the detail-oriented emphasis on science and assessment in the CICU, and one night I found out just how important it was to get these details right. I admitted a vascular patient from the cardiac catheterization (cath) lab. They had a stent placed in their right leg to help open up a stenotic (clogged or blocked) artery. They had a blood thinner running through a large IV called a sheath in their groin to help keep the artery patent. My orders were to check the pulses in the lower extremities every hour. The patient was in a lot of pain and said the pain in their leg was "excruciating." I told the patient that was not uncommon because their limb was being perfused (receiving blood flow) adequately again, and often this causes a lot of discomfort. I got them their scheduled pain medication and continued to monitor them as ordered. Pulses were auscultated with a Doppler (a type of small ultrasound machine to help find

pulses that cannot be palpated) upon arrival, and I assessed them as strong, meaning I could hear loud pulsing on the Doppler machine. As the night continued, however, the patient continued to complain of increasing pain in the leg with the new stent. I also began to have a harder time finding the pulses in the right leg. At 1 a.m., the foot on the affected side started to feel colder, and the pulse was hard to hear with the Doppler. At 2 a.m., the pulse was faint, and the patient's foot started to look grayish and patchy (mottled). I sent a message to the resident, who called me back and told me to "keep an eye on it." When I checked the pulses again at 3 a.m., I couldn't find the dorsalis pedis pulse at all. I searched for at least fifteen minutes with the Doppler and couldn't find a pulse. The patient was screaming in pain every time I touched their leg, so I asked my charge nurse to bring some pain medication and to call the resident. I then asked the charge nurse to come to the bedside and see if she could find the pulse herself. She had been a CICU nurse for over ten years, and I trusted her judgment. She couldn't find the pulse either.

Finally, the resident came and was visibly tired and irritated. I reported my findings—increasing difficulty finding the lower extremity pulse, and now the pulse was absent. Extremity increasingly cool to the touch and now appearing mottled. The resident rolled his eyes and asked if we had checked a pulse again after calling. I said I had. He then asked if I had used a Doppler, and if I was "sure" there was no pulse. Again, I said I had used the Doppler and was sure, but I had also had the charge nurse check. The resident was clearly unhappy at being woken up, but this was important, so I encouraged him to try and find the pulse himself. The resident grabbed the Doppler and began to search for a pulse. After ten minutes, he couldn't find one either and finally started to look worried; he ordered a formal ultrasound of the leg to be done STAT at the bedside and called the vascular fellow to come assess the patient. Within thirty minutes, the fellow had arrived and had also assessed there was no pulse. The ultrasound confirmed the formation of a new clot in the right leg that was occluding the flow of blood. Things moved very quickly after that; ultimately, the patient ended up emergently going back to the operating room around 6 a.m. for a thrombectomy (clot removal procedure). I'll never forget that night because even though the doctor was dismissive, I trusted my instincts and advocated for the patient. My assessment saved the patient's leg.

---

### Sites and Methods

While assessing a pulse, place two fingers on the pulse point. It is important to use your index and middle fingers to assess pulses; your own thumb has a pulse and may interfere with your assessment. Also, the index and middle fingers can easily access almost any pulse point. Pulse is created by the force of blood being pumped through the aorta from the left ventricle. This force manifests as a regular throb at a specific spot under the skin, called a **pulse point**, where the artery is close to the surface. Press down with your fingers until you can feel the pulsation, but not so forcefully that you are obliterating the wave of the force passing through the artery. Somewhere between light and firm is the best way to check a pulse, and then wait to feel the beat under your fingers.

With **palpation**, pulse is assessed by feeling with fingers. Palpation is the most frequently used method of assessing pulse, as it is readily available to do and can be done quickly if there is a critical need. Sites at which to obtain pulse measurements include the **radial artery** (pulse point located at each wrist below the base of the thumb), **carotid artery** (pulse point located on each side of the neck lateral to and above the trachea), **popliteal artery** (pulse point located behind both knees), **femoral artery** (pulse point located in the groin), **brachial artery** (pulse point located on each side of the upper arm on the medial aspect superior to the antecubital fossa), **posterior tibial artery** (pulse point located posterior to the medial aspect of the ankle), and **dorsalis pedis artery** (pulse point located roughly atop both feet). These common sites and methods of obtaining pulse measurements are listed in [Table 7.4](#).

Location	Illustration	Explanation
Radial artery (wrist)	 <p data-bbox="448 562 915 611"><b>FIGURE 7.15</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>	<p data-bbox="959 243 1406 474">Place the index and middle fingers where the thumb meets the wrist to assess the radial pulse. Note that radial pulses are difficult to palpate on newborns and children under the age of 5 years, so the brachial or apical pulses are typically obtained in this population.</p>
Carotid artery (neck)	 <p data-bbox="448 982 915 1031"><b>FIGURE 7.16</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>	<p data-bbox="959 663 1406 989">Place the index and middle fingers laterally on one side or the other of the trachea, taking special care not to press too hard to occlude blood flow or cause discomfort to the trachea. The carotid pulse is typically palpated during medical emergencies because it is the last pulse to disappear when the heart is not pumping an adequate amount of blood.</p>

**TABLE 7.4** Pulse Points

Location	Illustration	Explanation
<p>Popliteal artery (behind the knee)</p>	 <p><b>FIGURE 7.17</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>  <p><b>FIGURE 7.18</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>	<p>With the knee slightly bent, place the index and middle fingers on the medial aspect of the back of the knee. This can also be done with both hands to palpate both the medial and lateral aspects of the knee.</p>
<p>Femoral artery (groin)</p>	 <p><b>FIGURE 7.19</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>	<p>With the patient lying supine and relaxed, place the index and middle finger in the middle of the crease where the leg joins the anterior abdomen.</p>

**TABLE 7.4** Pulse Points

Location	Illustration	Explanation
Brachial artery (upper inner arm)	 <p><b>FIGURE 7.20</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>	<p>With the patient sitting upright or lying in bed, place the index and middle finger on the medial aspect of the upper arm superior to the antecubital fossa; this also is the place where the bladder of the blood pressure cuff is placed when taking a blood pressure. A brachial pulse is typically assessed in infants and children because it can be difficult to feel the radial pulse in these populations. If needed, a Doppler ultrasound device can be used to obtain the pulse.</p>
Posterior tibial artery (behind the ankle bones)	 <p><b>FIGURE 7.21</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>	<p>This is easiest to feel when the patient is lying supine. Place the index and middle fingers posterior to the ankle bones.</p>
Dorsalis pedis artery (top of the foot)	 <p><b>FIGURE 7.22</b> (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)</p>	<p>This is best done with the patient lying supine. Place two fingers on the top of the foot; often this pulse is located more medially, superior to the great toe.</p>

### LINK TO LEARNING

A demonstration of how to complete a [nine pulse points assessment on the body \(https://openstax.org/r/77pulsepoints\)](https://openstax.org/r/77pulsepoints) is presented in this video.

Sometimes, however, pulses cannot be palpated. This can be due to many reasons, such as trauma to the body or patient disease states, such as cardiovascular disease or peripheral artery disease. If a pulse is absent, a **doppler ultrasound device** is typically used to verify perfusion of the limbs. A Doppler is a handheld device that allows the examiner to hear the whooshing sound of the pulse. This device is also commonly used when assessing peripheral pulses in the lower extremities, such as the dorsalis pedis pulse or the posterior tibial pulse. Using a Doppler still requires the nurse to be able to identify the anatomical locations of pulses and to know which pulses are best to use in a given situation.

Follow these steps to use a Doppler to auscultate pulses:

1. Obtain a Doppler machine. Wash hands before any patient interaction. Don gloves and any other appropriate PPE necessary.
2. Locate the desired pulse to assess. Apply a small amount of medical-grade ultrasound gel to the desired pulse site.
3. Turn on the Doppler, and place it atop the gel. Gently press on the Doppler probe; as with manual palpation, do not press so hard as to occlude the artery, but do not place the probe so lightly as to not be able to assess the pulse.
4. Listen for a pulsing “whoosh” sound to know if the pulse has been located. Ensure that the sound heard is pulsing; a continuous “whoosh” indicates the Doppler has located a vein and not an artery. Once the pulse is correctly located, assess as if palpating for sixty seconds (or thirty seconds and multiply by two).
5. Wipe down the patient’s skin to clean off the ultrasound jelly; also wipe down the Doppler machine and clean with an alcohol wipe or according to facility policy.

### Normal Pulse Ranges

The normal adult pulse rate (heart rate) at rest is 60 to 100 bpm with different ranges according to age ([Table 7.5](#)). It is important to consider each patient’s situation when analyzing if their pulse rate is within normal range. Begin by reviewing their documented baseline pulse rate. Consider other factors if the pulse is elevated, such as the presence of pain or crying in an infant. It is best to document the assessment when a patient is resting and comfortable, but if this is not feasible, document the circumstances surrounding the assessment, and reassess as needed.

Age Group	Pulse Rate (bpm)
Preterm	120 to 180
Newborn (0–1 month)	100 to 160
Infant (1–12 months)	80 to 140
Toddler (1–3 years)	80 to 130
Preschool (3–5 years)	80 to 110
School age (6–12 years)	70 to 100
Adolescents (13–18 years) and adults	60 to 100

**TABLE 7.5** Normal Pulse Rate Range

### Assessing Respiratory Rate

A patient’s respiratory rate can be indicative of homeostatic imbalances in the body; thus, an accurate assessment

is invaluable to healthcare providers. Rapid rates can be due to pain or anxiety caused by external factors; they can also be responses to internal homeostatic imbalances such as **respiratory acidosis** or **respiratory alkalosis** (discussed in greater depth in [Chapter 20 Fluid, Electrolyte, and Acid-Base Balance](#)). Respiratory acidosis is a condition that occurs when your lungs cannot remove all the carbon dioxide produced by the body. This results in an overabundance of carbon dioxide that results in acidosis, or too much acid in the blood. This can happen for many reasons, some of which include very slow or shallow breathing. Respiratory alkalosis, on the other hand, is a condition when the lungs have removed too much carbon dioxide. This results in too little carbon dioxide in the blood and can occur with very rapid, deep breaths. Accurately assessing a patient's respiratory rate can help pinpoint whether these or other respiratory issues are occurring and can help the nurse and other healthcare providers make the appropriate care decisions necessary.

### Measuring Respirations

The easiest and most time-efficient way to measure respiratory rate is to first tell the patient that you will be assessing their pulse. Not telling the patient their respiratory rate is being measured ensures they do not unconsciously change their respiratory rate. Locate the radial pulse and then observe the patient's chest rise and fall; if the patient has a regular rate, count each respiration cycle for thirty seconds and multiply by two. If the patient's respirations are irregular, count each cycle for a full minute. Assessment of respirations also includes auscultating their breaths with a stethoscope. Depending on your practice location, the patient may be sitting up or lying down in bed. The ideal position for assessing respirations is sitting up and a bit forward; this is so gravity can help the lungs be as open as possible. If patient acuity does not allow for this, assessing respirations while supine or lying upright in bed is acceptable.

When obtaining a respiratory rate, the respirations are also assessed for quality, rhythm, and rate. The quality of a person's breathing is normally relaxed and silent. However, loud breathing, nasal flaring, or the use of accessory muscles in the neck, chest, or intercostal spaces indicates respiratory distress. People experiencing respiratory distress also often move into a tripod position, meaning they are leaning forward and placing their arms or elbows on their knees or on a bedside table. If a patient is demonstrating new signs of respiratory distress as you are obtaining their vital signs, it is vital to immediately notify the healthcare provider or follow agency protocol. Respirations normally have a regular rhythm in children and adults who are awake. A regular rhythm means that the frequency of the respiration follows an even tempo with equal intervals between each respiration. However, newborns and infants commonly exhibit an irregular respiratory rhythm.

### LINK TO LEARNING

Learn more about how to [assess respiratory rate accurately in patients \(https://openstax.org/r/77resprate\)](https://openstax.org/r/77resprate) by watching this video.

### Normal Respiratory Rate Ranges

Like all other vital signs, the normal respiratory rate is different based on the patient's age. In infancy, the normal rate is 30 to 53 breaths per minute. This decreases to 22 to 37 breaths per minute for toddlers, and 18 to 25 breaths per minute for school-age children. Then from adolescence through adulthood, the normal rate is 12 to 20 breaths per minute. Changes from these norms can be indicative of disease processes or homeostatic imbalances with the patient, or just as with the other vital signs, it can indicate the effect of external and modifiable factors such as anxiety, fear, or pain. It is important for the nurse to consider the respiratory assessment data in context with the other vital signs and other situational and correlating data obtained from the patient to direct the appropriate course of action.

### Assessing Oxygen Saturation

Oxygen saturation is measured with a machine called a pulse oximeter, which consists of a specialized probe that shines two LED lights—one red and one infrared—through the skin or the fingernail. The probe analyzes the lights as they shine through the red blood cells in the finger. The wavelengths of light differ according to the amount of hemoglobin attached to the red blood cells; the oximeter analyzes this and determines the patient's oxygen saturation. Pulse oximetry devices may be a disposable sticker that wraps around one of the patient's fingers and

attaches to a reusable oximetry machine or a clip that goes over the tip of the finger ([Figure 7.23](#)). These devices often assess the patient's heart rate as well as measure their oxygen saturation.

**FIGURE 7.23** Measuring oxygen saturation with a pulse oximeter can be done in a variety of healthcare settings, or even at home. (credit: modification of “Pulse oximeter” by Flickr, CC BY 2.0)

Nail polish or artificial nails can affect the absorption of light waves from the pulse oximeter and decrease the accuracy of the SpO<sub>2</sub> measurement when using a probe clipped on the finger. An alternative sensor that does not use the finger should be used for these patients, or the nail polish should be removed. If a patient's hands or feet are cold, it is helpful to clip the sensor to the earlobe or tape it to the forehead.

### Normal Oxygen Saturation Ranges

Across the life span, normal oxygen does not vary much; a healthy individual should have an SpO<sub>2</sub> reading between 95 and 100 percent, regardless of age. For patients with chronic respiratory conditions, such as COPD, the target range for SpO<sub>2</sub> is often lower at 88 to 92 percent. Although SpO<sub>2</sub> is an efficient, noninvasive method to assess a patient's oxygenation status, it is an estimate and is not always accurate. For example, if a patient is severely anemic and has a decreased level of hemoglobin in the blood, the SpO<sub>2</sub> reading is affected. Decreased peripheral circulation can also cause a misleading low SpO<sub>2</sub> level.

In practice, the nurse should be sure to check with the provider to familiarize themselves with the patient's baseline SpO<sub>2</sub> and ensure the proper orders are in place that outline the amount of oxygen a patient should get according to their disease state. Oxygen is a drug like any other medication, and a person can be given too little or too much. Nurses are licensed to apply oxygen as necessary in an emergency situation and can obtain an order from the healthcare provider after the fact. Some facilities may have standing orders based on vital sign readings.

### Assessing Blood Pressure

The accurate measurement of blood pressure is important for ensuring patient safety and optimizing body system function. Blood pressure measurements are used by healthcare providers to make important decisions about a patient's care. Blood pressure measurements help providers make decisions about whether a patient needs fluids or prescription medications. It is crucial to follow the proper steps to obtain a patient's blood pressure to ensure the care team has accurate data to help make healthcare decisions and determine a plan of care. A nurse must first select a blood pressure cuff that is the correct size for the patient, as noted in the facility's guidelines ([Figure 7.24](#)).

**FIGURE 7.24** Selecting the correct size blood pressure cuff is required in order to obtain an accurate blood pressure measurement. A blood pressure cuff that is too large for a patient’s arm can lead to a reading that is falsely low, whereas a blood pressure cuff that is too small for a patient’s arm can lead to a reading that is falsely high. (credit: “Sizes of Blood Pressure Cuffs” by National Library of Medicine, CC BY 4.0)

Blood pressure readings can be inaccurate if the cuff is too small or large for the patient’s arm. The width of the cuff should be 40 percent of the person’s arm circumference, and the length of the cuff’s bladder (part of the cuff that inflates) should be 80 to 100 percent of the person’s arm circumference. Keep in mind that only about half of the blood pressure cuff is the bladder, and the other half is cloth with a hook-and-loop fastener to secure it around the arm. The cuff must also be placed appropriately on the patient’s arm so the bladder is over the brachial artery. Another factor to be considered is if the patient has any restrictions on blood pressure being taken. It is important to assess any restrictions on locations for blood pressure readings. For example, patients who have had chest surgery, such as a mastectomy or lymph node dissection, may be advised to restrict blood pressure readings on that side of the body.

## LINK TO LEARNING

The [procedure for obtaining a blood pressure measurement \(https://openstax.org/r/77bloodpres\)](https://openstax.org/r/77bloodpres) is presented in this video.

### Sites and Methods

To assess blood pressure, place the patient in a relaxed reclining or sitting position. The patient should be seated quietly for at least five minutes in a chair prior to blood pressure measurement. Ask the patient which arm they prefer to use. Be aware of conditions that contraindicate the use of an arm for blood pressure measurement, such as a previous mastectomy or the presence of a fistula. During the procedure, both feet should be on the floor, and the arm should be supported at heart level. Adapt the procedure to life-span considerations of the patient, as appropriate. There are four main methods to assessing blood pressure:

1. To take a **manual blood pressure** reading, a stethoscope and a **sphygmomanometer** (manual blood pressure cuff) are used. This method entails placing the bell (smaller side) or diaphragm (larger side) of the

stethoscope on the brachial artery and compressing the artery with the blood pressure cuff. The following are completed to obtain a manual blood pressure:

- a. Gather the proper equipment: a sphygmomanometer, a stethoscope, and an appropriately sized blood pressure cuff. The cuff's bladder should encircle 80 to 100 percent of the patient's arm circumference (AHA, 2023). Wash your hands and don gloves (if necessary) before any patient interaction. Don any appropriate PPE as required per patient situation and facility guidelines.
- b. Remove or rearrange the patient's clothing so the cuff and the stethoscope are on bare skin.
- c. Center the bladder of the blood pressure cuff over the brachial artery with the lower margin 1 in above the antecubital space. Fit the cuff evenly and snugly. Palpate the brachial artery in the antecubital space.
- d. Locate the radial pulse.
- e. Close the valve on the air bulb and inflate the cuff rapidly (while palpating the radial or brachial pulse) to the level at which pulsations are no longer felt.
- f. With the eartips of the stethoscope placed downward and forward, place the bell/diaphragm lightly on the brachial artery and rapidly inflate the cuff to thirty points above where the brachial or radial pulse is no longer felt.
- g. Deflate the cuff gradually at a constant rate by slightly opening the valve on the bulb (2 to 3 mm Hg/second) until the first **Korotkoff** (pulse) sound is heard. Note the systolic pressure.
- h. Continue to deflate the cuff slowly at 2 mm Hg/second. Note the point at which Korotkoff sounds disappear completely as the diastolic pressure.
- i. Deflate the cuff completely and remove the patient's arm from the cuff.
- j. Inform the patient of the blood pressure reading.
- k. Cleanse all equipment as per facility policy.

See [Figure 7.25](#) for a visual of all the elements discussed.

**FIGURE 7.25** Measuring blood pressure manually entails obtaining the right cuff and placing the cuff in the right place over the brachial artery. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

2. Electric or **automatic blood pressure** is taken using an electric cuff/blood pressure machine; no stethoscope is required. The cuff is placed around the patient's upper arm, and the machine automatically compresses the artery and measures the blood pressure ([Figure 7.26](#)). As with a manual pressure, ensure the patient is properly positioned sitting upright with back and arm supported and legs uncrossed.

**FIGURE 7.26** Using an automatic blood pressure machine does not require a stethoscope but still requires a properly sized blood pressure cuff for accuracy. (credit: modification of “Automatic blood pressure cuff” by BCcampus, CC BY 4.0)

3. In some patient situations, a manual or automatic blood pressure cannot be obtained. The patient could be critically ill and not have peripheral pulses to measure a blood pressure, or they could have a type of heart failure that requires an artificial implant to circulate their blood called a **left ventricular assist device**. In these special cases, a **doppler blood pressure** is obtained. The procedure to obtain a Doppler blood pressure is similar to that used to obtain a manual or automatic blood pressure. The peripheral pulse is located and auscultated, and the properly sized blood pressure cuff is identified and placed. The cuff is inflated until the pulse on the Doppler machine can no longer be heard, and then the cuff is released, just as with a manual pressure. The number on the sphygmomanometer that correlates with the return of the Doppler pulse sound is the systolic blood pressure; no diastolic pressure is measured with this method.
4. Arterial pressure monitoring may be utilized in some situations where the patient is critically ill and needs continuous pressure monitoring, other methods of blood pressure monitoring are impractical, or the patient needs frequent arterial blood sampling (Saugel et al., 2020). An **arterial line** is a thin, hollow, flexible tube that is placed into a peripheral artery (often in the wrist or groin). In **arterial pressure monitoring**, an invasive measurement, a catheter is placed inside the patient’s body. The arterial line is connected to a transducer via a rigid fluid-filled tubing that converts the data to display on a monitor as arterial waveforms during heartbeats as well as numerical pressures (Nguyen & Bora, 2023). This method provides real-time, continuous information about the cardiovascular system ([Figure 7.27](#)). These constant measurements help the providers make care decisions such as medication selection and titration when these patients are critically ill. It is also a highly complicated method that requires proper skill in selecting the correct catheter site, choosing the correct catheter, leveling and zeroing the transducer, and monitoring the quality of the blood pressure waveform (Saugel et al., 2020).

**FIGURE 7.27** An arterial line blood pressure monitoring setup requires specialized knowledge not only to insert the tube but also to properly calibrate the pressure tubing in order for the machine to yield accurate blood pressure measurements. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Normal Blood Pressure Ranges

Abnormal blood pressure readings can signify an area of concern and a need for intervention. Normal adult blood pressure should be less than 120/80 mm Hg. The medical term for elevated blood pressure readings of 130/80 mm Hg or higher is **hypertension**. See [Table 7.6](#) for blood pressure categories according to the 2017 American College of Cardiology and American Heart Association Blood Pressure Guidelines (Welton et al., 2018). Prior to diagnosing a person with hypertension, the healthcare provider will calculate an average blood pressure based on two or more blood pressure readings obtained on two or more occasions.

Blood Pressure Category	Systolic mm Hg (Upper Number)	Diastolic mm Hg (Lower Number)
Normal	<120	<80
Stage 1 hypertension	130 to 139	80 to 89
Stage 2 hypertension	140 to 179	90 to 119
Hypertensive crisis	180 or above	120 or above

**TABLE 7.6** Blood Pressure Categories

The medical term for low blood pressure readings less than 90/60 mm Hg is **hypotension**. Hypotension can be caused by dehydration, bleeding, cardiac conditions, and the side effects of many medications. Hypotension can be of significant concern because of the potential lack of perfusion to critical organs when blood pressures are low. A drop in blood pressure that occurs when moving from a lying down (supine) or seated position to a standing (upright) position is **orthostatic hypotension**. When measuring blood pressure, orthostatic hypotension is defined as a decrease in blood pressure by at least 20 mm Hg systolic or 10 mm Hg diastolic within three minutes of standing. When a person stands, gravity moves blood from the upper body to the lower limbs. As a result, there is a temporary reduction in the amount of blood in the upper body for the heart to pump, which decreases blood pressure. Normally, the body quickly counteracts the force of gravity and maintains stable blood pressure and blood flow. In most people, this transient drop in blood pressure goes unnoticed. However, some patients with orthostatic hypotension can experience lightheadedness, dizziness, or fainting. This is a significant safety concern because of the increased risk of falls and injury, particularly in older adults.

## PATIENT CONVERSATIONS

### Validating Vital Signs

**Scenario:** Josiah is the intensive care unit nurse taking care of Derek Warner, who had heart surgery three days ago. The breathing tube he had inserted while in the operating room has been removed, and right now Derek only has a couple of intravenous (IV) lines for some medications. He has had mildly high blood pressure since the surgery, around 130s/70s with medications and 150s/90s without. His doctors have had him on IV blood pressure medications, and he is being transitioned to oral medications. His mother, Mrs. Warner, is visiting, and he is sitting up in the chair eating lunch. While he is finishing up, the monitor in the room starts alarming.

**Patient's mother:** Nurse! Nurse! We need some help in here!

**Nurse:** Hello Mrs. Warner, Derek. What can I help you with?

**Patient's mother:** The monitor was alarming! What's wrong?

**Nurse** [looks at the monitor]: I see what the problem is. The machine read Derek's blood pressure and heart rate as very high.

**Patient's mother** [sees monitor reads blood pressure 193/130 and heart rate 165]: Oh no! That's awful right? Shouldn't you call the doctor?

**Nurse:** Let me talk to Derek first. Derek, how are you feeling? Are you in any pain?

**Patient:** I'm feeling just fine. No pain really, just the same dull ache where my surgical incision is.

**Nurse:** That's good. I'm just going to take your vital signs again, all right? I'm also going to take a look at your monitoring equipment just to make sure everything is okay.

**Patient's mother:** You're wasting valuable time. My son could be very sick right now, and you're messing around with machines! Call the doctor!

**Nurse:** I will of course call the doctor if something is wrong; however, Derek says that he feels okay and is not experiencing any signs or symptoms that would warrant those extremely abnormal vital sign readings. This may just be an issue with the machines. That happens sometimes, especially when patients are getting better and starting to move around like Derek is. Just to be sure, though, I'll have the monitor take a manual blood pressure while I'm adjusting the rest of the equipment. [Josiah puts the blood pressure cuff on Derek and proceeds to check the rest of the vital sign monitoring equipment.]

**Nurse:** There, that looks much better.

**Patient's mother** [sees the blood pressure is now 120/70 and the heart rate is 95]: Are you sure? Maybe you just adjusted the machines to make it look better. I still think you should call the doctor.

**Nurse:** The blood pressure cuff is correlating with the arterial line; it says 124/72. This tells me that the abnormal readings were anomalies and not truly reflective of Derek's vital signs. Plus, Derek himself says that he is feeling okay. You seem worried, though, Mrs. Warner. Do you have some concerns you'd like to talk about?

**Patient's mother:** I'm just so worried, I've never had a child in the hospital before. I guess I'm okay. Sorry.

**Nurse:** It's not a problem at all. If you have some specific questions or concerns you'd like to ask, you can ask me, or I can get the doctor to speak with you when he makes his afternoon rounds. Would that work for you?

**Patient's mother:** Yes, it would. Thank you.

**Patient:** Thanks, man. I appreciate it.

**Nurse:** No problem at all. I will be monitoring you just outside the door here while I do some charting. [leaves the room]

**Scenario follow-up:** Josiah knows from how his patient looks that these data are abnormal and not valid. However, he does his due diligence and ensures that Derek is feeling okay and he also double-checks the blood pressure reading just in case. By ensuring that the abnormal vital signs were a false alarm, Josiah knows he can reassure the patient and the patient's mother as well as educate them about the measurement of vital signs.

---

## 7.3 Teaching Patients to Perform Vital Signs

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain why patients would need to self-monitor vital signs
- Describe the process of educating a patient about self-monitoring vital signs
- Recognize how a patient should validate the obtained vital sign data

An important responsibility of healthcare providers is not only to provide care but also to educate patients and their families on how to better care for themselves. Patient education is a major part of the duties of a nurse, and this sometimes includes teaching patients how to monitor their own vital signs. By teaching patients how to do this without the assistance of a licensed healthcare provider, nurses help patients understand their own bodies and physiological processes and empower them to live healthier lives.

### Educating a Patient to Self-Monitor

There are many situations that require patients to self-monitor their vital signs. Consider this situation: a patient has been going in to see the doctor, and their blood pressure readings are always abnormally high (150s/90s). The patient exercises regularly, maintains a healthy weight, and eats a reasonably healthy diet. The patient also has no symptoms of ongoing high blood pressure like vision problems or headaches. However, hypertension often has no symptoms, and people with healthy lifestyle habits can be diagnosed with hypertension, so the doctor and the healthcare team must take it seriously. It could be possible that the patient is unconsciously nervous when they go into the doctor's office, thus elevating their blood pressure higher than usual, a condition known as **white coat hypertension** or white coat syndrome. To figure out whether the patient genuinely has hypertension, the doctor needs the patient to monitor their blood pressure at home in a comfortable environment.

There are many scenarios in which a patient may need to monitor their own vital signs, for instance, a patient is on a

new heart medication, and the doctor needs to monitor the patient's pulse and blood pressure to ensure no harmful side effects. Or perhaps a patient has low white blood cells related to chemotherapy and needs to monitor their temperature for signs of fever. Or maybe a patient has cystic fibrosis or symptoms of long COVID and needs to monitor their oxygen saturation in case they have trouble breathing and need to go to the emergency room. In any case, it is important for healthcare providers to understand how to teach patients how to self-monitor. To self-monitor their vital signs, patients need to obtain the proper equipment, learn how to use it, learn how to validate their own results, and report their results accurately to their healthcare provider.

To teach self-monitoring, nurses first need to know how the patient best likes to learn; some people prefer to read brochures and articles, while others may prefer diagrams and pictures. Others may learn best with videos or with in-person demonstrations. Once the nurse has established how the patient best learns new information, they can begin teaching the patient how to obtain their own vital signs.

### Educating a Patient to Obtain Vital Signs

The following equipment is needed to obtain vital signs at home:

- properly sized electronic blood pressure cuff and blood pressure machine
  - In situations where patients take manual blood pressures, they will need a properly sized cuff, a stethoscope, and a sphygmomanometer.
- pulse oximetry machine to measure heart rate and/or oxygen saturation
- digital thermometer to measure temperature
  - Mercury thermometers are no longer recommended for home use due to the dangers of breaking glass and mercury poisoning.

Consistency is important for all vital signs measurements; thus, patients should be taught to take their vital signs at the same time of day every day. Because blood pressure is lowest in the morning before eating anything, teaching patients to take their vital signs when they first get up is most ideal. Patients will also need a method of recording their vital signs. Possibilities include writing them down in a notebook or keeping track on their cellphone in a memo app. There are also specialized health apps to help keep track of vital signs.

## PATIENT CONVERSATIONS

---

### You Can Always Learn Something New

**Scenario:** Mr. Atambe has been directed by his doctor to monitor his blood pressure at home. This is the first time he has had to do this, and he's not happy about it. Mr. Atambe's nurse, Wendy, realizes his reluctance and considers what would be the best way to help him.

**Nurse** [entering the room]: Hi, Mr. Atambe, how was your talk with the doctor?

**Patient:** Stupid. The man wants me to check my blood pressure at home. He says I might have high blood pressure. But that's what I come to the doctor's office for! Doing this at home myself is stupid. If I wanted to do something like this, I would have gone to medical school.

**Nurse:** I understand your frustration, but this is important information that will keep you healthy and away from the doctor's office in the long run! What can I do to help you and make this easier?

**Patient:** Ugh. Well, if I have to, I guess. But I'm probably going to get it wrong anyway, and I'll still have to come back all the time.

**Nurse:** Why do you think you're going to get it wrong?

**Patient:** Well, I never told anyone, but I can't read so well. Pictures and diagrams really confuse me too. I was such a bad student in school. And now my health depends on me learning something they teach doctors and nurses! This is horrible!

**Nurse:** I understand your concerns, and I want to reassure you that there are machines that can make taking your blood pressure very easy! People learn how to do it every day. Here, let me get a few things, and I will show you. Is

that okay?

**Patient:** I guess so.

[Wendy leaves the room briefly and returns with an automatic blood pressure machine, several sizes of blood pressure cuffs, and a laptop.]

**Nurse:** Okay! Here is a blood pressure machine and some cuffs. Getting the right-sized cuff is an important part of taking your pressure with a machine. I brought some cuffs to try on and see which one fits best. Then we can try using the blood pressure machine together—I will show you how to sit and position yourself for the best reading possible.

**Patient:** This is great, I really appreciate your help! But what if I forget the steps to do this? And how do I know when the numbers are good or not?

**Nurse:** I have some videos that explain everything. I'll add the number to the office, too, if you have any questions once you get started.

**Patient:** Thank you so much!

**Nurse:** Of course! Let's take a look at them now, and then let's try that blood pressure.

---

To obtain an oral temperature, a digital thermometer should be obtained. Patients should be instructed on proper placement of the thermometer in the mouth, under the tongue and back toward the sides of the mouth but not touching the gums. Patients should be instructed to refrain from eating or drinking anything thirty minutes prior to measuring their temperature so they do not artificially alter the reading.

To obtain heart rate and/or oxygen saturation, an oximetry probe and monitor must be obtained. Hands should be clean and dry before placing the probe on a finger without nail polish or fake nails. The patient should be seated upright and comfortably; to obtain the best reading possible, it may be helpful to instruct the patient to take a few deep, calming breaths before recording the results. Although patients can monitor their own respiratory rate at home, it may not be as accurate as when someone else does it when the patient is not aware. Patients tend to not breathe as they naturally do if they know they have to count respiratory cycles. If the patient has family or a caregiver who can monitor the respiratory rate while the patient is relaxing, that would be a better option.

To obtain blood pressure at home, patients must be taught proper body placement to ensure accuracy. They must sit upright with their back supported. The arm they will take their pressure in must be supported at heart level and bared to the upper arm. Legs must be uncrossed and feet flat on the ground. The cuff must be the correct size and wrapped snugly around the upper arm. It may be helpful to demonstrate proper cuff placement over the brachial artery for patients. A machine that is validated for home use and for the use of the particular patient should be selected. Each time the patient measures their blood pressure, they should do two readings, one minute apart (American Heart Association, 2023). This is recommended in the home setting because research has shown that monitoring the average of a series of readings gives the provider more accurate information about blood pressure fluctuations and can better manage hypertension (Kumar, 2021).

## LINK TO LEARNING

The [American Heart Association \(https://Openstax.org/r/77AmHeart\)](https://Openstax.org/r/77AmHeart) has helpful tips for patients on taking their blood pressure at home. Viewing this can give you ideas on how to educate your own patients.

---

## Validating Vital Sign Data

Similar to how nurses and other healthcare providers must analyze and validate (prove the accuracy of) the vital signs data they obtain, it is important to educate patients who are taking their own vital signs at home how to analyze and validate their own numbers. Is there an unusually high or low reading? Was there anything different about when the patient took that pressure? Were any new medications introduced? This information will provide much needed context to the readings and allow the physician to make a well-informed decision about care

decisions and medications prescribed going forward.

### Rechecking Abnormal Readings

When monitoring vital signs at home, patients should be given information regarding the normal ranges of vital signs to look for so that they can then identify results that fall out of these normal ranges (abnormal) ([Table 7.6](#)).

The nurse must also educate the patient on signs and symptoms to help validate their readings. If the patient takes their blood pressure at home and receives a reading of 190/110, the patient should ask themselves if they have any symptoms or are feeling differently. Do they have a headache or blurred vision? How does their heart feel? Do they have pain anywhere? Similarly, if they get a heart rate or oxygen saturation that is not within normal limits, the patient must be able to ask themselves if anything is different for them. It may be beneficial for patients to keep a journal or log with their vital sign readings as well as any corresponding symptoms. This will help keep a record of each event and will alleviate the burden of remembering the details that can then be discussed with the healthcare team.

### Notifying Provider of Abnormal Readings

Sometimes vital signs truly are abnormal, and if the patient has taken their vital signs and validated the data, they must inform their healthcare provider immediately. Some healthcare offices have urgent care lines where patients can call to report abnormal vital signs; others have mobile applications that the patient can use to directly contact a doctor, nurse, or healthcare provider at the practice. Check what the protocol is on reporting this information, and be sure the patient understands the process. Some facilities may prefer nurses to call the doctor via a hospital work phone, others may allow nurses to page the doctor through the computer system or through the charting record. Either way, if a nurse has determined the recorded vital signs are indeed valid, it is the nurse's duty to inform the doctor in a timely manner.

## Summary

### 7.1 Indicators of Physiologic Functioning

Vital signs are arguably the most frequently used metrics by healthcare providers because they are important and interrelated indicators of the body's homeostatic functioning. Vital signs in the normal range indicate the presence of homeostasis, or balance, in the body. Body temperature is regulated by the hypothalamus; its homeostatic mechanisms include involuntary actions such as sweating and shivering to reestablish temperature into the normal range. Pulse is the direct measurement of a patient's heart rate. The number of beats per minute is a strong indicator of how hard the heart is working to perfuse the body; irregular beats or a rhythm that is too fast or too slow can indicate alterations in cardiovascular homeostatic balance. Respirations are the mechanism by which the body brings in oxygen and exchanges it for carbon dioxide in the lungs to be exhaled as waste. Blood pressure is a measure of the pressure the blood exerts on the arterial walls; a certain amount of pressure is required for adequate amounts of blood to circulate through the body and bring the oxygen to the organs. Oxygen saturation is a percentage of total oxygen that the blood can carry throughout the body. The interrelation of the five vital signs gives healthcare providers vitally important information to determine what is going on with a patient.

### 7.2 How to Perform Vital Signs

The accurate measurement of vital signs is an essential duty of nurses when caring for patients. The most common methods of temperature measurement in the hospital setting include oral, tympanic membrane, axillary, and rectal routes, and the nurse must select the method that is most appropriate for their patient's developmental age. Pulse should be palpated manually via one of the pulse points located on the body; proper technique includes using the index and middle fingers of one hand and applying light but firm pressure to the site. Assessment of respirations must be done when the patient is unaware their respirations are being assessed, lest the patient change their respirations unconsciously. Oxygenation status is assessed using a pulse oximeter, which is most commonly applied to a finger but can also be applied to the forehead or earlobe. Blood pressure can be measured in four different ways; the method of measurement selected depends on the patient's acuity and care location.

### 7.3 Teaching Patients to Perform Vital Signs

Patients may be required to self-monitor their vital signs at home, and it is the responsibility of the nurse to educate the patient on how to properly do this. Nurses must first establish how their patient best likes to learn, and from there teach the patient the necessary information. Besides being able to take their own vital signs, patients must also be able to do basic analysis of their vital sign readings. Reference ranges for normal vital signs must be given to the patient, and if they get an abnormal reading, they must be able to troubleshoot and figure out if the reading is correct or not. Finally, nurses must establish the best way for patients to report their findings, particularly if they are abnormal, to the healthcare provider.

## Key Terms

**afebrile** when a patient's temperature is back at their normal baseline and is no longer elevated to indicate a fever

**arrhythmia** an abnormal heart rhythm caused by irregularities in electrical conduction through the heart or injury to the heart muscle itself

**arterial line** a thin, hollow, flexible tube that is placed into a peripheral artery, such as the wrist or groin

**arterial pressure monitoring** an invasive method of continuous blood pressure monitoring

**automatic blood pressure** blood pressure taken using an automated blood pressure machine; no stethoscope is required

**blood pressure** the pressure of blood as it presses against arterial walls

**brachial artery** pulse point located on each side of the upper arm on the medial aspect superior to the antecubital fossa

**bradycardia** when the heart rate (HR) is lower than the accepted norm of 60 beats per minute (bpm)

**carotid artery** pulse point located on each side of the neck lateral to and above the trachea

**conduction** a mechanism of heat transfer in which the skin encounters a cooler object, thus lowering its temperature

**convection** a mechanism of heat transfer in which cooler air surrounds the body to cool it down

**diastolic blood pressure** represents the arterial pressure of blood during ventricular relaxation, or diastole

- doppler blood pressure** blood pressure taken using a Doppler machine
- doppler ultrasound device** a handheld ultrasound tool that allows the examiner to hear the whooshing sound of the pulse
- dorsalis pedis artery** pulse point located roughly atop both feet
- evaporation** the transfer of heat through dissipation of sweat from the skin, thus cooling the body
- expiration** the act of exhalation or breathing out
- external respiration** the act of breathing in oxygen and breathing out carbon dioxide
- febrile** with fever
- femoral artery** pulse point located in the groin
- heart rate** the number of times the heart beats in one minute
- homeostasis** the process by which the human body maintains balance by adjusting to internal and external stimuli
- hypertension** elevated blood pressure readings of 130/80 mm Hg or higher
- hyperthermia** a condition that occurs when the core body temperature is more than 105.8°F (41°C)
- hypotension** low blood pressure readings less than 90/60 mm Hg
- hypothermia** a condition that occurs when the core body temperature is less than 95°F (35°C)
- inspiration** the act of inhalation or breathing in
- internal respiration** the exchange of oxygen and carbon dioxide in the lungs and the cells
- Korotkoff** pulse sound heard when obtaining a manual blood pressure
- left ventricular assist device** a type of cardiovascular device that supports heart function by stimulating the left ventricle to beat
- manual blood pressure** blood pressure reading taken using a sphygmomanometer and a stethoscope
- mean arterial pressure (MAP)** represents the “average” pressure of blood in the arteries, that is, the average force driving blood into vessels that serve the tissues
- normothermia** the targeted range for normal temperature
- orthostatic hypotension** a drop in blood pressure of at least 20 mm Hg systolic or 10 mm Hg diastolic within three minutes when moving from a lying down (supine) or seated position to a standing (upright) position
- oxygen saturation** measurement of the arterial oxyhemoglobin saturation (SpO<sub>2</sub>) of arterial blood
- palpation** feeling with hands or fingers
- popliteal artery** pulse point located behind both knees
- posterior tibial artery** pulse point located posterior to the medial aspect of the ankle
- pulse** the palpable way to assess the brief pressure increase in the arteries causing them to temporarily expand as the left ventricle pumps blood through them
- pulse equality** a comparison of the pulse forces on both sides of the body
- pulse force** the strength of the pulsation felt on palpation
- pulse oximeter** a machine utilized to measure the oxygen saturation of blood
- pulse point** where the artery is close to the surface
- pulse pressure** the difference between systolic pressure and diastolic pressure
- pulse rate** counted with the first beat felt by your fingers as “One.” It is considered best practice to assess a patient’s pulse for a full sixty seconds, especially if there is an irregularity to the rhythm
- pyrexia** fever; a state outside of normal body thermoregulation where the core temperature is greater than 100.4°F (38°C)
- radial artery** pulse point located at each wrist below the base of the thumb
- radiation** heat from the body moving to cooler air, thus cooling the body
- respiration** the action of breathing, including inhalation and exhalation
- respiratory acidosis** having a blood pH less than 7.35 with a concurrent increase in carbon dioxide (CO<sub>2</sub>)
- respiratory alkalosis** a systemic acid-base disorder that is caused by a reduction in carbon dioxide and a pH greater than 7.45
- sphygmomanometer** manual blood pressure cuff
- systolic blood pressure** reflects the arterial pressure resulting from the ejection of blood during ventricular contraction, or systole
- tachycardia** heart rate faster than 100 beats per minute
- thermoregulation** the automatic regulation of temperature that is carried out by the hypothalamus
- vital sign** five key metrics of homeostasis—temperature, pulse (heart rate), blood pressure, respirations, and

oxygen saturation—that are used by nurses and other members of the medical profession to ascertain a patient’s current physical status

**white coat hypertension** sometimes called white coat syndrome; elevated blood pressure that results from a person’s conscious or unconscious fear and anxiety at being at the doctor’s office or in the presence of healthcare personnel

## Assessments

### Review Questions

- The self-regulation of vital signs such as heart rate and blood pressure is an example of the body’s attempts to maintain its stability, also known as which of the following?
  - homeopathy
  - homeostasis
  - naturopathy
  - heterogeneity
- It is a hot summer day, and Christina is working in the emergency department. She has admitted a 24-year-old patient with dehydration—their lips are dry and cracked, and they are lethargic and complaining of dizziness. Which of the following heart rates would Christina *most likely* expect from this patient?
  - 45 bpm
  - 85 bpm
  - 99 bpm
  - 135 bpm
- A nurse takes an adult patient’s oral temperature and notes it is 99°F (37.2°C). What term would the nurse use to report this temperature?
  - afebrile
  - hyperthermic
  - febrile
  - hypothermic
- Adam is checking the oxygen saturation (SpO<sub>2</sub>) of a patient with asthma and notes it is 88 percent on room air. What should Adam do *first*?
  - Recheck the SpO<sub>2</sub> in an hour.
  - Record the oxygen reading in the chart.
  - Check the patient’s blood pressure.
  - Report the SpO<sub>2</sub> to the primary care provider.
- What is the most accurate description of blood pressure?
  - Blood pressure measures the force of blood through the body.
  - Blood pressure measures the force of the blood going into the heart.
  - Blood pressure measures the force of blood against the arterial walls.
  - Blood pressure measures the force of blood against the venous and arterial walls.
- Tony’s 38-year-old patient says he is anxious and hates being at the doctor. Which respiratory rate would Tony expect to find upon assessing the patient’s vital signs?
  - 37 bpm
  - 25 bpm
  - 15 bpm
  - 5 bpm
- Sarah works on an inpatient medical unit and is taking her 35-year-old patient’s blood pressure. She notes that it is lower than usual at 88/56, when usually it is 110/70. The patient has no complaints, they are sitting up in their chair watching TV. What should Sarah do *first*?

- a. Check the other vital signs and chart them accordingly.
  - b. Give the patient some juice.
  - c. Recheck the blood pressure and report the findings to the provider.
  - d. Call for emergency assistance.
8. Jose is coming on shift and receives in report that one of his patients has been running a 101°F fever. He goes into the room to obtain vital signs and do his assessment, and he notes that his patient has just taken a sip of hot tea from a thermos his mother brought him. How long should Jose wait before taking an oral temperature?
- a. five minutes
  - b. ten minutes
  - c. twenty minutes
  - d. thirty minutes
9. Xavier is working at an urgent care center, and he notes his patient's pulse rate is 155 bpm. The patient says they feel fine, though their "heart is racing a bit." What should Xavier do?
- a. Report the pulse to the provider immediately.
  - b. Call for emergency assistance.
  - c. Chart the vital sign accordingly.
  - d. Recheck the pulse in ten minutes.
10. What is the most accurate way to measure a patient's respirations?
- a. Inform the patient that you are taking their respirations.
  - b. Tell the patient you are taking their pulse, and then count their respirations for thirty seconds before counting their pulse for thirty seconds.
  - c. Ask the patient if you can take their blood pressure, and count their respirations as you take their pressure.
  - d. Count the respirations as you take the patient's temperature.
11. What statement demonstrates a lack of understanding of how an oxygen saturation probe works?
- a. I should ensure the patient's hands are warm before placing the probe.
  - b. Older adults and people with diabetes may not have the best circulation in their hands, so measuring their O<sub>2</sub> saturation can be difficult.
  - c. I should make sure that the finger I place the O<sub>2</sub> saturation probe on has nail polish on it to ensure a clear reading.
  - d. Pulse oximeters give a rapid estimation of peripheral oxygen saturation.
12. Minh is educating her patient on the importance of monitoring his blood pressure at home. What statement by Minh's patient indicates his understanding of taking his blood pressure?
- a. "I should take my blood pressure in the evening before I go to bed."
  - b. "I should take my blood pressure lying in bed, so it is lower."
  - c. "When taking my blood pressure, I should sit with my feet on the ground, and my legs should not be crossed."
  - d. "I can take my blood pressure any time during the day as long as I am calm."
13. What is *not* a good example of why a patient should self-monitor their vital signs at home?
- a. The patient has had high blood pressure at the doctor's office and the provider is trying to rule out "white coat syndrome."
  - b. The patient has started a new heart medication, and the doctor wants to ensure it is working well for the patient.
  - c. A side effect of a medication the patient has started can be fevers.
  - d. The patient wants to see if their hypertension is "getting worse" so they can adjust their own medications accordingly.

- 14.** Alexandra has just been taught by her nurse how to take her own blood pressure. What statement by Alexandra indicates that she *does not* understand what her blood pressure numbers mean?
- “If the top number of my blood pressure reading is over 150, I should not take my blood pressure medication and call the doctor’s office.”
  - “A good blood pressure is between 110 and 120 over 60 to 80.”
  - “If I feel dizzy and lightheaded after taking my blood pressure medication, I should call the doctor’s office immediately.”
  - “Having high blood pressure means my heart is working very hard, and that is bad for my heart and my blood vessels.”
- 15.** Lucy’s patient has been newly diagnosed with hypertension, and she is developing a collaborative plan with him to help him adhere to his new diet and medication regimen. When planning teaching for this patient, what is the first important learning goal?
- The patient will verbalize understanding of the plan.
  - The patient will articulate the best way they like to learn new material.
  - The patient will demonstrate understanding of their new medication and its side effects.
  - The patient will describe the benefits of adhering to their new low-sodium diet.
- 16.** What statement indicates patient understanding of external factors that can influence vital signs?
- “Drinking coffee before I take my vital signs will likely elevate my heart rate and blood pressure.”
  - “I should wait ten minutes after eating something to take my oral temperature.”
  - “My blood pressure is highest in the morning when I wake up so I should take it in the evening.”
  - “Being worried or anxious will increase my heart rate and lower my blood pressure.”

### Check Your Understanding Questions

- Name five factors that can affect a patient’s heart rate.
- Why would you expect a patient with a MAP of 50 mm Hg to have weak or absent pulses in the extremities?
- In your own words, explain the relationship between systole and diastole.
- What do you do if your patient with a history of COPD has a SpO<sub>2</sub> of 90 percent on room air?
- Sam’s patient has called the doctor’s office in a panic because his blood pressure is 200/110. What should Sam do?

### Reflection Questions

- When is a variation in blood pressure from 110/70 to 145/90 a normal or expected variation, and when is it something to be concerned about?
- Why does the patient’s age and developmental stage matter when taking their temperature?
- Why is it important to ask patients how they like to learn before beginning to teach them about self-monitoring their vital signs?

### What Should the Nurse Do?

- Charlie is a nurse in the emergency department (ED), and his admission just arrived. Jacob has housing insecurity and is well-known to the ED and was brought in by the police for altered mental status. Nursing staff were able to get vital signs monitoring equipment on Jacob, but now he is more agitated and will not let anyone near him. From a distance, Charlie can see that Jacob’s face is flushed, and he appears sweaty and anxious. His vital signs are as follows: BP 160/85 mm Hg, temperature 102.3°F (39.1°C), heart rate 110, respirations 25, and oxygen saturation 96 percent on room air. Which of these vital signs should be most concerning to Charlie? What can he do to obtain additional information?
- Laurel is obtaining vital signs on a 75-year-old patient during a wellness visit at the doctor’s office. She notices that the oxygen saturation probe is reading the patient’s SpO<sub>2</sub> level as 87 percent. Assessing the

patient, Laurel notes her patient appears comfortable and in no distress; the patient had just been telling Laurel about her granddaughter. What possible reasons can there be for this SpO<sub>2</sub> reading? What should Laurel do?

3. Markus enters the room to take his patient's vital signs and notices that the patient's family is visiting and that they have brought him his favorite chicken noodle soup from home. The patient is laughing and talking with his family. What should Markus consider when taking his patient's vital signs?
4. Ahmad has orders to take a series of blood pressures on his patient while lying in bed, sitting at the side of the bed, and standing next to the bed. The doctors are checking to see if the patient's blood pressure drops as they go from a lying, sitting, to standing position, called orthostatic pressures. When giving directions to his patient, what should Ahmad be mindful of in order to get the best possible readings? What safety considerations should Ahmad keep in mind when performing this assessment?
5. Aly is checking her patient's dorsalis pedis pulse and cannot find it either by palpation or with a Doppler. What should she do?
6. Manuela's patient is being sent home with a heart monitor and new medication to address a new diagnosis of hypertension and tachycardia. The patient is being directed to record their blood pressure and heart rate once a day. What are some of the important teaching points that Manuela should include in her discharge teaching for this patient?
7. Lucy's patient has been educated about the importance of taking their blood pressure medication. At their follow-up appointment, however, the patient states that they have not been taking their blood pressure medication because they "took it for a week" and when they checked their pressure, "it was fine." What are some questions that Lucy can ask her patient? What can she do to educate them further about their hypertension and blood pressure medication?

### Competency-Based Assessments

1. In pairs, identify each of the following pulses and check your partner's pulse: carotid, radial, brachial, popliteal, posterior tibial, dorsalis pedis.
2. In pairs, select an appropriately sized blood pressure cuff and demonstrate the proper application of the cuff to your partner's arm. Explain the importance of selecting the correctly sized cuff for a patient.
3. In pairs, demonstrate the proper technique for obtaining a tympanic temperature.
4. Explain how an oxygen probe monitors your oxygen saturation.
5. Demonstrate proper technique for obtaining a patient's respiratory rate.

## CHAPTER 8

# Admission, Transfer, and Discharge

**FIGURE 8.1** Discharge planning is initiated at the time of admission and continues throughout a patient's hospital stay. The admission process requires that the healthcare team discuss and agree upon goals for discharge. (credit: "Assisting Grady Hospital" by U.S. Army National Guard Sergeant Jeron Walker/Flickr, Public Domain)

### CHAPTER OUTLINE

- 8.1 Patient Admission
- 8.2 Patient Transfer
- 8.3 Patient Discharge

**INTRODUCTION** Admission, transfer, and discharge are key events in the healthcare delivery process, and the nurse is most often the frontline healthcare provider in all three of these events. Admission oversees the patient's entry into the healthcare system. The information learned and rapport developed upon admission are vital to planning a patient's course of treatment. Transferring a patient involves accurate communication of the patient's status between healthcare providers. The nurse must be concise and accurate when exchanging information. The patient exits the system upon discharge. It is crucial for the discharging nurse to explain the patient's medications and follow-up plan, providing further education if necessary. Research shows that the effectiveness of the discharge process increases patient satisfaction and improves quality of life for patients and their families (Carroll, 2007). There is a large potential for serious errors and patient harm to occur due to mistakes made during admission, transfer, and discharge, so it is imperative that these processes are done conscientiously and thoroughly.

## 8.1 Patient Admission

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify different types of patient admissions
- Describe nursing preparation in the admission process
- Recognize how to establish an effective nurse–patient relationship during the admission process

There are many situations that require admission to a healthcare facility. These situations can range from a calm and planned procedure to a traumatic and life-threatening emergency. Nurses play a vital role as the initial point of entry into the healthcare system because they are responsible for the initial assessment, evaluation, and documentation of a patient's healthcare status, needs, and concerns. The information gained through the admission process sets the stage for the patient's course of care. It is the role of the admitting nurse to use clinical judgment skills and strong communication techniques to obtain necessary information about the patient and their condition ([Figure 8.2](#)). Therefore, it is crucial that the nurse conducting the admission is organized and thorough.

**FIGURE 8.2** Nurses are often the first interaction patients experience with the healthcare system, and it is a nurse's responsibility to begin the admission process. (credit: Untitled by "RDNE Stock project"/Pexels, Public Domain)

### UNFOLDING CASE STUDY

#### Unfolding Case Study #2: Part 1

A 65-year-old patient presents to the emergency room with reports of severe chest pain radiating to the left arm and new onset shortness of breath. Patient appears pale, diaphoretic, and visibly anxious.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, coronary artery disease</p> <p><b>Family history:</b> Mother deceased, father alive with severe dementia; two healthy sons in their early 40s.</p> <p><b>Social history:</b> Previous divorce, married to current husband, George, for twenty years.</p> <p><b>Allergies:</b> Latex</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Aspirin 81 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Lisinopril 10 mg PO once daily</li> <li>• Atorvastatin 30 mg PO once daily</li> </ul>
Flow Chart	<p><b>0815: Assessment</b></p> <p>Blood pressure: 160/100 mm Hg</p> <p>Heart rate: 110 beats/minute</p> <p>Respiratory rate: 24 breaths/minute</p> <p>Temperature: 98.6°F (37°C)</p> <p>Oxygen saturation: 92 percent on room air</p> <p>Pain: 7/10 (chest pain that is “tight”)</p>
Provider’s Orders	<p><b>0817: New orders</b></p> <p>Page cardiology team for urgent consult.</p> <p>Administer 325 mg aspirin orally.</p> <p>Conduct 12-lead ECG stat.</p> <p>Administer supplemental oxygen to maintain saturation &gt; 94 percent.</p> <p>Establish IV access and administer IV nitroglycerin per protocol.</p> <p>Conduct cardiology lab panel and HbA1c.</p> <p>Admit patient.</p>
<ol style="list-style-type: none"> <li>1. Recognize cues: What cues are present that confirm the need for admitting this patient to the hospital?</li> <li>2. Analyze cues: Based on the recognized cues and provider orders, what do you think is going on with the patient?</li> </ol>	

## Types of Admissions

There are different types of admissions to ensure that patients are routed to the proper level of care. It is important that patients go to the right point of entry to the healthcare system—for example, a doctor’s appointment, an urgent care clinic, or an emergency room visit—to receive the best and most efficient medical treatment required. Admission placements can change quickly; for example, an admission to an ambulatory clinic for monitoring during administration of a medication can become emergent if the patient’s vitals become unstable. Situations such as this are not uncommon. With the ongoing evolution of medical care and the growing complexity of patient illnesses and comorbidities, the role of nursing in the admission process is vital to detecting these changes quickly. Nurses must understand the different types of admissions, assess their patients’ situations accurately, and advocate for escalation to a higher level of care when necessary.

### Acute Care Admissions

Acute care admissions begin in hospital settings, most often in the emergency department. The **acute care** is for patients who require inpatient monitoring and medical care under professionally trained healthcare providers. Their medical situation has been assessed as one that could potentially endanger their life if the problem is left unaddressed ([Table 8.1](#)). Some examples include difficulty breathing, chest pain, a fever over 103°F (39.4°C) that is unrelieved by over-the-counter medications, uncontrolled bleeding, or an injury that resulted in a loss of consciousness. Symptoms that are less likely to require an acute care admission include chronic headaches, a laceration requiring stitches, a severe cough, or abdominal pain with vomiting. In many cases, however, symptoms

such as these may also warrant an acute care admission; many other elements such as the patient's medical history, current medications, and vital signs all factor into an acute care evaluation.

Mild Symptoms (Nonacute)	Severe Symptoms (Acute)
Hives (red, swollen, itchy areas on the skin)	Loss of consciousness
Skin rash (persistent, dry, itchy skin)	Shortness of breath or wheezing
Redness of the skin or around the eyes	Swelling of the lips, tongue, and/or throat
Itchy mouth or ears	Trouble swallowing
Diarrhea	Bluish discoloration of the skin
Stomach pain	Drop in blood pressure
Nasal congestion or sneezing	Chest pain
Slight, dry cough	Weak pulse
Odd taste in mouth	

**TABLE 8.1** Mild Symptoms (Nonacute) Versus Severe Symptoms (Acute)

Emergency department nurses that assess patients for acute care admission employ a prioritization system called triage. When a nurse evaluates patients according to the severity of their symptoms and ensures that those with the most serious and potentially life-threatening symptoms are seen first it is called **triage**. If a nurse has an asthmatic patient with mild wheezing but stable vitals and a patient with mild chest pain and very unstable vitals, the nurse will see the patient with the chest pain first. The admission process also involves additional nursing responsibilities including completing an admission history, performing a physical assessment, completing a medication reconciliation, developing the care plan, and documenting a belonging inventory.

## PATIENT CONVERSATIONS

### Triage in the Emergency Department: Who Is the Priority?

**Scenario:** It is a busy night in the Emergency Department (ED) and Jacqui is the triage nurse. Two patients come in, one after the other, and are directed to the waiting area near security. One patient is wheezing and holding an inhaler. The other is pale and sweaty and looks distressed. Jacqui approaches the wheezing patient.

**Nurse:** Hi there. My name is Jacqui and I'm the nurse that is here to assess you. What is your name? What brings you in tonight?

**Patient 1:** My name is Leah, and I can't breathe. I have asthma and my inhaler isn't working. I need help now.

**Nurse:** It's okay, Leah, you are in the right place, try to remain calm. I'm going to put this monitoring equipment on you, and it is going to measure your heart rate, blood pressure, and level of oxygen. While the machine is doing this, I'm going to talk to this other patient, and I'll be right back.

[Then nurse brings a second set of monitoring equipment over and approaches the second patient.]

**Nurse:** Hi, my name is Jacqui and I'm your nurse right now. Are you feeling okay? You look pale; are you in pain?

[While introducing herself, the nurse places the monitoring equipment on the patient.]

**Patient 2:** I don't know how I feel, my chest aches and I'm sweaty. I feel like something is very wrong and I'm scared so I came here.

**Nurse:** What is your name? On a scale of 1 to 10, how badly does your chest hurt? 1 is no pain at all, and 10 is the worst pain you've ever been in.

**Patient 2:** My name is Paul, and my pain is like a 7 or an 8. My chest aches a lot and my heart feels funny and I . . . I just don't feel good at all.

[The nurse looks at Paul's vitals and sees he is severely hypertensive (186/108), tachycardic (143), and his oxygen saturation is 86 percent on room air. She glances at Leah's vitals and sees her blood pressure (132/90) and heart

rate (118) are slightly elevated, and her oxygen saturation is 93 percent on room air. Jacqui knows Paul's symptoms are more serious, and immediately calls for assistance on the hospital phone. Two nurses come into the ED; one is pushing a wheelchair.]

**Nurse:** Paul, I'm glad you came in. We need to take you into the ED immediately for testing and further monitoring. We will take you in this wheelchair to your room, and the doctor will be in shortly.

[The nurse looks over at Leah.]

**Nurse:** Hey Leah, I will be right back. This nurse will be keeping an eye on you, and someone will come talk to you soon, okay?

[The nurse helps Paul into the wheelchair and escorts him back.]

**Scenario follow-up:** Paul is exhibiting the classic signs of a potential myocardial infarction, or heart attack. His vitals are not normal and are unstable enough to quickly decline into a life-threatening emergency. Leah's symptoms are also not normal and need to be addressed, but at this time Paul's symptoms have the greater potential to decline into an emergency. Jacqui triages her patients and prioritizes Paul to be seen before Leah.

---

### Observational versus Inpatient Admissions

Observational admissions are typically one- or two-night stays where the patient needs to be closely monitored by a professional for a limited amount of time. Situations for observational admission could include vital signs monitoring during administration of a medication that can have severe side effects (such as chemotherapy) or potential for an allergic reaction (such as intravenous immunoglobulins), monitoring after setting a broken bone, monitoring bleeding from a severe laceration that has been sutured, or monitoring after a procedure where the patient was sedated. Sometimes patients will be kept in observation awaiting diagnostic test results, such as computed tomography (CT) or magnetic resonance imaging (MRI) scans.

Inpatient admissions are for problems that require more than just observation. Examples may include abdominal pain of unknown origin with concurrent changes in vital signs, or intravenous antibiotic administration for a serious bacterial infection. These patients have the potential to decline to a life-threatening level if not monitored by a healthcare professional.

### Unplanned Admissions

Many admissions to the hospital are unplanned and are usually an emergency, such as a motor vehicle accident, trauma, or a collapse in the field due to a myocardial infarction (heart attack). Strokes are unplanned admissions that require rapid assessment and intervention; many hospitals have a stroke protocol that streamlines their admission into the system and often dictates what treatments must begin immediately ([Figure 8.3](#)).

**FIGURE 8.3** In an emergency, time is critical. Having available protocols or decision trees, such as this example protocol, helps clinicians rapidly obtain the correct tests and medications for their patients. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Exacerbation of chronic conditions such as asthma or heart failure can also result in an unplanned admission. A patient may be at a clinic for a routine appointment but on assessment their vitals are found to be unstable, at which time the clinic staff will call an ambulance or 911. Generally, unplanned admissions are routed through the ED of a hospital. Sometimes unplanned admissions may be transferred from other healthcare facilities, such as a rehab facility or nursing home, directly to an inpatient unit. Admitting an unplanned patient requires rapid assessment and action on the part of the entire healthcare team.

### Planned Admissions

Of course, not all entries into the hospital system are emergent. One example of a planned admission is childbirth, which includes a mother in labor, a scheduled cesarean section, or an induction. Many planned admissions are prearranged surgeries, such as hip and knee replacements (arthroplasties). A patient may work with their cardiologist and cardiac surgeon to receive a planned coronary artery bypass graft (CABG) or to have a stent placed

to relieve vessel blockage. These surgeries are planned because they are nonurgent at the time but can become life-threatening in the future. Sometimes patients can even be sent as an admission direct from a doctor's appointment because their provider deemed their admission necessary, such as a patient with heart failure who is fluid overloaded and needs IV diuretic therapy. Because these admissions are planned, the patient's entry into the system is generally organized and structured.

### Thirty-Day Readmissions

Admissions to the hospital that happen within thirty days of a prior admission are monitored by the Centers for Medicare and Medicaid Services (CMS). Only certain conditions are monitored under this thirty-day rule and include heart failure, recent CABG surgery, knee/hip surgery, acute myocardial infarction, pneumonia, or chronic obstructive pulmonary disease (COPD). This thirty-day measure was started to ensure that patients with these conditions were not being readmitted due to careless or poorly administered care.

### Hospital Readmissions Reduction Program (HRRP)

By monitoring readmissions through the Hospital Readmissions Reduction Program (HRRP) and giving hospitals financial incentives to prevent readmissions for these conditions, only patients who genuinely require further hospitalization are readmitted, thus improving the overall quality of care (Centers for Medicare and Medicaid [CMS], 2023a). HRRP, a program run by CMS, manages hospital reimbursements based on the number of readmissions reported. Hospitals are reviewed according to their performance on these metrics and reimbursement is determined accordingly. If a facility has high readmission rates for patients with conditions monitored under this program, then CMS may not reimburse the hospital for care provided. Linking reimbursements to readmission rates encourages healthcare facilities to be thorough and efficient when admitting and treating their patients and planning their discharge care.

### Hospital Value-Based Purchasing (VBP) Programs

Similar to HRRP, hospital value-based purchasing (VBP) programs seek to reduce readmissions and improve patient care through financial incentives at the hospital. VBP functions by basing Medicare payments on the quality of the care provided instead of the quantity (CMS, 2023b).

VBP in hospitals begins with their Inpatient Quality Reporting (IQR) measures. To qualify for VBP, hospitals must submit data to CMS that show they are adhering to the measures required to keep patients safe. Each measure is scored, weighted, and then generated as a Total Performance Score (TPS). These scores are then used by CMS to determine payment adjustments for that hospital. The hospital receives the payment amount, and the cycle of incentivized VBP begins again ([Figure 8.4](#)).

**FIGURE 8.4** Hospital value-based purchasing (VBP) programs seek to reduce readmissions and improve patient care through financial encouragement at the hospital. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Ambulatory Care Admissions

The **ambulatory care** is care given in outpatient settings, which includes doctor's offices, clinics, and outpatient

surgery centers. Nurses admitting patients in the ambulatory setting generally obtain a set of vitals and conduct a short assessment. If there are no complications, the patient goes home after the visit or procedure is completed. Examples of outpatient surgery include a tumor biopsy, laser eye surgery, or cataract surgery. Sometimes patients need to be admitted from these settings to the acute care setting, perhaps for a complication related to the surgical procedure or for an exacerbation of a chronic problem during the procedure, such as asthma, diabetes, heart failure, or hypertension. Admissions from these settings are often serious or emergent, and it is important to ensure that information to the admitting nurse is conveyed clearly and all details are given. Reports that are organized and structured help ensure the patient's safe transition to a higher level of care.

## LINK TO LEARNING

The Agency for Healthcare Research and Quality (AHRQ) has [a toolkit for ambulatory settings \(https://openstax.org/r/77AmbulaToolkit\)](https://openstax.org/r/77AmbulaToolkit) to ensure there are no gaps in patient care during this transition. The toolkit includes a rationale, a short step-by-step guide to implement these tools, an assessment template, a PowerPoint presentation for healthcare team member training, and a checklist for patients to empower themselves when receiving care in an ambulatory setting (Agency for Healthcare Research and Quality, 2017b). These tools are comprehensive enough to offer a more consistent and standardized flow for patient safety in ambulatory care while still being customizable for a facility's individual needs.

### National Patient Safety Goals for Ambulatory Care

The Agency for Healthcare Research and Quality (AHRQ) has noted that efforts to maintain patient safety have mainly been focused on acute care and inpatient settings, and that ambulatory settings provide “unique” challenges to patient safety (Agency for Healthcare Research and Quality, 2019). The Joint Commission (TJC), a United States healthcare regulatory nonprofit, ensures continuous quality improvement and excellence in patient care. TJC partnered with AHRQ to create national patient safety goals for ambulatory care ([Table 8.2](#)). These standards ensure patient safety when transitioning from ambulatory to acute care (TJC, 2023).

Goal	Guidelines to Goal
Identify patients correctly.	Use at least two ways to identify patients, ideally name and date of birth.
Use medicines safely.	Label all medications without a label before a procedure. Be cautious with patients on blood thinners (such as heparin or warfarin). Reconcile medications as best as possible with the patient and communicate information clearly and completely. Ensure the patient is educated on their medications
Prevent infection.	Use guidelines from the Centers for Disease Control and Prevention (CDC) for handwashing.
Prevent mistakes in surgery.	Ensure correct surgery is being done on the correct patient and at the correct place on the patient's body. Mark the correct place where the surgery is to be done. Pause before the surgery and do a final check to ensure no mistakes are being made.

**TABLE 8.2** Ambulatory Health Care National Patient Safety Goals (2023)

These goals are very similar to those that have been and are still used in inpatient and acute care settings. The application of these goals to an ambulatory care setting raises the standards of patient care throughout healthcare facilities nationwide, ensuring that patient safety is at the forefront of all patient care at all points of admission into the system.

## LINK TO LEARNING

---

The [National Patient Safety Goals for hospital admissions \(https://openstax.org/r/77HospSafeGoals\)](https://openstax.org/r/77HospSafeGoals) are described on The Joint Commission's website.

---

### Long-Term Care Admissions

Patients with chronic health problems who no longer require inpatient acute care but cannot be managed at home are often admitted to facilities for continuing care. A **long-term acute care (LTAC) facility** is very similar to acute care facilities in that it will take on acute patient tasks such as ventilator weaning, wound care, and/or intravenous (IV) antibiotics. The difference between LTAC and acute care facilities is that an LTAC facility is approved for longer periods of stay. LTAC facilities care for patients with acute care problems that require long-term care; examples of these admissions may include tracheostomy care, ventilator weaning, feeding tube maintenance, or patients with long-term wound care needs. A **long-term care (LTC) facility** and a **nursing home**, on the other hand, are not acute care facilities. Rather, they are permanent residences that provide medical assistance and care to their residents, just not at the acute care level. The main difference between an LTC and an LTAC facility is the length of stay. An LTC facility is approved for a longer admission time; LTC facilities are licensed for patients to stay for approximately thirty to ninety days compared to an LTAC facility that has a maximum reimbursable stay of twelve days or less. As with any other medical admission, it is important that patients are routed to the appropriate facility for their level of care. Other types of long-term admissions include home health care and assisted living, each with individual state-mandated guidelines.

### Federal Guidelines for Nursing Home Admissions

CMS and the U.S. Department of Health and Human Services (HHS) offer guidelines for admission to nursing homes and other types of LTC facilities. These guidelines help prevent unnecessary admissions to nursing homes and ensure that people who can be cared for safely in their own home can remain there. To this end, Medicare has federal guidelines that Medicare-certified nursing facilities must use when assessing patients for admission. A form (generally state-specific) outlines a Level 1 and Level 2 Preadmission Screening and Resident Review (PASRR) assessment. The overall goal of these guidelines is to ensure patient safety while still meeting patients' personal goals and needs.

## LINK TO LEARNING

---

The [CMS website provides guidelines and documents about nursing home \(https://openstax.org/r/77NursHomeGuide\)](https://openstax.org/r/77NursHomeGuide) admissions and operations. There are also links to guidelines governing various other types of LTC facilities.

---

### Nursing Preparation in the Admission Process

What an admitting nurse assesses and learns upon admission is important to all members of the healthcare team in planning the patient's course of treatment. It is also an opportunity to develop a rapport with the patient and their family. There is a lot to learn about a patient in the first stages of caring for them, so it is important to be organized in the admission process.

Many hospitals have an admission template in the electronic health record (EHR), which guides the questions and assessments needed when admitting a patient. During the initial stages of admission, the nurse may get a report from an emergency medical technician (EMT) or a nurse from the ambulatory facility. It is important to be prepared and have an organized set of questions that cover all the necessary information. Using a report sheet can be helpful; some hospitals have them predesigned ([Figure 8.5](#)).

## Nurse Report

**FIGURE 8.5** Nurses use an admission report sheet to get an accurate report on their patient. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Regulatory Guidelines for Patient Admission

Guidelines from CMS exist regarding hospital inpatient admissions. CMS guidelines tie back into reimbursement for service. TJC and other regulatory agencies, such as HHS and the American Hospital Association (AHA), establish strict standards and guidelines for healthcare facilities and institutions. These organizations, along with CMS, are in place for patient safety, and hospitals found in violation can be severely fined. The TJC standard is that each patient's need for admission must be assessed by a registered nurse (RN). These guidelines ensure that patients are admitted to inpatient care under a commonly held standard of necessity. To understand the clinical decisions nurses make on important assessments, refer to a learning framework such as the Clinical Judgment Measurement Model (CJMM).

## LINK TO LEARNING

---

The National Council of State Boards of Nursing (NCSBN) website discusses the [Clinical Judgment Measurement Model \(CJMM\)](https://openstax.org/r/77NCSBNCJMM) (<https://openstax.org/r/77NCSBNCJMM>) framework for nursing students to learn clinical decision-making. Utilizing this framework provides measurable decision points for making reasoned clinical judgments. It takes what often seems like a subjective, experiential, and instinctive process and turns it into a defined learning format.

---

### Preparing the Room

A key part of a successful admission is ensuring the room is stocked with all the necessary equipment. Ensure basic supplies are available—linens, pillows, a hospital bed. Check that vital sign and monitoring equipment are functioning and that all connecting cords and sensors are present. Ensure the call light is working. Have basic toiletries available for the patient. Depending on the patient's level of mobility, the nurse may want to have a walker, urinal, or bedside commode present.

Preparing a room for an admission also depends on the condition of the patient being received, such as critical versus stable. Consider a patient in heart failure being admitted from their doctor's office for shortness of breath. Because they are having difficulty breathing, ensure an oxygen hookup and tubing are available. If it seems likely that IV medications are going to be required, have IV pumps and tubing available, as well supplies to place additional IVs if necessary.

Also, consider the patient's mental status. If they are confused or at risk of a fall, place them in a room close to the nurse's station, apply bed alarms, and/or place nonskid pads on the floor. Preparing for an admission may also involve delegating, or assigning specific jobs or tasks to coworkers, especially if the patient is an acute admission.

### Specialty Equipment

Sometimes special equipment is required for an admission; when receiving a report on a patient, it is important to ask if the patient has any specific needs. In a critical care unit, the nurse may need a ventilator or specialized oxygen equipment such as a high-flow nasal cannula ([Figure 8.6](#)). If the patient has specialized lines, such as arterial lines, a Swan-Ganz catheter, or an intra-aortic balloon pump (IABP), ensure the equipment they are coming with is compatible with the admitting hospital's equipment.

**FIGURE 8.6** Nurses in intensive care units (ICUs) must learn to use a wide range of medical equipment to monitor critically ill patients. Often, specialized training and yearly continuing education are required to use these machines daily. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

It is good nursing practice to have the proper supplies and tools to convert the patient to the hospital's approved equipment available or have a backup on hand in case the equipment malfunctions. Does the patient need a bariatric bed? Even if one is not available until after the patient arrives, ordering one before the patient arrives reduces the time the patient has to be in the wrong-sized bed and minimizes the risk of skin injuries and breakdown.

#### Personal Preparation for Increased Workload

Admitting a patient on top of caring for current patients can be a difficult process for new nurses. Experience is the best teacher, and being well organized is essential. Think ahead:

- When is the patient arriving?
- Is the room set up with the necessary equipment?
- Is any special equipment necessary?
- Will you need additional help to move the patient?
- Am I caught up on tasks for my other patients?
- Will the family be accompanying the patient?

Review the tasks that must be done for current patients to ensure they are comfortable and that their needs are met before the admission arrives. Administer scheduled medications, if possible. Check that IV drips are sufficiently full. Obtain help from colleagues to monitor current patients while handling a new admission. Review what admission tasks can be delegated (such as weighing or bathing an admission) and notify the appropriate unit staff (such as the nurse's aide or patient care technician).

### Preparing for Admissions Report

The nurse should have an organized and standardized report sheet prepared ahead of receiving report that can be clearly and quickly referenced for information about the patient. This also helps to ensure all relevant information is obtained from the nurse giving the report. Missing information can have negative repercussions on the unit and/or hospital, such as an unreported skin wound or decubitus ulcer. Skin issues such as these that are present on admission are treated differently with CMS from ones that develop while the patient is on the unit, and they can result in increased costs, decreased reimbursement, and/or the healthcare facility assuming liability for the injury.

It is also important to think through what the relevant questions and concerns are for the admission: Why is the patient being admitted? What medical conditions does the patient have, and what information does the nurse need about them? Asking the right questions during the report ensures the patient is safe for transport and that the nurse is well prepared for the admission. Standardized reports, such as an SBAR, are discussed in [Chapter 2 Communication](#).

### Informed and Voluntary Consent

Patients, their chosen decision-maker, or **power of attorney (POA)**, must consent to any procedures done while admitted to the hospital. A POA is a legally binding agreement that documents that the patient is giving the authority to manage personal matters (such as medical care, financial business, or property) to another person. When giving consent, the patient acknowledges what procedure they are going to have, what the benefit is, and what the potential risks and side effects are. This is informed consent, meaning that the patient is aware of the risks and benefits of the procedure and has accepted those risks and benefits. This includes major procedures such as surgery and minor ones such as invasive line placement or blood product administration. The **voluntary consent**, on the other hand, is simply agreeing to treatment. The distinction between the two is a fine one, but very important.

Generally, it is the role of the doctor, resident, or midlevel advanced practice provider (APP) to obtain consent, though nurses are often asked to witness consent being given. It is not the nurse's role to obtain consent, but the nurse can alert the doctor and ensure consent is obtained while the patient is still conscious, or while the patient's decision-maker or POA is present at bedside. Nurses must ensure that the patient and family understand what was discussed during the consent process. They can also ensure a qualified translator is present if the patient and the doctor do not speak the same language.

### Preparing Interprofessional Team Members of Patient Admission

It is good practice, especially if the admission is emergent, to alert all members of the interprofessional team of a patient's arrival. Departments such as the cardiac catheterization lab, radiology, and/or perfusion may need to be notified. If the admission is an emergency, such as a stroke, the facility will have protocols in place to alert the necessary staff—hematology, neurosurgery, and radiology, to name a few. Depending on the patient's situation, other members of the interprofessional team may include nutritionists, physical therapists (PTs), occupational therapists (OTs), social workers, and discharge planners. Sometimes spiritual counselors, chaplains, or other therapists are involved as well. Ensure the unit clerk knows an admission is coming so they can enter the patient into the system, and make sure the charge nurse is updated. Pharmacy may also be alerted to an incoming admission, often if the patient has had a stroke and/or is critical enough to require rapid availability and administration of certain medications. It often falls to the nurse to alert all necessary team members to an admission, so be aware of the facility's resources and how to find them before the admission arrives.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Teamwork and Collaboration

**Definition:** Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision-making to achieve quality patient care.

**Skill:** The nurse will:

- Demonstrate awareness of your own strengths and limitations as a team member, and communicate effectively within your own scope of practice.
- Clarify roles and accountabilities to ensure patient safety and an effective, efficient admission.

**Knowledge:** The nurse will:

- Demonstrate your own strengths, limitations, value, and knowledge when functioning as a team member.
- Describe scope, practice, and role of team members.

**Attitude:** The nurse will:

- Acknowledge your own potential to contribute as a functioning member of the team.
  - Appreciate the importance of collaboration among team members.
- 

### Preparing for Optimal Patient Safety

Knowing a patient's level of mobility and function at home helps the nurse keep a patient safe while in the hospital. This is a key part of report and the admission process. If the patient is older, has a history of falling, and/or has impaired mobility and requires a walker or cane, ensure the patient understands they must call for assistance every time they need to get up, and reinforce this often if necessary. If the patient is confused due to dementia, Alzheimer disease, or **sundowning** (a phenomenon where adults [often older] become confused when the sun goes down [Canevelli et al., 2016]), consider utilizing a bed or chair alarm. These devices monitor the pressure of the patient's weight on its surface, and if that weight lessens or disappears, an alarm goes off. If the patient becomes increasingly confused, reorient them kindly and frequently.

Another good practice for patient safety is to review all orders placed by the provider for the patient's care. Is the patient to go for a procedure early in the morning and therefore has orders to not eat or drink anything? Have parameters for their vital signs been placed, indicating when to alert the provider if the patient's vitals cross them? Knowing these orders guides the care the nurse provides for the patient. For instance, the nurse may have to teach the patient about the importance of not eating or drinking before a procedure.

Once the patient is settled and aware of the current plan, ensure everything the patient needs is within reach before leaving the room: set up their bedside table with water and/or snacks if allowed, any personal equipment such as glasses, hearing aids, or a cup for dentures if necessary. Ask if they have a cell phone and want it near them, or if they would like it charged. Ensure the call light is within reach and that the patient knows how to use it. If available, place mats or padding on the floor. Ensure the room is clean and organized, and no excessive cords or wires are on the floor as potential hazards.

If the patient cannot speak or cannot communicate in words or sentences, some hospitals have communication boards with pictures and phrases to help patients who cannot articulate their needs ([Figure 8.7](#)). These boards generally are flat, plastic, or laminated sheets with pictures on them. Some have words, others can simply be facial expressions or pictures of things (a phone, chair, or toilet, for example). The patient can point to the picture or word-and-picture that expresses what they want, and the nurse will be able to respond accordingly.

yes <b>yes</b>	no <b>no</b>	down 	up 	bathroom 
lights on/off 	thirsty 	hot/cold 	pain 	medicine 
glasses 	need a pillow 	need a blanket 	call my family 	don't leave 
call doctor 	call nurse 	ice chips 	reposition 	trouble breathing 

**FIGURE 8.7** A communication board like this example can be used with patients who have difficulty conveying their needs. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## REAL RN STORIES

### Keeping a Patient Safe

**Nurse:** Ann, RN

**Clinical setting:** Assisted living facility

**Years in practice:** 2

**Facility location:** Chicago, Illinois

When I was a relatively new nurse, I was caring for an older White female in her mid-70s who had been admitted from her assisted living facility for new onset atrial fibrillation. She was fully alert and oriented and had been so all day. She was really the nicest lady, so kind and friendly! We had a great day chatting about her grandchildren and great-grandchildren. Around 5:30 p.m., I went into the room with the patient's evening meds and found her sitting in her chair with a frown on her face and staring out the window. I asked her if she was okay and if anything was wrong. She kept staring out of the window, but snapped back sharply, "Do I look okay to you? Stupid girl. Go away."

I was so shocked; this was not the patient I had taken care of when I came on shift at 7 a.m. Instead of being kind and friendly, she was mean and withdrawn. I thought maybe she was sundowning, so I carefully began an assessment. I found that she was no longer oriented, she thought she was at the grocery store and that the car was late to take her home to "get the laundry and see the baby." As we were talking, she became increasingly agitated, wringing her hands and shaking her head. I tried to gently reorient her by saying "Mrs. Mueller, do you know where

you are? You know you are in the hospital, right?” Well, that was the wrong thing to say. She became even more agitated. She called me a liar for saying she’s in the hospital, and that she was going to call the police because I won’t let her “see the baby.”

I asked a coworker to keep an eye on her while I went to speak with the doctor. I told him about her mental status change. I asked, “Do you want to give her something to calm down? She is safe now but at this rate she could become unsafe.” The doctor replied, “I’d prefer not to give her any medication at this time; she is probably sundowning because she is in an unfamiliar place, and it will eventually pass. The meds may make her sundowning worse anyway. Let me know if she starts to get combative.”

With no meds available to help my patient calm down and get reoriented, I had to figure something out. I remembered something my nursing preceptor told me when I first started. I went to the linen cart and brought out a pile of pillowcases and towels. I went to the patient and said, “I am so sorry, ma’am, you were right, there is a lot of laundry for the baby. Can you help us fold it?” She glared at me suspiciously but allowed me to set her up in her chair with a table and the linens in front of her. I snuck a bed alarm onto the seat and told her she could page me (with her call light) if she needed anything. To my amazement it worked! She calmed down and quietly began folding the stack of towels and pillowcases. She said she was glad I had finally seen reason and stopped being so stupid. I went back to the nurse’s station and made sure I could see her from my computer while I finished my day’s charting.

---

## Preparing to Establish an Effective Nurse–Patient Relationship

Admitting a patient to the hospital is the nurse’s best opportunity to begin a positive and effective nurse–patient relationship. Verbal and nonverbal communication is key to this process. The verbal communication involves using words and language to convey meaning, whereas **nonverbal communication** involves reading the meaning behind gestures and movement. This often sets the tone for the patient’s interactions going forward at the hospital. Research shows the nurse–patient relationship can reduce the length of hospital stays, improve patient satisfaction, and increase the quality of nursing and medical care (Molina-Mula, 2020). Be professional, friendly, and culturally respectful when introducing yourself. Establishing trust and respect between the patient and nurse encourages communication between all parties. Engage **active listening**: make eye contact, be present in the conversation, and let the patient speak without interrupting them. Show the patient that staff are available to help and that the patient is an important part of the care team. Often, nurses are the main communicator between the patient and the physicians and specialty teams. The nurse’s ability to communicate effectively and compassionately with their patient is a key to facilitating clear and open communication between the patient and all members of the healthcare team.

## CULTURAL CONTEXT

---

### Cultural Considerations When Admitting New Patients

Living in a diverse society, nurses need to be considerate of patients’ backgrounds and cultural norms. Not every culture greets people with a handshake, while other cultures find it rude if you don’t offer your hand. Some cultures find direct eye contact rude. In some Asian cultures, there is a strong sense of age- and gender-centered hierarchy. “Elders” are not to be contradicted, and while a patient may agree to a medication, they may have to ask their spouse or eldest male family member for approval.

Some cultures and religions are very uncomfortable with casual physical touch; it is good to talk through an assessment with patients and ask if something is okay to do. For example: “Mrs. X, I need to listen to your heart. To do so I need to place this stethoscope under your shirt. Is that okay?”

Some religions and religious sects will refuse to have nurses or doctors of the opposite sex. When that happens, do not be offended; let the patient know you understand and will try to see if their requests can be accommodated.

In general, when dealing with diverse populations, be professional and empathetic. Do not make assumptions. Be observant. Mistakes are likely to be made, but the important thing is to be humble, apologize if necessary, and try again. Approach interactions with people that are different from you with intentionality, respect, and kindness, and

you will continue to learn and do your best to bridge these divides.

### Reduce Patient Anxiety

Being admitted to the hospital can be a very frightening experience for the patient as well as their family members. This may be the first time the patient has ever been admitted, or they may be sicker than they have ever been. This understandably can make patients anxious, and this anxiety can manifest in many ways. Anxiety, panic, feelings of helplessness, and loss of control can result in the patient showing maladaptive health behaviors (Otto, 2018). It is important to identify these behaviors and reactions for what they are and to provide the reassurance the patient needs. Give the patient choices as much as possible, staying within the limits of proper patient care and maintaining their safety. Regaining a small sense of control by being able to make a choice as simple as when they want to take their nighttime sleeping pill can help ease patient anxiety and increase their comfort. Ultimately, clear communication is a key factor in relieving patient anxiety; assessing a patient's anxiety level upon admission enables the nurse and healthcare team to develop a plan to address it sooner rather than later (Baldwin, 2019).

## PATIENT CONVERSATIONS

### Addressing Patient Anxiety with Intuition and Therapeutic Communication

**Scenario:** Jamal Brown is a 58-year-old male who has been admitted to acute care from his doctor's office; he has heart failure, shortness of breath, and oxygen saturations in the mid-80s, and he is on 2 L of oxygen via nasal cannula. Until his diagnosis of heart failure, Jamal was very active and independent. He does not like feeling vulnerable or helpless. He has just been wheeled in by emergency medical services (EMS) and transferred to the bed. Anh is his admitting nurse.

**Nurse:** Hi, Mr. Brown. My name is Anh, and I will be your nurse tonight. I've got a few questions to ask you. Do you prefer to be called Mr. Brown or Jamal?

**Patient:** Jamal is fine. I really need help though. Is the doctor coming in soon? Where is my daughter? Is she coming?

**Nurse:** Yes, the doctor will be in shortly. Your daughter called and she is on her way. Are you in any pain right now?

**Patient:** [frustrated] Didn't my doctor tell you when they called to say I was coming? I'm not in pain, I can't breathe. How old are you? Do you even know what you are doing?

**Nurse:** Yes, they told me. I just wanted to know if anything else was bothering you.

**Patient:** [frustrated] That's stupid, you already know why I'm here. I thought this was a good hospital. I want a nurse who knows what side is up. Go away.

**Nurse:** [patiently] I understand all of this is really scary, Jamal. I want to reassure you that you're in a safe place and we are all here to help you. Please just give me a moment to ask a couple of questions until the doctor comes in.

**Patient:** [angrily] No! I feel awful and you're making me feel worse. I want a new nurse when he comes in. Get out.

**Nurse:** I can step out if you want a minute to yourself. I can see from our monitors though that your blood pressure is a bit high, your heart rate is fast, and your oxygen is just a little over 90 percent, which is a bit low and could be why you feel short of breath. I'm going to increase the oxygen flow in your nasal cannula to 4 L. Does that feel any better?

**Patient:** [breathing a bit more slowly] Yes, that does feel a bit better. I don't know why my breathing is so bad when it's my heart that is sick. Why is this happening?

**Nurse:** When you have heart failure, you can accumulate a lot of fluid in your body because your heart can't pump as well as it should, and that can make it harder for you to breathe. Plus, coming to the hospital is scary, and that doesn't help. We will help you through this. Do you want to hold off on the rest of the admission questions until your daughter gets here?

**Patient:** Yes, please, if that's okay. She always knows the right things to say.

**Nurse:** That’s not a problem. Here are your belongings along with your cell phone. I’ll step out and take care of a couple things; just know that you’re on our hospital monitors now [points at screen] and we will be watching and making sure you’re okay. Call me if you need anything, otherwise I’ll be back to check on you in ten minutes.

**Patient:** [grateful] Thank you, Anh. I’m sorry I yelled at you; I’m really scared. I appreciate you being so understanding.

**Nurse:** It’s all right, Jamal. Here’s your call light, I will be back soon.

**Scenario follow-up:** Anh could sense Jamal’s anxiety both in his verbal and nonverbal communication (tone of voice). Anh understands that while the admission process is important, it is okay to give the patient some space to cope with what is happening. The patient is still safe because he is hooked up to the telemetry monitoring so Anh can watch his vitals while giving him some time. Also, Anh knows that waiting for his daughter to arrive is another way to ease his anxiety; once she is at the hospital, Anh can try the admission assessment again.

---

### Orientation of Routines in Care

Even if the patient has been in the hospital before, it is always good practice to explain the care routines that happen on the unit. These routines may differ greatly between units in the same facility—acute care units may take vitals every four to eight hours, whereas in the ICU vitals are measured every hour. Assessment times can vary as well, from every hour to as long as every eight hours. Some assessments must happen hourly, such as those for patients who have had a stroke or have neurological disorders, or every two hours, such as peripheral vascular pulse checks. Assessments can also vary in the degree of involvement: Is there an automatic blood pressure cuff or does the nurse have to manually take the blood pressure? Is the patient asked questions they must answer, or can they be asleep? Routine tests and procedures also can vary in their necessity or frequency. When are labs drawn? Are x-rays daily or as needed? Daily hygiene and cleanliness should also be discussed; patients must be bathed or can receive assistance with bathing daily.

Another step in orienting the patient and their loved ones to the healthcare facility is informing them about visiting hours and policies regarding who can come and how many at a time. Policies can differ from one unit to another in the same facility; visiting hours on an acute care unit are very different from those on a critical care unit where the patients are sicker and require closer monitoring. Ensuring everyone is clear on the policies of the unit helps prevent potential misunderstandings that can increase patient and family anxiety. Other details that are helpful to share with the family of patients in the hospital are when meals are delivered, what dining and amenity options are available, or how to get information about the patient’s status.

### Encouraging Involvement in Decision-Making

Health care is a team-oriented process, and the patient is perhaps the most important part of that team. Nothing is done without the approval of the patient or their designated decision-maker; thus, it is important that patients and their family be engaged with healthcare providers. Decisions regarding the care plan should be clearly discussed with the patient, and the patient should feel empowered to ask questions and express their concerns. It is the role and responsibility of the entire healthcare team (doctors, nurses, therapists, technicians) to ensure the patient can make the most educated decision they can.

### Initiation of Discharge Goals

One of the most important parts of the admission process is discharge planning, which begins when the patient is admitted. Consider all details, such as the examples listed here, that can be observed upon admission and can be discussed among the healthcare team as the patient’s hospital stay progresses.

- Does the patient seem like they understand what their disease process is and what is happening to them? Will this be a problem when they are discharged?
- Do they need more education and what kind?
- What resources are available for follow-up?
- Can they access their medications? Do they understand what their medications are for? Can they afford their medications?
- Does social work or case management need to get involved?
- Will the patient need a home health nurse to check their blood pressure or blood sugar, or do a dressing

change?

- Will they need rehabilitation, or physical or occupational therapy?
- Are they safe at home, or are they at risk?
- Are there any noticeable red flags that are concerning, perhaps in what the patient says or one of their family members or caregivers says?

Keep the patient's whole picture in mind and remember that discharge planning begins upon admission.

## 8.2 Patient Transfer

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe steps for patient transfer to and from an external acute care facility
- Describe steps for patient transfer within the same facility
- Recognize the process for patient transfer to an extended care facility
- Identify how the nurse can ensure patient needs are met during transfer

Patient transfers occur between healthcare facilities, and even within the same facility. These transfers happen depending on the patient's condition, and information between facilities and units must be clear and accurate.

There are many different units with varied specialties within the same hospital. Consider a patient who was admitted for several large lacerations on their body because of a construction accident. They had serious bleeding and required surgery to repair the damage. The patient's vitals are tenuous and require blood product administration and surgery, so they are admitted from the emergency department (ED) directly to the operating room (OR). From the OR they may go to the **intensive care unit (ICU)** for close monitoring. The patient's condition improves, and they are allowed to transfer to the step-down unit, and from there to the medical-surgical unit where they are eventually discharged back home. A **step-down unit** is an inpatient unit in many hospitals that serves as a transition point between intensive care and the **medical-surgical unit**, also known as the general medical unit, where the least critical patients who still require inpatient acute care are housed. The difference between these units lies in the **acuity**, or the severity and complexity of patient illness, and in patient care routines such as the frequency of vitals, assessments, and visitation limitations as discussed in [8.1 Patient Admission](#). For an initially emergent admission, it is vital that the patient's medical information and condition are quickly and accurately conveyed between each of these points of care.

All aspects of the patient's medical story are important, but nurses and healthcare providers must know what information is most important to the people currently caring for the patient and focus their transfer report accordingly. Priorities may change. For example, in the ED or ICU, the patient may be in a lot of pain and require significant pain medications and frequent assessments. Interventions such as physical therapy and rehabilitation for improving mobility are important but not necessary at this point. Once the patient begins to heal and is more stable, their care priorities may change. The nursing and medical staff must be able to adapt to the patient's changing needs as they transfer from different units and facilities. Details such as wound care, a skin tear obtained on the unit, or consistently high blood sugar levels also need to be conveyed. Each point of transfer is another step in the patient's healthcare journey, and each point has the potential for crucial information to not be conveyed, negatively affecting patient care.

### Steps to a Patient Transfer

In an acute care setting, the process of patient transfer begins with decisions made by the patient's primary team of providers. This can include doctors, surgeons, and/or specialists. Nurses and advanced practice providers such as physician assistants (PAs) and nurse practitioners (NPs) may also be a part of this team. Other providers can be social workers and case managers, who coordinate with insurance and sometimes Medicare and Medicaid to ensure the patient's care is covered by the relevant entity. Pharmacy may be involved as well to give their input on medications the patient may need.

Once a decision is made to transfer a patient, multiple calls are made to the receiving unit or location. The doctors call and discuss the case with the receiving doctors. The transferring charge nurse speaks with bed management and the charge nurse on the receiving unit to arrange for report. Social work and case management may be involved if the patient is being transferred externally to a different facility. Once all approvals are in place, the nurse or charge

nurse contacts the unit clerk and arranges for transportation, either via patient transport if the transfer is within the facility to another unit, or via EMS or an ambulance to an outside facility.

## Patient Transfer between Facilities

Sometimes a patient is transferred from a community hospital to a larger facility for a higher level of care or for care that the smaller facility with fewer resources cannot handle. Sometimes transfers occur due to insurance issues. Whatever the case, larger hospitals—often in cities or sizeable metropolitan areas—are often affiliated with teaching universities or medical schools and thus have many resources at hand. When transferring a patient to a higher level of care, it is important to anticipate the questions the nurse will have and to try to have the information readily available if not already part of report. Transfers between healthcare facilities, also known as an **interfacility transfer**, are key points where information may be missed because many hospitals are not on the same charting or record-keeping system. A standardized report covering every possible, necessary piece of data ensures nothing is missed.

When receiving a transfer, it is key to assess the patient thoroughly, paying particular attention to important tasks such as checking the skin and bony prominences for bruises, cuts, scrapes, skin tears, or pressure ulcers. Check for any wounds, and if present, the dressings on the wounds. Any access lines such as IVs, gastric tubes, and urinary catheters should be carefully documented; per facility policy, some lines may need to be switched out. Drains should be documented and assessed. These points are all assessed under quality improvement measures and monitored by TJC, and if they are missed or not documented and addressed upon admission, the injury can become the responsibility of the facility and can negatively affect their reimbursements from CMS.

## REAL RN STORIES

### Paying Attention to the Details

**Nurse:** Liz, RN

**Clinical setting:** Acute care hospital

**Years in practice:** 8

**Facility location:** Tulsa, Oklahoma

It was 6 p.m. on a Friday evening and I was informed by my charge nurse that I was getting an admission from an assisted living facility. The patient was a 67-year-old male with no known allergies, being admitted for altered mental status and low blood sugar. His history included hypertension, diabetes, and high cholesterol. The nurse at the assisted living facility was on the phone ready to give report. As I started talking to her, I felt like something was off because she seemed distracted, and her details did not make sense. She said the patient is generally alert and oriented, but tonight was found sitting in his chair in front of his dinner tray sleepy, confused, and lethargic. His blood sugar was 55, so the nurse said she gave him 8 ounces of apple juice. That made sense, so I asked if the juice had improved his blood glucose. She replied “What? What do you mean improved?” I said, “Did you recheck his blood sugar fifteen minutes later to make sure that the juice helped?” “No,” she replied, “he responded to me when I asked if he was okay, so I figured he was fine. I have six other patients, so I couldn’t go back and check.” I requested she get the patient care technician (PCT) to check the patient’s sugar while she continued to give me report.

Next, I asked if the patient had received his evening insulin. She said he had and that he was eating dinner when he was found lethargic. I asked if his sugar had been checked before the meal, and she said no. That was a *big* red flag for me: blood sugar should always be checked before administering insulin. I started to get frustrated, but I remained calm and professional. I then asked how much the patient had eaten today and when he was found. She said he had a big breakfast, was tired and skipped lunch, and his dinner tray had only been about 15 to 20 percent eaten. To me, this sounded like the patient had gotten too much insulin. The PCT came back to say that the patient’s blood sugar was 60. I told the nurse the patient clearly needed some more juice; she instructed the PCT to give the patient another two 8-ounce containers of juice, and then continued with report. Later when the patient arrived, his blood sugar was in the 80s and he was more alert. I was so glad I asked the nurse to recheck the sugar; if I hadn’t, the patient might have been in critical condition or worse before he arrived at my hospital.

## Patient Transfer within Facilities

Transfers within an acute care facility are some of the most frequent patient transfers that occur when a patient transitions from one level of care to another. Consider a patient who is transferred from the ED to the ICU and how nurses ensure the patient's information is complete, ranging from the reason they are admitted to the condition of their skin after a four-hour operation. The key to having complete information is consistent assessments, standardized charting, and efficient reports between nurses upon each transfer. Information must be complete, focused, and relevant. If the patient is transferring from the OR to the ICU, the nurse needs to know what IV medications the patient is on and what their labs and vital signs are. Is there any damage to their skin? Do they have any wounds? Do they have surgical lines or drains? Their level of mobility or whether they were continent before the surgery is good to know but can be conveyed via nursing documentation in the patient's chart. Later, when the patient transfers to the general medicine floor or to an outpatient rehab, report should focus on the relevant information the nurses will need there. Some necessary information will remain the same, such as vitals, labs, and skin condition. Information that was less relevant before, such as continence and mobility, become more relevant when the patient transfers to decreasing levels of acuity. In short, transfers between units must be complete but focused, thorough, and well documented.

### Report between Units

Report between units is the point where information is conveyed from one unit to the next. Different levels of care require different areas to emphasize when giving report. If the patient is being transferred for observation, it is important to know the basics of their condition, the medications they require, and the status of their mobility and orientation. Understanding the patient's medical conditions and needs when transferring them is vital to giving the receiving nurse a report with all the necessary information to care for the patient safely.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Reformulating SBAR to ISBARR

To help facilitate safe patient transfers, evidence-based communication methods, such as **SBAR** (Situation, Background, Assessment, Recommendation), have been used. While SBAR works, the system can always be improved (Muller et al., 2018). Research has been done to improve the SBAR format to include an introduction when beginning to give report and a readback at the end ([Figure 8.8](#)).

## ISBARR Report

Use this format to report your concerns about a patient's condition to a health care provider. Before calling the provider, assess the patient and review the progress notes from the past 24 hours.

<b>I</b> Introduction	My name is _____ and I am a nurse calling from _____
<b>S</b> Situation	I am calling about: <i>Patient name and location</i> The problem I am calling about is: <i>State the problem, how severe it is, and when it started.</i> The most recent vital signs are: <i>BP _____, pulse _____, respiratory rate _____, O<sub>2</sub> sat _____, temperature _____</i> The patient is <i>stable/appears to be getting worse</i>
<b>B</b> Background	Pertinent background information includes: <i>Medical diagnoses:</i> <i>Code status:</i> <i>Recent lab/diagnostic work:</i> <i>Allergies:</i>
<b>A</b> Assessment	I have just assessed the patient and I am concerned about: <i>State assessment findings that you are concerned about</i>
<b>R</b> Recommendation	I am asking for you to: <i>State what you would like the provider to do, such as reassess the patient, order a lab/diagnostic test, prescribe or change medication, etc.</i>
<b>R</b> Repeat Back	I am repeating back your order to confirm you would like to: <i>Repeat back the order</i>

**FIGURE 8.8** ISBARR is one way to organize communication about a patient in a concise manner. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Transfer of Personal Belongings

The transfer of patient belongings may seem minor, but it is a crucial part of the transfer process. Ensuring the patient's possessions go with them preserves positive relationships and maintains a good rapport with the patient and their family. Items such as cell phones, tablets, phone chargers, eyeglasses, dentures, and earbuds frequently get lost in the transfer process. Canes, walkers, and crutches are also important belongings to keep track of for patients, as they are expensive and are often purchased through the patient's insurance. Personal mementos, such as religious icons, greeting cards, and photos, are sometimes displayed in a patient's room and should also be considered part of the patient's transfer. If the patient is too ill to participate, make the primary family contact aware of the patient's transfer so that expensive and valuable possessions such as cell phones and wallets can be located and perhaps taken home for safekeeping. Patients and their loved ones appreciate it when these details are as looked after and cared for as the patients themselves.

### Family Notification of Transfer

Ideally, the patient's family is closely involved in the care plan developed with the healthcare team and they are aware of the plan to transfer, but this does not always happen. Ensuring that the patient's family is aware of the transfer ensures clear communication and positive relationships with the patient and family. Urgent notification of family is sometimes necessary as in the case of a decline in patient status requiring return to surgery or transfer to the ICU. For nonemergent transfers, if the family visits in the morning and it is several hours before the transfer is to

occur, it is acceptable to inform them of the transfer at that time. However, if the family is unable to visit until closer to the transfer time or afterward, a simple phone call update is strongly suggested. It is a small amount of time that results in a large amount of appreciation and comfort for the family.

### Transfer to an Extended Care Facility

When a patient no longer needs acute inpatient care but still has significant medical needs that their family cannot attend to, the patient may be admitted to an extended care facility. This includes nursing homes, LTC facilities, and LTAC facilities. Again, as with other transfers, it is important the patient's entire story is communicated; however, report should be focused and specific on what the transferring facility needs to know. Facts that are most important, besides vitals, involve orientation, mobility, medications, and wounds. Report should be thorough, complete, and focused.

#### Mode of Transportation

There are many ways that a patient can be physically transferred from one facility to another. Depending on their acuity, they may be sent via EMS in an ambulance, or even a critical care specialist ambulance if the patient has a ventilator or certain IV medications that require special training. If the patient requires transfer from a very rural or remote area, the patient may be flown in via helicopter. Special teams of doctors and nurses staff these flight ambulances; they are trained in critical care life support and the use of medications, machines, and devices to sustain the patient until they arrive at their receiving facility. Patients may also be transferred via private ambulance, usually if the patient or the family wants a transfer to a particular facility. These transfers are usually arranged by the transferring facility, although sometimes the family arranges the service or transfers the patient themselves, though rarely. Regardless of the mode of transport, it is important that the nurse coordinates the patient's departure with all involved parties: the doctors should be aware, the charge nurse and unit clerk must be notified, report must be given, belongings must be packed, and the patient must be prepared (dressed, cleaned, ambulated/toileted).

#### Transfer of Advance Directives

The patient's code status and advance directives should also be clearly conveyed as part of transfer report, especially if the patient is being sent to an outside facility. The advance directives are rules that are legally set by the patient that dictate their end-of-life care. It is vitally important that this is communicated *clearly*, with no room for questions or error. Not communicating that a patient does not want chest compressions in the event their heart stops can cause great distress to the patient and family, as well as potential legal ramifications for the facility.

### Ensuring Patient Needs Are Met during Transfer

Leaving the hospital for somewhere new can bring on a lot of anxiety for patients and family members, especially if the patient's mobility or overall health has been impacted by their inpatient stay. There may even be fear or anger.

Consider where the patient is going. Report to an assisted living facility may be very different from report to an LTC facility or an inpatient rehab floor. Is the patient going home? Are there new medical devices going home with the patient? Who needs to be educated? What can the family or patient expect? What are the plans for follow-up? The rapport built with a patient will factor into how the nurse can help the patient transition to this next phase in their healthcare journey.

#### Patient Comfort

Patients may be very anxious upon transfer to a new unit. Their health may have drastically changed for better or worse since admission and this new transition can cause fears, anxieties, or even trauma to resurface. Nursing can play a large role in easing this process for patients as well as their family members. The nurse may need to provide medication before the transfer such as anti-anxiety or pain medications.

Be transparent about the process and the schedule. If a patient is leaving an acute care facility for an LTC facility, arrangements may take a while to find the right facility and ensure all medications and follow-up appointments and care are set up. Setting up post-hospital care with insurance, Medicare, or Medicaid can also be a long, arduous, and frustrating process. Educate the patient and family about what is happening. Do not scare them but be realistic about how long the process can take. Acknowledge and validate their feelings. Provide active listening and be empathetic.

Assist the patient by packing all belongings and ensuring nothing is forgotten. Assist the patient with any needs or

bodily functions before transfer. Do they want to bathe or brush their teeth? See if the family wants to bring the patient clothes. Does the patient want help getting dressed? Are there any hospital supplies that can be sent with the patient, such as dressing change supplies or extra hygiene products? These are small and considerate touches that can help ease the transition for the patient and their loved ones.

### Patient Safety

Patient safety is of the upmost importance during the transfer process. Scenarios, such as medication errors, unassessed wounds, falls, or skin breakdown from incontinence, can occur if a proper and thorough report is not given to the admitting facility. Nurses must include all pertinent information when giving a hand-off report, and this includes educating the patient and family about the transfer process. The following questions, in addition to standard hand-off report, can ensure information regarding patient safety is considered:

- What is the patient's mobility status?
- Is the patient continent?
- Are they confused? Are they sundowning?
- Has patient and family education been completed?

## CULTURAL CONTEXT

---

### Cultural Considerations Regarding Patient Safety

Some cultures are very uneasy about letting anyone care for their loved ones other than direct family members. Asian and South Asian cultures may tend to feel it is a familial and filial duty to care for elders when they are not well. Not to take on that responsibility may possibly be seen as disrespectful, which can conflict with some Western and American perspectives. It can be difficult to reconcile these traditions with the level of care a patient requires, especially if it is care that the family may not be able to handle due to language barriers or financial concerns.

One way to open the conversation in such a situation is to arrange a family meeting with a translator (if needed) and the primary doctor or surgeon that has cared for the patient. Emphasize that keeping the patient as safe and healthy as possible is the common priority of everyone there. The ultimate decision and outcome may not be ideal or what was expected but it is the healthcare provider's role to use their medical knowledge to educate and guide as best as possible.

---

### Patient Teaching

Patient teaching largely depends on where the patient is being transferred to, and what the level of care is going to be. For example, consider a patient who is being treated for esophageal cancer and is going to an assisted living facility with a new **percutaneous endoscopic gastrostomy (PEG) tube**, a type of feeding tube inserted into the patient's abdomen that enables them to receive tube feedings instead of being fed orally. The patient and family have never seen or heard of anything like this before and they are terrified. Teach the patient and their family about this tube, describing how to care for the tube site and how to work the feeding pump. Educate the patient and family on how to know when the PEG tube is normal and when they should call for assistance. The nurse should also get case management and social work involved to ensure the patient will have all the necessary supplies at their next facility, and that the details of the patient's insurance coverage is worked out.

## UNFOLDING CASE STUDY

### Unfolding Case Study #2: Part 2

Refer back to [Unfolding Case Study #2: Part 1](#) for a review on the patient data.

Nursing Notes	<b>0830: Assessment</b> 12-lead ECG performed, ST depression noted, cardiology team aware. 2 L oxygen via nasal cannula applied with improvement in shortness of breath noted. Left AC IV inserted, nitroglycerin infusing per protocol. Patient reports improvement in chest pain.
Lab Results	LDL cholesterol: 165 mg/dL (normal: < 100 mg/dL) Troponin: 23 ng/mL (normal: < 0.04 ng/mL)
Diagnostic Test Results	Chest x-ray: no acute findings
Provider's Orders	<b>0833: New orders</b> Transfer to cardiac unit for close observation.

3. Prioritize hypotheses: Why do you think the patient is being transferred to the cardiac unit? Is there anywhere else you would expect this patient to go?
4. Generate solutions: What information is the most important for the emergency room nurse to include in the report to the cardiology unit nurse?
5. Take action: The emergency room nurse prepares to take the patient to the cardiology unit. What are some considerations the nurse should think about before initiating the transfer?
6. Evaluate outcomes: After taking the patient to the new unit, what outcomes would indicate that the transfer was successful?

## 8.3 Patient Discharge

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the steps for discharge from a healthcare facility
- Understand the issues with patients leaving against medical advice
- Explain the process of discharge from home health agencies

Discharging a patient from a healthcare facility is the final transition point in a patient's journey through the healthcare system, although there may be other points or stops in a patient's healthcare journey. During admission, a healthcare plan is discussed and constructed, which is when the plan begins to come into focus; discharge is the part of the healthcare plan ensures that the patient has the education, knowledge, supplies, and necessities to maintain their health. Follow-up appointments, such as with the primary team, specialty doctors, rehab, and physical therapy (PT) and/or occupational therapy (OT), get arranged. A thorough and well-planned discharge plan helps the patient progress through the healing process as smoothly as possible. Discharge planning is also the first step in care coordination and a vital part of patient-centered care.

### Discharge from a Healthcare Facility

Discharge from a healthcare facility has many layers and procedures. Inpatient doctors collaborate and give their approval that all necessary patient benchmarks have been met: Has the patient been transitioned to medications that are available and safe for them to take outside of an acute care setting? Are the patient's vital signs stable or within normal limits for them? Does the patient have a place to go? Does the patient have the resources to either properly care for themselves or have someone care for them?

Specialty teams that have been consulted during the patient's care must also agree that the patient is ready for discharge. For example, the renal/nephrology team may require the patient to attend hemodialysis; once the patient is able to tolerate outpatient dialysis, the team gives approval and arranges follow-up for the patient after discharge. The endocrine team may have concerns about a patient's blood sugar management. The cardiology team may want

to have the patient wear a heart monitor to watch for arrhythmias. If the patient has diabetes, a specialist may want to speak with the patient and family about glucose monitoring or skin and wound care. Dietary needs might need to be considered. Social work may need to get involved to ensure the patient gets the support they need. There are many aspects to consider when arranging discharge.

### Guidelines for Discharge Planning

The importance of discharge planning cannot be understated. A readmission within thirty days of discharge can incur financial penalties for the healthcare institution, which includes reduced or no reimbursement for healthcare costs incurred (Patel, 2023). Yet, no formal standards exist for discharge planning. Successful discharge planning involves the patient and their family from the beginning; again, this is why discharge planning begins upon admission. The plan must be based on collaboration with all individuals involved, and depends on follow-up, ongoing guidance, and education.

### LINK TO LEARNING

The Agency for Healthcare Research and Quality (AHRQ) has [an excellent resource for healthcare providers for implementing discharge planning systems \(https://openstax.org/r/77DischargePlan\)](https://openstax.org/r/77DischargePlan) at healthcare facilities. It includes roles for all members of the healthcare team, rationales for each role, and tools to help implement the guidelines. Medicare also has [a handbook for patients and their families \(https://openstax.org/r/77PatFamHandbk\)](https://openstax.org/r/77PatFamHandbk) to guide their involvement in the discharge process.

### Interdisciplinary Team Decisions

From morning huddles to daily rounds, all members of the healthcare team discuss their patients. Nursing generally reviews the patient load on their floor as a unit before handing out assignments for the shift. For physicians and surgeons, this process is typically called **rounds**, and their action is called rounding. Rounds involve a brief recap of the patient from admission and the most recent update on their condition. This may occur in a huddle, similar to what nursing does, or the physicians may physically walk the unit to each patient room. Research shows that conducting rounds in front of the patient and their family increases their involvement and improves outcomes (Strathdee et al., 2023). Respiratory therapy (RT), PT, OT, pharmacy, and all specialists (such as cardiology and nephrology) review their patients within their discipline as well.

However, all these disciplines need to collaborate to benefit a patient. Consider a patient admitted for abdominal surgery. According to the surgical team and internal medicine, the patient needs acute rehabilitation. Social work says an assisted living facility is needed to accommodate those needs. The nurse also informs the team that the patient has expressed concern about their dressing changes once they leave rehab. The patient only trusts their daughter to change the dressings, but she lives two hours from the patient's home and cannot come every day. Also, the patient is showing a lot of reluctance to the dietary changes that come with managing their diabetes despite nursing's efforts to educate. Each of these issues is intertwined with the other. What can be done? Are there other learning materials that can be given to the patient? Can a nutritionist speak with the patient about ways they can incorporate their current diet into a healthier diet? Can social work help coordinate a wound care nurse to come help with the dressing changes on the days the daughter cannot come? Successful discharge planning depends on the effectiveness of these interdisciplinary team conversations and decisions.

### CLINICAL SAFETY AND PROCEDURES (QSEN)

#### QSEN Competency: Patient-Centered Care

**Definition:** Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs.

**Skills:** The nurse will:

- Discuss patient needs and requirements for discharge by evaluating the patient's health situation from the patient's point of view.

- Value and appreciate the patient’s own knowledge and experiences regarding their health.
- Respect that the patient and their family may have different values regarding the patient’s health and preferences regarding their level of involvement in the patient’s care.

**Knowledge:** The nurse will:

- Include multiple dimensions of patient-centered care.
- Respect how different cultures, economic backgrounds, and ethnicities serve as foundations for personal values.

**Attitude:** The nurse will:

- Seek to enhance personal knowledge in all aspects of human diversity.
- Try to see healthcare needs through the patient’s eyes.
- Respect the patient’s expertise with their own healthcare needs and symptoms.

### Characteristics of Effective Interdisciplinary Teams

An effective interdisciplinary team (IDT) in health care is much like any effective team in any profession. They should be cooperative, professional, respectful, thorough, and thoughtful. The team comes together with the same priorities for the patient, and the value comes from their different specialties, which lend different perspectives on the patient’s needs. The most necessary element of an interdisciplinary team is strong, competent leadership ([Table 8.3](#)). This can come from the doctors and surgeons or can be a collaboration with nursing and social work.

Characteristic	Example of Behavior
Positive communication strategies	Communicate clearly and professionally. Show mutual respect for all members of the team. Respond in a timely manner to queries.
Appropriate skill combination	Ensure all necessary members of the team are informed.
Supportive team climate	Inform fellow team members when changes to the patient’s plan of care are made (do not assume they will see it in the chart). Be proactive and considerate.
Appropriate resources	Ensure necessary supplies are available, and/or specialists are available to provide their input.

**TABLE 8.3** Characteristics of Effective Interdisciplinary Teams

## REAL RN STORIES

### Being an Effective Team Member

**Nurse:** Lia, RN

**Clinical setting:** Surgical intensive care unit

**Years in practice:** 11

**Facility location:** A large metropolitan area near Skokie, Illinois

I think the best interdisciplinary team I have ever been a part of was on the surgical intensive care unit. The hospital was the biggest hub for organ transplants in the tristate area. We did kidney, kidney-pancreas, and liver transplants on my unit; on the cardiothoracic intensive care unit (CTICU), they did heart and lung transplants. It was such fun and inspiring work, I just loved it.

The kidney and liver surgeons did their rounds together and were all seated around the table. Sitting on the

periphery were the residents, the transplant social worker, the case coordinator, and the transplant pharmacist. Nursing had a designated space by the door because we only stepped in to discuss our patients before returning to the floor. On the morning I'm thinking of, I had just gotten report on a patient we were very familiar with. She was a female in her mid-40s who had nonalcoholic steatohepatitis, also known as NASH; basically, this was liver disease not caused by alcohol. She was very sick and had been in and out of our unit for years. It was a great day because she had been admitted two nights prior, and the day before she had finally gotten a healthy liver! She had gotten to our unit late in the night and had stayed on the ventilator all night. In the morning on rounds, we were going to discuss her case.

The transplant residents gave the surgeons a brief but detailed report on how the patient had done overnight, including her vitals, her labs, urine output, and so forth. She had been a bit unstable on arrival, but as the night went on, her vitals improved and nursing had been able to wean off much of the IV drip support and sedation. Nursing reported that with the sedation weaned, she had passed her breathing test, indicating she could be extubated (taken off the ventilator) to breathe on her own. The surgeon agreed, and one of the residents quietly picked up their hospital phone to alert respiratory therapy to prepare the patient for extubation. The residents and surgeon discussed the plan for the next few days, and articulated benchmarks with labs and vitals to look for to indicate positive progress. Pharmacy then said that the patient's levels of antirejection meds were good per the morning labs. Social work gave an update on the family, and case management provided the rehabilitation facility the family had chosen for the patient after discharge. The surgeons turned to me at that point and asked for nursing's update. I said that the patient was calm and oriented now that sedation was weaned and agreed that she was ready for extubation. Vitals were good, and her surgical incisions and drains were all in good condition. I answered a couple more questions about her vitals and input/output, and then I was dismissed. One of the transplant residents left with me to supervise the extubation; by the time I got back to my patient's room, respiratory therapy was there preparing to extubate.

I loved being a part of the transplant IDT rounds. It was such a positive team atmosphere. Everyone pitched in and knew their part, and when something needed to happen, such as an extubation, it felt like an organized, well-oiled machine. Even though the patient was still at least a week or more away from discharge, we were actively planning for it. It felt so hopeful. When we had great success stories like this one, it just felt like we were truly making a difference.

---

### Leadership and Structure

Generally, the **primary team** is the one that leads the discharge discussion. This is the team that admitted the patient; perhaps it is the internal medicine team and they coordinate with specialty teams, such as cardiology, endocrine, or renal. Sometimes the patient is admitted under a specialty team such as cardiology. The patient may have an extensive cardiac history and requires cardiology's management, or maybe they were admitted from their cardiologist's office.

Once the primary team approves the patient for discharge, other members of the IDT begin their tasks to prepare the patient. Pharmacy looks at the patient's medication list and ensures there are no duplicates; they may have questions or discuss issues regarding the patient's medications with the doctor. A large burden of planning patient discharge often comes down to nursing and social work. Once the necessary elements the patient needs are confirmed, nursing implements the discharge plan, conducts the required education, and finds resources/staff/specialists to educate and inform the patient and their family. Nursing and social work may work together to ensure the patient gets their necessary supplies and medications.

### Identifying Patient Needs

The type of needs a patient had when admitted to the hospital more often than not have changed, sometimes drastically, by the time they are to be discharged home. Needs such as pain management may have been addressed by the inpatient stay, but now a patient may require teaching and resources to manage a new health problem. Does the patient need to go to an LTAC facility, but there isn't one close to where they live, or that takes their insurance? Is the patient newly diagnosed with diabetes and now needs to know how to test their blood sugar? Was a PEG tube placed, and now the patient's family member requires teaching on how to set up the feeding pump? Does the patient need further education on diabetes management? Does the patient understand why they need to take their medications as prescribed?

These are just a few examples of the patient issues, needs, and planning/logistics problems that may arise upon discharge. Many of these issues are related to the patient's health literacy, or their ability to learn how to understand and manage information and teaching about their medical condition (Centers for Disease Control and Prevention [CDC], 2023). Understanding what patients need upon discharge and their level of health literacy helps the IDT know how best to address those needs. PT teaches patients how to use canes or walkers to get around. OT teaches patients how to get in and out of cars, or how to shop at the grocery store without straining a surgical incision. Nursing (sometimes with help from pharmacy) teaches patients about new medications and potential side effects. Nursing may also teach about how to set up a feeding pump and proper care of a PEG tube site. Specialty educators such as a diabetes nurse educator may spend multiple sessions while the patient is in the hospital, teaching them how to manage their diabetes, how to take their blood sugar, how to dose their insulin, or how to follow a specialized diet.

### **Risk of Caregiver Role Strain**

Caring for a chronically and/or critically ill family member can take an emotional and physical toll on a person. Anyone can become a caregiver to a loved one. A caregiver could be the teenaged children of a seriously ill adult or the ill adult's older parents with health issues of their own. A caregiver could be someone caring for their spouse while simultaneously holding down one or more jobs and caring for children. Sometimes the caregiver does not have a network of family or friends to help with caregiving, which means the person is doing everything with no interruption or relief.

It is difficult to see someone ill, and the demands of caring for a sick individual can be overwhelming, especially if the caregiver is unprepared. Family should be assessed as caregivers well before discharge, and the resources of the family should be seriously considered when creating a discharge plan for a patient. Could the family need respite care, a temporary caregiver (sometimes a nurse or a patient care aide) who can step in and take over the patient's care while the primary caregiver takes a break? Respite care can be for a few hours; sometimes it can be for a whole day or more.

Sometimes the lack of social support and community for a patient can make it difficult to ensure they have a successful discharge. What kind of care does the patient need? Do they need in-home care, a nurse to stop by, or a day-care facility for the patient to go to during working hours? In extreme cases, a patient may need to go to an LTC or LTAC facility because they need medical devices or care that no one around the patient is able to provide. The more nurses can address myriad aspects of a patient's care, the better the patient will do after discharge.

## **LIFE-STAGE CONTEXT**

---

### **Caregiver Role Strain**

Caregivers who are young, such as teenagers or adults in their 20s, or those with young children and families of their own can have a very difficult time coping with a new caregiver role. It can be difficult or frustrating to put personal needs aside and put someone else's needs ahead of your own. Resources such as support networks, respite care, and psychological counseling are available to help ease potential caregiver role strain.

As healthcare providers, it can be hard to see patients and their loved ones go through such pressure. It is important to be respectful as well as thoughtful and imaginative in ways that nurses can help ease the strain of young caregivers. Thinking ahead to what a family with considerable caregiver responsibilities may need helps a lot.

### **Development of Patient Goals**

Part of a patient's recovery involves establishing goals for the patient to work toward, and how the healthcare team can help the patient achieve those goals. Sometimes goals can come spontaneously from the patient themselves: they want to attend a grandchild's graduation, or they want to stop being on so much insulin. Nurses work with patients to translate goals into achievable statements. One way to help a patient articulate their goals is by using the SMART goal mnemonic (Table 8.4). When executed properly, SMART goals help patients articulate what they want to achieve and give them a plan to reach this goal in an effective manner.

	<b>S</b> Specific	<b>M</b> Measurable	<b>A</b> Attainable	<b>R</b> Relevant	<b>T</b> Timely
Definition	Add in as many details as possible.	Create a goal that is trackable.	Reflect on whether the goal is reachable.	Think about why this goal is important to you.	Keep yourself accountable.
Ask yourself ...	What will I do? Why and by when?	How will I measure my goal?	Can I accomplish this goal within a certain timeline?	Does this goal align with my values and other goals?	By when do I want to accomplish this goal? How long will it take?
Example	I want to stop having to inject insulin every day. To do that, I have to get my blood sugar consistently under control, which my doctor says is less than 180 two hours after eating. To get my sugar under control, I have to improve my diet, which means I need to eat more vegetables and fruits, and cut back on processed foods.	My blood sugar after meals must be checked with my glucometer and should be less than 180 two hours after eating. I will check my sugar as directed by my doctor and keep a record of my results.	The changes I need to make to achieve this goal are also changes that will make me healthier in the long run, so outside of this goal it is a good choice for my overall health.	Being a healthier person will help me live a longer and better life.	Change doesn't happen overnight, but in six months I would like to see my blood sugar consistently at 180 or less when checked two hours after eating.

**TABLE 8.4 SMART Goals**

Putting goals together often becomes an interdisciplinary and collaborative process because the patient's baseline level of function, their support system, and their financial and community resources all need to be taken into consideration.

### LINK TO LEARNING

The National Lipid Association's resource sheet for clinicians on helping patients make SMART goals (<https://openstax.org/r/77SmartGoalsNLA>) is helpful because lifestyle modifications are some of the hardest modifications to make. This resource is very clear and offers tips on how nurses can help patients to name and reach realistic goals.

### Patient Education

Making SMART goals goes hand in hand with patient education about their health and their health literacy, which is a

person's ability to learn and utilize information and resources regarding their health in order to make educated decisions (CDC, 2023). Nurses help patients increase their health literacy.

Determining how best to provide the patient with the necessary educational resources is part of the nurse's job. Ask the patient how they like to learn. Some patients are visual learners, so diagrams and handheld/tactile teaching materials are the best. Others prefer to read their information but perhaps do not have an appropriate literacy level for the materials available. Collaborate with the patient to figure out the best way they understand their health. One technique, often used in nursing and medical schools, is called "See one, do one, teach one." For example, to prepare for discharge, the patient or family member may watch the nurse make a dressing change, then do one themselves with supervision, and then do one on their own. This teaches the patient how to care for their own medical needs after they leave the healthcare facility.

## LINK TO LEARNING

---

This video provides details about [the teach-back method \(https://openstax.org/r/77TeachBackVid\)](https://openstax.org/r/77TeachBackVid) for teaching others.

---

Established rapport with patients and their family members aids in educating patients and improving their health literacy. Communication should be easier because patients will feel comfortable asking questions. The key to patient education is teaching them to take ownership of their health.

### Teaching and Evaluation of Discharge Plan

Nurses review discharge orders with the patient and their family member or designated learner. The **designated learner** is the person, either the patient, someone chosen by the patient, or a family member, who receives the education necessary for the patient's discharge plan. All the discharge plans are summarized in the discharge summary, which is usually a formatted printout from the patient's chart that reviews the patient's reason for admission, the medications they were on before admission and the ones they are on currently, and scheduled appointments for follow-up ([Figure 8.9](#)). Pharmacy or the doctor often reconciles the medications beforehand to ensure all medications and dosages are correct and there are no duplications. Nurses may also check in with case management to ensure that all the medications on the discharge plan are going to be obtainable by the patient or covered by their insurance. The discharge plan also discusses any specific instructions the patient may need, such as how to make dressing changes, directions on wound care, caring for lines and drains, and instructions for follow-up as an outpatient. All members of the IDT collaborate to create the discharge plan, and because nursing is most often the last to be face-to-face with the patient, nurses must ensure the plan is clear, and if not, find ways to help clarify the discharge instructions. Nurses can remind patients that most discharge instructions will also be included in the online patient portal for easy access at a later time.

<b>Discharge Summary Format</b>	
<b>Patient name:</b>	
<b>Admission date:</b>	
<b>Discharge date:</b>	
<b>Attending physician:</b>	<i>(the physician in charge of the patient's care)</i>
<b>Admitting diagnosis:</b>	<i>(the primary reason for admission to the hospital)</i>
<b>Discharge diagnosis:</b>	<i>(complete list of active problems, including the admitting diagnosis, that were addressed during the patient's hospital stay)</i>
<b>History of present illness:</b>	<i>(short summary of the events that brought the patient to the hospital for this particular stay)</i>
<b>Procedures:</b>	<i>(names and concise descriptions of any procedures the patient underwent)</i>
<b>History and hospital course:</b>	<i>(a summary of clinical course beginning from the time of admission and covering the major events throughout their stay)</i>

**FIGURE 8.9** Discharge summary paperwork is a vital part of summarizing a patient's hospital stay and instructing them on how to care for themselves going forward; it can also be overwhelming. Thus, the ability of the IDT to meet the patient at their level of health literacy and teach them about their condition is essential to a safe and proper discharge. Remember that this summary will be used by fellow healthcare providers; use a problem-oriented approach and write a separate paragraph for each problem included. Be sure to provide what the problem was attributed to, interventions performed, events that occurred, and outcome(s). Do not simply list lab values. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

After the nurse reviews the discharge plan with the patient or designated learner, any necessary teaching must take place. Teaching can cover a wide array of topics, from explaining how to perform tasks such as wound dressing changes, monitoring vital signs at home, or explaining new medication regimens or diets. Discharge teaching must be documented in the patient's chart and include what and how something was taught, as well as how evaluation of the learning took place. Most facilities conduct follow-up surveys via phone call or questionnaire to evaluate how effective the transition from discharge is. Follow-up surveys usually discuss the patient's hospital stay, the discharge process, and any recommendations for improvement. Getting feedback from the patient's perspective is always encouraged when making process improvements.

### Leaving Against Medical Advice (AMA)

Sometimes, the plan of care created with the medical team during an inpatient or hospital stay does not coincide with patient expectations. If this is the case and the patient no longer wishes to receive care from the healthcare facility or provider, the patient may decide to leave without the doctor's approval and a formal discharge, known as leaving **against medical advice (AMA)**. If a patient insists on leaving AMA, it is the duty of the nurse and staff on duty to ensure the patient is fully informed regarding the risks of leaving AMA, and if they insist on leaving, that they leave as safely as possible.

#### Patient's Right to Leave AMA

Treatment is always with patient consent, so if a patient has problems with the planned course of treatment, they are under no obligation to continue with it. The medical team can work with the patient to educate and reassure, or

to reevaluate the plan depending on the patient's needs and preference while keeping the patient's best interests at the center of the discussion. However, if the medical team and the patient cannot come to an agreement, the patient may leave the hospital or healthcare facility AMA. Legally, in most cases, the patient cannot be compelled to stay for treatment they do not want, and they always have the right to leave AMA. If a patient insists on leaving AMA, there is a form to sign for hospital records. This form acknowledges that the patient was told they are not ready to leave the hospital, and that they have been advised that leaving can be detrimental to their health (Figure 8.10). It is preferred that patients sign the AMA form but not required.

### Refusal of Care Against Medical Advice

To refuse care, patient must meet all the following:

- Over the age of 18
- Exhibits no evidence of:
  - Altered level of consciousness
  - Alcohol or drug ingestion that would impair judgment
- Understands the nature of the medical condition, and the risks and consequences of refusing care

**Acknowledgment of Information** (initial on line) \_\_\_\_\_

I have been advised that medical care on my behalf is necessary, and that refusal of care and assistance could be hazardous to my health, and under certain circumstances, including disability or death.

**Release of Liability** (initial on line) \_\_\_\_\_

By signing this form, I am releasing [name of hospital] of any liability or medical claims resulting from my decision to refuse care against medical advice.

I have read and understand that Acknowledgement of Information and Release of Liability.

Signature \_\_\_\_\_ Date \_\_\_\_\_

**Witness Information**

Signature \_\_\_\_\_

Name Printed \_\_\_\_\_

Date \_\_\_\_\_

**FIGURE 8.10** This example of an AMA form documents that the patient understands that their healthcare team does not recommend they leave the hospital at this time. Forms like this are then placed in the patient's medical record. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## PATIENT CONVERSATIONS

### Turning a Difficult Conversation into an Opportunity

**Scenario:** Joseph is a 65-year-old male who is housing insecure. Joseph also has diabetes and has a very hard time controlling his blood sugar and diet largely because of his housing insecurity and learned behaviors from that insecurity that he has gained over the years. Joseph was picked up by the police two nights ago for sleeping on the

street and brought to the hospital after he showed signs of severe hyperglycemia. Joseph also has long-term damage from his diabetes, including impaired vision and peripheral neuropathy (nerve damage). Today, he is very angry with his nurse, Jason, because he does not want to adhere to the diet he has been prescribed.

**Patient:** This is ridiculous! I want what I ordered for lunch! What is this garbage?

**Nurse:** Unfortunately, Joseph, you cannot have what you ordered for lunch because it will make your blood sugar skyrocket. You ordered a hamburger, a grilled cheese sandwich, potato chips, and extra ice cream. This is not part of your diet and will make you feel sick.

**Patient:** Yeah? So? It's what I want and I'm just going to eat it when I leave. Maybe I should just leave now so I don't have to listen to your stupid face tell me these stupid things about my blood sugar.

**Nurse:** We are only trying to help you feel better, Joseph. You were feeling pretty terrible when you were admitted two nights ago.

**Patient:** Yeah, that's true. But I didn't ask to come here. I didn't ask for any of this. You know what? Forget this. I'm out.

**Nurse:** What do you mean "I'm out?" Can you be more specific?

**Patient:** I mean I'm OUT. I'm LEAVING.

**Nurse:** Well, I can talk to the doctor, but I don't think you're ready to be discharged yet. Your blood sugar is still very high. At the last check it was over 300.

**Patient:** Didn't you hear me? I don't CARE. I want to leave because I hate this place.

**Nurse:** It is your right to leave whenever you want, Joseph. But if you leave, you know you aren't going to feel better. You may get to eat the food you want, but after that you are just going to feel worse. I'm trying to help prevent you from feeling that way.

**Patient:** ...

**Nurse:** Staying with us can only help you feel better. And if you feel better and learn the ways that you can *stay* feeling better, maybe you won't have to be here as often. Will you consider it?

**Patient:** [grudgingly] Maybe. If I do want to leave, can I just leave?

**Nurse:** I hope you don't, but if you insist, yes, of course, you can leave. I would appreciate it if you'd let me know if you are going to leave, though. I'll bring you a paper to sign that says that you are leaving against medical advice (AMA). Once you sign it, you are free to leave if you wish.

**Patient:** Really? I just have to sign a stupid paper. That's it? Why do I have to sign anything then? You aren't going to arrest me?

**Nurse:** No, of course not! As a patient you have every right to refuse care. The paper is just for our records to show that you made your own decision to leave. I'm just trying to explain to you the reasons for your care decisions, and why it is better for you if you stay. Maybe if you understand why you'll be more willing to try our ideas?

**Patient:** Maybe. Can I have a snack and some soda pop while I think about it?

**Nurse:** Sure, no problem. Thank you for considering, Joseph.

[The nurse leaves the room and goes to the kitchen to get Joseph a package of saltines and some sugar-free ginger ale. He pours the ginger ale into a pitcher with some ice and brings it back to Joseph with a cup and the crackers.]

**Scenario follow-up:** Jason explains what AMA means to Joseph calmly and professionally. He knows that he may not change Joseph's mind, but he is giving him the tools he needs to make the decision for himself.

---

### Mental Capacity to Leave AMA

There are, of course, exceptions to leaving AMA. These exceptions can include the patient not having the ability to make that choice for themselves. Perhaps they are not fully oriented—they don't know their name, where they are,

or the date—or their departure is impossible or incredibly unsafe (such as the patient is in critical condition and connected to lifesaving medications or machines). Sometimes, a patient may be a direct threat to themselves or someone or something else. In those instances, documentation by the nurse and treatment staff is important. On occasion, security services may be warranted to ensure the safety of the patient and staff. In extreme cases, a patient may be detained under a mental health hold to ensure their safety and the safety of the people that will be around them outside the healthcare facility. In general, however, most patients are legally decisional and can decide to cease treatment and leave at any time. Nurses must document the patient’s mental status and any interaction with the patient regarding the patient’s desire to leave AMA.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Analyze Cues: What Are Some of the Advance Warning Signs of an Impending AMA Departure?

Observant staff can usually pinpoint warning signs and behaviors that indicate the potential for a patient to leave AMA. This can include anger, agitation, combative behavior, and outright threats to leave the hospital. Constant arguing with nurses, doctors, and staff can also be a sign. Overt signs can include the patient physically dressing to leave or packing their belongings. Reasons for leaving AMA can include frustration with the plan of care often because the patient feels their needs are not being met and requests are not being heard. Other examples include family or work obligations. Sometimes this may also come in the form of requests for second opinions or referrals to alternate healthcare facilities. Remember, in these situations, safety is paramount—safety of the patient, safety of other patients, and safety of the staff and healthcare personnel around the patient.

#### Interventions to Avoid Leaving AMA

Empathetic, therapeutic communication is a key part to preventing an AMA discharge. Therapeutic communication is the use of both verbal and nonverbal clues to communicate with another person. It is the nurse’s job to try to find from where the patient’s dissatisfaction stems. Is the patient confused about what the medical team is saying? Is fear or anxiety a root cause of their dissatisfaction? Sometimes a patient threatening to leave AMA is just frustrated because they are in pain, or they felt their questions were not answered adequately. Leaving against medical advice (AMA) puts the patient at risk for adverse outcomes. Healthcare providers and nurses mitigate these risks as much as possible before a patient leaves the hospital by being thorough and detail oriented and using therapeutic communication skills. Many nurses are now trained in forms of conflict resolution and nonconfrontational methods of defusing potentially volatile situations.

Health care is a dynamic profession that changes with every patient encounter, and as frontline healthcare providers, nurses are the first to identify a patient situation as well as potential ways to address the issue. Does the patient understand the treatment plan? Does the patient understand what may happen if they leave before the doctor says they are ready and safe to leave? Sometimes, a patient’s dissatisfaction can be resolved by getting a different healthcare provider (another doctor, nurse, or social worker) to speak with the patient to try to encourage them to stay.

#### Nursing Documentation for AMA Discharge

Documentation of an AMA discharge is very important because of the risks of leaving AMA. Thus, it is incredibly important for nursing to properly document the AMA departure. While it isn’t an absolute necessity, it is helpful if the patient signs the AMA form. Otherwise, the nurse should enter a progress note into the patient’s chart documenting the issues and conversations leading up to the AMA discharge. These documented notes can ultimately be subpoenaed and used in court, so it is important to be factual, professional, and clear.

Leaving AMA means the patient’s medical condition continues to be untreated or inappropriately addressed. This can lead to a worsening of the problems that got the patient admitted in the first place and can ultimately lead to increased mortality. If at all possible, attempt to give the patient at least some of their discharge instructions. Leaving AMA with unresolved medical issues also affects the hospital/healthcare facility. Depending on the severity of the issues, the patient may be readmitted soon after the discharge, and it is possible the facility will not be fully reimbursed for the costs of the patient’s care. Ensure that all documentation of the patient’s care and the situation surrounding the AMA discharge is complete and professionally written.

## Discharge from Home Health Agencies

A **home health agency (HHA)**, or a service that provides medical care in a patient's place of residence, has strict rules regarding the discharge process. Often, patients need additional medical care but not enough to stay admitted to an acute care facility. Instead, HHAs are utilized. HHAs provide a full range of services, such as food preparation, assistance with hygiene, wound care, and medication setup. Nurses also complete weekly or biweekly assessments to monitor for decline or improvement in health status. Nurses working for HHAs develop individualized schedules for each patient based on the discharge orders and services needed, but can also serve as an on-call healthcare professional to provide an assessment to determine if a trip to the hospital is warranted. The HHA nurses have instant communication with the provider caring for the patient, which allows for needs to be met in the comfort of the patient's residence. Most patients are approved for a sixty-day or thirty-day period of care.

Discharge from an HHA takes place when all treatment goals of the plan of care have been met. For discharge from an HHA to occur, an admissions RN must reevaluate the patient. In this meeting, all discharge teaching and an evaluation of the patient's response to learning must be documented in a timely manner. If determined goals have been met, the patient may be discharged from the HHA's services, but just as in an acute care facility, if the patient's condition changes, they can be readmitted or have the current plan extended if needs are identified.

### LIFE-STAGE CONTEXT

---

#### The Importance of Being Clear: Home Health Agency Discharge

When discharging an older adult from an HHA, it is imperative that discharge teaching be done just as if the patient were leaving an acute care or extended care facility. Learning needs must be assessed. Does the patient tend to get confused or forgetful? Does the patient fully understand the medications they are taking and when they should take them? Is the patient's living space safe for them without home health monitoring? Sometimes it is appropriate for a secondary learner to be present when doing discharge teaching to ensure a caregiver also understands what needs to be done and how to do it.

---

## Summary

### 8.1 Patient Admission

There are many different types of patient admissions to healthcare facilities. It is important to ensure the patient is admitted to the correct level of care. Acute care admissions are for patients who require inpatient monitoring and/or a professional level of care. Observational admissions are typically for one or two nights. Admissions to the hospital can be planned or unplanned. Some come from an ambulatory care setting, while others arrive from home or via EMS.

The admitting nurse must be organized and structured in their approach to admitting a patient. The admitting nurse must receive a complete and accurate report, ensure that their other patients are safe and their needs are met, and make their coworkers aware of an impending admission and their role, if necessary, to help with the admission. Maintaining patient safety in the hospital is very important. The nurse must be observant and thoughtful in preparing the room, tailoring it to their patient's specific needs.

Developing a rapport with the patient is key to ensuring the patient makes the most informed decisions possible regarding their care. Orienting the patient to the hospital and the routines of care is also important in ensuring patient safety and comfort. Encourage patient participation in their care while in the hospital.

### 8.2 Patient Transfer

Patient transfers are an important transition point in care. They can be from one facility to another or within the same healthcare facility. There are many steps to a safe patient transfer that must be considered, and all members of the healthcare team should participate. Transfer to a higher level of care or within an acute care facility is very different from transfer to an extended care facility. All information is part of the patient's history, but the nurse ensures that report is focused on the level of care the patient needs at the facility to which they are transferring. Emphasize the information the receiving unit requires and ensure the rest of the information is available in the chart. Transfer is one more step in the healthcare journey from entrance to exit, so it is important that all details are conveyed and accurately communicated.

### 8.3 Patient Discharge

Discharge planning begins the moment a patient is admitted to a facility. Ensuring goals are being developed in the beginning allows all team members to be involved in the patient's care early on. Discharging patients from a healthcare facility is an important step in the healthcare process and requires education and collaboration to create a successful discharge plan that is tailored to the patient's specific physical, medical, psychosocial, and educational needs. Care coordination among all interdisciplinary team members from start to finish ensures that quality, effective patient-centered care has been provided. Sometimes a patient may discharge themselves, leaving the hospital AMA; in cases like this, it is important to educate the patient about the ramifications of their actions, and if the patient still decides to leave, the nurse must document the discharge professionally and thoroughly. There are numerous reasons for a patient to choose to leave against medical advice (AMA), and many times it is not because they do not want to receive care. Sometimes, it is because they have no other choice; for example, a single parent needs to take care of their children, or the financial provider of the family cannot miss work. The process for discharge from a home health agency is similar to that from any other healthcare facility. The patients' needs must have been met, goals have either been achieved or there has been major progression toward being achieved, and services have been deemed no longer necessary. Regardless of where discharge is occurring, the nurse needs to remember the importance of well-performed and documented patient education.

## Key Terms

**active listening** a communication technique in which the listener intentionally places all their attention on the person speaking; this can include multiple forms of verbal (not interrupting, asking pertinent questions) and nonverbal communication (facing the person, eye contact)

**acuity** the severity and complexity of patient illness

**acute care** a type of inpatient medical care for patients who require monitoring and medical assistance from professionally trained healthcare providers

**against medical advice (AMA)** when a patient under inpatient medical care voluntarily leaves the hospital even

though the medical team does not recommend it; also the name of the documentation form that is placed in the patient chart if the patient insists on leaving the facility

**ambulatory care** patient care given in outpatient settings, which includes doctor’s offices, clinics, and outpatient surgery centers

**designated learner** the patient or family member who accepts the discharge teaching and instructions given to the patient upon discharge

**home health agency (HHA)** a service that provides medical care in a patient’s place of residence

**intensive care unit (ICU)** an inpatient hospital unit for patients who are critically ill and require very close monitoring

**interfacility transfer** the transfer of patient care between medical facilities; this can include from one acute care hospital to another, or from an LTAC or LTC facility to an acute care inpatient unit

**long-term acute care (LTAC) facility** a type of care for patients with long-term acute care needs

**long-term care (LTC) facility (also, nursing home)** a type of permanent medical facility that provides subacute care

**medical-surgical unit** an inpatient hospital unit for patients with medical needs that cannot be addressed in an ambulatory setting but are not severe enough to warrant critical care admission

**nonverbal communication** the use of gestures and facial expressions to convey meaning

**nursing home** a long-term care facility that provides permanent residence and medical assistance to its residents

**percutaneous endoscopic gastrostomy (PEG) tube** a tube that is inserted into a patient’s abdomen to enable them to receive tube feedings; typically needed when a patient is unable to swallow food safely

**power of attorney (POA)** a legally binding agreement that documents that an individual gives authority to manage personal matters (such as medical care, financial business, or property) to a chosen representative, often a significant other or close family member

**primary team** the team that admits the patient and leads the discharge discussion

**rounds** a daily routine in the inpatient setting that involves a recap of the patient’s hospital course from admission to the most recent update on their condition

**SBAR** the Joint Commission’s best practice standard, an evidence-based communication tool that stands for Situation, Background, Assessment, Recommendation

**step-down unit** a transitional inpatient unit, usually when the patient is well enough to leave the intensive care unit but still requires more monitoring than a patient on the medical-surgical unit

**sundowning** a phenomenon where adults (often older) become confused when the sun sets

**triage** a method of evaluating patients according to the severity of their complaints and ensuring that patients with the most serious and potentially life-threatening symptoms that can be helped are seen first

**verbal communication** the use of words and language to convey meaning

**voluntary consent** documented consent from a patient that they agree to treatment

## Assessments

### Review Questions

1. A 45-year-old male complaining of “heaviness” in his chest and feeling “really tired” would likely need what kind of admission?
  - a. ambulatory care
  - b. observational
  - c. acute care
  - d. long-term care facility
2. A nurse in the emergency department is having a busy night and has to triage four patients. Which patient should be prioritized to be seen first?
  - a. 89-year-old female with a hip fracture
  - b. 55-year-old male who fell and hit his head, briefly losing consciousness
  - c. 37-year-old male with a history of diabetes with blurred vision
  - d. 18-year-old female who twisted her ankle during track practice and is crying in pain
3. A patient needs to go to the operating room for a procedure. Who on the healthcare team is required to obtain

- informed consent from the patient for this procedure?
- the nurse
  - the power of attorney
  - the chaplain
  - the provider
4. What is the term for the phenomenon of older adults becoming confused in the evening?
- sundowning
  - dementia
  - Alzheimer disease
  - sunsetting
5. When does discharge planning begin?
- two days before discharge
  - after the patient's procedure
  - when the patient is admitted
  - one day before discharge
6. A nurse works in an intensive care unit in a large metropolitan hospital. What patient information should be first considered when receiving report on a ventilated, unconscious patient transferring from an external acute care facility?
- mobility status
  - continence
  - latest vital signs and labs
  - discharge plan
7. A patient has improved greatly and is transferring from the intensive care unit to the step-down unit. What is the least important patient detail to convey in report to the step-down unit nurse taking the patient?
- mobility status
  - continence
  - latest vital signs and labs
  - list of the patient's belongings they brought with them to the hospital
8. What does SBAR stand for?
- Situation, Background, Assessment, Recommendation
  - Status, Background, Action, Review
  - Situation, Brief history, Action, Response
  - Status, Barriers, Assessment, Recommendation
9. It is 9 a.m. and a nurse receives a tentative plan that a patient might transfer from the step-down unit to the general medicine floor this evening at 5 p.m. The patient's family is very involved, but because of work is unable to visit until at least 6 or 7 p.m. What time would be a good time to notify the family of the patient's transfer?
- as soon as possible
  - 5 p.m.
  - when the definitive transfer order arrives
  - whenever they arrive
10. What is an example of a well-written SMART goal?
- In two weeks, my blood pressure will be in a healthy range.
  - In two months, my blood sugar will be in a healthy range between 120 and 180 before eating meals.
  - In six months, I want to eat a healthier diet with fewer processed foods to reduce my blood sugar before meals to consistently read below 180 in order to lead a longer and healthier life.

- d. In one year, I want to lose thirty pounds by running and exercising three times a week.
- 11.** What patient should the nurse recommend have a secondary learner on hand when discharging from home health teaching?
- 65-year-old native English speaker with a learning disability
  - 34-year-old student from China who is fluent in English and attends an American university
  - 45-year-old native English speaker from a rural area
  - 75-year-old immigrant from Mexico who cannot read English but speaks English fluently
- 12.** A patient is leaving AMA. What is the most important thing to do before they leave?
- obtain prescriptions
  - call security
  - tell them they are making a mistake
  - ensure they sign the AMA form and place it in the patient's chart

### Check Your Understanding Questions

- What is the difference between an acute care and ambulatory admission?
- Why are guidelines from organizations such as CMS and TJC necessary regarding the healthcare admission process?
- What is the benefit to preparing an SBAR report?
- What are the steps required in preparing a patient transfer to another unit? How does that differ from transferring to another healthcare facility?
- Describe the steps for discharge from a healthcare facility.
- Does a patient leaving AMA need to sign the form? Why or why not?
- Why are healthcare providers not allowed to prevent an alert, oriented, and decisional patient from leaving AMA?

### Reflection Questions

- What are three ways a nurse can develop a rapport with a patient?
- Why does discharge planning begin with admission?
- What are potential problems that can occur when patient transfers are not managed efficiently or well?
- What does it mean when a patient leaves AMA? What are the potential issues surrounding an AMA discharge, and what can the nurse do to try to mitigate the circumstances?

### Critical-Thinking Questions about Case Studies

- Refer to [Unfolding Case Study #2: Part 1](#). Do you think the patient should be admitted as observational or inpatient? Provide a rationale for your answer.
- Refer to [Unfolding Case Study #2: Part 2](#). Give an example of an SBAR handoff from the emergency room nurse to the cardiology unit nurse.

### What Should the Nurse Do?

- Mehul works on a medical-surgical unit and is informed by his charge nurse that he is receiving an admission. The patient has diabetes and is being admitted from their nursing home for severe hypertension and hyperglycemia. From report, Mehul also knows that the patient has class 3 obesity (as determined by the BMI index) and has difficulty with mobility and performing his activities of daily living (ADLs) such as showering and going to the bathroom without assistance. Given this information, what kind of specialty equipment

should he have available?

2. A nurse is admitting a patient who has a history of falls and is being admitted for yet another fall at home. The ambulance has picked up the patient from their home in the suburbs and will be at the hospital in an hour. The patient is a 95-year-old female who lives with her adult daughter. She is generally alert and oriented but gets “pleasantly confused” at night. The patient is usually able to get around with a walker without falling, but in the past few months she has been more unsteady on her feet and has fallen twice. This evening the daughter heard a “thump” and found the patient lying on the floor next to her favorite chair. EMS was called and brought the patient in for observation. The nurse must set up the patient’s room. What equipment and supplies should be available? What safety measures should be installed in the patient’s room?
3. A nurse has gotten report on a patient who is transferring to the acute care general medicine unit from a nursing home. The report seems complete, but when the patient arrives, the nurse finds several discrepancies. What should the nurse do?
4. A nurse is transferring an 85-year-old patient, Marcia Hartman, to an external nursing facility. She was admitted to the hospital after falling at home and hitting her head. She had extensive bruising on her skin, and lacerations on her arm and leg where she fell. She also fractured her hip and had to have minor orthopedic surgery to fix it. She is mildly confused, but pleasant. She knows her name and her birthday but can be forgetful about where she is and what time it is. She is ambulatory again after her surgery, though fairly deconditioned; Marcia is able to get up with a walker and with two people assisting her. She usually doesn’t try to get up without calling for help, but now and then the nurses have caught her trying to get out of bed or the chair. This most often happens when she needs to go to the bathroom, which after meals can be quite frequent. Her incision site from the surgery is mostly healed, she has a few surgical tape strips that hold her incision together, and she has no complaints of pain. What bothers her more are the lacerations and bruising; she gets very angry when nurses or doctors try to examine them. She denies that she is in pain when she gets angry, saying she’s not a wimp. She responds well to acetaminophen, though, especially before going to bed. Her family is very attentive; they were extremely concerned when she was admitted, and they call frequently for updates. How would a nurse structure an SBAR report for Marcia?
5. The nurse is discharging an older patient from an acute care facility home under the care of an HHA. The patient has diabetes and a history of not managing their blood sugar very well. What are some questions the nurse would want to ask in order to assess health literacy and learning needs of this patient?
6. A primarily Spanish-speaking patient is being discharged with home health care. The patient has a surgical dressing that needs changing twice a week, but the home health nurse can only come once a week. The patient does not have reliable transportation to get their medications from the pharmacy because they live in a rural area. What should the nurse do to help ensure the patient receives their medications and necessary wound care? Whom should the nurse talk to? What other considerations should be taken into account to ensure this patient’s safety?

### Competency-Based Assessments

1. A nurse works in a critical care unit that has two patients and is about to receive a third from the ED. Their current patients are stable and are almost ready for transfer out of the ICU. One patient needs blood sugar checked in an hour; the other patient needs their evening meds. Both tasks need to happen before dinner is brought to the patients. The admission is coming in thirty to forty-five minutes. The patient is being admitted for severe hyperglycemia and will likely need an insulin drip. Describe how the nurse would ensure their patients’ needs are met, and delegate specific tasks if necessary to colleagues in order to prepare for the admission.
2. Describe the differences in report between a nurse giving report to the ICU versus to a medical surgical floor.
3. Describe a complete discharge report.
4. Demonstrate how a nurse would conduct discharge teaching for a patient. How should a nurse educate a patient about their medications and ensure the patient understands instructions for following up with their healthcare provider?

## CHAPTER 9

# Safety and Security

**FIGURE 9.1** Nurses are often the first line of defense when it comes to identifying and preventing potential safety risks, such as falls or medication errors. (credit: "Holding Dad's Hand," by Deb/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

- 9.1 Safety: Individual and Environmental
- 9.2 Safety: Violence
- 9.3 Security: Privacy and Informatics

**INTRODUCTION** Nurses play a critical role in promoting safety for patients in various healthcare settings. From hospitals and clinics to long-term care facilities and homes, nurses are responsible for ensuring that their patients are receiving care in a safe and secure environment. Nurses also have a vital role in educating patients and their families on how to maintain safety both inside and outside the healthcare setting. Education can include providing information on how to prevent the spread of infections, how to properly use medical equipment, and how to manage chronic conditions to prevent complications. Nurses must also advocate for their patient's safety and privacy rights, ensuring patients are not subjected to any form of abuse or neglect and that personal information is kept confidential. By taking an active role in promoting safety and privacy, nurses can create an environment of trust and security that is essential for effective patient care.

Nursing students are preparing to enter a field that is dedicated to improving the health and well-being of others. However, it is important to remember that the nurse's safety and privacy are just as crucial as those of patients. In today's world, violence and threats to personal safety are unfortunately common occurrences which makes it essential for nurses to obtain the knowledge and tools to manage these situations effectively. This chapter explores the critical aspects of individual safety, privacy, and management of violence that every nursing student should be aware of to provide the best care possible while keeping themselves and their patients safe.

## 9.1 Safety: Individual and Environmental

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify safety concerns regarding the individual
- Identify safety concerns related to the environment
- Recognize how social determinants of health relate to one's safety

Nurses play a pivotal role in ensuring the safety and well-being of patients, as well as their own personal safety. In health care, there are many potential hazards and risks that can threaten patient safety, including medical errors, falls, infections, and medication errors. Similarly, these hazards may exist in the homes of patients and the environments in which we live and work. Nurses must be knowledgeable about these risks and take proactive measures to prevent them. Additionally, nurses are responsible for maintaining their own physical and emotional health, as they are often exposed to high levels of stress and emotional strain in their work. In this way, safety and health are intertwined, and nurses must prioritize both in their daily practice.

Choices and actions regarding safety can be influenced by many factors; this might include situations we are in, where we live, our income, and our education. These factors are known as the social determinants of health (SDOH). This section explores various aspects of individual safety and the tools nurses need to use to respond to safety concerns.

### Individual Safety

Safety is a basic human need and always receives priority in patient care. In prioritizing patient needs, nurses refer to Maslow's hierarchy of needs ([Figure 9.2](#)), often concentrating on the lower two tiers of the pyramid, as security is closely linked with basic physiological requirements.

**FIGURE 9.2** Maslow's hierarchy of needs suggests that security and safety are fundamental requirements for individuals to fulfill their basic physiological and psychological needs. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Consider the following scenario: You are driving back from a relaxing weekend at the lake and come upon a fiery car crash. You run over to the car to help anyone inside. When you get to the scene, you notice that the lone person in the car is not breathing. Your priority is not to initiate rescue breathing inside the burning car but to move the person to a safe place where you can safely provide CPR. This is an illustration of how safety is intertwined with nursing care.

The term **individual safety** can be defined as the state of being free from physical or psychological harm. Individual safety is a fundamental concern across the life span. Individual safety concerns are unique to each developmental stage and are influenced by many different factors, including individual differences, environmental factors, and cultural norms. To promote and maintain individual safety, consider the developmental stage of the individual and plan interventions that address safety concerns in a holistic manner. For example, Barbara is an 85-year-old female living alone. Having encountered several falls, her family expresses concern for Barbara's safety and urges her to consider relocating to an assisted living facility. Barbara wants to remain in her home where she feels safe; there are no concerns regarding her competency to make decisions regarding her care. This is an example of a situation where nurses must balance the developmental needs of the patient within a holistic framework. While Barbara might have experienced a few instances of falling, there are no other indications that she is not safe in her home, and she may only need minimal assistance to maintain her residence. The nurse works to balance the safety of a patient with the patient's need for independence.

Individual safety encompasses various aspects of safety, such as occupational safety, environmental safety, and personal safety, and all are crucial for maintaining good health:

- The goal of **occupational safety** is to protect workers from injury, particularly those who work in high-risk industries such as health care. Workplace injuries and illnesses cost U.S. businesses approximately \$170 billion per year (Occupational Safety and Health Administration [OSHA], n.d.).
- The practices and measures taken to promote **environmental safety** are geared to protecting and preserving the natural environment, ecosystems, and human health from potential hazards and harmful impacts to health. Exposure to environmental hazards such as air pollution, water pollution, and hazardous waste can have significant impacts on an individual's health. For example, one study found that exposure to air pollution is associated with an increased risk of heart disease, stroke, and respiratory illnesses (Landrigan et al., 2018).
  - Test one
  - Test two
- The goal of **personal safety** is to keep oneself free from injury. This includes taking measures to prevent accidents and injuries in everyday life, such as wearing seat belts while driving, using protective equipment during sports and recreation, and avoiding risky behaviors such as smoking and drug use.

Personal safety and individual safety, while not synonymous, share similarities. Individual safety pertains to safety measures designed to establish frameworks supporting individuals' safety, while personal safety is reflected in the choices individuals make to implement safeguards for themselves. For example, as the COVID-19 pandemic waned, masking requirements were loosened; however, there was still recognition of the need to provide guidelines for those who were more at-risk. The guidelines advocating for mask usage in certain situations demonstrate individual safety, whereas personal safety involves the individual's decision to wear a mask. In nursing, individual safety and occupational safety go hand in hand. The physically demanding nature of nursing work and the exposure to infectious diseases put nurses at a heightened risk of workplace injuries. Individual safety measures adopted by nurses play a crucial role in safeguarding them during the execution of their healthcare duties, ensuring their well-being to continue providing care for patients.

### Risk Factors Affecting Individual Safety

Individual risk factors are considered correctable or modifiable because they are often influenced by behaviors, choices, or lifestyle habits that individuals can consciously change or improve. For instance, nurses are advised to wear gloves during tasks involving potential blood exposure. If a nurse is observed not adhering to this practice, education and reinforcement of proper procedure can be implemented to modify their behavior. Individual risk factors frequently contribute to healthcare-related issues. Addressing these individual risk factors is crucial for maintaining an individual's safety.

Risk factors can fall into two categories: modifiable and nonmodifiable. A **modifiable risk factor** refers to a factor that can be altered or controlled by an individual or society. Modifiable risk factors include behaviors and lifestyle choices, such as diet, exercise, smoking, alcohol consumption, and exposure to environmental pollutants. They can be modified through education, lifestyle changes, and policy interventions, among other means. A **nonmodifiable risk factor**, on the other hand, cannot be controlled or altered by an individual or society. Nonmodifiable risk factors include genetic predispositions, age, gender, and certain geographical and climatic conditions. These factors are beyond an individual's control and may be inherent or innate, making them less responsive to intervention. In

general, modifiable risk factors tend to be more responsive to intervention and change, whereas nonmodifiable risk factors require a different approach to manage their impact on one's health.

### Age and Developmental Considerations

Age and developmental factors play a crucial role in individual safety, influencing an individual's ability to comprehend and respond to potential hazards. Nurses should be knowledgeable about safety risks associated with age and developmental stages, as the types and frequencies of accidents vary among different age groups (Centers for Disease Control and Prevention [CDC], 2020a).

Regardless of a person's age or developmental stage, nurses must be ready to discuss mental health, family, and social connections with every patient. Nurses can prepare for these conversations by having community resource information readily available to direct any patient in need to the right entity for help. Nurses do not have all the answers, but they should always be knowledgeable about where to refer patients for help.

### Children

Drowning is the leading cause of death in children ages 1 to 3 years. Motor vehicle accidents ([Figure 9.3](#)), falls, choking, and accidental poisoning are also safety concerns for this age group. Infants and toddlers are curious, but they lack the judgment to recognize the dangers of their actions, so childproofing the home and providing adult supervision are essential for this developmental age group (CDC, 2023c).

**FIGURE 9.3** An infant car seat is used to protect infants in the event of a motor vehicle accident. Nurses help educate parents about the proper use, positioning, and installation of car seats. (credit: "ARISE Newborn in Car Seat 144049.jpj," by Arise project, CC BY 4.0)

For children ages 4 to 11 years, motor vehicle injuries are a major cause of unintentional injury, along with drowning and poisoning. This age group is more aware of dangers and limitations, but adult supervision is still important. The nurse should educate parents of school-aged children about safety seats, booster seats, or shoulder seat belts while riding in the car (CDC, 2023c). Bicycle accidents are also a common concern in this age group. Many bicycle accidents involve the head or face because of the lack of helmet use. Nurses should provide education to school-aged children regarding bicycle safety and helmet use ([Figure 9.4](#)).

**FIGURE 9.4** Bicycle helmets are a key means of protecting oneself from injury, regardless of age. (credit: “Amelia and Reese Riding,” by Donnie Ray Jones/Flickr, CC BY 2.0)

## LINK TO LEARNING

The CDC provides educational materials and comprehensive [information about concussion and traumatic head injuries \(https://openstax.org/r/77headsupindx\)](https://openstax.org/r/77headsupindx) for parents, coaches, players, and healthcare providers as part of their “Heads Up” program.

Because this age group is beginning to enjoy more independence, education on how to recognize and respond to potentially dangerous situations with strangers should also be provided. Parents should also be educated about the AMBER Alert system that can be activated if a child is missing and believed to be kidnapped or in danger. The AMBER Alert system uses the resources of law enforcement and the media to notify the public about a possible abduction or a missing child in danger.

Nurses must also be aware of signs of maltreatment and child abuse because millions of children are affected each year. Child abuse includes physical, sexual, and emotional abuse and neglect. After abuse or violence, many children develop mental health problems, including depression and post-traumatic stress disorder (American Academy of Child and Adolescent Psychiatry [AACAP], 2021). These children may also have serious medical problems, learning problems, and problems getting along with friends and family members. Every state has laws that require healthcare professionals to report suspected child abuse no matter what form this abuse takes (AACAP, 2021).

## LINK TO LEARNING

Read more about trauma and child abuse within the [Trauma and Child Abuse Resource Center \(https://openstax.org/r/77traumaabuse\)](https://openstax.org/r/77traumaabuse) provided by AACAP.

Children between the ages of 6 to 11 years are often an at-risk group when it comes to safety, as they are not yet fully developed physically, mentally, or emotionally and have a greater risk of accidents such as drowning, burns, poisoning, or other injuries. These risks may occur in the form of accidents or sports injuries at home, at school, or in their communities. Children in this age group are more likely to experience social issues such as bullying, peer

pressure, and some forms of social exclusion. They are also at risk for physical and emotional abuse in the home, and this needs to be considered when performing assessments. These can be difficult safety concerns to manage as the child may be reluctant to discuss these issues, and early indicators for parents and caregivers may come in the form of behavior changes.

Nurses must take a role in educating parents and caregivers about safety protection for children. It is important for parents and caregivers to take appropriate precautions to protect children, such as supervising them, teaching them about safety, and providing a safe physical environment, along with addressing bullying and any suspicions of abuse.

### Adolescents

Motor vehicle accidents are a leading cause of death for adolescents. Teens ages 16 to 19 years are three times more likely to be in a fatal crash than drivers older than age 20 years. Adolescent males are twice as likely to die in a motor vehicle accident than females of the same age (CDC, 2023c). Texting while driving is a common cause of distracted driving and accidents in adolescents. Because much of an adolescent's time is spent away from home, it is difficult for parents to control many of the decisions that adolescents make. Nurses can assist in providing safety education to adolescents by teaching them how and why we use seat belts, why speed limits must be obeyed, and why they should never text while driving (CDC, 2023c). Substance use is another significant concern in the adolescent population and is discussed in [9.2 Safety: Violence](#).

## LIFE-STAGE CONTEXT

---

### Risk-Taking Behaviors of Young People

It is said that the young often feel they are invincible. As a result, they may make choices that are not in their best interests to “fit in” with their peers. Adolescents lack developed judgment skills at this age and tend to engage in risk-taking behaviors, for example, smoking and trying alcohol or drugs. Adolescents may take risks when performing activities such as skateboarding. Often, they fail to grasp the significance of potential negative outcomes from these activities. This is part of the expected developmental stages for adolescents where they are learning and discovering who they are. This can be difficult for parents and healthcare providers, and it is important to know that adolescents can be encouraged to foster this risk-taking in healthy ways, for example, via activism or athletic endeavors (UCLA Center for the Developing Adolescent, 2023).

---

### Adults

The leading cause of death for adults in the United States is heart disease, followed by cancer and COVID-19 (CDC, 2023b). Being an adult does not mean one is immune to the need to consider individual safety. Adults may still engage in risk-taking behaviors, including the use of substances, that can put them at risk. Adults are also at risk of experiencing workplace injuries, particularly young adults who may just be entering the workforce. Some adults may be at increased risk of hazards related to financial instability and personal safety in relationships and their communities. Adulthood may also be a time when individuals begin to experience life with chronic disease, which can impact safety from a physical, cognitive, or emotional perspective (CDC, 2019a). It is important for adults to consider their individual safety risks and take precautions to maintain good health and be aware of potential risks around them.

### Older Adults

Falls and motor vehicle accidents are the leading causes of injury in older adults. However, several other issues pose significant hazards for this population, such as fires, accidental overdosing on medications (due to poor eyesight and confusion), abuse, and being taken advantage of financially (CDC, 2021). Older adults are also at risk for age-related changes, such as mobility changes, that can create a safety risk. Older adults are more likely to live on their own, increasing their vulnerability, whether that be from injury or events such as elder fraud (financial exploitation or deceptive practices specifically targeting older individuals). Older adults living alone are at greater risk of experiencing depression linked to social isolation. Those living alone, especially older adults with dementia, may encounter challenges in maintaining hygiene, nutrition, and household tasks. For instance, a person living with dementia who is not eating may experience the effects of malnutrition (Alzheimer's Association, n.d.). When assessing an older adult who is living alone, the nurse should ask questions regarding their ability to complete activities of daily living.

### Lifestyle and Behavior Considerations

Protecting the body from harm, injury, or death is key to maintaining physical safety. Personal actions taken toward one's health influences individual safety. Adopting healthy lifestyle practices, such as eating a healthy diet, exercising regularly, getting adequate sleep and rest, and limiting or avoiding the use of drugs and alcohol, has a positive impact on individual safety. Engaging in high-risk activities, such as bicycling without a helmet or driving without wearing a seat belt, can negatively impact safety. Individual safety must also be considered when engaging in local and global community activities. Maintaining infection prevention, following travel precautions, and proactive planning safeguards individual health and contributes to the overall well-being of communities, thereby minimizing the risk of transmitting illnesses.

### LINK TO LEARNING

---

The World Health Organization provides information concerning [risks when traveling \(https://openstax.org/r/77travelrisk\)](https://openstax.org/r/77travelrisk) in a question-and-answer format. This website provides travelers with helpful information regarding health and other risks, such as political unrest. Travelers can then take precautions or make decisions regarding planned travel to ensure they remain safe.

---

### Health Knowledge Deficits

A **health knowledge deficit** is a lack of information or understanding regarding health-related topics that can impact an individual's ability to make informed decisions about their health and well-being. Such deficits can result in inadequate self-care, inappropriate use of medications, ineffective management of chronic conditions, and poor adherence to medical advice or treatment plans (Berkman et al., 2011). Examples of health knowledge deficits include the following:

- lack of knowledge about healthy lifestyle behaviors, such as proper nutrition, exercise, and stress management
- insufficient understanding of medical conditions, their causes, symptoms, and treatment options
- inadequate knowledge about medications, including their proper use, potential side effects, and interactions with other drugs
- poor understanding of risky health behaviors, such as smoking or excessive alcohol consumption
- insufficient knowledge about preventive measures, such as vaccines, cancer screenings, and regular checkups
- lack of knowledge about where to find accurate, unbiased, and credible health information

Addressing health knowledge deficits is crucial for promoting optimal health outcomes and reducing the risk of chronic diseases and other health problems. This can involve providing education, counseling, and support to individuals, as well as promoting health literacy and patient empowerment.

Individuals with knowledge deficits have unique safety risks to address. Those living with knowledge deficits may be at risk of physical harm due to a lack of understanding related to the actions they take. A patient with a health knowledge deficit may have difficulty understanding health teaching; for example, a patient may not understand they should not get a cast wet because water dissolves the stability of the plaster. Nurses need to assess the patient's understanding of education. This could include asking the patient to repeat the steps of a procedure back to them or demonstrating how to perform an activity. This is known as a **teach-back method**, a way for healthcare providers to present information to patients clearly and determine the patients' understanding of the information (Agency for Healthcare Research and Quality [AHRQ], 2021). The goal is to make sure patients and their families have received and understood important healthcare information. After providing information to the patient and family, the healthcare provider asks them to repeat the information back, in their own words (AHRQ, 2021). This method allows nurses to hear what the patient and family understood and clarify any misinformation. To address knowledge deficit, the nurse must teach the patient what to do and what not to do. In the earlier example of not getting a cast wet, it is possible the patient heard "don't take a bath." A better way to prevent misunderstanding is for the nurse to follow "don't get the cast wet" with "this is how you can shower or take a bath with a cast." Then, have the patient perform a return demonstration of how they would protect their cast while taking a bath.

 **PATIENT CONVERSATIONS**

---

**Diabetes Education**

**Scenario:** Luisa, a 65-year-old female who was recently diagnosed with type 2 diabetes, is admitted to the hospital for uncontrolled blood glucose levels. The nurse walks into the patient's room to conduct a morning assessment.

**Nurse:** Good morning, Luisa. How are you feeling today?

**Patient:** I'm okay, just a bit tired.

**Nurse:** I understand. I wanted to talk to you about managing your diabetes. Do you have any questions or concerns about your condition?

**Patient:** Actually, yes. I don't know much about diabetes or how to manage it.

**Nurse:** That's perfectly okay. Diabetes is a complex condition, but with the right education and support, you can manage it effectively. Let's start with the basics. Do you know what causes diabetes?

**Patient:** Not really, no.

**Nurse:** Diabetes occurs when your body can't produce or use insulin properly. Insulin is a hormone that helps regulate your blood sugar levels. When your body can't produce enough insulin, or if it can't use it properly, your blood sugar levels can rise too high. This can cause a range of complications, including damage to your nerves, eyes, and kidneys.

**Patient:** I see, so what can I do to manage my diabetes?

**Nurse:** There are a few things you can do. First, you'll need to monitor your blood sugar levels regularly. This involves testing your blood using a blood glucose meter. We'll show you how to do this before you leave the hospital. Second, you'll need to make some changes to your diet. This means reducing your intake of sugar and carbohydrates and increasing your intake of fruits, vegetables, and whole grains. Finally, you'll need to stay active. Regular exercise can help regulate your blood sugar levels and improve your overall health.

**Patient:** That all sounds very overwhelming.

**Nurse:** I understand that it can seem overwhelming at first, but we're here to support you every step of the way. We'll provide you with resources and education to help you manage your diabetes effectively. I will bring them next time I come in your room. I will also have our diabetic educator come visit with you later today.

**Patient:** Thank you, I appreciate your help.

**Nurse:** Of course, Luisa. We're here to help you live a healthy and fulfilling life with diabetes. Do you have any other questions or concerns for me?

**Patient:** No, not currently. I will let you know after we go over the resources you are bringing regarding my food choices, and I will wait for the diabetic educator to come by and visit with me before being discharged. I look forward to learning more about how to better manage my health. Thank you.

---

**Alterations in Physical Health**

Health and safety are interrelated aspects of an individual's life. Health can impact safety, and safety can impact health. A person experiencing physical health challenges may face an increased risk to personal safety because of illness or injury. Changes in one's ability to perform activities safely on their own may increase risk of injury. For example, a person who now has balance issues and showers without assistance may be at increased risk for a fall.

Side effects from necessary medications which lead to alterations in physical health may also increase one's risk for injuries or accidents. Some medications are known to cause drowsiness, necessitating a warning label informing those taking it to take care when operating machinery or driving vehicles. Medications, such as those used to treat pain, may also impair an individual's judgment and response times. It is important for individuals to be aware of any risks associated with medications and to take necessary precautions to prevent injury or accidents.

## LIFE-STAGE CONTEXT

---

### Narcotic Use and Risk of Falls in Older Adults

The use of certain medications, such as narcotics, is sometimes necessary to manage pain. With aging, there is an increased likelihood of requiring medical interventions like surgery or other treatments. Consequently, narcotics may be prescribed to aid in the recovery process. Narcotics can increase the risk of falls, particularly for older adults; thus, they must be prescribed and used with caution. Patients should be educated regarding their increased fall risk and exercise caution when using these medications (Virnes et al., 2022).

---

### Impaired Mobility

Maintaining individual safety is of particular importance for those living with mobility issues. Impairments can affect an individual's ability to move safely within their environment and community, making them more susceptible to accidents or injury. The home is often the main place where injury can occur (WHO, 2018). A well-decorated home may have rugs, a lot of furniture, and dim lighting. While attractive, these features increase the risk of falls in compromised patients. To keep oneself safe at home, it is important to do the following:

- Clear pathways going into and around the home to ensure there is no clutter or other tripping hazards, such as loose paving stones.
- Install handrails on stairs both inside and outside of the house to help with stability and prevent falls.
- Install grab bars and nonslip mats in the bathroom to prevent falls.
- Ensure the bed is kept at a reasonable height to make it easy to get in and out.
- Be careful with the use of throw rugs that can be a fall hazard.

Individuals must also consider outdoor safety in their communities. Sidewalks can pose a risk if they are uneven or have cracks or obstacles embedded into their surface. For regions that experience snow and ice, sidewalks can be particularly dangerous to navigate. Those living with mobility issues should consider how they will navigate public transportation to ensure they are utilizing services that are accessible and support their mobility. Individuals living with mobility concerns should communicate with those around them and have a plan in place in case of emergency to ensure their safety.

## LIFE-STAGE CONTEXT

---

### Mobility Concerns for Older Adults

Mobility becomes more challenging with age, putting older adults at risk for falls. Nurses should observe older patients as they walk into the room to determine any challenges with gait or balance. The nurse should consider utilizing a well-created questionnaire when preparing a patient for discharge. Each question should be clear enough to reveal any possible hazards or barriers to the patients' mobility and safety when they return home. Simply asking if they have running water and indoor plumbing is not enough. Even patients who are financially privileged can have barriers to mobility and safety. Consider a very successful patient who lives in an affluent historic district. They might not be able to walk safely outside because historic districts tend to have large trees that disrupt the sidewalk or have no sidewalks at all. Nurses must ask clear questions to obtain a clear picture of what the patient will experience when they return home.

---

### Altered Sensory Perception

A vital aspect of functioning in everyday life is sensory perception, defined as the ability to see, hear, touch, taste, and smell. Alterations in sensory perception can have a significant impact on an individual's ability to navigate their environment. Any changes to these senses create risk for the individual; for instance, a person who cannot smell may not notice the first signs of something burning in their home. [Table 9.1](#) describes some common sensory perception impairments and how to address them.

Sensory Impairment	Impact	Ways to Address
Visual impairments, including full or partial blindness	May not have the ability to safely navigate personal and public environments	Using a white guide cane (white indicates blind or visually impaired), guide dogs, or other assistive devices to help with navigation
Hearing impairments, including complete or partial deafness	May not hear alarms or the voices of people calling out safety warnings	Using assistive devices, such as hearing aids; having an emergency plan in place to ensure safety
Touch impairments, not able to sense or feel changes in temperature	Can create risks for burns and frostbite or other potential hazards in the environment	Monitoring external temperatures and taking measures to protect from extreme temperature changes (e.g., use a thermometer to obtain a water temperature when bathing to prevent burns from hot water)
Taste and smell impairments	Impact ability to sense hazards, such as a gas leak or food that has spoiled	Asking a caregiver to smell foods to ensure they are not spoiled; having a trained therapy dog that can detect harmful odors, such as gas leaks in the home

**TABLE 9.1** Common Sensory Perception Impairments

### Alterations in Psychosocial Health

An individual's **psychosocial health** refers to the psychological and social aspects of that individual's overall health and well-being. It encompasses the interplay between a person's mental health and their relationships with others and the world around them. Psychosocial health is crucial for a person's overall health, as it impacts their ability to cope with stress, form relationships, and make decisions. A person with good psychosocial health tends to have a positive outlook on life, feel socially connected, and be able to adapt to life's challenges in a healthy way. Poor psychosocial health can lead to a range of health alterations, encompassing mental health conditions like depression and anxiety, social isolation, substance misuse, and physical health issues such as high blood pressure and heart disease. A lack of social support and poor coping skills can also lead to a higher risk of chronic diseases, such as diabetes and obesity.

### Stress

Stress is a natural part of life; we all experience stress at varying points. However, too much stress can create unsafe environments for individuals. Chronic stress can affect an individual's physical, emotional, and mental well-being, which may decrease their ability to respond to potential hazards or make safe decisions. See [Table 9.2](#) for examples of how different types of stress impact one's health. An individual living with anxiety may have difficulty completing a task that requires focus and attention, thus leading to increased risk of an accident. Those living with diagnoses such as phobias or depression may find their judgment clouded, making it difficult to adequately assess risk.

Type of Stress	Example	Impact on Individual Safety and Health
Physical stress	Overexertion	<ul style="list-style-type: none"> <li>Increases the risk of high blood pressure, stroke, and heart disease</li> <li>Weakened immune system due to chronic stress, increasing the risk of illness</li> <li>Symptoms can include shortness of breath or chest pain</li> </ul>
Mental health stress	Loss of one's job	<ul style="list-style-type: none"> <li>Increases the risk of depression, anxiety, and other mental health conditions</li> <li>Can impact an individual's ability to think clearly and make safe decisions</li> <li>May be situational or related to a mental health diagnosis</li> <li>May experience trouble concentrating on work</li> <li>May be more emotional or quick to anger</li> <li>May find themselves unable to engage in activities</li> </ul>
Social or behavioral stress	Loss of an important relationship	<ul style="list-style-type: none"> <li>More likely to engage in impulsive behaviors as a coping mechanism</li> <li>May include reckless driving, using substances, or engaging in risky sexual behavior</li> <li>May arise from experiences at school or in the workplace (e.g., bullying) or may be linked to an identifiable diagnosis; results in challenges in social engagement</li> <li>May withdraw or rely on drugs or alcohol to manage feelings in social situations</li> </ul>

**TABLE 9.2** Stress and Impact on Individual Safety

To effectively manage one's psychosocial health to prevent injury, individuals should understand their own response to stress as well as steps they can take to mitigate risk factors. One can manage this by practicing self-care techniques, reducing stress, and addressing the emotional and psychological factors that are harming health. Self-care can include meditation, exercise, yoga, spending time in nature or with friends, and sleep. Remaining healthy from a psychological and emotional perspective also means seeking help and support when needed.

### Cognition

The mental processes that enable individuals to think, learn, remember, and make decisions to act are referred to as cognition. Alterations in cognition can result in changes in an individual's ability to think clearly and act appropriately. Conditions like dementia or mild cognitive impairments can hinder an individual's ability to recognize potential hazards and make safe decisions, as they may be unaware that their actions pose risks. This is important for caregivers and family members to understand. The patient is not purposely engaging in risky, careless behavior, and their actions do not indicate a lack of intelligence. They are experiencing a change in their mental processes and must be treated with respect while the situation is being resolved. The use of medications like pain relievers and sedatives, intended for pain management or sleep assistance, can negatively impact an individual's cognitive abilities and judgment. Sleep deprivation, which may occur during illness or if an individual is a caregiver, can impair an individual as much as using substances. Lack of adequate sleep can make it difficult to think clearly and make safe decisions.

Individuals concerned about cognitive changes can take measures to ensure a safe environment. These include getting sufficient sleep and rest, conducting medication reviews with a pharmacist, minimizing or discontinuing use of substances that may impact cognition (e.g., sedatives and narcotics), maintaining open communication with caregivers and family members, and establishing an emergency response plan. Caring for a loved one with dementia can increase stress for caregivers, and in turn, increase the risk of illness for them. Families should seek professional intervention when a loved one is diagnosed with dementia to ensure both the patient and family receive

adequate support and services. This may include respite services, providing caregivers with opportunities to take a break and participate in self-care activities. Professional assistance may be required to begin the process of in-home care or long-term placement in a care facility.

### **Suicide Risk**

Suicide is a leading cause of death and a significant public health concern. Most institutions require nurses to complete a suicide risk assessment for all patients, utilizing evidence-based tools to evaluate their potential risk of self-harm (CDC, 2021). For any patient who is at risk of suicide, the nurse must include the patients' support system and initiate a safety plan. Suicide risk can be influenced by several factors, including mental health conditions, life events, and having access to substances or physical objects that could be used to cause harm. Individuals at risk of suicide may be more likely to engage in risky behaviors due to an underlying mental health crisis.

### **Environmental Safety**

The environment plays a crucial role in health and well-being. Environmental factors such as air quality, water quality, and exposure to hazardous materials can all have a significant impact on individual health. It is important for individuals to be aware of local environmental conditions and concerns and to take the necessary steps to reduce the risks.

The environment can encompass several things: it can be used to describe one's home and surroundings, a neighborhood, or a work setting. The environment can also describe work settings or the community as well as the land we live on, the water we drink, and the air we breathe. Each of these environmental settings has an impact on individual and collective health. For example, a train derailment may cause the release of toxic chemicals into the land and water surrounding a community. A patient in the suburbs might have access to a walking path through a large park where vehicles are prohibited, while a patient in a more urban area may have to continually cross streets with dangerous traffic. Crime rates and the availability of community support can influence safety; for example, a patient in an area with frequent street crime may feel uncomfortable taking a daily walk or going to the pharmacy. Geography can also impact safety. For example, those living in rural communities may have less access to the infrastructure and resources necessary to remain safe. The geographical remoteness of these areas often results in longer response times for emergency personnel to reach the location of an incident, which may be critical in situations where immediate medical attention or intervention is required. Living in areas where the air quality is poor or where there is a greater risk of natural disasters, such as wildfires or flooding, impacts personal safety.

#### **Factors Affecting Environmental Safety**

Environmental factors can be broadly classified into two categories: modifiable and nonmodifiable factors. Modifiable environmental factors are linked to pollution levels and occupational exposure through the influence of individual choices and behaviors. Lifestyle and behavior choices, such as transportation methods, use of energy sources, and adherence to safety practices in the workplace, for instance, can directly impact pollution levels and occupational exposure. These factors can be influenced through various means, including policy interventions, education and awareness campaigns, and personal behavior changes. Nonmodifiable environmental factors, on the other hand, are determined by geography, climate, genetics, and age. Examples of nonmodifiable environmental factors include natural disasters, genetic predisposition to certain diseases, and the age-related decline in immune function. In general, modifiable environmental factors are more responsive to intervention and can be altered to promote health and prevent disease. While some environmental factors, such as exposure to toxic chemicals or infectious agents, can have an acute and immediate impact on our health, others may have more insidious effects that only become apparent over time, such as prolonged exposure to certain environmental factors that lead to chronic diseases and other health problems ([Table 9.3](#)).

Factor	Potential Outcomes	Interventions
Air quality	Can cause health problems, such as respiratory disease, cardiovascular disease, and cancer. Air pollution or poor ventilation can increase the risk of suffocation. For instance, a person with severe asthma may experience a life-threatening respiratory episode if exposed to an irritant.	Monitor air quality and avoid exposure if the air quality is poor. Individuals with known respiratory disease may require the use of medications to assist in breathing when the air quality is poor and should be educated to stay indoors as much as possible.
Water quality	Exposure to contaminated water can cause gastrointestinal issues, skin irritation, and neurological damage.	Monitor water quality alerts, test the quality of well water, use water filters, and take precautions when traveling.
Natural disasters	Individuals who live in areas that are more likely to experience flooding, fires, hurricanes, or earthquakes are at higher risk for harm.	While these events are out of the individual's control, it is important to take action to minimize potential harm.
Hazardous materials	Exposure to hazardous materials such as lead, asbestos, or chemicals can cause serious health implications or death.	Be aware of safety labels on chemicals and cleaning products, reduce exposure to harmful substances, and properly dispose of any hazardous materials.
Political and social factors	Living in areas where there is political unrest, wars, or terrorism increases an individual's risk.	These events are out of the control of the individual, but it is important to be prepared to minimize their risk.

**TABLE 9.3** Factors Affecting Environmental Safety

### Risk for Falls

Falls are a common and serious problem for many individuals, and even more so for older adults. Falls can result in serious injuries such as broken bones, head injuries, and even death (AHRQ, 2023). Physical factors such as poor balance, weak muscles, and limited mobility can increase the risk of falls. Each year, 3 million older people are treated in emergency departments for fall injuries, and over 800,000 patients a year are hospitalized because of a head injury or hip fracture resulting from a fall (CDC, 2023a). “Prevent residents from falling” is one of the National Patient Safety Goals for nursing care centers (The Joint Commission, 2023). Many older adults who fall, even if they are not injured, become afraid of falling. This fear may cause them to limit their everyday activities. However, when a person is less active, they become weaker, which further increases their chances of falling (CDC, 2020a).

## LIFE-STAGE CONTEXT

### Preventing Accidents in Older Adults—Implementing a Unique Model

The CDC (2020b) developed a program called “STEADI: Stopping Elderly Accidents, Deaths & Injuries” to help reduce the risk of older adults falling at home. This model was created in response to fall risk as well as a desire to implement a strengths-based model to assist older individuals to stay safely at home. The model consists of three screening questions to determine risk for falls:

- Do you feel unsteady when standing or walking?
- Do you have worries about falling?
- Have you fallen in the past year? If yes, how many times? Were you injured?

If the individual answers “Yes” to any of these questions, further assessment of risk factors is performed. This additional assessment supports nurses and other healthcare providers in implementing measures to support people in remaining safe in their homes.

Many conditions contribute to patient falls, including the following (CDC, 2020a):

- lower body weakness
- vitamin D deficiency
- difficulties with walking and balance
- medications, such as tranquilizers, sedatives, antihypertensives, or antidepressants
- vision problems
- foot pain or poor footwear
- environmental hazards, such as throw rugs or clutter that can cause tripping

Most falls are caused by a combination of risk factors. The more risk factors a person has, the greater are their chances of falling. Many risk factors can be changed or modified to help prevent falls.

## UNFOLDING CASE STUDY

### Unfolding Case Study #2: Part 3

Refer back to [Chapter 8 Admission, Transfer, and Discharge](#) for Unfolding Case Study Parts 1–2 to review the patient data. A 65-year-old patient was admitted to the cardiology unit for observation after a suspected myocardial infarction. The patient went to the cardiac catheterization lab, where two coronary artery stents were successfully placed. The patient has just returned to her room after the procedure. During morning rounds, the team noted the patient appears restless and agitated. She repeatedly attempts to get out of bed without assistance, despite reminders to call the nurse before getting up.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, coronary artery disease</p> <p><b>Family history:</b> Mother deceased, father alive with severe dementia; two healthy sons in their early 40s</p> <p><b>Social history:</b> Previous divorce, married to current husband, George, for twenty years</p> <p><b>Allergies:</b> Latex</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Aspirin 81 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Lisinopril 10 mg PO once daily</li> <li>• Atorvastatin 30 mg PO once daily</li> </ul>
Flow Chart	<p><b>1200: Assessment</b></p> <p>Blood pressure: 135/82 mm Hg</p> <p>Heart rate: 97 beats/min</p> <p>Respiratory rate: 20 breaths/min</p> <p>Temperature: 98.6°F (37°C)</p> <p>Oxygen saturation: 95 percent on room air</p> <p>Pain: 5/10 (headache)</p>
Nursing Notes	<p><b>1200: Assessment</b></p> <p>Patient reports headache pain rated 5/10 on numerical scale. Oxycodone previously administered at 1030 for postprocedure pain.</p>

1. Recognize cues: What cues are most concerning to the nurse at this time?
2. Analyze cues: Based on the recognized cues, what safety concerns should the nurse have?

3. Prioritize hypotheses: What factors do you think may be contributing to the patient's inability to remain safely in bed?

### Risk for Fires

Fires are frightening and pose a significant risk for serious injuries, loss of property, and even death. The kitchen poses the highest likelihood of fire hazards within a home. These can occur from improperly using equipment, leaving cooking food unattended, having flammable materials near stoves or open fires, and not turning off appliances when they are not in use. Another common fire hazard can occur from smoking in bed, falling asleep while smoking, and improperly disposing of smoking equipment. Heating sources also pose a risk to safety, particularly items such as unattended space heaters, fireplaces, and candles. By taking steps to reduce the risk of fire and having fire safety equipment present in the home and workplace, individuals can decrease their risk.

### Risk for Poisoning

Poisoning is a serious public health issue and can result in serious injury or death, particularly in small children. Household hazards such as cleaning products, laundry products, or medications can pose a poisoning risk. Additionally, consumption of contaminated food or beverages can lead to food-related poisoning, while exposure to lead or carbon monoxide in homes or workplaces can result in fatal outcomes. There are numerous steps individuals can take to ensure their own safety and prevent illness, injury, or death from poisoning. One of the first steps is education. Patients must be taught which products in the home may be toxic if they are ingested, such as household cleaning products or laundry pods. These products contain warning labels, and any products that are considered toxic or harmful should be stored in a safe place away from children and pets. Keep poison control numbers nearby in case of emergency, and recognize when to get assistance.

### Risk for Suffocation

Suffocation occurs when an object impairs an individual's airway. Infants and young children are most susceptible to the risks of suffocation. Choking hazards, like small toys or food, pose a risk of becoming lodged in a child's airway. Additionally, suffocation may occur if an infant or young child's airway becomes obstructed during sleep, commonly attributed to bedding. Nurses can educate parents on safe sleeping practices to reduce the risk of suffocation for infants. This includes placing the infant on their back to sleep, using firm mattresses, avoiding pillows or additional bedding, refraining from co-sleeping, ensuring the infant is at a comfortable temperature, and keeping soft or loose objects away from the sleeping area (Moon, 2022).

Other risks for suffocation for children include scarves or ties from clothing, such as hoodies, becoming caught and playing with items that might become caught around their throat. Ensure children do not have coats or mittens with strings that might get caught while playing on outdoor equipment causing suffocation and ensure individuals do not perform risky activities with items around their neck or mouth (Nemours KidsHealth, 2023).

Adolescents and adults also experience suffocation risks, most often from inhalation or aspiration of foreign substances or food and inflicted injury from strangulation or hanging (Sasso et al., 2018). Educate adolescents not to engage in dangerous or life-threatening activities, such as social media trends that may be dangerous and are not proven safe. For adults, ask if they indulge in air deprivation or suffocation games. Discuss educational resources to help educate patients on suffocation prevention while engaging in sexual activity. These conversations might be awkward and embarrassing, but they are necessary to ensure the safety of patients.

### Risk for Exposure to Substances

Substance use has a negative impact on health and can also increase the individual risk for harm or illness. Substances to which individuals may be exposed include alcohol and drugs (both legal and illegal). Unfortunately, some patients become dependent on drugs that may have been prescribed to manage pain, such as opioids, leading to substance use disorders. As substance use disorder evolves, patients seek out more ways to obtain drugs to manage the symptoms of withdrawal. The effects of substance use are discussed in greater detail in [9.2 Safety: Violence](#).

### Risk for Impaired Thermoregulation

The ability of the body to maintain its internal temperature within a narrow range is called thermoregulation. Impaired thermoregulation refers to a condition where the body's ability to regulate its internal temperature is

compromised. When thermoregulation is impaired, the body may struggle to maintain its temperature within the normal range. This can lead to either hypothermia or hyperthermia, both of which can be dangerous and potentially life-threatening.

A condition that occurs when the body loses heat faster than it can produce it is called hypothermia. This can result in a dangerously low body temperature and can be life threatening. Individuals should do the following to reduce the risk of hypothermia:

- Dress appropriately for the weather to reduce the risk. In severe cold, individuals should avoid being outdoors if possible.
- Stay active to generate body heat and reduce the risk of hypothermia.
- Avoid alcohol and drugs, as they can impair judgment and increase the risk of hypothermia. For example, a person who is impaired by either alcohol or drugs may choose to go outside when the weather is extremely cold and may not recognize how cold it is, perhaps losing consciousness or falling asleep in the cold, leading to hypothermia.

A condition that occurs when the body produces or retains too much heat is hyperthermia. This can result in a dangerously high temperature and can be life threatening. To reduce the risk of hyperthermia, individuals should do the following:

- Stay hydrated to help regulate body temperature.
- Avoid strenuous activity in hot weather to reduce risk, and if possible, stay in air-conditioned areas during extreme heat.
- Wear appropriate clothing, such as lightweight, light-colored clothing in hot weather.

### Workplace Safety Concerns

The workplace can present a variety of safety concerns, ranging from physical hazards such as slips, trips, and falls, to chemical exposure to ergonomic concerns and stress. The repetitive nature of work can lead to workplace injuries. The design and arrangement of workspaces, tools, equipment, and tasks to optimize comfort, efficiency, and safety for employees is called **ergonomics**. Ergonomics involves assessing how people interact with their work environment and identifying potential hazards or discomforts, such as uncomfortable chairs, poorly designed workstations, repetitive motions, heavy lifting, and inadequate lighting that can result in musculoskeletal injuries or other health problems. To implement ergonomic principles, workplaces should provide training and education to employees, offer support and resources for stress management, and create a positive organizational culture that prioritizes employee well-being.

Employees should stay vigilant about workplace safety hazards and understand their employers' legal obligations to ensure a secure work environment. Reporting safety issues to the relevant authorities, engaging in mandatory safety training, and adhering to prescribed safety procedures are crucial. Additionally, workers should be mindful of workplace stressors and seek methods to alleviate physical, mental, and emotional stress.

### Never Events

Adverse events that are clearly identifiable, measurable, serious (resulting in death or significant disability), and preventable are called **never events**. In 2007, the Centers for Medicare and Medicaid Services (CMS) discontinued payment for costs associated with never events, and this policy has been adopted by most private insurance companies (AHRQ, 2019). Never events are publicly reported, with the goal of increasing accountability by healthcare agencies and improving the quality of patient care. The current list of never events includes seven categories of events:

- surgical or procedural event, such as surgery performed on the wrong body part
- product or device, such as injury or death from a contaminated drug or device
- patient protection, such as patient suicide in a healthcare setting
- care management, such as death or injury from a medication error
- environmental, such as death or injury as the result of using restraints
- radiological, such as a metallic object in an MRI area
- criminal, such as death or injury of a patient or staff member resulting from physical assault on the grounds of a healthcare setting

Table 9.4 demonstrates the various ways in which patients can be impacted by never events. To reduce the chance and impact of never events, healthcare providers should focus on preventing these events using evidence-based practices, robust quality improvement processes, and patient engagement and empowerment. Patients can take steps to avoid experiencing never events by becoming informed and engaged in their own health care by asking questions and speaking up if they have concerns.

Action	Potential Outcome
Physical	Pain, infection, or another injury that might result in long-term complications and impact the quality of life
Psychological	Anxiety, depression, and post-traumatic stress disorder may occur and be long lasting
Increased healthcare costs	Longer hospital stays, additional treatments, and rehabilitation services can cost the healthcare system billions of dollars
Loss of trust	Loss of trust between the patient and provider and the healthcare system in general

TABLE 9.4 Potential Effects from Never Events

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety

**Definition:** Minimizes risk of harm to patients and providers through both system effectiveness and individual performance.

**Knowledge:** The nurse will delineate general categories of errors and hazards in care.

**Skill:** Describe factors that create a culture of safety (such as open communication strategies and organizational error reporting systems).

**Attitude:** Seeking to value one's role in preventing error. For example, one type of "never event" is a wrong-site surgery. This refers to a surgical procedure performed on the wrong part of the body, such as the wrong limb or organ. To prevent wrong-site surgery, the Quality and Safety Education for Nurses (QSEN) project emphasizes the importance of implementing a preoperative verification process. This involves verifying the correct patient, correct site, and correct procedure before the surgery takes place. This process can involve multiple healthcare team members, including the surgeon, anesthesiologist, and nursing staff. By emphasizing the importance of a preoperative verification process and the use of standardized protocols, QSEN helps to ensure that healthcare teams are equipped with the tools and knowledge to prevent errors and provide safe care.

### Near Events or Misses

A **near event** is a warning signal of a potential hazard or incident that may cause harm to patients. Near events can have significant negative impacts; however, they can also provide an opportunity for learning and improvement. A **near miss** is an error that has the potential to cause harm but is identified before it happens. Near misses, such as those involving medications, allow nurses to make changes to practice and policy. Near misses are rarely the result of poor motivation or incompetence of the healthcare professional but rather are often caused by key contributing factors such as poor communication, less-than-optimal teamwork, memory overload, reliance on memory for complex procedures, and lack of standardization of policies and procedures.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Recognize Cues: Noticing Patterns and Responding

The nurse is responsible for recognizing cues and responding to cues that are out of the norm or not expected.

In the instance of a near event involving the administration of a mislabeled medication, this would involve recognizing an error on the medication bottle and intervening before the medication is given. Upon noticing the error, the nurse should immediately stop medication administration and return to the medication cart. They should seek to understand reasons for why a near miss occurred. The nurse should speak with a supervisor to identify the issue and seek resolution to prevent such an error from occurring again.

### Sentinel Events

A **sentinel event** is like a near event but is not necessarily preventable. A sentinel event is defined as an unexpected occurrence involving death or serious physiological or psychological injury, or the risk thereof. For example, injury or death from a properly prescribed and administered medication is a sentinel event. The Joint Commission mandates reporting of sentinel events and the performance of a root cause analysis by the healthcare agency. A **root cause analysis** is a structured method used to analyze serious adverse events to identify underlying problems that increase the likelihood of errors, while avoiding the trap of focusing on mistakes by individuals. A multidisciplinary team analyzes the sequence of events leading up to the error with the goal of identifying how and why the event occurred. The goal is to prevent future harm by eliminating hidden problems within a healthcare system that contribute to adverse events.

Root cause analysis uses human factors science as part of the investigation. A **human factors** approach focuses on the interrelationships among humans, the tools and equipment they use in the workplace, and the environment in which they work. Safety in health care is ultimately dependent on humans—the doctors, nurses, and healthcare professionals—providing the care. For example, when a medication error occurs, a root cause analysis goes beyond focusing on the mistake by the nurse and looks at other system factors that contributed to the error, such as similar-looking drug labels, placement of similar-looking medications next to each other in a medication dispensing machine, or vague instructions in a provider order.

### Culture of Safety

A culture of safety is a workplace culture that prioritizes the well-being and safety of employees, patients, and the public. Culture can have many definitions but generally refers to a way of being or acting. A **culture of safety** is characterized by open communication, collaboration, and continuous improvement, with a focus on reducing errors, adverse events, and harm. A culture of safety significantly impacts individual safety, as it sets the tone for safety practices, behaviors, and attitudes in the workplace. One example of a culture of safety initiative is the implementation of crew resource management (CRM) training in healthcare settings. In healthcare, CRM is a human factors approach that focuses on improving communication, teamwork, and situational awareness among healthcare providers. Studies have shown that CRM training can improve patient safety outcomes, reduce adverse events, and improve overall healthcare team performance (Weaver et al., 2011).

## REAL RN STORIES

### Near Miss with Medication

**Nurse:** Sarah, RN

**Clinical setting:** Emergency department

**Years in practice:** 3

**Facility location:** Southern California

One night, I was assigned to a patient who required several medications, including a new medication that I had not administered before. Despite being a seasoned nurse, I was a little nervous about administering the medication correctly, but I double-checked the dose and the medication order before administering it. As I was administering the medication, I noticed the medication label looked different from the other medications I had administered before. I quickly realized that I had grabbed the wrong medication bottle and was about to administer the wrong medication to the patient. I immediately stopped the administration and reported the near-miss incident to the charge nurse. This quick thinking and attention to detail prevented a medication error from occurring. I realized that even experienced nurses can make mistakes, but the key is to double-check and be vigilant about medication administration. I also recognized the importance of reporting near misses and adverse events to ensure that the

healthcare team can learn from the incident and take steps to prevent similar errors in the future.

---

### Just Culture

A **just culture** can be defined as a culture where people feel safe raising questions and concerns and reporting safety events in an environment that emphasizes a nonpunitive response to errors and near misses. Clear lines are drawn between human error, at-risk behavior, and reckless behavior:

- *Simple human error* occurs when an individual inadvertently does something other than what should have been done. Most medical errors are the result of human error due to poor processes, programs, education, environmental issues, or situations. These errors are managed by correcting the cause, looking at the process, and fixing the deviation.
- *At-risk behavior* occurs when a behavioral choice is made that increases risk where the risk is not recognized or is mistakenly believed to be justified. For example, a nurse scans a patient's medication with a barcode scanner prior to administration, but an error message appears on the scanner. The nurse mistakenly interprets the error to be a technology problem and proceeds to administer the medication resulting in the wrong dosage of a medication being administered to the patient, instead of stopping the process and further investigating the error message. In this case, ignoring the error message on the scanner is considered at-risk behavior because the behavioral choice was considered justified by the nurse at the time.
- *Reckless behavior* occurs when an action is taken without regard for a substantial and unjustifiable risk. For example, a nurse arrives at work intoxicated and administers the wrong medication to the wrong patient. This error is due to reckless behavior because the decision to arrive intoxicated was made with conscious disregard for substantial risk.

Creating a just culture in which employees are not afraid to report errors is a highly successful way to enhance patient safety, increase staff and patient satisfaction, and improve outcomes. Success is achieved through good communication, effective management of resources, and an openness to changing processes to ensure the safety of patients and employees.

### National Patient Safety Goals

Every year, to improve patient safety, The Joint Commission publishes **National Patient Safety Goals** that include goals and recommendations tailored to seven different types of healthcare agencies based on patient safety data from experts and stakeholders. The seven healthcare areas include ambulatory healthcare settings, behavioral healthcare settings, critical access hospitals, home care, hospital settings, laboratories, nursing care centers, and office-based surgery settings. These goals are updated annually based on safety data and include evidence-based interventions. The National Patient Safety Goals for nursing care settings (otherwise known as long-term care centers) are described in [Figure 9.5](#).

**FIGURE 9.5** It is important for nurses to be aware of the current National Patient Safety Goals for the settings in which they provide patient care and adhere to the associated recommendations. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## UNFOLDING CASE STUDY

### Unfolding Case Study #2: Part 4

Refer back to [Unfolding Case Study: Unfolding Case Study #2: Part 3](#) for a review of the patient data.

Nursing Notes	<p><b>1400: Assessment</b></p> <p>During hourly rounding, patient was found lying on the floor. Patient states, "I needed to go to the bathroom, but you were taking too long to come help me!" Upon further assessment, the bed alarm was turned off, and there was no evidence of the patient's call light being pushed for assistance. Patient was helped back to bed by three nursing staff and fall reported to charge nurse.</p>
---------------	--

4. Generate solutions: What interventions could the nurse implement to prevent the patient from falling again?
5. Take action: What are the priority actions by the nurse at this time?
6. Evaluate outcomes: After implementing fall risk precautions for the patient, what findings would indicate that the interventions were successful?

## Social Determinants of Health

The social determinants of health (SDOH) are the economic, social, and environmental factors that influence an individual's health and well-being. The term health disparity describes the differences in health outcomes that result from SDOH. The SDOH are conditions in the environment where people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes. Resources that enhance quality of life can have a significant influence on population health outcomes. Examples of resources include safe and affordable housing, access to education, public safety, availability of healthy foods, local emergency/health services, and environments free of life-threatening toxins (Healthy People 2030, n.d.).

At-risk populations experience increased prevalence and burden of diseases, as well as problems accessing quality health care because of SDOH. Health disparities negatively impact groups of people based on their ethnicity, gender,

age, mental health, disability, sexual orientation, gender identity, socioeconomic status, geographic location, or other characteristics historically linked to discrimination or exclusion (Healthy People 2030, n.d.). A related term is **healthcare disparity** which refers to differences in access to health care and insurance coverage. Health disparities and healthcare disparities can lead to decreased quality of life, increased personal costs, and lower life expectancy. More broadly, these disparities also translate to greater societal costs, such as the financial burden of uncontrolled chronic illnesses.

### Limited Access to Food and Water

Limited access to food and clean water can have a significant impact on individual safety and well-being. Addressing this issue through policies and programs that ensure access to safe and nutritious food and clean water is essential for improving health outcomes and reducing health disparities. Limited access to food and water can lead to health issues, such as malnutrition, dehydration, foodborne illness, and waterborne illness, and impact mental and physical health in general. Some communities are further impacted by “food deserts,” or areas where it is impossible for those who are poor to purchase affordable, quality, healthy food due to location and lack of adequate public transportation.

### Substandard Housing

Adequate and affordable housing is a critical social determinant of health. Poor housing conditions, including overcrowding, lack of heat and running water, and exposure to toxic substances, can lead to a range of health problems, including respiratory diseases, injuries, and mental health conditions. A well-constructed questionnaire can help nurses eliminate bias while obtaining necessary information.

### Limited Support System

A limited support system can have a significant impact on individual safety and well-being. Support systems may consist of family, friends, or neighbors who maintain contact with those living alone to ensure their safety and well-being. A limited support system can lead to individuals having a lack of assistance with daily activities, increased isolation and loneliness, difficulty navigating health systems, limited access to resources, and increased risk of neglect and abuse. Addressing this issue through policies and programs that support social connectedness and provide access to resources and services is essential for improving health outcomes and reducing health disparities.

## 9.2 Safety: Violence

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize different types of abuse to make informed clinical decisions regarding patient care
- Identify forms of family violence and provide appropriate nursing interventions for patient care
- Describe various categories of social violence

Healthcare workers play a crucial role in providing care to patients, but their job can also come with significant risks to their own health and safety. One of the most pressing risks is workplace violence, which can cause physical and psychological harm. Violence may come from patients or family members as well as from colleagues or other workers in the healthcare system. It can take various forms, ranging from verbal abuse to physical assault, and can have long-lasting effects on the individual’s well-being. Additionally, healthcare workers may become aware of violence or abuse suffered by their patients. Nurses play an integral role in keeping themselves and their patients safe.

Ensuring the safety of healthcare workers is critical to the delivery of quality healthcare services. However, addressing this issue requires a multifaceted approach that involves collaboration between healthcare organizations, policymakers, law enforcement agencies, and other stakeholders. This can include implementing comprehensive violence prevention programs, providing training and education to healthcare workers, improving communications between staff and patients, and ensuring that appropriate support is available to those who have experienced violence. Nurses must participate in organizational training and be well informed about the steps to take when a potential threat is identified.

### Forms of Abuse

The term **abuse** refers to physical, emotional, verbal, or sexual acts toward another which can cause harm. Abuse

can take many different forms and occur in a variety of settings, including at home, in the workplace, and in institutions such as schools or care facilities. Abuse is not limited by factors such as age, gender, or sexuality. The effects of abuse on an individual can be far reaching and devastating. Depending on the type, severity, and duration of the abuse, the impact can be physical, emotional, and psychological.

A victim of abuse may experience physical injuries, such as bruises, broken bones, or internal injuries, and may require medical attention. They may also experience emotional distress, such as fear, anxiety, and shame, and psychological trauma, such as post-traumatic stress disorder or dissociative disorders. Long-term effects of abuse can be even more profound. Victims may struggle with low self-esteem, trust issues, and difficulty forming healthy relationships. They may self-blame or feel ashamed to be in the situation. They may also be at higher risk for developing mental health disorders, such as depression, anxiety, or substance misuse. In some cases, the impact of abuse can be so severe that it can lead to suicidal thoughts or behaviors.

It is essential for anyone who has experienced abuse to seek help and support from trained professionals as well as from family and friends to begin the healing process and move forward with their lives. With the right help and support, healing from abuse is possible. In some instances, the perpetrators of abuse, such as financial abuse of elders, sexual abuse, or child abuse, may face legal charges for their actions.

### Physical Abuse

The act of **physical abuse** involves any use of force or violence to cause physical harm, serious injury, or even death, such as hitting, kicking, or choking. Physical abuse may look different across the life span. For instance, there are higher rates of physical abuse reported by pregnant women (Symes, 2011). The rates of physical abuse toward those identifying as female are higher than those identifying as male; however, all genders are at risk (Symes, 2011).

A person who experiences physical abuse may have visible wounds, bruising, or unexplained injuries (Washington State Department of Social and Health Services, n.d.). Nurses should assess patients to identify signs of physical abuse, such as unexplained injuries or bruising. The patient may keep bruised areas covered or have inconsistent stories or explanations regarding how injuries occurred. Often abusers will purposely use force on bodily areas that can be covered with clothing to prevent any questions from being asked (Washington State Department of Social and Health Services, n.d.). However, the nurse should not assume a lack of an apparent wound means the patient is not a victim of abuse. Other signs of physical abuse may include social isolation and withdrawal by the victim. The nurse may suspect abuse if any of these signs are present, especially if the patient seems fearful in the presence of their abuser.

Most facilities have requirements to assess all patients for safety. If a nurse suspects someone is being abused, they can ask the patient if they feel safe at home. It is important to ensure the patient is alone when initiating any conversation about abuse to prevent angering the abuser. The victim of abuse may be too frightened to talk to anyone, so ensure there is a follow-up assessment in place. A nurse who suspects abuse should inform their supervisor and the attending provider and follow protocol to assess the patient and preserve any and all evidence for potential legal proceedings. The nurse must also be aware of reporting requirements in their state or organization, as there may be requirements to contact adult protective services.

### Psychological Abuse

In **psychological abuse**, also referred to as verbal or emotional abuse, words or actions are used to manipulate or control a person's feelings and behavior. This may include name-calling, belittling, or using insults or threats, and it can lead to long-term psychological harm. It may also involve isolating a person from friends and family or controlling their access to resources, such as money or transportation. All genders are susceptible to psychological abuse (Symes, 2011).

Signs of psychological abuse may include being withdrawn or isolated, emotional reactions that are not consistent with the situation, or other behavior outside the norm for that person (Washington State Department of Social and Health Services, n.d.). The patient may also share they are experiencing psychological abuse to trusted friends or caregivers (Washington State Department of Social and Health Services, n.d.).

A nurse who suspects a patient is experiencing psychological abuse should follow similar steps to those for physical abuse. The patient should be given information that may assist them in leaving the abusive situation. Additionally, the nurse should inform the treating provider or supervisor. It is important for patients to know that psychological

abuse is as significant as physical abuse.

### Financial Abuse

In **financial abuse**, a person's financial resources are exploited or misused, often by a trusted individual, such as a family member or caregiver. This type of abuse can take many forms, including theft, fraud, forcing the individual to give away money, or the misuse of financial accounts or assets. The impact of financial abuse on an individual can be severe, as it can leave them financially at-risk and potentially destitute, leading to poverty, debt, or even housing insecurity. Financial abuse can also have a significant impact on a person's mental health and well-being, as it can erode their sense of trust and security as well as their confidence in their own judgment and decision-making abilities.

Spotting financial abuse can be challenging, as it often occurs behind closed doors. Some signs that financial abuse may be occurring include sudden changes in a person's financial situation, such as unexplained bank withdrawals or transfers, missing funds or assets, or unpaid bills. Other red flags may include a caregiver who seems overly interested in a person's finances, refuses to let the person make their own financial decisions, or insists on managing all financial matters without input from the person. If a nurse suspects someone is experiencing financial abuse, seek support from trained professionals, such as social workers or elder abuse advocates, to protect the person and help them regain control over their finances.

### Sexual Abuse

Any unwanted sexual behavior such as touching, groping, or rape is considered **sexual abuse** and is a violation of a person's bodily autonomy and consent. It can occur within relationships, in the workplace, or in institutions, such as schools or care facilities. Victims of sexual abuse often experience long-term psychological and emotional trauma as well as physical injuries. Sexual abuse is a criminal act in most countries and can result in serious legal consequences for the perpetrator.

Signs of sexual abuse may be physical or psychological. Physical signs of sexual abuse can include bruises around the breasts or genital area, unexplained sexually transmitted disease, genital infections, or unexplained vaginal or anal bleeding (Washington State Department of Social and Health Services, n.d.). Psychological signs may include depression, anxiety, anger, or in the case of a child or adolescent, "acting-out" behaviors. The patient may also report they have been sexually abused. If a nurse suspects sexual abuse, follow state and facility guidelines regarding reporting. Sexual abuse may require police reports, so it is essential to be aware of legally required steps nurses must take.

### Substance Misuse

Substances such as drugs, alcohol, and tobacco are increasingly prevalent in many communities and can have serious consequences for health and safety. Drugs, both legal and illegal, can impair an individual's ability to make safe decisions (National Institute on Drug Abuse, n.d.). While there are variations by state, in 2022 there were 287 arrests per 100,000 citizens for driving while impaired (SafeHome, 2022). Similarly, alcohol use can impair an individual's ability to make safe decisions and result in serious health problems (Davis-Stober, 2019).

The consumption of excessive alcohol is associated with liver disease, while the excessive use of cannabis may elevate the risk of experiencing depression and anxiety. Despite the adverse effects of substance use on health, if someone chooses to use substances, it is crucial to prioritize safety. Key considerations include refraining from using substances when alone, ensuring the absence of flammable objects during use, and carrying drugs like Naloxone to address potential drug overdoses. Substance abuse heightens the risk of suffocation, primarily due to the suppression of the respiratory system by the ingested drug. Therefore, promoting safe substance use practices is imperative to mitigate the potential harm associated with these substances.

### Family Violence

A form of abuse that occurs within a family or intimate relationship is called **family violence**, also known as **domestic violence**. It can take many forms, including physical, psychological, sexual, and financial abuse. Anyone can be at risk of family violence, regardless of their gender, age, or socioeconomic status. However, women and children are disproportionately affected, with women being the most common victims of intimate partner violence (Huecker et al., 2023). Family violence is cyclic, meaning that children exposed to violence in the home may themselves go on to demonstrate violence toward others. Early intervention can disrupt this cycle by focusing on

healing the victims through therapeutic interventions.

Identifying family violence can be challenging, as it often occurs behind closed doors. Some signs that family violence is occurring include unexplained injuries or bruises, isolation from family and friends, changes in behavior or personality, or a partner who tries to control or dominate their partner's thoughts or actions. Remember that family violence is never the victim's fault, and there are resources available to help those who are experiencing abuse. If a nurse suspects that a patient is experiencing family violence, seek help from trained professionals, such as domestic violence advocates or social workers, to ensure the patient's safety and well-being.

### Intimate Partner Violence

In **intimate partner violence (IPV)**, there is physical or sexual violence, stalking, and psychological or coercive aggression by current or former intimate partners (Figure 9.6). Intimate partner violence is widespread in the United States and is the most prevalent adult safety issue. Victims can be female or male, and sexual orientation can be heterosexual or lesbian, gay, bisexual, transgender, queer/questioning, intersex, asexual, or others (LGBTQIA+). The nurse is often the initial healthcare professional in contact with a victim of IPV. Prompt recognition of a potential or actual threat to patient and staff safety is crucial. It is often the nurse's assessment that plays an important role in identifying a patient experiencing IPV. Compassion and understanding are important to show to this at-risk population. Effective communication is necessary to help victims come forward and share their experiences of abuse. IPV is a complex issue, and the victim may not initially consider leaving the abuser as an option.

**FIGURE 9.6** Women are more likely to experience intimate partner violence and suffer greater consequences as a result. (credit: "Fast Facts: Preventing Intimate Partner Violence," by Centers for Disease Control and Prevention, Public Domain)

### LINK TO LEARNING

The [Danger Assessment tool \(https://openstax.org/r/77dangertool\)](https://openstax.org/r/77dangertool) is a self-administered survey that is free to use and available in several languages (Campbell, 2004). Nurses can refer patients experiencing IPV to the National Center on Domestic Violence, Trauma, and Mental Health for resources, and the National Domestic Violence Hotline for free and confidential support (National Center on Domestic Violence, n.d.).

### Child Abuse

Any form of physical, emotional, or sexual harm or neglect inflicted upon a child is **child abuse**. It can take many forms, including physical abuse (such as hitting or kicking), emotional abuse (such as verbal threats or manipulation), sexual abuse (such as inappropriate touching or sexual exploitation), and neglect (such as failing to provide for a child's basic needs, such as food, shelter, or medical care) (CDC, 2021b). Children of all ages and backgrounds can be at risk of abuse, but those who are at-risk due to factors such as poverty, disability, or family dysfunction may be at increased risk (CDC, 2021b). Identifying child abuse can be challenging, as children may be reluctant or unable to report abuse, and abusers may go to great lengths to hide their actions.

Some signs that a child may be experiencing abuse include unexplained injuries, changes in behavior or mood, reluctance to go home or spend time with a certain caregiver, or sudden changes in academic or social performance (CDC, 2021b). It is important to remember that child abuse is a crime and should be reported to authorities immediately if suspected. In the event of a child facing abuse, it is crucial to intervene to safeguard their well-being and ensure their safety. This may involve reporting the abuse to Child Protective Services, providing the child with

access to medical or mental health care, or working with law enforcement to hold the abuser accountable. It is also important to provide the child with emotional support and connect them with resources such as counseling or support groups to help them heal from the trauma of abuse.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Patient-Centered Care: As Related to Abuse

**Definition:** Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for the patient's preferences, values, and needs.

**Knowledge:** Demonstrate comprehensive understanding of the concepts of pain and suffering, including physiological and psychological models of pain and comfort.

**Skill:** The QSEN initiative emphasizes the importance of providing safe and effective care to patients, including those who are at risk for abuse. One way nurses can promote clinical safety and apply QSEN principles related to abuse is by using screening tools to identify patients who may be experiencing abuse. For example, a nurse working in an emergency department might use a screening tool like the ICAST data tools to assess for possible child abuse (ISPCAN, n.d.). Nurses can also apply QSEN principles related to abuse by helping to promote clinical safety and improve the quality of care for patients who are at risk for abuse.

---

### Elder Abuse

A form of mistreatment of an older adult is **elder abuse**. In most reported cases of elder abuse, a caregiver or a person in a trusted relationship is the perpetrator. For various reasons such as fear and disappointment, most of these cases go unreported. Abuse, including neglect and exploitation, is experienced by about one in ten people aged 60 years and older who live at home. From 2002 to 2016, more than 643,000 older adults were treated in the emergency department for nonfatal assaults, and over 19,000 homicides occurred (CDC, 2021a).

## LINK TO LEARNING

---

Older patients may be targets for financial exploitation. The [National Adult Protective Services Association \(NAPSA\)](https://openstax.org/r/77NAPSA) (<https://openstax.org/r/77NAPSA>) provides information about adult protective services and getting help in specific geographic regions.

---

Most victims of elder abuse are seen in the emergency department several times before they are admitted to the hospital. Nurses must be alert to any indications of elder abuse, such as suspicious injuries or behaviors, and report suspected incidents to local adult protective services agencies. Common signs of elder abuse or maltreatment include (Hartford Institute for Geriatric Nursing, n.d.):

- bruises, cuts, burns, or broken bones that are unexplainable or suspiciously explained
- malnourishment or weight loss
- poor hygiene, an unkempt appearance, unclean clothing, or dirty, matted hair
- foul odor from clothing or body
- anxiety, depression, or confusion
- unexplained transactions or loss of money
- withdrawal from family members or friends

### Social Violence

The intentional use of force or power to harm individuals or groups within a community is referred to as **social violence**, also known as **community violence** (National Institute of Justice, 2021b). This can take many forms, including gang violence, hate crimes, and mass shootings. Those who are at risk of social violence may include individuals who belong to marginalized communities, such as communities of color, the LGBTQIA+ community, or those experiencing housing insecurity or living in poverty (National Institute of Justice, 2021b).

Identifying social violence can be challenging, as it often occurs suddenly and unpredictably. Some signs that social violence may be imminent include threats or acts of violence, the presence of weapons or other dangerous objects, or social media posts or other communications that indicate an intent to harm. If a nurse suspects that someone may be at risk of social violence, it is important to take action to protect them. This may involve contacting law enforcement or other authorities, encouraging the person to seek shelter or other forms of protection, or providing them with emotional support.

Addressing social violence requires a multifaceted approach that addresses the root causes of violence and promotes community safety and well-being. This may involve investing in programs that provide education, job training, and other opportunities to help individuals in at-risk communities to build better lives. It may also involve promoting policies that reduce access to weapons and other dangerous objects as well as addressing issues such as poverty, discrimination, and inequality that can contribute to social violence. Finally, it is important to provide support and resources to those who have been impacted by social violence, including counseling, mental health care, and other forms of support to help them heal from the trauma of violence.

### Bullying

The term **bullying** can be defined as physical or emotional acts, such as hitting or making harmful comments, toward another person. Bullying can also involve excluding the victim from activities. Bullying is a pervasive issue that can have serious consequences for both the victim and the perpetrator. Those who are at risk of bullying include individuals who are perceived as different or vulnerable, such as individuals with a higher weight, with disabilities, or from underrepresented groups. Bullying can take many forms, including physical aggression, verbal taunts, and exclusion from social groups, and it can have a profound impact on an individual's mental and physical health. Bullying has been linked to a range of health risks, including depression, anxiety, substance abuse, and even suicide. Bullying has an impact on everyone involved, including witnesses and the person who is doing the bullying. When it occurs during childhood, it can have devastating effects and is considered an adverse childhood experience, which is a potentially traumatic event with lasting impacts through adulthood (stopbullying.gov, 2020).

Technology has added a new layer of complexity to bullying, and individuals of all ages may be the victims of **cyberbullying**, a form of bullying that occurs via social media, texting, or emails. The type of bullying that takes place face-to-face can also occur virtually, generally targeting the victim by posting photos, videos, or information intended to cause emotional harm.

It is important to identify bullying early. Signs that an individual may be experiencing bullying include unexplained injuries, changes in behavior or mood, reluctance to go to school or work, or difficulty sleeping or eating. It is also important to be aware of signs that an individual may be bullying others, such as aggression or a lack of empathy for others. If bullying is suspected, it is important to take action to address the issue.

Nurses play a pivotal role in addressing and preventing bullying within healthcare settings. A primary responsibility is advocating for a healthy work environment that prioritizes respect, collaboration, and support. Encouraging open communication, nurses foster an atmosphere where patients and colleagues feel safe reporting incidents without fear. Serving as role models, nurses should exhibit respectful and collaborative behavior, setting a positive example for their peers and other members of the healthcare team. Additionally, nurses can provide emotional support and assistance to individuals who are targets of bullying, guiding them through the reporting process and connecting them with available resources.

School nurses play a pivotal role in addressing bullying within the school environment. In addition to actively promoting awareness and education about bullying, they serve as a trusted resource for students, providing a safe space for discussions related to bullying concerns. The nurse is instrumental in prevention efforts by collaborating with school staff to implement antibullying programs. When incidents occur, the nurse supports both victims and perpetrators, offering guidance and collaborating with other staff members for targeted interventions. Their regular interactions with students enable them to identify potential signs of bullying, and they collaborate with parents and guardians to ensure a coordinated approach in addressing and preventing bullying.

### Incivility

Rude or disrespectful behavior that can have a negative impact on individuals or groups is known as **incivility** (Porath & Pearson, 2013). It can take many forms, including name-calling, shouting, interrupting, and making derogatory comments. Incivility can occur in any setting, including workplaces, schools, and public spaces, and it

can have a profound impact on the mental and emotional well-being of those who are affected.

There are several types of incivility, including verbal, behavioral, and environmental. Verbal incivility involves the use of disrespectful or derogatory language, while behavioral incivility may include actions such as ignoring or excluding others or making inappropriate physical contact. Environmental incivility involves creating a hostile or unpleasant atmosphere, such as by playing loud music or using offensive scents (Cortina et al., 2008).

Anyone can be at risk of experiencing incivility, but some groups may be particularly at risk. These groups may include individuals who belong to marginalized groups, such as women, people of color, and members of the LGBTQIA+ community, as well as those who work in high-stress or high-pressure environments. It is important to identify and address incivility early to prevent it from escalating into more serious forms of aggression or violence (Porath & Pearson, 2013). This may involve promoting a culture of respect and civility in all settings, providing education and resources to help individuals recognize and prevent incivility, and holding those who engage in uncivil behavior accountable for their actions.

### Workplace Violence

Any act of aggression or violence that occurs in the workplace, including physical assault, verbal abuse, threats, and harassment, is referred to as **workplace violence** (Lamborghini et al., 2020). Workplace violence can have serious consequences for employees, including physical injuries, psychological trauma, and decreased job satisfaction. Healthcare workers face a particularly high risk of workplace violence due to the nature of their work. This may include physical assaults, verbal abuse, and even sexual harassment from patients or their family members (Yusoff et al., 2023).

To identify workplace violence, it is important to be aware of the warning signs. These may include increased tension or hostility, threats or aggressive behavior, and a history of violent incidents. It is also important to create a culture of respect and zero tolerance for violence in the workplace and to provide education and training to employees on how to prevent and respond to workplace violence. Employers should have clear policies in place for reporting incidents of violence and providing support to employees who have been affected. This may include strategies such as de-escalation techniques, training in self-defense, and the use of panic buttons or other safety devices.

### Horizontal Violence

A form of workplace aggression called **horizontal violence** (also called lateral violence) occurs between colleagues who are at the same level of authority or hierarchy within an organization. This type of violence can take many forms, including verbal abuse, undermining, sabotage, and exclusion. Horizontal violence can have serious consequences for the workplace, including decreased job satisfaction, increased staff turnover, and decreased patient safety. Anyone can be at risk of horizontal violence, but it is particularly prevalent in high-stress work environments such as health care. A review of the literature on horizontal violence in nursing found that 87 percent of nurses included in the studies reported experiencing horizontal violence (Zhang et al., 2022).

To identify horizontal violence, it is important to be aware of the warning signs, which may include frequent conflict between colleagues, gossiping and spreading rumors, and frequent complaints about a colleague's work performance. It is also important to create a culture of respect and zero tolerance for violence in the workplace and to provide education and training to employees on how to prevent and respond to horizontal violence. Employers should have clear policies in place for reporting incidents of violence and providing support to employees who have been affected, including access to counseling and mediation services. Addressing horizontal violence requires a collective effort from all staff, management, and administration to promote a positive work culture that prioritizes open communication, respect, and teamwork.

Researchers have identified a specific category of lateral violence that can occur between or among members of historically marginalized groups (Gaia & Hayes, 2018; Robinson 2018). These behaviors can include gossiping, bullying, or undermining, and the practice can be difficult to identify or address because it occurs within a community and may be seen as isolated or expected. However, like other types of lateral violence, this type can have significant impact on a person's mental health and well being.

### Client-on-Worker Violence

The most common type of workplace violence in healthcare settings is violence perpetrated against healthcare

workers by clients, patients, or others receiving services or support, including patient family members. Research indicates that this type of violence occurs most frequently in emergency or psychiatric/mental health settings, but is not limited to those. It may occur suddenly on only one occasion, or may be committed as a part of a pattern. Violence by patients can be especially problematic when it is trivialized, or considered unimportant, unpreventable, or expected. Nurses, administrators, and others may feel that enduring violence is "part of the job," and reports or prevention may not be taken seriously.

Preventing client-on-worker violence usually involves extensive procedures and training. Nurses can look for patterns and behaviors, such as agitation, raised voices, drug-seeking behavior, and a sense of either victimization or entitlement. While violence can occur in any setting, those that completely isolate the nurse and patient, such as a room out of eyesight and earshot of anyone else, may pose greater risk. Nurses working in tandem with other professionals can also prevent or somewhat mitigate occurrences of violence.

### Hate Crimes

Criminal offenses called **hate crimes** are motivated by prejudice or bias against an individual or group based on their race, ethnicity, religion, sexual orientation, gender identity, or other characteristics (Levin & Nolan, 2019). Hate crimes can take many forms, including physical assault, verbal harassment, property damage, or even murder (Federal Bureau of Investigation, 2020). Anyone who belongs to a group that is historically marginalized or discriminated against can be at risk of being the target of a hate crime.

It is important to be aware of the signs of hate crimes, such as the use of hate speech, symbols of hate, or a pattern of similar incidents in the area. If a nurse witnesses a hate crime or suspects that one has occurred, the nurse should report it to the appropriate authorities, such as the police or a community organization that supports victims of hate crimes (McDevitt & Levin, 2021). To prevent hate crimes from occurring in the first place, it is essential to promote education and awareness about the harmful effects of prejudice and discrimination and to foster a culture of inclusion and respect for diversity.

### Human Trafficking

The crime of **human trafficking** involves the exploitation of individuals for forced labor or commercial sex (United Nations Office on Drugs and Crime, 2020). Anyone can be a victim of human trafficking, regardless of age, gender, or nationality. However, some groups are at higher risk, including women and children, those living in poverty, migrants, and those with a history of abuse or trauma (International Labour Organization, 2022). Identifying victims of human trafficking can be challenging, as they may be kept in isolation, have limited contact with others, or be forced to deny their situation.

Signs that someone may be a victim of human trafficking include being forced to work excessively long hours, living in overcrowded or unsafe conditions, showing signs of physical abuse or malnourishment, and being unable to move freely or leave their place of work or residence (Hodge & Lietz, 2018; Piscitelli & Pienaar, 2019). Tattoos can also serve as potential indicators of human trafficking. Traffickers may brand or tattoo their victims with symbols, numbers, or names as a form of control and marking ownership. Symbols can vary widely and may include barcodes, dollar signs, or specific words, reflecting the trafficker's tactics and the type of exploitation involved, such as forced labor or sex trafficking (National Association of Pediatric Nurse Practitioners Partners for Vulnerable Youth, n.d.) ([Figure 9.7](#)). Identification of these tattoos is complex, as victims may conceal them due to fear of reprisals. Awareness about the potential connection between certain tattoos and human trafficking is crucial for recognizing and aiding victims.

**FIGURE 9.7** A barcode tattoo may be a warning sign of human trafficking, symbolizing ownership and control exerted by traffickers over their victims. (credit: "Neck barcode tattoo.jpg" by The finished Tattoo/Wikimedia Commons, CC BY 2.0)

Intervening in cases of human trafficking is crucial to prevent further harm to victims. Many victims are forced to remain in their situation because they do not have a way out. If a nurse suspects someone is a victim of human trafficking, it is important to contact law enforcement or a local anti-trafficking organization. In some cases, it may be necessary to involve a professional interpreter, as victims may not speak the local language or be hesitant to share their experiences.

## PATIENT CONVERSATIONS

Having Difficult Conversations Regarding Intimate Partner Violence and Human Trafficking

**Scenario:** This scenario involves a nurse initiating a conversation with a patient they suspect is the victim of IPV. The nurse demonstrates gentle questioning techniques and supportive listening to help develop trust with the patient.

**Nurse:** Hi, Ruhi, I wanted to ask you a few questions to make sure that you are safe and okay. Have you been feeling okay lately?

**Patient:** Yeah, I'm fine.

**Nurse:** Okay, that's good to hear. I noticed that you have some bruises on your arms and legs. Can you tell me how you got those?

**Patient:** Oh, I just fell.

**Nurse:** Okay, do you feel comfortable telling me a little bit more about what happened? We're here to help you, and we want to make sure that you're safe.

**Patient:** Well, I don't know if I should say anything.

**Nurse:** That's okay. If you don't feel comfortable talking to me, that's all right. But I want you to know that we're here to help you, and we're not going to judge you or get anyone in trouble without your permission. Sometimes, when people are hurt or scared, they need someone to talk to.

**Patient:** Okay, well, my boyfriend gets angry sometimes. He hits me and makes me do sexual things I don't want to do with his friends. He does not allow me to see or talk to my family and friends.

**Nurse:** I'm so sorry to hear that, Ruhi. It sounds like you might be experiencing something called human trafficking and IPV. That's when someone is forced to do things against their will, like work or have sex. It's not your fault, and you're not alone. We can help you get the support you need to stay safe.

**Patient:** Really? You can help me?

**Nurse:** Absolutely. We have a team of people who are specially trained to help people who have been trafficked. We can connect you with resources like counseling, legal help, and safe housing. And we can make sure that you're not in danger while you're here in the hospital.

**Patient:** Thank you so much. I didn't know what to do.

**Nurse:** You're welcome, Ruhi. We're here for you, and we're going to do everything we can to help you.

---

## 9.3 Security: Privacy and Informatics

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify privacy measures when using technology in nursing
- Explain how informatics has enhanced health care
- Describe the vital roles technology plays in patient care

As the use of technology in health care continues to expand, nurses play an increasingly important role in ensuring the security and privacy of patient information. Technology can both assist and potentially cause harm to individuals; it provides access to information while also increases the risk of cyberbullying or other online attacks.

Protecting patient information is a critical responsibility that is not only required by law but is also essential for maintaining the trust of patients and their families. Nurses must be knowledgeable about the risks associated with the use of technology and understand how to prevent and respond to security breaches. Privacy and security in informatics refer to protecting the confidentiality, integrity, and availability of electronic health information. Confidentiality refers to safeguarding health information so that it is not disclosed to unauthorized individuals. Integrity refers to the way data are captured, used, and saved in healthcare settings, and focuses on maintaining the accuracy and completeness of the health information. Nurses must demonstrate integrity when obtaining and using information related to their patients. Availability ensures the information is accessible and usable when needed. Privacy and security are interrelated concepts, and both are necessary for protecting patient information from unauthorized access, use, or disclosure.

Nurses must be aware of the various threats to patient information, including hacking, phishing, and other forms of cyberattacks. They should be knowledgeable about the technical and administrative safeguards used to protect patient information, such as firewalls, access controls, and encryption. Nurses must also be able to recognize potential security breaches and respond appropriately to minimize harm to patients and mitigate risk to the organization. By understanding the importance of privacy and security in informatics, nurses can play a vital role in protecting patient information and maintaining the trust of patients and their families.

### Privacy

In healthcare, **privacy** means that an individual's information is kept confidential; it is only shared with individuals on a need-to-know basis. Privacy is a fundamental right of patients in healthcare, and healthcare workers have a responsibility to protect this right. Patients share sensitive and personal information with healthcare workers to receive care, and it is essential this information is kept confidential (American Nurses Association [ANA], 2015). Healthcare workers must ensure patient information is only shared with authorized individuals on a need-to-know basis, and that appropriate safeguards are in place to prevent unauthorized access, use, or disclosure of patient

information (ANA, 2015). Healthcare workers must also be aware of the legal and ethical implications of privacy breaches and the impact that these breaches can have on patients and their families. By prioritizing privacy in health care, healthcare workers can help to build trust and strengthen the relationship between patients and healthcare providers (ANA, 2015).

### Protected Health Information

Any individually identifiable health information that is transmitted or maintained by a covered entity or business associate is **protected health information (PHI)**. This information includes demographic information (e.g., name, address, birth date), medical histories (including medical record number), test results, and health insurance information. Healthcare workers have a responsibility to ensure the privacy and security of PHI to protect the confidentiality, integrity, and availability of this information. Nurses can ensure they are protecting patients' information by using a password to log into the computer, logging off after each interaction, ensuring no one unauthorized is viewing the computer screen, and taking care when having conversations where patient information may be shared. All PHI is protected under the Health Insurance Portability and Accountability Act (HIPAA) and the Health Information Technology for Economic and Clinical Health (HITECH) Act. Healthcare workers must understand the regulations and policies surrounding PHI, including the minimum necessary standard, which requires healthcare workers to only access and disclose the minimum amount of PHI necessary to perform their job duties. By understanding the importance of protecting PHI, healthcare workers can help to maintain patient trust and promote the safe and effective delivery of healthcare services.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Informatics 1

**Definition:** A nurse's ability to safeguard patient information from unauthorized disclosure or access.

**Knowledge:** This competency involves understanding the legal and ethical principles related to privacy, confidentiality, and security of patient information.

**Skill:** Nurses who are competent in protecting health information:

- are aware of the importance of maintaining the privacy and confidentiality of patient information
- are knowledgeable about the HIPAA regulations that govern the use and disclosure of PHI
- understand the implications of security breaches and the consequences of unauthorized disclosures of patient information

**Attitude:** Protect confidentiality of PHI in electronic health records.

---

### Health Insurance Portability and Accountability Act

The **Health Insurance Portability and Accountability Act (HIPAA)** is a federal law that was enacted in 1996 to protect the privacy and security of patients' health information (U.S. Department of Health and Human Services, 2018). The regulations of HIPAA apply to covered entities, including healthcare providers, health plans, and healthcare clearinghouses, as well as their business associates. The law requires covered entities to implement administrative, physical, and technical safeguards to protect patients' PHI from unauthorized access, use, or disclosure (Figure 9.8). Also, HIPAA gives patients the right to access their PHI, request corrections to their PHI, and receive an accounting of disclosures of their PHI. Healthcare workers must understand and comply with HIPAA regulations and policies to protect the privacy and security of patient information and avoid potential legal and ethical consequences (American Medical Association, 2024; ANA, 2015). Another initiative to help protect PHI has been recommended as a best practice standard from The Joint Commission. This initiative involves the patient assigning a code word upon admission to a hospital. Anytime a loved one or family member calls the facility for an update, the nurse must request they provide the assigned code word in order to receive information about the patient's status. This is just one example of the many ways healthcare facilities are attempting to ensure the privacy of PHI.

Data from Ponemon Institute, 2010 Benchmark Study on Patient Privacy and Data Security

**FIGURE 9.8** Protecting the privacy of patient information is the responsibility of all healthcare providers. Nurses must ensure they take the necessary steps to adequately protect patient's information. (data source: Ponemon Institute, 2010 Benchmark Study on Patient Privacy and Data Security; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

If a patient expresses concerns about information captured using technology in the healthcare setting, a nurse can have a conversation to address their concerns and provide reassurance. The nurse might start by acknowledging the patient's concerns and asking for specific details about what they are worried about. For example, the nurse might ask if the patient is concerned about their PHI being shared with unauthorized individuals or if they are concerned about the security of the facility's technology systems. Once the nurse has a better understanding of the patient's concerns, they can provide information about the facility's policies and procedures for protecting patient privacy and ensuring the security of technology systems. The nurse can explain the measures that are in place to protect patient information, such as using secure networks and encrypting data. They can also discuss the importance of patient privacy and reassure the patient that their information is only accessed on a need-to-know basis. Finally, the nurse can ask the patient if they have any additional questions or concerns and provide resources for the patient to learn more about the facility's technology policies and procedures. This conversation can help the patient feel more comfortable with the use of technology in their care and build trust between the patient and health care.

### Informatics

The definition of **informatics** is the interdisciplinary study of information processing and management, including the use of technology and data analytics to inform decision-making and improve outcomes in various fields, including healthcare. In the nursing profession, nursing informatics integrates nursing science, computer science, and information science to support the delivery of safe, effective, and patient-centered care (ANA, 2015). Nurses who specialize in informatics use their expertise to develop and implement health information technology systems, analyze data to inform quality improvement initiatives, and ensure the privacy and security of PHI (ANA, 2015). Nursing informatics is a growing field that plays an increasingly important role in healthcare delivery, and nurses who are knowledgeable and skilled in informatics are well positioned to help shape the future of health care (ANA, 2015; International Council of Nurses, 2019).

### LINK TO LEARNING

Nursing informatics is a growing area of nursing practice, with many nurses working in informatics roles. Additionally, it is an expectation that all nurses will possess basic knowledge and competencies in nursing informatics. The [Healthcare Information and Management Systems Society website \(https://openstax.org/r/77HIMSS\)](https://openstax.org/r/77HIMSS) has valuable information regarding the role of nurse informaticists as well as the educational requirements.

### Telehealth

In **telehealth**, electronic communication technologies are used to provide remote healthcare services, including consultations, monitoring, and education (ANA, 2020; National Council of State Boards of Nursing [NCSBN], 2020). Nurses play an important role in telehealth delivery by providing triage, assessment, education, and care coordination to patients who are unable or prefer not to access care in person. Nurses who specialize in telehealth

must be knowledgeable about the technology and equipment used as well as the legal and ethical issues related to remote healthcare delivery. They also need to be skilled in communication and patient education to ensure that patients receive safe, effective, and patient-centered care (ANA, 2020; NCSBN, 2020). As the use of telehealth continues to grow, nurses who are proficient in telehealth technologies and practices will be in high demand and play a critical role in expanding access to care and improving patient outcomes (Figure 9.9).

**FIGURE 9.9** Telehealth provides a means of improving access for both patients and providers. (credit: “190605-N-AW702-012,” by Navy Medicine/Flickr, Public Domain)

Telehealth can improve access to health care in rural settings where patients may not have a primary care provider. The use of telehealth applications also means rural residents do not have to take on the expenses of traveling to urban centers for care. During the COVID-19 pandemic, the use of telehealth as a component of care was essential and demonstrated both the benefits and challenges of its use.

## LINK TO LEARNING

Telehealth has been a key part of health care for some time. The COVID-19 pandemic increased the use of telehealth applications and thus the need for information and education of nurses regarding telehealth use. Find [resources to help nurses, providers, and patients prepare for telehealth visits \(https://openstax.org/r/77telhealthHRSA\)](https://openstax.org/r/77telhealthHRSA) at the Health Resources and Services Administration website.

### Health Information Technology for Economic and Clinical Health Act

The **Health Information Technology for Economic and Clinical Health (HITECH) Act** is a federal law that was enacted as part of the American Recovery and Reinvestment Act of 2009. The law was designed to promote the adoption and meaningful use of health information by encouraging the implementation of the electronic health record (EHR), a digital version of a patient’s paper chart that contains their comprehensive health information. The purpose of EHRs is to facilitate the sharing of patient information among healthcare providers, enhancing coordination and continuity of care while promoting efficiency and accuracy in healthcare delivery. The HITECH Act provides financial incentives to eligible healthcare providers and facilities that demonstrate the meaningful use of certified EHR technology as well as provides penalties for those who fail to adopt EHRs and demonstrate meaningful use. The HITECH Act also includes provisions for strengthening the privacy and security of health information, such

as increased penalties for HIPAA violations, and the establishment of the Office of the National Coordinator for Health Information Technology (ONC) to coordinate health information technology efforts at the national level. Overall, the HITECH Act has played a significant role in advancing the adoption and use of health information technology in health care and has helped to improve the quality, safety, and efficiency of healthcare delivery.

### Meaningful Use

An essential component of nursing practice in today's healthcare environment is **meaningful use** of technology, ensuring technology being utilized in healthcare settings is done so purposefully and with the intention of improving outcomes. Nurses use various technologies, such as EHRs mobile devices, telehealth, and clinical decision-support systems (CDSSs), to improve patient care, safety, and outcomes (ANA, 2018). Nurses who understand and use technology effectively can enhance their practice and improve the quality of care they provide (Lee & Mills, 2018). Meaningful use of technology also requires nurses to be knowledgeable about legal and ethical considerations related to technology use, such as data privacy, security, and confidentiality. Nurses must also stay up to date with new technologies and be able to adapt to changes in technology and software applications.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Informatics 2

**Definition:** Use of information and technology to communicate, manage knowledge, mitigate error, and support decision-making.

**Knowledge:** Clinical safety and QSEN procedures related to the use of technology in the healthcare setting are essential to ensure patient safety and improve the quality of care. These procedures include guidelines for the safe and effective use of technology, such as EHRs, medication administration systems, and CDSSs. QSEN procedures emphasize the importance of teamwork and communication among healthcare providers to ensure safe and effective use of technology. This includes involving patients and families in the care process as well as using best practices for documentation, communication, and handoff processes.

**Skills:** QSEN also emphasizes the importance of ongoing education and training for healthcare providers to maintain competency and keep up to date with technological advancements. Clinical safety procedures related to the use of technology include procedures for risk assessment, system analysis, and incident reporting. These procedures are designed to identify potential risks and hazards associated with the use of technology and to develop strategies to prevent and manage adverse events.

**Attitude:** Clinical safety procedures also emphasize the importance of monitoring and evaluation to ensure the effectiveness of interventions and to continuously improve patient safety. By following these procedures, healthcare providers can mitigate potential risks associated with technology and provide safe and effective care to their patients.

---

### Technology's Role in Patient Care

Technology plays an increasingly important role in patient care, and it has revolutionized the way healthcare providers deliver and manage care. From EHRs and telehealth to mobile applications and wearable devices, technology has made it easier for patients to access care and for providers to deliver personalized, timely, and efficient care. For example, EHRs allow providers to access patient information quickly and accurately, reducing the risk of errors and improving patient safety. Telehealth enables patients to receive care remotely, which can be particularly beneficial for those who live in rural or remote areas, have limited mobility, or have chronic conditions. Wearable devices, such as fitness trackers and smartwatches, can monitor patients' vital signs, activity levels, and other health metrics, helping them to manage their health and prevent or manage chronic conditions. Technology's role in patient care will continue to grow and evolve as new innovations such as artificial intelligence emerge, and it has the potential to transform healthcare delivery and improve patient outcomes. Nurses and other healthcare providers must learn and stay updated on any technology being used in their organization. Proper training and proper usage will decrease the risk of user error.

## PATIENT CONVERSATIONS

### Teaching Technology Access

**Scenario:** Mark is a nurse caring for Adnan, a 65-year-old being discharged post myocardial infarction. Mark notices that Adnan is wearing a smartwatch that tracks heart rate and blood pressure.

**Nurse:** I see that you use a smartwatch, do you track health information on this?

**Patient:** Yes, I do, I like to take charge of my health and with my recent health issues would like to find a way to have more control over my healthcare appointments and test results.

**Nurse:** Have you registered for online access to your EHR? Did you know that having access allows you to see your lab results quickly as well as manage your appointments?

**Patient:** No, I was not aware of that; do you have information on how I can set this up?

**Nurse:** Yes, I do, here let me help you. Just so you are aware, all information collected is protected, and only you have access to this. Here is the website to get started.

**Scenario follow-up:** Mark's role is to ensure that Adnan is aware of the access to his own EHR and how he can use this to manage his healthcare results and appointments.

### Documentation

Technological advances have improved connectivity and access to information and resources in healthcare settings. Computers used to access an EHR can be found in patient rooms, on wheeled carts, in workstations, or even on handheld devices. Nurses and other healthcare workers are able to quickly obtain results from point-of-care testing or share images to consult with colleagues ([Figure 9.10](#)).

**FIGURE 9.10** Electronic health records are essential tools in healthcare settings. Nurses play key roles in collecting data and transmitting it to the healthcare team. (credit: "Winn Army Community Hospital Pharmacy Stays Online During Power Outage.jpg," by MC4 Army/Flickr, CC BY 2.0)

## LINK TO LEARNING

---

Nurses have an integral role to play when it comes to the safe use of EHRs. The [ANA statement on EHRs \(https://openstax.org/r/77stateEHRs\)](https://openstax.org/r/77stateEHRs) provides information to nurses to ensure they understand their role and expectations for safe use.

---

### Point-of-Care Testing

In **point-of-care testing (POCT)**, diagnostic testing is performed at or near the patient's bedside, rather than in a centralized laboratory (Bellartz et al., 2022). This approach allows for rapid diagnosis and treatment decisions, which can improve patient outcomes and reduce healthcare costs. In the nursing profession, POCT is becoming increasingly important as it allows nurses to quickly assess and monitor patients as well as to make informed decisions about their care. For example, blood glucose monitoring is a common type of POCT used by nurses to monitor patients with diabetes.

Other types of POCT include tests for infectious diseases, such as influenza and strep throat, and tests for cardiac biomarkers, such as troponin. While POCT can provide many benefits, it is important for nurses to be trained in its use and to follow appropriate quality control measures to ensure accurate results. Additionally, nurses must be knowledgeable about the limitations and potential sources of error associated with POCT.

## PATIENT CONVERSATIONS

---

### Alleviating Patient Concerns When Using Technology

**Scenario:** The nurse walks into the patient's room to complete an assessment, and the patient starts exhibiting signs of fear and anxiety. The patient pulls the covers up to their chest tightly. The patient will not take their eyes off the portable vital sign machine.

**Nurse:** Hi, my name is Sara, and I am going to be your nurse today. Do you mind verifying your name and date of birth for me?

**Patient:** uhm . . . , sure it's Jon Blankenship and 01/12/1952. What are you going to do to me?

**Nurse:** Hi, Mr. Blankenship, I would like to check your vital signs if that is okay.

**Patient:** What does that mean? Does it hurt? Just a minute ago, they brought a machine in here and took blood from my finger and it still hurts. They said they were checking my blood sugar levels, but I don't have blood sugar problems or diabetes. I am afraid you all do not know what you are doing, and I want to go home.

**Nurse:** Mr. Blankenship, I can understand your fear. Let me try and explain; we recognize you do not have a history of diabetes. Your provider wants us to monitor your blood sugar levels because the new medication he started you on for your chronic obstructive pulmonary disease can cause blood sugar levels to get extremely high in some patients, and we just want to keep an eye on things for your safety.

**Patient:** Oh, well, that makes sense. Then what is that machine for?

**Nurse:** This is a portable vital sign machine that lets me check your heart rate, blood pressure, and temperature. If all is well, we only need to check your vital signs every 6 hours while you are here. If any of your vital signs change drastically, then we may have to monitor them more frequently. Obtaining vital signs does not hurt, and it will only take a few minutes. May I go ahead and complete them now?

**Patient:** It is okay. You can go ahead but go slow.

**Scenario follow-up:** The nurse collects the patient's pain level, heart rate, respiration rate, blood pressure, and temperature. The nurse uses the bed scale to collect his current weight.

**Nurse:** Okay, I am done; your vital signs are good and are within the range of what we like to see. Do you have any further questions or concerns I can assist you with before I go?

**Patient:** No, I am good for now, thanks.

---

### Assistive Clinical Decision-Making Tools

Assistive clinical decision-making tools are computer-based systems that provide clinicians with decision support for patient care (Pawloski et al., 2019). These tools use algorithms, artificial intelligence, and other technologies to analyze patient data and provide recommendations to the clinician. Examples of assistive clinical decision-making tools include decision-support systems for medication prescribing, clinical practice guidelines, and diagnostic decision-support systems. These tools can improve the accuracy and efficiency of clinical decision-making, reduce the risk of errors, and improve patient outcomes. However, it is important for clinicians to be trained in the use of these tools and to understand their limitations. In addition, these tools should be integrated into clinical workflows in a way that does not disrupt care delivery or create additional burdens for clinicians (Sutton et al., 2020). All healthcare professionals who use these assistive tools must abide by the safety measures used to prevent breaches of confidentiality. Assistive tools might be linked to the internet or to the organizations' wireless network. This means that the tools can be vulnerable to hacking or security breaches if safety protocols are not followed and maintained.

### Technology in Patient Education

Technology can play a vital role in providing and supporting patient education in health care. To provide patients with access to their medical records and educational resources, EHR systems and patient portals are used. These resources can include videos, audio recordings, interactive graphics, and written materials that can help patients better understand their conditions and treatment options. Mobile applications and wearable devices can be used to help patients track their health status, monitor symptoms, and adhere to treatment plans (Buvik et al., 2019; Välimäki et al., 2016). Telehealth and remote monitoring technologies can provide patients with access to healthcare professionals and educational resources in real time. This is particularly important for patients who are unable to attend in-person appointments due to distance, mobility issues, or other barriers (Rickard et al., 2019). Virtual education sessions, webinars, and group discussions can also be held using videoconferencing software to promote patient engagement and collaboration. Technology has the potential to enhance patient education and improve health outcomes by providing patients with timely and accessible educational resources, increasing their engagement in their own care and promoting better communication between patients and healthcare providers. However, it is important to ensure these technologies are accessible to all patients, including those with limited digital literacy, and that they are designed in a way that meets patients' needs and preferences. And, while patients are free to use their personal devices to communicate with their healthcare team, healthcare professionals must always use the device provided by the organization to communicate with their patients. Using personal devices creates a breach in the security and confidentiality of the patients' private health information.

## LIFE-STAGE CONTEXT

---

### Helping with Technology

Older adults may have difficulty using, accessing, and reading from computer devices. It is important to offer information to older adults in many different formats such as handouts or demonstrations or to involve a family member as necessary to ensure the patient receives and understands the required information.

---

## Summary

### 9.1 Safety: Individual and Environmental

Individual safety is an essential component of good health, and it should be prioritized above anything else. There are many aspects for the nurse to consider when maintaining individual safety including understanding a patient's developmental stage of life, physical and psychosocial health risk factors, and any knowledge deficits. Nurses can incorporate Maslow's hierarchy of needs to help prioritize care. Environmental safety is also a major concern. Nurses must educate their patients on topics such as falls, fires, poisoning, suffocation, exposure to substances, and weather-related issues like hypothermia. Occupational safety is needed to prevent or reduce the risk of work-related injuries. Occupational, environmental, and personal safety are all interconnected and must be prioritized to prevent accidents, injuries, and illnesses.

Safety measures must also be taken regarding the nurse themselves. Creating a just culture is one way to help reduce errors such as near misses and never events. Just culture allows nurses to learn from their mistakes and the mistakes of others without the fear of judgment. Just culture also allows the organization to see why a mistake happened and how to best keep it from happening again.

Nurses play an important role in educating patients, families, and communities regarding safety concerns but should consider any SDOH when planning education. Nurses assess and address patient safety risks related to each individual situation. There are many populations that experience increased prevalence and burden of diseases. These populations are more at risk because of the lack of access to quality health care. This is defined as SDOH. The SDOH include a person's lack of access to sufficient water, shelter, food, support, and financial resources. Many groups of people experience health disparities related to age, gender, ethnicity, socioeconomic status, and mental health. Nurses must be mindful of each individual's unique situation and plan care accordingly to help minimize any risk to safety.

### 9.2 Safety: Violence

There are many different forms of abuse that can occur across the life span. The nurse needs to have a thorough understanding of different types of abuse to effectively plan care for their patients. Recognizing cues associated with physical, psychological, financial, and substance abuse is one way the nurse can make informed clinical decisions. For example, if a nurse was to notice bruising or other markings on a patient consistent with physical abuse, they would report these findings immediately per the facility's protocol. Family violence is also a concern for the nurse when making clinical decisions. Family violence includes intimate partner, child, and elder abuse. Sometimes the nurse is the first person to discover this form of abuse, whether it be in a primary care office, hospital, or community resource location. Nurses must perform comprehensive assessments to properly recognize signs, plan appropriate interventions, and provide the patient with resources.

Social violence can take place in many different forms and settings. A few examples include bullying, incivility, workplace violence, and human trafficking. Nurses need to address social violence from a multifaceted approach. This means identifying the root cause to promote safety and well-being of the person and community. Nurses can advocate by promoting policies that reduce access to weapons and other dangerous objects as well as addressing issues such as poverty, discrimination, and inequality that can contribute to social violence. After discovery of an act of social violence, nurses can provide support and resources to those who have been impacted. Examples of such resources to help patients heal from the trauma of violence include counseling and mental health care.

While it may seem as though bullying, other forms of social violence, and workplace violence are outside the role of the nurse, nurses do work in schools and in communities and can be a vital link to help those who are suffering. Nurses have a vital role in assessing for and intervening in circumstances of violence that require assessment and intervention from a nursing perspective. Nurses can do this in a way that is supportive of the needs and wishes of the victims of violence.

### 9.3 Security: Privacy and Informatics

While technology has enhanced nursing practice and healthcare delivery, it has also presented some challenges. The introduction of technology has led to the need for increased attention to privacy and the protection of patients' personal health information. Nurses must ensure patient information is protected, and thus, they play a vital role in

the use of healthcare technology. The introduction of technological advancements, such as EHRs, has made it easier for healthcare providers to share accurate patient information with one another. Patient access to EHRs has increased the ability for patients to take accountability for their own health care by accessing lab results and managing their appointments. Technologies related to patient care have evolved, making care safer and more efficient. Nurses have and will continue to have a key role in this, evidenced by the emergence of nursing informatics as both a specialty and expected competency for all nurses. Artificial intelligence and similar new technologies challenge nurses to adapt their practice while continuing to meet expected requirements related to protection of information and privacy.

## Key Terms

**abuse** physical, emotional, verbal, or sexual acts toward another which can cause harm

**bullying** physical or emotional acts, such as hitting or making harmful comments, toward another person

**child abuse** any form of physical, emotional, or sexual harm or neglect inflicted upon a child; can take many forms, including physical abuse, emotional abuse, sexual abuse, and neglect

**culture of safety** culture characterized by open communication, collaboration, and continuous improvement, with a focus on reducing errors, adverse events, and harm

**cyberbullying** a form of bullying that occurs via social media, texting, or emails

**elder abuse** all direct actions and neglectful actions by a caregiver that cause harm or risk of harm to an older adult

**environmental safety** practices and measures taken to protect and preserve the natural environment, ecosystems, and human health from potential hazards and harmful impacts to health

**ergonomics** the design and arrangement of workspaces, tools, equipment, and tasks to optimize comfort, efficiency, and safety for employees

**family violence (also known as domestic violence)** a form of abuse that occurs within a family or intimate relationship; can take many forms, including physical, psychological, sexual, and financial abuse

**financial abuse** the exploitation or misuse of a person's financial resources, often by a trusted individual, such as a family member or caregiver

**hate crimes** criminal offenses motivated by prejudice or bias against an individual or group based on their race, ethnicity, religion, sexual orientation, gender identity, or other characteristics

**Health Information Technology for Economic and Clinical Health (HITECH) Act** a federal law that was enacted as part of the American Recovery and Reinvestment Act of 2009; designed to promote the adoption of electronic health records (EHRs)

**Health Insurance Portability and Accountability Act (HIPAA)** a federal law that was enacted in 1996 to protect the privacy and security of patients' health information

**health knowledge deficit** lack of information or understanding regarding health-related topics that can impact an individual's ability to make informed decisions about their health and well-being

**healthcare disparity** differences in access to health care and insurance coverage

**horizontal violence** (also called lateral violence) a form of workplace aggression that occurs between colleagues who are at the same level of authority or hierarchy within an organization

**human factors** the interrelationships among humans, the tools and equipment they use in the workplace, and the environment in which they work

**human trafficking** a crime that involves the exploitation of individuals for forced labor or commercial sex

**incivility** rude or disrespectful behavior that can have a negative impact on individuals or groups

**individual safety** the state of being free from physical or psychological harm

**informatics** the interdisciplinary study of information processing and management, including the use of technology and data analytics to inform decision-making and improve outcomes in various fields, including health care

**intimate partner violence (IPV)** physical or sexual violence, stalking, and psychological or coercive aggression by current or former intimate partners

**just culture** an organizational principle that fosters open and honest reporting of errors and balanced accountability and encourages systemic examination to prevent errors in the future

**lateral violence** when members of a group who have been historically oppressed or marginalized, such as communities of color, Indigenous peoples, or women, engage in harmful behaviors toward one another

**meaningful use** ensuring technology being utilized in healthcare settings is done so purposefully and with the intention of improving outcomes

**modifiable risk factor** a factor that others may influence; a factor that can be altered or controlled by an individual or society

**National Patient Safety Goals** goals and recommendations tailored to seven different types of healthcare agencies based on patient safety data from experts and stakeholders

**near event** warning signal of potential hazard or incident that may cause harm to patients

**near miss** error that has the potential to cause harm but is identified before it happens

**never event** an adverse event that is clearly identifiable, measurable, serious (resulting in death or significant disability), and preventable

**nonmodifiable risk factor** a factor that cannot be influenced; a factor that cannot be controlled or altered by an individual or society

**occupational safety** the practice of protecting workers from injury, particularly those who work in high-risk industries such as health care

**personal safety** the act of keeping oneself free from injury

**physical abuse** any use of force or violence to cause physical harm, serious injury, or even death

**point-of-care testing (POCT)** diagnostic testing that is performed at or near the patient's bedside, rather than in a centralized laboratory

**privacy** in healthcare, an individual's information is kept confidential and only shared with people who need to know; a fundamental right of patients, and healthcare workers have a responsibility to protect this right

**protected health information (PHI)** any individually identifiable health information that is transmitted or maintained by a covered entity or business associate, including demographic information (e.g., name, address, birth date), medical histories (including medical record number), test results, and health insurance information

**psychological abuse** also referred to as verbal or emotional abuse; involves the use of words or actions to manipulate or control a person's feelings and behavior

**psychosocial health** the psychological and social aspects of an individual's overall health and well-being

**root cause analysis** a structured process to determine factors that underlie errors and adverse events

**sentinel event** an unexpected occurrence involving death or serious physiological or psychological injury, or the risk thereof; like a never event but is not necessarily preventable

**sexual abuse** any unwanted sexual behavior such as touching, groping, or rape; is a violation of a person's bodily autonomy and consent

**social violence (also known as community violence)** the intentional use of force or power to harm individuals or groups within a community

**teach-back method** a way for healthcare providers to present information to patients clearly and determine the patients' understanding of the information; the goal is to make sure patients and their families have received and understood important healthcare information

**telehealth** the use of electronic communication technologies to provide remote healthcare services, including consultations, monitoring, and education

**workplace violence** any act of aggression or violence that occurs in the workplace, including physical assault, verbal abuse, threats, and harassment

## Assessments

### Review Questions

1. What factor is considered a nonmodifiable risk?
  - a. smoking
  - b. age
  - c. riding a motorcycle without a helmet
  - d. diet
  
2. The nurse is educating a patient on how to take and record their blood pressure at home. The nurse explains the newly prescribed medication requires daily monitoring of blood pressure readings. The nurse explains monitoring the blood pressure before taking each dose will reduce the risk of a medication error, which can cause a safety risk. Which nursing action can ensure the patient is fully informed and engaged related to

- taking a proactive approach in their healthcare needs?
- Use teach-back method to confirm patient understanding.
  - Provide the patient with a list of other treatment options to discuss with the provider.
  - Encourage the patient to make decisions based on their personal values and preferences.
  - Assume decision-making responsibilities on behalf of the patient.
3. What nursing action should be taken first to facilitate collaboration with other healthcare professionals, such as providers and pharmacists, to address safety concerns and ensure coordinated care for individual patients?
- Conduct monthly interdisciplinary meetings to discuss patients' care.
  - Share information and updates on patient condition and treatment plan with the family members.
  - Make a decision on your own regarding medication management.
  - Establish a clear communication plan for patient care handoffs.
4. Mr. Jahn recently had knee replacement surgery and is ready to be discharged home from the hospital with his wife. He has completed physical therapy and is considered stable to independently walk but must remain cautious of his surroundings. When considering the patient's risk for falls at home, Mr. Jahn and his wife should be educated to make what adjustment to their home environment?
- Remove all throw rugs from areas frequently walked.
  - Maintain home thermostat at a comfortable temperature.
  - Keep all overhead lights on brightest settings twenty-four hours a day.
  - Position bed at lowest level.
5. A nurse is working in a busy hospital with a high patient load. She notices that her workplace environment poses several safety risks that could endanger both patients and staff members. The nurse is concerned about the risks and wants to take action to address the situation. What should the nurse do to address the workplace safety risks?
- Report the safety risks to their immediate supervisor or manager.
  - Ignore the safety risks and focus solely on patient care.
  - Confront the staff members responsible for creating the safety risks.
  - Wait for someone else to address the safety risks.
6. A nurse is caring for a child who has signs of physical and emotional abuse. What should the nurse do to ensure the safety and well-being of the child?
- Report the signs of abuse to the appropriate authorities.
  - Ignore the signs of abuse and focus on providing medical care.
  - Confront the child's family members about the abuse.
  - Discharge the child and refer them to another healthcare facility.
7. A nurse is caring for a patient who discloses they are experiencing family violence. What nursing action would not support the patient and promote their safety?
- Provide a safe environment for the patient to further disclose their experience.
  - Conduct a thorough assessment to identify potential safety risks and resources.
  - Report the patient's accusations to other members of the family.
  - Provide emotional support and connect the patient with community resources.
8. A nurse is caring for a patient who is a victim of IPV. The patient has indicated they do not wish to address the violence in their relationship. What should the nurse do to ensure the patient's safety and well-being?
- Provide the patient with information about community resources and support groups.
  - Develop a safety plan with the patient to minimize the risk of further abuse.
  - Encourage the patient to stay in the abusive relationship to prevent further harm.
  - Ignore the signs of abuse and focus on providing medical intervention.

9. A nurse is working in a community clinic and suspects a child may be experiencing abuse based on the child's physical presentation and behavior. What immediate nursing action should the nurse take to ensure the child's safety and well-being?
  - a. Document the observations in the child's medical record.
  - b. Report the suspected abuse to the appropriate authorities.
  - c. Provide emotional support and connect the child with community resources.
  - d. Conduct a thorough assessment of the home to gather additional information about the child's situation.
  
10. Nurses incorporate telehealth in patient care plans. What service would not be representative of this technological advance?
  - a. diagnostic testing
  - b. easy access to specialists
  - c. health and fitness apps
  - d. early warning and detection technologies
  
11. A nurse looks up information for her patient using an app and reviews notes from the patient's previous admission. The nurse is specifically looking for any reactions to a particular antibiotic. What term describes the nurse's actions?
  - a. meaningful use
  - b. privacy
  - c. confidentiality
  - d. point-of-care testing
  
12. What patient action describes the vital role technology plays in patient care?
  - a. visiting a sick friend in the hospital
  - b. looking up recent lab test results in the patient portal
  - c. calling the provider's office and asking for a medication refill
  - d. carrying paper records from provider to provider

### Check Your Understanding Questions

1. Describe how a nurse assesses the fall risk of a patient.
2. How can the social determinants of health impact a patient's safety?
3. Describe how a school nurse supports a child who reports they are being bullied in the school.
4. Describe the steps a nurse should take if they are aware of a new nurse colleague experiencing horizontal violence in the work setting.
5. What should a nurse do if they overheard a patient's PHI being discussed in a public area?
6. What should a nurse do if they received a phone call from a family member asking for an update on their loved one's condition?
7. What considerations must be in place to manage emerging technologies, such as artificial intelligence?

### Reflection Questions

1. What information would the nurse need to gather if they suspected a patient was the victim of IPV?
2. A nurse is completing an assessment on a patient who is a victim of assault. The patient does not wish to have the police called or to press charges. How should the nurse respond?
3. How does a nurse ensure patient privacy and confidentiality when using technology in the clinical setting?
4. How does a nurse ensure that they are using technology appropriately and ethically in their clinical practice?
5. What do you see as the nurses' role in the development or implementation of technology in healthcare?

settings?

## Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #2: Part 3](#).

What interventions could the nurse implement if it was determined that the patient was experiencing visual impairments?

## What Should the Nurse Do?

Ms. Garcia is a 45-year-old female who has been struggling with housing insecurity and substance use disorder. She has been experiencing housing insecurity for several months, and her addiction to opioids has been worsening. Ms. Garcia has been coming to the clinic regularly for treatment of her substance use disorder, but she has not been able to find stable housing. During her most recent visit to the clinic, the nurse is tasked with assessing her risk for harm related to her unstable living situation. The nurse begins by conducting a thorough assessment of Ms. Garcia's health status and current living situation.

1. What questions should the nurse ask Ms. Garcia to determine any individual risks she may have?
2. From the case scenario, what is the most pressing concern for Ms. Garcia?

## Competency-Based Assessments

1. Use the internet to find information to define nursing informatics and explain how informatics has enhanced health care.
2. Write a paragraph describing how technology can enhance nursing practice.

## CHAPTER 10

# Infection Control and Prevention

**FIGURE 10.1** Handwashing is the single most important technique to stop the spread of infection. (credit: “20120106-OC-AMW-0074” by Flickr/USDA, Public Domain)

### CHAPTER OUTLINE

- 10.1 Infection Cycle
- 10.2 Asepsis and PPE
- 10.3 Sterile Technique
- 10.4 Infection Control and Patient Safety

**INTRODUCTION** Nurses are responsible for consistently providing patient care that adheres to current evidence-based practices and meets professional standards and guidelines. There are effective scientific and practical control methods to prevent the development of infection and the transmission of diseases in a healthcare setting. Nurses provide healing care to patients of all ages and stages of life. While they are able to foster the emotional aspects of healing, clinical safety must be at the forefront of decisions to make sure both patients and healthcare providers remain safe. While it is widely understood that practices such as handwashing and covering a sneeze are important in everyday life, nurses hold a deeper responsibility to prevent and control infection against the most dangerous infectious agents.

## 10.1 Infection Cycle

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the infection cycle
- Identify the different stages of infection
- Explain the two responses the body has as defense mechanisms against infection

Nurses are on the front lines of **infection control**, which is the discipline of stopping or preventing the spread of infectious agents, and play an essential role in the prevention of infectious diseases. It is crucial for nurses to understand how infectious diseases spread to ensure vigilance and perform proactive initiatives to prevent and control infections. Microorganisms play a major role in the transmission of diseases. By understanding the conditions that foster the spread of infection, nurses can implement evidence-based interventions to break the cycle and stop the chain of infection. The process of infection control includes handwashing, environmental sanitizing, proper waste management, and adherence to isolation precautions. The main goal of infection prevention for nurses is to prevent the transmission of diseases. Nurses must understand how infections occur and how infection-prevention protocols work to prevent such infections. In doing so, they will ultimately protect themselves and their patients against exposure to infectious agents. Such knowledge includes an understanding of the infection cycle, how and why infections manifest, use of personal protective equipment (PPE) and sterile technique, and the most effective ways to control infections. While proper handwashing is a critical component of infection prevention, there are a number of other ways that nurses can stem the spread of infection and protect themselves and their patients.

An infection that has developed within a healthcare setting is called a **healthcare-associated infection (HAI)**. HAIs can develop from contact within the healthcare setting or as a result of healthcare interventions that take place outside of a healthcare setting. HAIs can spread rapidly and are a serious threat to nurses, patients, families, and the overall hospital system. Patients who develop any infection are at risk for prolonged hospital stays, long-term complications, and/or death, but HAIs are specifically dangerous as they are typically resistant to bacterial treatment and spread rapidly to often immunocompromised hospitalized patients. In the 2021 National and State Healthcare-Associated Infections Progress Report, the Centers for Disease Control and Prevention (CDC) found that each day approximately one in thirty-one U.S. hospital patients will contract an infection associated with their health care (CDC, 2022).

### UNFOLDING CASE STUDY

#### Unfolding Case Study #2: Part 5

Refer back to [Chapter 8 Admission, Transfer, and Discharge](#) and [Chapter 9 Safety and Security](#) for Unfolding Case Study Parts 1–4 to review the patient data. A 65-year-old patient who presented to the emergency department with chest pain and shortness of breath was diagnosed with a myocardial infarction and treated successfully with placement of two coronary artery stents. The patient has been staying on the cardiology unit for post-procedure observation for the last three days. In the last two hours, the patient has developed a cough and reports shortness of breath.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, coronary artery disease</p> <p><b>Family history:</b> Mother deceased, father alive with severe dementia; two healthy sons in their early 40s</p> <p><b>Social history:</b> Previous divorce, married to current husband, George, for twenty years</p> <p><b>Allergies:</b> Latex</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Aspirin 81 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Lisinopril 10 mg PO once daily</li> <li>• Atorvastatin 30 mg PO once daily</li> </ul>
Flow Chart	<p><b>Post Procedure Day 3</b></p> <p><b>2000: Assessment</b></p> <p>Blood pressure: 136/81 mm Hg</p> <p>Heart rate: 110 beats/minute</p> <p>Respiratory rate: 26 breaths/min</p> <p>Temperature: 100.6°F (38.1°C)</p> <p>Oxygen saturation: 88 percent on room air</p>
Nursing Notes	<p><b>2100: Assessment</b></p> <p>Patient reported increased shortness of breath. Crackles noted in base of right lung. Patient experiencing dyspnea and anxiety. Productive cough with yellow sputum noted.</p>

1. Recognize cues: What cues should the nurse recognize as most concerning?
2. Analyze cues: Based on the recognized cues, what do you think is going on with the patient?

## The Infection Cycle

In order for an infection to spread from one individual to another and cause disease, six specific phases must occur. This process is known as the **chain of infection**, and it only results in infection if all six links of the chain are present and intact (Figure 10.2). The six links are a causative agent, a source, a means of exit from the body, a method of spread, a way into the body, and a susceptible host. This chain can occur from a direct transmission between a current and future host or through a more complex pathway where transmission results from multiple intermediate hosts. If, at any time, one of the links breaks, the spread of the infection will halt. In order to break the chain, it is important for nurses to understand how the sequence and function of each link in the chain operates.

**FIGURE 10.2** Each of the stages within the chain of infection represents a requisite condition necessary for the spread of infectious diseases. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Causative Agent: Microorganisms

Single-celled, microscopic organisms called microorganisms are too small to be seen by the naked eye. Their presence as the “causative agent” is the first step in the chain of infection. The term microorganism encompasses

different life-forms with individual and unique sizes and characteristics. The most common types of microorganisms are bacteria, viruses, and fungi. They are found in all elements of life, including water, soil, air, and the human body. Not all microorganisms that live on the human body cause negative outcomes, and certain bacteria are beneficial to human health and well-being. Still, certain microorganisms can cause severe infection, spoil food, and destroy other materials.

### Normal Flora

The community of microorganisms that can live on another living organism or inanimate object without causing any diseases or complications is called **normal flora**. From the moment of birth, humans are colonized with normal flora by passage through the birth canal. This normal flora helps to prevent individuals from becoming colonized with more dangerous bacteria, which could result in infection. There are two groups of normal flora.

- Resident flora is predominantly present in a particular area of the body and cannot typically be removed with standard hand hygiene. When disturbed, it re-establishes itself harmlessly in deep layers of skin.
- Transient flora includes microorganisms that are acquired by contact with objects or another person. These microbes can be nonpathogenic or pathogenic. Handwashing is effective in removing these microbes.

### Infectious Agent

A **pathogen** is defined as any type of microorganism that causes disease to its host. Pathogens are also referred to as infectious agents, because they cause infections within the body. Pathogens are comprised of viruses, bacteria, fungi, protozoa, worms, or prions. Temperature, moisture, pH levels, oxygen, and access to water are all factors that contribute to a pathogen's ability to grow.

Bacteria are single-celled organisms that can live in or on people's bodies. Certain bacteria are beneficial to humans and can help digest food or enhance the immune system. However, when bacteria cause an infection, antibiotics can be used to either kill the bacteria or prevent their multiplication. Viruses, by contrast, do not have cells of their own; they are built from short sequences of either DNA or RNA that are required for the virus to reproduce. Viruses invade healthy cells that they establish as a host and then begin to multiply from within those cells. Their mode of replication occurs as a burst of thousands of particles from a single virus over a short period of time. Outside of a healthy host cell, viruses are dormant and unable to reproduce due to a lack of materials. Antibiotics do not work to kill viruses, but antivirals may be available to lessen the severity of symptoms. Treatments such as antipyretics, throat lozenges, and saline spray can be provided to support symptom management and support the patient's immune system as they work to fight an active infection. Vaccinations are an excellent example of a tool available to help prepare the immune system to recognize and fight a viral infection by providing passive immunity.

Normal flora can become a pathogen if it presents itself in a region of the body where it is not typically found. For example, multiple bacteria found in the bowels are harmless within that environment, but they can cause an infection if present in the urinary tract. The body's extreme response to widespread infection, called **sepsis**, is the outcome of an inappropriate immune response to an infection that results in function failure in multiple organ systems within the body. Severe complications to organs may occur if untreated, which can ultimately lead to death.

### Reservoir

All infectious disease agents require a host species to flourish. The **reservoir** is the habitat or source of the pathogen. The reservoir can be viewed as the pathogen's home, providing a place for the pathogen to survive, grow, and multiply. Most pathogens thrive within a warm, moist, and dark environment. This is why the human body is the most common reservoir for pathogens. Additionally, animals, insects, food, water, and environmental surfaces can all be reservoirs for pathogens.

Human reservoirs may or may not show signs and symptoms of infection or illness. A carrier is a person who does not display any signs of infection but can still transmit the pathogen to other people. An asymptomatic carrier may have the pathogen, but do not display any symptoms. Many times, they do not know they have the pathogen and unintentionally contribute to the spread of infection throughout a given population. But pathogens do not only travel from human carriers to other humans. People can also become infected from pathogens that have animal reservoirs. Most of these pathogens are transmitted between animals, but a human may become an accidental host. The term **zoonosis** refers to an infectious disease that can naturally transmit from animal to human. Common examples of zoonotic diseases include *Yersinia pestis* from rodents, *Bacillus anthracis* from sheep, ZIKA from mosquitos, and *Flaviviridae* from birds. Environmental matter, such as water and soil, can also act as a reservoir for certain

infectious agents. The agents that cause tetanus (*Clostridium tetani*) and botulism (*Clostridium botulinum*) can survive for years within soil and remain infectious for humans. So, whether a pathogen comes from a human or animal reservoir or from environmental matter, it can still cause disease once it is transmitted.

### Portal of Exit

For an infection to spread, a pathogen must leave its existing reservoir. The **portal of exit** is the path by which the pathogen leaves the reservoir; in the case of humans, the most frequent route is through bodily fluids or coughing/sneezing. The body's natural response is to remove a pathogen and attempt to expel it. The portal of exit usually corresponds to the localized site of the pathogen. Examples of this include the influenza virus, which exits the respiratory tract through coughing and sneezing, or *Clostridioides difficile* in the gastrointestinal tract, which exits through stool. Broken skin—such as wounds, abrasions, bites—can serve as a portal of exit for pathogens through blood and purulent drainage, which is commonly known as pus, and appears as thick white, yellow, or brown fluid. Blood-borne pathogens can transmit from mother to fetus by crossing the placenta.

### Methods of Transmission

The method that a pathogen uses to spread from one host to another is called **transmission**. The most frequent mode of transmission of pathogens is through contact, either direct or indirect (Figure 10.3).

<b>Germ Transmission</b>	<b>Direct</b>	<b>Indirect</b>	<b>Droplet</b>
			
<b>Airborne</b>	<b>Waterborne</b>	<b>Foodborne</b>	<b>Vector-borne</b>
			

**FIGURE 10.3** Germs can be transmitted via multiple routes, which include direct contact, indirect contact, droplets, the air, water, food, and vectors. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

- A process called **direct transmission** occurs when a pathogen transfers directly from an infected person. The pathogen can be passed from person to person through direct transmission. This mode of transmission can occur during any physical contact with a patient, including activities such as bathing, changing dressings, drawing blood, turning, and activities of daily living.
- A process called **indirect transmission** occurs when a pathogen is spread to a new host through an intermediary such as the air, food, water, animals, or objects. Certain pathogens can live only a few minutes outside of a host while others can live for years in the proper environment. Indirect transmission can occur in a hospital from, for example, ineffective hand hygiene, improper cleaning of medical equipment, and failure to change gloves between patients. Other forms of indirect transfer from within a hospital include equipment that is transferred from one patient's room to another, such as medication carts, vitals machines, and glucose monitors. These items require extra care when cleaning.
- A process called **droplet transmission** occurs when a pathogen travels through a spray of water droplets that are released when an infected person coughs, sneezes, or talks. These droplets are typically inhaled through the nose, mouth, or eyes. Due to their larger size ( $> 5 \mu\text{m}$ ), droplets are propelled only a short distance through the air and do not remain suspended, so droplet spread is classified as direct transmission and does not require an intermediary. Examples of diseases that transmit through droplets include influenza, rubella, pertussis, and meningococcal infection.
- A process called **airborne transmission** occurs when pathogens are carried by dust or the nuclei of an evaporated droplet and remain suspended in the air. Because of their small size ( $5 \mu\text{m}$  or smaller), these nuclei can remain suspended in the air for long durations of time, float considerable distances, and potentially infect large groups of people. For instance, SARS-CoV-2 coronavirus transmission can occur in a room in which

an infected person had previously been, because the virus remains suspended in the air. Because airborne transmission occurs through the inhalation of the pathogen by a susceptible host, healthcare facilities need to put into place special air-handling processes, such as negative pressure, to prevent infection.

- A process called **vector transmission** occurs when blood-feeding arthropods infect animals or humans. Examples of blood-feeding arthropods are fleas, ticks, and mosquitos. Commonly known vector-borne diseases include malaria, Lyme disease, and West Nile virus.

### Portal of Entry

The site through which a pathogen enters the susceptible host is called the **portal of entry** (Table 10.1). Commonly, pathogens enter a new host using the same portal of exit utilized to leave the reservoir. For example, if the pathogen is transmitted from the respiratory tract through a sneeze or cough, then the portal of entry would also be the respiratory tract of the new host from inhalation of the droplets or touching a surface contaminated with the droplet and touching a mucous membrane. In healthcare settings, wounds, surgical sites, intravenous access sites, and indwelling catheters can all provide a portal of entry for pathogens.

Portal of Entry	Description
Mucosal	Through the eyes or nose
Respiratory	Through the respiratory tract
Genitourinary	Through the urinary tract
Cutaneous	Through wounds or abrasions
Gastrointestinal	Through the intestinal tract

**TABLE 10.1** Portals of Entry for Infection

### Susceptible Host

The final link in the chain of infection is a **susceptible host**, the organism or person at risk for infection. The degree to which a host is at risk is dependent on their immunity and ability to resist or limit susceptibility. A host may have specific immunity to a particular pathogen through protective antibodies. The antibodies may have developed as a response to a previous infection, toxin, or vaccine. Factors that increase susceptibility include age, chronic illnesses, a compromised immune system, or immune deficiency.

## LIFE-STAGE CONTEXT

### Susceptibility to Infection

Age is a nonmodifiable risk factor. As adults age, their functional immunity declines, which increases their susceptibility to infection. Older adults are more prone to developing an infection due to multiple factors: the immune system no longer functions as optimally or vigorously; they may experience cognitive impairments, which could make them less likely to comply with necessary hygiene practices; and they are more likely to be diagnosed with comorbidities, such as diabetes, heart failure, or renal insufficiency, all of which can affect the body's ability to fight infections.

As individuals age, their lifestyles typically change as well. Nutritional intake can decrease, reducing protein, vitamins, and electrolytes. This can lead to a decrease in body mass, which increases susceptibility to infections.

The National Institute on Aging recommends vaccination as the number one way to prevent infections in an aging population. The Institute also seeks to reduce the number of infections by promoting healthy aging. This entails remaining active and continuing modified physical activity, enjoying proper nutrition, and maintaining regular and routine appointments with health providers (National Institute on Aging, 2022).

## Stages of Infection

All infections progress through a predictable course of four stages (Figure 10.4). Each pathogen can produce distinct and diverse symptoms. An individual's immune response to the pathogen will determine the length and intensity of each stage and account for variability seen between one individual and another.

**FIGURE 10.4** Infections are either localized or systemic, but all infections go through four stages. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Incubation Period

The stage of infection known as the **incubation period** begins once a pathogen successfully enters a new host. During the incubation period, a person does not show signs and symptoms of an infection because there are not enough pathogens to cause symptoms. The person therefore does not suspect they have been infected. One example is the common cold. The patient feels healthy for one to three days, but then starts to demonstrate symptoms of illness once the level of pathogen has increased in their system. Despite being asymptomatic those first few days, pathogens are continually multiplying and can still be spread to other hosts. Because of this, the longer the incubation period is, the more likely a person is to be unknowingly spreading infection to other people. The incubation period can vary in time from as little as one day, as with the influenza virus, to two to three months, as with the hepatitis B virus. It can even last years, as with the human immunodeficiency virus.

### Prodromal Stage

The stage of infection called the **prodromal period** begins at the initial appearance of mild or vague symptoms. These symptoms arise as a result of activation of the immune system and typically present as fever, pain, soreness, or inflammation. Symptoms at this stage are often too general to indicate a specific disease. Referring to the patient exposed to the common cold, after one to three days of feeling healthy, they may then have symptoms such as a headache, scratchy throat, and watery eyes. Though present, these symptoms are nonspecific and could be associated with a variety of other illnesses. This stage can vary in its duration, but it is typically shorter than the incubation period.

### Illness

The **illness period** stage of infection begins when a person experiences the specific signs and symptoms of a certain disease. This period represents the peak of the infection, and it is during this time that a person is highly contagious. In this stage, our patient who was exposed to the common cold will start to show specific symptoms such as mild

hacking cough, sneezing, achy muscles and bones, and low grade fever. If the individual's immune system (with or without medical intervention) is able to combat the pathogens, a period of decline in the pathogens begins. The infection begins to weaken, and symptoms decrease.

### Convalescent Period

The final stage of infection is the **convalescent period**. This is the stage where recovery and healing begin. Closing out our example of the patient who has the common cold, the patient's symptoms will fade, and the patient will report feeling back to baseline. During this time, a person is gradually able to return to their normal functions; some infections, however, can result in permanent damage from which the body is unable to repair and recover.

### Body's Natural Defense Mechanism Against Infection

The human body's immune system provides a mechanism for staying healthy through protection against harmful pathogens. An immune response can be classified as either nonspecific, meaning it targets pathogens in a nonspecific, less effective manner, or specific, which allows for a high level of adaptation and effectiveness. Nonspecific immunity includes physical, chemical, and cellular defenses that are classified as either primary or secondary. Secondary defenses are broken down further into inflammatory and immune responses. Specific defense would be antibodies from the immune system targeting a specific antigen that they are designed to identify and destroy.

#### Primary Defenses

Primary defense barriers prevent pathogens from entering the body through structural barriers, destroy them once they have entered the body, or flush them out of the body (Table 10.2). These barriers are not triggered as a response to pathogens but instead serve as a continuous first line of defense against infection.

Defense	Description
Skin	The skin provides a highly effective physical barrier to infection. The top layer of skin, the epidermis, is made up of cells containing keratin, which makes the skin surface mechanically tough. If skin integrity is compromised due to injury, such as abrasions, cuts, incisions, or burns, the barrier is breached, which creates a portal of entry.
Mucous membranes	The mucous membranes that line the nose, mouth, lungs, and digestive and urinary tracts are coated with secretions that aid in fighting against potential pathogens. The nares, trachea, and bronchi are coated with mucous membranes that trap pathogens. Coughing and sneezing allow pathogens to be forcibly expelled from the body.
Stomach	The acidic environment of the stomach destroys pathogens that enter the digestive tract. Normal peristalsis—the muscles moving food through the digestive tract—as well as vomiting and diarrhea work to remove pathogens that enter the tract. Additionally, the natural flora of the body, specifically in the gastrointestinal system, serves as a defense mechanism.
Eyelashes and eyelids	These structures provide a physical and mechanical barrier from dust and airborne microorganisms through blinking; tears wash away organisms.
Cilia	Housed in the nares, cilia move a layer of mucus that covers the airways. This mucus traps pathogens, preventing them from reaching the lungs.

**TABLE 10.2** Primary Defense Barriers to Infection

#### Inflammatory Response

Pathogens that are not stopped by primary mechanisms and are able to enter the body trigger a second set of defenses. Nonspecific, innate immune responses work to recognize and eliminate pathogens.

One of the first responses that occurs when a pathogen breaches the nonspecific innate immune system is an **inflammatory response**. This response can entail an area of the body by swelling, turning red, feeling hot, having

pain, or losing function. Although inflammation is often perceived as a negative consequence that results from injury, it actually establishes a physical barrier against infection. The process of inflammation aids in the recruitment of cellular defenses, which remove pathogens and damaged cells while initiating repair mechanisms.

The process of inflammation is triggered when damaged cells release histamines and other chemicals. The rise in histamines increases the permeability of the blood vessels, which results in additional blood flow to the area. This additional blood flow manifests as localized warmth and redness. Because the blood vessels are more permeable, fluid leaks from them and accumulates in surrounding tissue, resulting in swelling at the site. The swelling places pressure on nerve endings, resulting in pain.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Recognize Cues: Assessment of Inflammatory Response

The cognitive skill of recognizing cues requires the nurse to collect patient data from health assessments, the environment, and health records, and identify abnormal findings.

A nurse assessing a patient who has a suspected infection will consider findings related to an inflammatory process, such as increased body temperature, heat at the site, redness, or swelling. Additional assessment data gathered should include physical history, degree of pain, loss of function, and lab levels that indicate infection, such as an increased white blood cell count.

A **fever** can be one of the body's responses to pathogens that cause inflammation; it is defined as a rise in core body temperature and is a component of the inflammatory response extended past the localized site. A low-grade fever is a natural immune response and defense mechanism; many providers will not initiate pharmacological interventions until it rises above 102°F (38.9°C). After all, a fever enhances the nonspecific immune defenses by stimulating an increase in white blood cells (WBCs). WBCs are produced in the bone marrow and are an essential part of the immune system as their function is to find, fight, and destroy infection within the body. If WBCs are elevated, this can indicate an immune response from the body and demonstrate actively fighting a disease. The rise in temperature can also prevent the growth of many pathogens and can trigger specific immune responses.

#### Immune Response

In contrast to a nonspecific immune response, specific acquired immunity occurs when an individual's immune system acquires antibodies from a different source. In other words, this type of immunity provides a targeted response to a specific pathogen and can be acquired either actively or passively. The main function of the immune system is to recognize self from nonself and initiate a response accordingly. An **antigen** is anything the immune system recognizes as a foreign object or substance and subsequently initiates formation of antibodies. Immunoglobulins, or **antibody**, are proteins created in the body in response to an antigen in order to fight the identified substance or toxin.

When a pathogen enters the body and **active immunity** occurs, antibodies form to help protect the body from that pathogen. In subsequent invasions from that same pathogen, the body is able to respond rapidly to the antigen. Active immunity can be acquired through infection, such as with chicken pox, or artificially, through immunizations. The result of antibodies being passed from one person to another is **passive immunity**. This can occur naturally through the placenta or breastfeeding, or it can occur artificially through injections of serums or blood products that contain antibodies.

### LINK TO LEARNING

As part of its mission to promote health and prevent disease, the CDC publishes [written recommendations for vaccinating U.S. children and adults \(https://Openstax.org/r/77recvaccine\)](https://Openstax.org/r/77recvaccine).

## 10.2 Asepsis and PPE

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the two types of asepsis
- Recognize the negative implications healthcare-associated infections have on healing
- Correlate appropriate personal protective equipment with their necessary uses

Nurses in all roles are in a unique position to create a safe patient care environment. From bedside nurses to executives, fostering safe healthcare environments can prevent the transfer of pathogens and the spread of infection. With evidence-based practices, nurses can facilitate a patient's plan of care and recovery while minimizing risks and complications related to infections. Proper use of infection-control measures can directly affect patient morbidity and mortality.

### Asepsis

The state of being free from disease-causing contaminant is referred to as **asepsis**. These contaminants include bacteria, viruses, fungi, and parasites. The term *asepsis* can also refer to the process of preventing infection by minimizing the number of contaminants present and decreasing the ability to transport pathogens. The two types of asepsis include medical and surgical (Table 10.3). Furthermore, medical asepsis has three degrees: sanitization, antisepsis, and disinfection. An example of sanitization is physically removing microorganisms by cleaning linen. An example of antisepsis would be preoperative skin cleansing. Disinfection kills microorganisms on objects such as tables or blood pressure cuffs that come into contact with the patient or patients. This process utilizes strong chemicals called disinfectants, which should not be used on skin.

Medical Asepsis	Surgical Asepsis
Referred to as “clean technique”	Referred to as “sterile technique”
Reduces number of pathogens	Eliminates all pathogens
Used in administering: <ul style="list-style-type: none"> <li>• Medications</li> <li>• Enemas</li> <li>• Tube feedings</li> <li>• Daily hygiene</li> </ul>	Used when performing: <ul style="list-style-type: none"> <li>• Dressing changes</li> <li>• Catheterizations</li> <li>• Surgical procedures</li> </ul>

TABLE 10.3 Types of Asepsis

#### Medical Asepsis

The techniques and procedures used to decrease the potential for the spread of microorganisms and infection is called **medical asepsis**. Medical asepsis is also referred to as “clean technique” in the healthcare environment because it is a standard practice used to avoid spreading infection from one person to another throughout a facility. The core practices of medical asepsis include hand hygiene, environmental cleanliness, and the use of protective equipment and isolation.

#### Surgical Asepsis

The absence of all microorganisms within any type of invasive procedure is called **surgical asepsis**. Maintaining surgical asepsis requires the use of sterile technique, a set of specific practices and procedures that are performed to make an environment and equipment in that environment free of all microorganisms. Principles of sterile technique help control and prevent infection. Sterile technique is discussed in depth in [10.3 Sterile Technique](#).

#### Hand Hygiene

The term hand hygiene refers to the act of handwashing, hand rubbing (using alcohol-based hand sanitizer), or surgical hand antisepsis. Hand hygiene is regarded as one of the most important elements in the prevention and control of infections. Hand hygiene that is timely and effective protects patients, healthcare workers, and the

healthcare environment from the spread of infection. Hand hygiene should be performed when arriving and leaving a patient care unit, before direct contact with a patient, before and after removing gloves, after contact with patient's skin, and when hands are visibly dirty or soiled with blood or bodily fluids. Healthcare providers may be required to wash their hands as many as 100 times in a twelve-hour shift, depending on the number and acuity of patients.

## LINK TO LEARNING

The World Health Organization has created [the Five Moments of Hand Hygiene \(https://Openstax.org/r/775momenthand\)](https://Openstax.org/r/775momenthand) to help healthcare workers improve understanding of hand hygiene and the five moments when it is required.

Cleaning hands using an alcohol-based sanitizer is an effective form of hand hygiene if the hands are not visibly soiled. The advantages of alcohol-based hand hygiene are that it takes only twenty to thirty seconds, can be completed directly at the point of care, and does not require a sink, water, or towel. Alcohol-based hand sanitizers can kill most pathogens. Keep in mind, however, that certain bacteria are not removed by hand sanitizers. These bacteria are only removed by handwashing. One example of bacteria that is only removed with soap and water is *Clostridioides difficile* (*C. diff*). Nurses who take care of patients with *C. diff* or other stubborn bacteria will usually be told before they commence care. When these instances occur, the nurse will know to avoid the hand sanitizer and choose to wash their hands with soap and water instead. When in doubt, washing your hands is the best choice.

Washing hands with soap and water is recommended if the hands are visibly dirty, soiled, or are contaminated with blood or other bodily fluids. It is essential to spend the proper amount of time on handwashing; washing hands for at least thirty seconds removes up to ten times the number of bacteria as does washing for fifteen seconds.

## PATIENT CONVERSATIONS

### Understanding When to Use Soap and Water for Hand Hygiene

**Scenario:** The nurse is entering a patient's room to complete q4h vital signs. This patient is currently positive for *Clostridioides difficile*. After donning personal protective equipment, the nurse enters the room.

**Nurse:** Hi, Ms. Lee, it's your nurse Bryan. I'm here to get your vital signs. Let me wash my hands, and we will get started. How are you feeling?

**Patient:** I'm doing okay, I suppose. I'm not in any pain right now, so that's good news.

**Nurse:** That's excellent. Let me just put on a pair of gloves, so I can verify your name on your wristband. Can you tell me your name, date of birth, and if you have any allergies?

**Patient:** Yang Lee, 03/27/1942. I'm allergic to iodine. Why did you wash your hands when you came in here when there's hand sanitizer over by the door?

**Nurse:** Performing proper hand hygiene is a critical component of preventing the spread of infections, especially in the hospital. Alcohol-based hand sanitizers are a great method for cleaning your hands, but there are times when it is not effective.

**Patient:** Is getting my vital signs one of those times?

**Nurse:** The stool sample that was sent to the lab on Monday came back positive for a bacteria called *Clostridioides difficile*, or *C. diff*. Alcohol alone cannot kill *C. diff* spores, and studies have shown soap and water to be much more effective at removing them. In order to prevent the spread of infection, you'll notice that all of the healthcare workers will be washing their hands with soap and water when they enter and exit your room.

**Patient:** So, should I wash my hands too?

**Nurse:** Since you already have *C. diff*, you cannot infect or re-infect yourself. However, washing your hands will prevent you from getting bacteria such as *C. diff* in the future. Additionally, washing your hands will help prevent

spread to others inside and outside of the hospital. Nurses always wash our hands frequently because it washes away all kinds of bacteria. It really is the best way to prevent spreading bacteria.

**Patient:** That makes sense. I wouldn't want anyone else to get sick from what I have. Thank you for being so careful.

---

## Healthcare-Associated Infections

Healthcare-associated infections (HAIs), also known as nosocomial infections, are infections acquired while receiving medical treatment in a healthcare facility. Although preventable, HAIs are some of the most common complications for patients within a healthcare setting and can prolong hospital stays and recovery time. According to the CDC, one in every twenty-five hospitalized patients will contract an HAI (CDC, 2022). The most common HAIs are associated with invasive devices such as catheter-associated urinary tract infections (CAUTIs), central line-associated bloodstream infections (CLABSIs), ventilator-associated pneumonia (VAP), and surgical site infections (SSIs).

The risk for developing an HAI is dependent on the infection-control policies within a facility and the degree of adherence to them. Additional risk factors include a patient's immune status, age, underlying comorbidities, and the prevalence of pathogens within the environment. Length of hospitalization, number of invasive procedures, and amount of antibiotic therapy received all increase a patient's risk for acquiring an HAI.

### LINK TO LEARNING

The Global Alliance for Infections in Surgery has outlined [seven strategies to prevent healthcare-associated infections \(https://Openstax.org/r/77previnfect\)](https://Openstax.org/r/77previnfect) in the healthcare setting.

---

## Preventing Healthcare-Associated Infections

Nurses are at the front line for preventing the transmission of pathogens through infection-control policies and procedures. These evidence-based prevention strategies and control practices can directly reduce HAIs. Appropriate hand hygiene and glove usage heavily contributes to an increase in patient safety and the prevention of HAIs. Keeping a healthcare environment clean by disinfecting equipment between patients is an additional vital prevention measure. Additionally, the use of proper personal protective equipment can prevent the transmission of pathogens. Nurses must stay current with how to protect themselves from newly identified pathogens and adhere to the protocols put in place. In recent history, viruses such as Ebola and the coronavirus that caused the COVID-19 pandemic all required specific infection-control measures. Healthcare providers were and still are on the front lines in these instances and must also educate the public and their patients about necessary protocols.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety: Preventing HAIs

**Definition:** Quality and Safety Education for Nurses (QSEN) competencies were designed to emphasize key elements that pre-licensure nursing students should be competent in at the time of graduation. Safety is defined as minimizing risk of harm to patients through both systems effectiveness and individual performance.

**Knowledge:** Students will examine human factors and other basic safety design principles as well as commonly used unsafe practices, using evidence-based sources to enhance knowledge.

**Skills:** Students will demonstrate effective use of strategies to reduce risk of harm to self or others.

**Attitudes:** Students will value their own role in preventing errors and reducing the spread of infections.

**Clinical scenario:** A new nurse is working on a medical-surgical unit. Bedside shift report is beginning, and the nurse notices a sign on one patient's door stating that the patient is on airborne precautions. The box of masks located outside the patient's room is empty.

**Step 1:** The nurse uses *knowledge* to recognize that the patient's condition warrants airborne precautions and that

masks are the first line of defense for reducing the spread of airborne pathogens. The nurse uses knowledge of evidence-based sources to confirm that entering the room without a mask would place themselves and other patients on the unit at risk for exposure to the identified pathogen.

**Step 2:** The nurse identifies the *skill* of replacing the empty box before anyone can enter the room as an effective use of infection-control strategies to reduce risk of harm to self or others.

**Step 3:** The nurse stops and replaces the supplies outside the patient's room before continuing with the morning report. The nurse can now begin the shift with a positive *attitude*, knowing value is placed on their role in reducing the spread of infection and providing quality, competent nursing care.

---

### Reporting Healthcare-Associated Infections

As part of its mission in healthcare safety, the CDC has developed the National Healthcare Safety Network (NHSN), the nation's most widely used system for tracking and surveillance of HAIs (CDC, 2022). More than 38,000 healthcare facilities provide data to the NHSN, which are, in turn, used for analysis and development of prevention initiatives by states, regions, and national public health agencies. These agencies include acute care/critical access hospitals, long-term care facilities, ambulatory surgery centers, long-term acute care facilities, inpatient psychiatric facilities, inpatient rehabilitation facilities, and dialysis facilities. The report provides data on CLABSIs, CAUTIs, ventilator-associated events (VAEs), SSIs, methicillin-resistant *Staphylococcus aureus* (MRSA) bloodstream events, and *C. diff* events. Federal government bodies such as the Centers for Medicare and Medicaid Services (CMS) use these data to determine performance incentives. Community members can use this information to select the healthcare facilities that they feel best fits their needs.

### Personal Protective Equipment

Healthcare workers use **personal protective equipment (PPE)** as a means of barrier protection for their eyes, nose, mouth, and skin from exposure to blood and other potentially infectious bodily fluids and materials. The most commonly worn PPE includes gloves, gowns, face masks, protective eyewear, and face shields. These barriers are used in both standard precautions as well as in transmission-based precautions. Every nurse must be knowledgeable about the appropriate PPE to wear in various situations. Simply wearing all available PPE is not appropriate practice and is wasteful considering healthcare resources.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Take Action: Initiating the Use of Additional Personal Protective Equipment

This scenario requires a nurse to take action to prevent infection from spreading. A nurse is reviewing a patient's morning laboratory results. The nurse notes that the patient's stool culture has come back positive for vancomycin-resistant *Enterococci* (VRE). Knowing the method of transmission of VRE (contaminated equipment, surfaces, hands), the nurse analyzes these data and prioritizes how they will be incorporated into the patient's care. The nurse knows that additional interventions will need to be implemented.

The nurse hangs a contact isolation sign on the door and places a PPE cart next to the room. The cart contains masks, gloves, face shields, hand sanitizer, and disinfectants, among other PPE items. When the nurse enters the patient's room, they don the appropriate PPE per facility policy. They also provide the patient with education regarding why they will be seeing staff wearing additional PPE.

### Gloves

The use of gloves in the healthcare setting prevents contamination of the hands and reduces the likelihood of the transmission of pathogens (Figure 10.5). Medical gloves should be worn when providing care to protect the healthcare provider as well as the patient. Further, sterile gloves should be worn for procedures that pose greater risk of contamination to the patient, which are indicated as sterile procedures. Gloves are only effective in infection prevention if they are used properly, and the wearer performs proper hand hygiene before and after wear. Gloves should be removed and hand hygiene should occur once contact with blood or bodily fluids has ended, once contact with a single patient has ended, when leaving a patient's room, and when there is a need for hand hygiene. The same pair of gloves should never be worn more than once.

**FIGURE 10.5** Donning nonsterile gloves in a healthcare setting is one of the most effective ways to prevent infection. (credit: “13550,” by Amanda Mills/Centers for Disease Control and Prevention, Public Domain)

### Gowns

A **medical isolation gown** is a long-sleeved garment that covers the body front and back from the neck to the thighs, overlaps or meets in the back, fastens at the neck and waist, and is easy to put on and take off. They are used in the healthcare setting as a broad barrier against blood or bodily fluids. Gowns are used for patients who are on contact and droplet precautions and for any potentially splash-generating procedures. Medical isolation gowns must be removed before leaving an individual patient area and hand hygiene must occur. A **surgical gown** is worn by healthcare personnel during a surgical procedure to protect both the patient and the personnel from transmission of pathogens. Examples of gowns can be seen in [Figure 10.6](#).

**FIGURE 10.6** Multiple styles of gowns may be available within a healthcare setting. (a) Medical and (b) surgical isolation gowns can be worn with additional forms of PPE such as masks, gloves, goggles, and shoe covers. (credit a: "Call to Service: Army psychologist on the COVID-19 battlefield" by unknown, Public Domain; credit b: "USMC-080618-M-0884D-002.jpg" by Sgt. Rocco DeFilippis, Public Domain)

### Masks

Healthcare workers should wear a mask when caring for a patient on droplet precautions or when providing care to patients who are immunocompromised. A **surgical mask** is worn over the nose and mouth to prevent the transmission of large particle droplet matter generated through coughing or splash-generating procedures. These masks have either ear loops or ties and can be either pleated or made of molded material. An **N95 respirator mask** is a tight-fitting cover that, when properly fitted, protects the wearer from very small particles that float in the air, such as tuberculosis (TB), measles, chickenpox, and COVID-19 ([Figure 10.7](#)). When properly worn, an N95 mask can block at least 95 percent of non-oil-based particles that are 0.3 microns or larger. Any time a mask becomes wet from exhaled moist air, it weakens the integrity of the mask, warranting a mask change.

## Three Key Factors Required for a Respirator to be Effective

① The respirator must be put on correctly and worn during the exposure.

② The respirator must fit snugly against the user's face to ensure that there are no gaps between the user's skin and respirator seal.

③ The respirator filter must capture more than 95 percent of the particles from the air that passes through it.

\*If your respirator has a metal bar or a molded nose cushion, it should rest over the nose and not the chin area.

**FIGURE 10.7** While the N95 respirator can be highly effective at stopping particles from passing through, it must fit tightly on the wearer's face and must be donned and doffed properly in order to provide optimal protection. (credit: modification of "Three Key Factors Required for a Respirator to be Effective" by Centers for Disease Control and Prevention, Public Domain)

### Eyewear and Shields

The use of eyewear and shields form a barrier and protect the membranes of the eyes, nose, and mouth when performing tasks that could produce splashes of bodily fluids or blood. Goggles should fit snugly around the eyes and protective face shields should cover the entire forehead, extend past the chin, and wrap around the sides of the face (Figure 10.8).

(a)

(b)

**FIGURE 10.8** (a) Goggles and (b) face shield add protection for healthcare providers. These can be worn with additional PPE, while considering placement and appropriate use of each item. (credit a: "CCP treats 1st hospitalized, COVID-positive GAFB member" by Senior Airman Abbey Rieves, Public Domain; credit b: "UAMTF 352-1 assists Philadelphia health care workers" by U.S. Army photo by Pfc. Joshua Cowden, 22nd Mobile Public Affairs Detachment, Public Domain)

### Donning PPE

The type of PPE used in a healthcare setting is based on the level of precaution and isolation that is required. The meticulous use of PPE is a vital step to reduce contamination and transfer of infectious diseases. The CDC recommends a standardized procedure for donning, or applying, PPE, but the procedure should always be tailored to the specific type of PPE being used. Prior to donning PPE, always perform hand hygiene. The steps for donning PPE should follow the guidelines outlined by the CDC.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

**QSEN Competency: Donning Personal Protective Equipment, Evidence-Based Practice**

**Definition:** Quality and Safety Education for Nurses (QSEN) competencies were designed to emphasize key elements that pre-licensure nursing students should be competent in at the time of graduation. Employing evidence-based practice means “integrating best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.”

**Clinical scenario:** Here are some evidence-based steps issued by the CDC (n.d.) on donning PPE:

**Step 1:** An isolation gown should be donned first. The gown should be picked up by the shoulders, which allows it to fall open without touching the floor. The gown should be positioned to fully cover the torso (from the neck to the knees) and arms (to wrists), and it should wrap around the back. Fasten the ties at the neck and the waist.

**Step 2:** After securing the gown, don the face mask or N95 mask. Ensure that the ties or elastic band fits at the middle of the head and neck. The mask should be snug to the face and below the chin. N95 masks should be fit checked to ensure proper seal.

**Step 3:** Once the face mask is in place, goggles will be placed over the top of the edge of the mask. A face shield is placed over the eyes.

**Step 4:** The final step for donning PPE is the application of gloves. The glove cuff should extend over the gown cuff. Ensure that the correct size gloves are selected to prevent them from falling off or ripping.

### Doffing and Disposal of PPE

Once patient care is completed, all PPE except for a respirator will be removed, or doffed, prior to exiting a patient’s room. All personal protective equipment (PPE) is discarded in the appropriate receptacle as outlined by facility policy. Following the removal of PPE, perform hand hygiene immediately. The steps for doffing PPE should follow the guidelines outlined by the CDC.

### UNFOLDING CASE STUDY

#### Unfolding Case Study #2: Part 6

Refer back to [Unfolding Case Study #2: Part 5](#) for a review on the patient data.

Flow Chart	<b>Post Procedure Day 3</b> <b>2200: Assessment</b> Blood pressure: 132/79 mm Hg Heart rate: 105 beats/minute Respiratory rate: 22 breaths/min Temperature: 100.6°F (38.1°C) Oxygen saturation: 92 percent on 3 L nasal cannula
Diagnostic Test Results	Chest x-ray: bilateral lung infiltrates present
Provider's Orders	<b>2230: New Orders</b> Collect sputum culture. Administer vancomycin IV 15 mg/kg q8 hours. Titrate supplemental oxygen to maintain saturation > 92 percent. Initiate droplet precautions.

3. Prioritize hypotheses: How do you suspect the patient developed pneumonia while in the hospital?

4. Generate solutions: What is the rationale for each of the provider's orders?

## 10.3 Sterile Technique

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the different levels of clean and how to achieve each
- Recall common methods of sterilization and disinfection in the healthcare setting
- Demonstrate the different principles of sterile technique

Environmental cleanliness is a foundational concept in nursing. Maintaining a clean environment is essential for preventing infectious disease and the spread of HAIs. In the absence of a properly cleaned environment, the acts of handwashing and donning PPE are substantially less effective in the spread of infection and transfer of pathogens. Nurses must recognize which items in the healthcare environment should be cleaned as well as the proper way this cleaning should be done. They must also be able to identify when an item is contaminated and the proper steps that must be taken for disposal or sterilization. Agency policies, along with governmental guidelines, will help nurses seeking specific answers to these questions.

### Levels of Clean

For the chain of infection (see [Figure 10.2](#)) to be broken, it is critical that nurses comprehend the proper knowledge and resources for how to clean their environment. To minimize the risk of transmission of infection, there are three levels of cleanliness, in increasing degrees of purity, that specify how specific objects and items should be cleaned: sanitization, disinfection, or sterilization. The concepts of asepsis discussed in [10.2 Asepsis and PPE](#) provides a strong foundation for the three levels of cleanliness.

#### Sanitization

The removal of visible soil from objects and materials using water with detergents or products that are enzymatically formulated to inhibit microbial growth is called **sanitization**. Sanitization and cleaning coincide with the goal of medical asepsis, which is to keep all employee and patient-care areas free of debris and contamination. All items must first be cleaned before they can be disinfected or sterilized.

#### Disinfection

The process of **disinfection** removes microorganisms and disease-causing pathogens from inanimate objects. This process is completed on both semicritical and noncritical items. Semicritical items include items that have contact with mucous membranes or nonintact skin. Examples of these types of items include reusable devices, such as endoscopes and respiratory therapy equipment. Noncritical items have contact with skin but not mucous

membranes. Because of this, they do not carry a high risk of infection transmission. Examples of these items include stethoscopes, blood pressure cuffs, and bed linens.

### Sterilization

The process of **sterilization** is a procedure that eliminates all microorganisms and spores in or on an object. Critical items require sterilization due to their high risk for infection if they are contaminated. Examples of this include all surgical instruments, catheters, needles, and chest tubes.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Take Action: Use of an Autoclave

A tool that nurses may use in a healthcare setting is an autoclave ([Figure 10.9](#)). Autoclaves use high-pressure steam for a designated amount of time to kill pathogens on objects of various shapes and sizes. Common examples are surgical tools, lab instruments, and pharmaceutical objects. Nurses may have various roles in sterilization dependent upon their healthcare setting. Nurses in an outpatient office setting may be responsible for the entire sterilization process, while in contrast, in a surgical setting there may be technicians who complete this process. Nurses must be aware of their specific responsibility in sterilization and develop those skills accordingly.

**FIGURE 10.9** An autoclave can sterilize reusable instruments. (credit: "Autoclave," by Tom Beatty/Flickr, CC BY 2.0)

## Methods of Sterilization and Disinfection

The process of disinfection is carried out by using chemical disinfectants. While some chemicals may have a broad spectrum of effectiveness, those that have a narrower spectrum are typically easier to use and less toxic. Common chemicals used as disinfectants include alcohol, hydrogen peroxide, and chlorine. Sterilization can be done by both physical and chemical methods, or a combination of both.

### Physical

The process of physical sterilization within a hospital uses large equipment, such as autoclaving with steam. The steam heats up to 250 to 273°F (121 to 134°C) and inactivates all fungi, bacteria, viruses, and bacterial spores. Steam sterilization is the most common form of physical sterilization used in hospitals. Heat can also be used to sterilize by heating, flaming, incineration, boiling in water, and dry heat.

### Chemical

Chemical sterilization uses products, such as ethylene oxide, concentrated bleach, and formaldehyde. This type of sterilization is typically used for instruments, such as those containing rubber, plastic, or glass, that could not tolerate high heat temperatures and/or humidity.

## LINK TO LEARNING

In May 2022, the World Health Organization released a [Global Strategy on Infection Prevention and Control \(https://Openstax.org/r/77globalprevn\)](https://Openstax.org/r/77globalprevn) to promote the prevention of infections in all healthcare settings.

### Principles of Sterile Technique

A **sterile technique** is the use of practices and procedures that inhibit microorganisms in a specific environment and prevent contamination. This technique is an essential element for patient safety, and it is vital that all nurses understand the principles of the skill. Sterile technique is most commonly practiced in operating rooms and during special procedures, diagnostics, and labor and delivery. It is also used at the bedside for sterile procedures, such as the insertion of chest tubes, central venous lines, and indwelling urinary catheters.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

**QSEN Competency: Preparing for Sterile Technique, Evidence-Based Practice**

**Definition:** Quality and Safety Education for Nurses (QSEN) competencies were designed to emphasize key elements that pre-licensure nursing students should be competent in at the time of graduation. Employing evidence-based practice means “integrating best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.”

Sterile technique entails using evidence-based practices and procedures to minimize pathogens and deter contamination in a healthcare environment. Student nurses must know these practices, as recommended by governmental bodies and healthcare-setting policies. Students must demonstrate effective use of sterile technique to reduce risk of harm to self or others.

**Clinical scenario:** Prior to initiating sterile technique, the nurse must take several critical steps to ensure sterility:

**Step 1:** Always perform hand hygiene before initiating any sterile procedure.

**Step 2:** Ensure all working surfaces remain clean and dry.

**Step 3:** Verify you have all supplies that are needed and that they are within the expiration date.

**Step 4:** Keep all supplies in reach to prevent them rubbing against things or dropping.

**Step 5:** Bring a second pair of sterile gloves in the event of a break in sterility.

### Opening a Sterile Package

Remove any paper or plastic layer that is used to form a barrier between the work surface and inner wrapper. Inspect the package to ensure that it is intact and within the expiration date. To open a sterile package, lay it on a clean and dry surface so that the flaps are facing up, and the top flap is pointed down (forming an upside-down triangle like an envelope). The outside of the package is unsterile as is the 1 in (2.5 cm) border of the package.

## LINK TO LEARNING

Proper technique when preparing a sterile field is critical in order to provide safe care to patients during procedure. Lecturio Nursing has put together a [video that describes how to open a sterile kit \(https://Openstax.org/r/77sterilekit\)](https://Openstax.org/r/77sterilekit) that reviews this skill.

### Applying Sterile Gloves

Clean gloves are different from **sterile gloves** because with sterile gloves the sterilization process is completed by the manufacturer; they are free from microorganisms and are individually packaged as a pair to remain free of pathogens. Prior to applying sterile gloves, determine your size. The gloves should fit snugly but not tightly. Place the glove package on a clean and dry surface. Using the outside flaps that form the 1 in (2.5 cm) border, open the glove package so that the cuffs are closest to you. Using your nondominant hand, pick up the opposite glove,

touching only the inner cuff (the part that will touch skin). Keeping the hand flat and the thumb tucked in, slide your dominant hand into the glove, being careful not to lower hands below the waist ([Figure 10.10](#)). Using the gloved hand, slip your fingers into the cuff of the remaining glove. Lift the glove up and away from the table. Slide your nondominant hand into the glove. Keep the gloved thumb up and back to prevent it from touching bare skin. Once both gloves are on, you can adjust to fit fingers as needed. Keep hands above the waist and within the visual field to avoid breaking sterility.

**FIGURE 10.10** Be sure to only touch the cuff of a sterile glove while donning. (credit: “5727” by Kimberly Smith and Christine Ford/Centers for Disease Control and Prevention, Public Domain)

### Preparing and Maintaining a Sterile Field

In order to maintain a sterile field, it is critical to follow several protocols. The nurse must always be able to see the field. This means that if you turn your back and can no longer see the field, sterility is broken. Do not reach over the sterile field; even after donning sterile gloves, your arms and sleeves are not sterile. Be aware of any stethoscopes or bandages that may hang into the field, breaking sterility. Any sterile object that is held below the waist is considered nonsterile, including a sterile-gloved hand. Any objects that become wet are no longer considered sterile due to the ability for bacteria to grow rapidly in a wet environment.

### Pouring Sterile Solutions

Part of a sterile field may include the use of sterile solution. In order to pour a sterile solution, healthcare providers must follow several steps to avoid breaking sterility. Note first that a solution is sealed and unexpired. Sterile solutions should be poured 6 in (15 cm) away from the field into a sterile bowl or tray from the side of the sterile field, not directly over it. Pour solutions slowly to prevent splashing.

### LINK TO LEARNING

As with all aspects of a sterile field [pouring sterile solutions \(https://Openstax.org/r/77poursterile\)](https://Openstax.org/r/77poursterile) should be done following appropriate technique.

## 10.4 Infection Control and Patient Safety

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify how the nurse can promote patient safety through infection control
- Recognize important principles when dealing with multidrug-resistant organisms
- Verbalize steps the nurse can take to prevent occupational exposure

Healthcare organizations are required to meet quality and safety needs for patients, staff, and visitors. An organization's stated commitment to a culture of patient safety can directly enhance infection prevention. The goal of infection prevention is to decrease the risk of infection to patients and healthcare personnel, identify and correct problems that are recognized as deterrents to infection prevention, minimize risks associated with procedures, and maintain compliance with hospital and governmental policies associated with infection prevention. The CDC has recognized the urgent issue of microorganisms that are resistant to drugs and the immediate need for intervention. Furthermore, the American Nurses Association promotes safeguarding antibiotics and the integration of a comprehensive approach to preventing inappropriate use.

### Maintaining Patient Safety through Infection-Control Measures

The role of nursing in patient safety and infection prevention is significant. Nurses provide care at the bedside and have the direct ability to impact care and influence positive patient outcomes by helping to identify and prevent the spread of infectious agents. The interventions implemented by a nurse have an integral role in infection prevention. Nurses are part of the team responsible for executing appropriate isolation protocols, modeling infection-control measures, monitoring others for safe practice, identifying barriers to appropriate practice, and educating patients and other interdisciplinary team members as needed. Specific protocols for isolation and infection control will depend on several factors including mode of transmission, environmental circumstances, and available resources.

#### Standard Precautions: Tier 1

The first tier of precautions to protect healthcare staff and patients from infection are **standard precautions**. These precautions apply to all patients, regardless of their diagnosis or presumed infection status. The components of standardized precautions include hand hygiene, respiratory hygiene, cleaning and disinfecting, personal protective equipment, safe injection practices, needlestick and sharps injury prevention, and waste disposal.

#### Transmission-Based Precautions: Tier 2

In situations where standard precautions are not adequate to prevent infection transmission, **transmission-based precautions**. These types of precautions are specific to infections and should be implemented immediately following patient presentation of signs and symptoms specific to certain infections. These precautions fall into the categories of airborne, droplet, and contact. Transport for patients who are under transmission-based precautions should be limited and only done when essential.

### PATIENT CONVERSATIONS

#### Mental Health Needs for Patients on Isolation Precautions

**Scenario:** The nurse is entering a negative pressure airborne isolation room. The patient has a diagnosis of pneumonia and has tested positive for COVID-19. The nurse recognizes that the patient breakfast tray is sitting on the bedside table, uneaten.

**Nurse:** Hi, Mr. Garces. How are you feeling? Were you not hungry this morning?

**Patient:** (not looking at the nurse) I was . . .

**Nurse:** Is there something wrong? Are you feeling nauseous?

**Patient:** No. I was hungry, but when my breakfast tray got here, it was very cold. It must have sat outside the door for a while before the tech brought it in. I feel like everyone forgets about me since I'm stuck in this room.

**Nurse:** I'm so sorry to hear that happened. I will call down to dietary right now to get a new hot tray sent up. I

understand being sick and in an isolation room can be difficult. Do you want to talk about how you are feeling?

**Patient:** It's just really lonely in here. I don't want my family to come visit me and get sick. But I miss talking to them.

**Nurse:** I see you have your cell phone on the nightstand. Have you been able to call them?

**Patient:** No, I forgot my phone charger at home, and the battery ran out days ago.

**Nurse:** We have an extra charger at the nurse's station I can bring in. It is very important to be able to stay in contact with loved ones and have someone to talk to. Technology has made that a lot easier these days.

**Patient:** That would be great and mean a lot to me. Thank you.

### Airborne Precautions

When a patient is known or suspected to be infected with pathogens that are transmitted through droplet nuclei, **airborne precautions** should be used. Patients on airborne precautions, such as those being treated for chicken pox or measles, should be placed in negative pressure rooms. If a negative pressure room is unavailable, the patient should be masked and placed in a private room with the door closed. The personal protective equipment (PPE) for airborne isolation includes the use of a fit-tested NIOSH-approved N95 or higher-level respirator. If transport outside of the room is necessary, patients must wear an N95 mask. These precautions prevent the pathogen from gaining access to the hospital's ventilation and possibly infecting other patients.

### Droplet Precautions

The use of **droplet precautions** are implemented when patients are known or suspected to be infected with pathogens transmitted by respiratory droplets from coughing, sneezing, and talking. Patients in acute care should be placed in a single patient space. The PPE needed when treating patients in droplet isolation includes donning a mask upon entering a room and discarding it before exiting the room. If transport outside of the room is necessary, patients must wear a surgical mask.

### Contact Precautions

The use of **contact precautions** are indicated for patients who have known or suspected infections that can be transmitted through direct skin-to-skin contact or indirect contact with environmental surfaces or equipment. Patients in acute care should be placed in a single patient space. The PPE needed when treating patients in contact isolation includes gloves and an isolation gown whenever touching the patient, discarding them before exiting the room. Disposable or dedicated patient equipment should be used for the patient. When it is unavoidable to utilize common use equipment, ensure that it has been properly cleaned and disinfected before use on another patient. (Figure 10.11) provides a quick guide comparing contact, droplet, and airborne precautions.

**FIGURE 10.11** Understanding the aspect of (a) contact, (b) droplet, and (c) airborne precautions is vital for nurses to provide safe and effective care. (credit: modification of “Contact Precautions,” “Droplet Precautions,” and “Airborne Precautions” by Centers for Disease

Control and Prevention, Public Domain)

## Dealing with Multidrug-Resistant Organisms

The impact of HAIs extends past the individual patient level. At the community level, it has been linked to the development of multidrug-resistant infections. In other words, many HAIs are caused by **multidrug-resistant organisms** (MDROs), which are bacteria that have become resistant to certain antibiotics, so much so that these antibiotics can no longer be used to control or kill the bacteria.

Examples of MDROs include *Clostridioides difficile*, methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant *Enterococci* (VRE), and multiresistant gram-negative bacilli. HAIs that are caused by antibiotic-resistant bacteria are of particular concern, because they are typically difficult to treat and pose a significantly higher risk for severe illness and complications.

## LIFE-STAGE CONTEXT

### Susceptibility to Infection

The overall misuse and overuse of antibiotics has created a risk of MDROs to all populations, yet older adults have increased risk. Older adults tend to spend more time in hospitals and/or long-term care facilities with more chronic conditions, which increases exposure to different pathogens. Furthermore, age-related physiologic changes decrease immune system efficiency, thus increasing vulnerability to such infections.

### UNFOLDING CASE STUDY

#### Unfolding Case Study #2: Part 7

Refer back to [Unfolding Case Study #2: Part 5](#) for a review on the patient data.

Diagnostic Test Results	Sputum culture positive for methicillin-resistant <i>Staphylococcus aureus</i> (MRSA)
Provider's Orders	<b>2230: New Orders</b> Infectious disease consult. Titrate supplemental oxygen to maintain saturation > 92 percent. Continue droplet precautions.

- Take action: The nurse is preparing to enter the patient's room. What personal protective equipment (PPE) is appropriate?
- Evaluate outcomes: What findings would indicate that the patient's condition is improving?

### Nursing Advocacy for Patient Safety

Nurses in all disciplines have the responsibility to ensure patients are receiving the safest care. Health care today is more complex than ever, and patients have more complex needs and conditions. Progress in treatments means more extensive intervention, prevention, monitoring, and care. By advocating for wellness and safety for patients, nurses can contribute to high-standard working environments with improved regulations and patient-centered policies. Safer healthcare environments lead to positive patient outcomes. Education is another consideration in the role of an advocate. Nurses often are the ones educating patients and/or their families on specific care needs, as well as how to navigate the healthcare system as a whole. Adjusting for specific needs and learning styles of the patient/family is critical to provide effective education. Nursing advocacy demonstrates an increased level of investment in safety by taking the extra time to meet the needs of the patients.

## REAL RN STORIES

---

### Advocating for Proper PPE Use

**Nurse:** Shiela, BSN

**Clinical setting:** Medical oncology unit

**Years in practice:** 15

**Facility location:** Buffalo, New York

Five years ago, I began working as the charge nurse on a medical oncology unit. I'm very involved in the care of all the patients on the unit and attend rounds daily. I provide a listening ear and discuss with patients how their treatment is going. One day during my rounds, I had a patient's daughter voice several concerns.

This particular patient was on contact isolation, and healthcare workers were required to don PPE before entering the room. The patient's daughter stated that several nurses, nursing assistants, and therapists had entered the room without wearing any PPE. I acknowledged the daughter's concerns and promised to investigate what was happening.

After discussions with the staff, I learned that the issue was multifaceted. Several of the assistants did not understand what PPE was required, so I provided proper education. Other staff members stated that the floor was frequently out of PPE and that they did not have time to search the hospital. I assured the staff that I would speak to the supply chain to ensure that proper PPE was always available; then I reeducated them not to enter isolation rooms without it. I was able to advocate for the patient's safety by providing needed education for the staff. The issue also brought about an opportunity for me to advocate for staff safety by guaranteeing that the necessary items were available to provide safe care.

---

## Preventing Occupational Exposure

It is vital that healthcare workers are able to recognize and reduce risks associated with exposure to blood, bodily fluids, and biologic hazards. The recent emergence of the previously unknown pathogen COVID-19 highlights the critical need for safety in health care and the increasing importance for protecting against pathogens.

### Latex Sensitivity

Latex products are made from a natural rubber, and sensitivity can develop if there is repeated exposure. Individuals in health care wear gloves at a much higher frequency than the general public; the increased exposure places them at a higher risk for developing sensitivity, which could lead to allergy. If a nurse has indicated a sensitivity to latex, alternative products should be used, such as latex-free gloves made of neoprene or vinyl. In addition, such nurses should avoid areas where latex is likely to be inhaled, such as an area of high prevalence in the use of latex gloves. Some symptoms of a latex allergy include itching, rash/hives, sneezing, watery/itchy eyes, skin redness, cough, wheezing, and difficulty breathing. For patients with a latex allergy, prevention is key for good outcomes. All clinicians involved in caring for the patient should be a part of the prevention plan to avoid incidental exposure.

### Reducing Risk Exposure

Identifying why and how exposures occur is a critical component to the success of a healthcare prevention program. All healthcare employees must receive proper training and education regarding how to reduce their risk for exposure. Emphasis must be placed on following proper hand hygiene, and proper personal protective equipment (PPE) protocols can greatly reduce risk of exposure. Compliance must also be recognized when removing PPE to prevent contamination. PPE can not only protect the patient but also the nurse providing care to the patient who may be contagious or pose a risk to specific populations. Reducing exposure to toxic medications, such as chemotherapy, and following proper protocols for disposal of medications are important for nurses to understand. Following safety procedures and protocols along with using clinical judgment is the best way for nurses to minimize their risk.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety: Disposing Sharps Safely

**Definition:** Quality and Safety Education for Nurses (QSEN) competencies were designed to emphasize key elements that pre-licensure nursing students should be competent in at the time of graduation. Safety is defined as minimizing risk of harm to patients through both systems effectiveness and individual performance.

**Clinical scenario:** Nurses should have the following knowledge and skills regarding disposal of sharps:

- Do not throw a needle or sharp in the trash. Dispose of it in a marked sharps container immediately after use ([Figure 10.12](#)).
- Never recap a used needle; lay it down or remove a used needle from a disposable syringe.
- When disposing of a needle in the sharps container, never use force or reach into the container.
- If a needlestick occurs, immediately report the incident, and follow your facility's guidelines and protocols.

**FIGURE 10.12** Sharps should always be placed in a marked sharps container after use. (credit: “Sharps Container.jpg” by “The finished Tattoo”/Wikimedia Commons, CC BY 2.5)

### Improving Sharps Safety

Sharp injuries are among the top occupational threats to nurses and healthcare workers. Needlestick injuries can occur at any point during the use, disassembling, or disposing of needles. Sharp injuries put workers at risk for blood-borne diseases, such as hepatitis B, hepatitis C, and HIV. Needles that are not disposed of properly can cause injury to any individual who encounters them unexpectedly. The term **sharps** includes needles as well as other objects, such as lancets, razor blades, scissors, clamps, pins, staples, and glass items.

The Needlestick Safety and Prevention Act (2000) made needle safety a top priority in hospitals. It is critical, however, that all healthcare workers are aware of and alert to the dangers associated with sharps. Needlestick safety should focus on education and prevention. All healthcare workers should receive hands-on employee training that focuses on the use, handling, and disposal of all sharps. All sharps do not have the same safety mechanisms. Therefore, hands-on training with the sharps currently being used or those that will be adopted must be a priority to ensure nurse and patient safety. Policies and procedures should be implemented regarding safe disposal of sharps and should include routine evaluation of sharps container access. All containers should be fitted with a tight lid and placed at shoulder height with safety features that reduce exposure to fingers and hands.

### Safety Devices

It is recommended that healthcare facilities use needleless systems whenever possible. Needleless systems use adaptors and Luer-locks in conjunction with IV tubing and vials, allowing access through a valve system. When the

use of a needleless system is not feasible, safety devices should be put into place. Safety-engineered sharps are devices with a built-in safety feature or mechanism that effectively reduces the risk of needlesticks. Examples of safety-engineered sharps include syringes with guards or sliding sheaths ([Figure 10.13](#)), retractable needle systems, and shielded or retracting scalpels.

**FIGURE 10.13** Many types of safety mechanisms exist for sharp instruments in health care, including needles with guards. (credit: "231018-F-RI324-1019," by Airman Cade Ellis/Moody Air Force Base, Public Domain)

## Summary

### 10.1 Infection Cycle

By understanding the conditions that foster the spread of infection, nurses can implement evidence-based interventions to break the cycle and stop the chain of infection. Nurses must have a thorough understanding of how to protect themselves and their patients from exposure to harmful pathogens. Nurses should gather the signs and symptoms of infections through examination, patient history, and healthcare records. The infection cycle has six specific phases that all must be completed in order for an infection to matriculate. These six pieces are causative agent, reservoir, portal of exit, mode of transmission, portal of entry, and susceptible host. Breaking this chain at any point can stop the spread of infection. Understanding the various types of immune responses will help nurses to identify infection and initiate treatment. The human body's immune system provides a mechanism for staying healthy through protection against harmful pathogens. An immune response can be classified as either nonspecific, meaning it targets pathogens in a nonspecific manner, or specific, meaning it allows for a high level of adaption and effectiveness against a specific pathogen.

### 10.2 Asepsis and PPE

Comprehensive knowledge related to infection prevention and control is essential for nurses to protect themselves and patients from the transmission of infection. The two types of asepsis are medical and surgical. Medical asepsis is often referred to as clean technique, while surgical asepsis is often referred to as sterile technique. Understanding the use of personal protective equipment and knowing when to use which type of equipment are key components of infection prevention. By incorporating thorough assessment and applying prevention strategies, nurses are empowered to reduce transmission of pathogens within healthcare environments and the community. One major risk factor to hospital admittance is healthcare-associated infections. The most common HAIs are associated with invasive devices: catheter-associated urinary tract infections (CAUTIs), central line-associated blood stream infections (CLABSIs), ventilator-associated pneumonia (VAP), and surgical site infections (SSIs). These infections often have intensive treatment and compound on the original reason for hospitalization, leading to increased healing time for patients.

### 10.3 Sterile Technique

Environmental factors play a large role in infection prevention and transmission. Environmental cleaning is a fundamental principle of infection prevention because contaminated equipment and surfaces play a major role in transmission. Improving cleaning practices and increasing compliance reduces the exposure to pathogens and, therefore, reduces incidences of infection. To minimize the risk of transmission of infection, there are three levels of cleaning of which nurses should be knowledgeable: sanitization, disinfection, and sterilization. Moreover, it is critical that nurses understand and utilize the principles of the skill of sterile technique as an essential element of patient safety.

### 10.4 Infection Control and Patient Safety

Nurses play a critically important role in ensuring patient safety while providing care directly to patients. When standard precautions are not enough to protect patients and healthcare workers against pathogens, nurses must use transmission-based precautions, which provide additional support for infection prevention. Nurses can advocate for themselves, patients, and families to ensure that agencies follow proper policies and procedures to promote the highest patient outcomes. All healthcare employees must receive proper training and education regarding how to reduce their risk for exposure. This may include exposure to certain substances as well as sharps safety. Emphasis must be placed on following proper hand hygiene, and proper personal protective equipment (PPE) protocols can greatly reduce risk of exposure. Special considerations should be made regarding the use of antibiotics to not increase the incidence of MDROs. Patient education on this topic helps to prevent infection with these resistant bacterial agents.

## Key Terms

**active immunity** immunity that results from the production of antibodies to help protect the body from a pathogen that has entered the body

**airborne precaution** a practice indicated for patients known or suspected to be infected with pathogens that are

transmitted through droplet nuclei

**airborne transmission** the spread of pathogens that are carried by dust or the nuclei of an evaporated droplet and remain suspended in the air

**antibody (also, immunoglobulin)** a protective protein produced by the immune system to help the body fight invaders

**antigen** a toxin or foreign substance introduced to the body that elicits an immune response

**asepsis** the state of being free from disease-causing contaminants

**chain of infection** the six stages of infection that must be present for the transmission of a pathogen from one place or person to another

**contact precaution** a practice implemented for patients who have known or suspected infections that can be transmitted through direct skin-to-skin contact or indirect contact with environmental surfaces or equipment

**convalescent period** the time when recovery and healing begin

**direct transmission** the spread of a pathogen that is transmitted directly from an infected person

**disinfection** the process of removing microorganisms and disease-causing pathogens from inanimate objects

**droplet precaution** a practice implemented when patients are known or suspected to be infected with pathogens transmitted by respiratory droplets from coughing, sneezing, and talking

**droplet transmission** the spread of a pathogen that travels through a spray of water droplets that are released when an infected person coughs, sneezes, or talks

**fever** a rise in core body temperature

**illness period** the third stage of infection, which starts when a person experiences the specific signs and symptoms of a disease

**incubation period** the initial stage of infection when a pathogen successfully enters into a new host

**indirect transmission** the spread of a pathogen to a new host through an intermediary, such as the air, food, water, animals, or objects

**infection control** the discipline of stopping or preventing the spread of infectious agents

**inflammatory response** one of the first responses when a pathogen breaches the nonspecific innate immune system; it aids in the recruitment of cellular defenses to remove pathogens

**medical asepsis** techniques and procedures used to decrease the potential for the spread of microorganisms and infection

**medical isolation gown** a garment worn in the healthcare setting as a broad barrier against blood or bodily fluids

**microorganism** a single-celled organism that is microscopic in size and too small to be seen by the naked eye

**multidrug-resistant organisms** a bacterium that has become resistant to certain antibiotics

**N95 respirator mask** a tight-fitting mask that protects the wearer from very small particles that float in the air

**normal flora** microorganisms that can live on another living organism or inanimate object without causing diseases or complications

**passive immunity** the result of antibodies being passed from one person to another

**pathogen** any type of microorganism that causes disease to its host

**personal protective equipment (PPE)** a means of barrier protection for eyes, nose, mouth, and skin from exposure to blood and other potentially infectious bodily fluids and materials

**portal of entry** the site at which a pathogen enters the susceptible host

**portal of exit** the path by which the pathogen leaves the reservoir

**prodromal period** the second stage of infection, which begins at the initial appearance of mild or vague symptoms

**reservoir** the habitat or source of the pathogen that provides a place for survival and growth

**sanitization** the removal of visible soil from objects and materials

**sepsis** the body's extreme response to a widespread infection

**sharps** needles and other objects, such as lancets, razor blades, scissors, clamps, pins, staples, and glass items

**standard precaution** the first tier of precautions to protect healthcare staff and patients

**sterile gloves** a glove that is free from microorganisms and individually packaged as a pair to remain free of pathogens

**sterile technique** a set of specific practices and procedures employed to maintain sterility of the sterile field (e.g., equipment, instruments, drapes)

**sterilization** a procedure that eliminates all microorganisms in or on an object

**surgical asepsis** the absence of all microorganisms in any type of invasive procedure, achieved through rigorous

sterilization processes and meticulously maintained through sterile technique

**surgical gown** a garment worn by healthcare personnel during a surgical procedure to protect both the patient and the personnel from transmission of pathogens

**surgical mask** a mask that prevents transmission of large particle droplet matter generated through coughing or splash-generating procedures

**susceptible host** the organism that is susceptible to or at risk for infection

**transmission** the method that a pathogen uses to spread from one host to another

**transmission-based precaution** a practice implemented in situations where standard precautions are not adequate to prevent infection transmission

**vector transmission** the spread of a pathogen that occurs when blood-feeding arthropods infect animals or humans

**zoonosis** an infectious disease that can naturally transmit from animal to human

## Assessments

### Review Questions

1. A patient being seen in urgent care is complaining of vague and generalized symptoms. What stage of the infection process is the patient in?
  - a. incubation
  - b. prodromal
  - c. illness
  - d. convalescent
2. A patient has been experiencing a cough and sore throat for several days. While at work, the patient sneezed several times while sitting close to a coworker. Two days later, the coworker developed the same symptoms. What mode of microbial transmission took place here?
  - a. direct contact
  - b. indirect contact
  - c. droplet transmission
  - d. vector transfer
3. After receiving the varicella vaccination, a patient states that they now have immunity against this virus. What type of immunity does the patient have?
  - a. natural active immunity
  - b. natural passive immunity
  - c. artificial passive immunity
  - d. artificial active immunity
4. A patient presents to urgent care after cutting themselves with a knife while eating an apple. The patient became concerned after noticing redness and warmth at the injury site. What education can the nurse provide related to these findings?
  - a. An artificial passive vaccine should be administered to prevent further damage.
  - b. The patient should expect the cut to turn black before healing begins.
  - c. Redness and warmth are expected assessment findings.
  - d. The patient may be allergic to apples and will need additional allergy testing.
5. What does the CDC recommend as the length of time someone take to perform hand hygiene using an alcohol-based hand sanitizer?
  - a. ten to fifteen seconds
  - b. twenty to thirty seconds
  - c. forty to fifty seconds
  - d. fifty to sixty seconds
6. A nurse is preparing to enter the room of a patient on droplet precautions. What is the correct order for

application of PPE?

- a. handwashing, gown, mask, eye protection, gloves
  - b. handwashing, mask, gloves, gown, eye protection
  - c. mask, handwashing, gown, eye protection, gloves
  - d. mask, handwashing, gloves, gown, eye protection
7. A nurse is setting up a sterile field to insert an indwelling catheter into an older patient who has dementia. During the setup, the patient accidentally drops their leg inside the sterile field. What is the appropriate nursing action?
    - a. Call for another nurse to hold the patient's leg and continue setup.
    - b. Remove the portion of the field that was contaminated and continue setup.
    - c. Continue setup because no objects were touched by the patient.
    - d. Discard the supplies and prepare a new sterile field with another nurse assisting in holding the patient.
  8. A nurse is preparing a sterile field to complete a sterile wound dressing change. What action would indicate a break in the sterile field?
    - a. remaining 1 ft (30 cm) away from nonsterile areas
    - b. placing additional sterile items in the sterile field
    - c. not utilizing the 1 in (2.5 cm) border of the sterile field
    - d. reaching 1 ft (30 cm) over the sterile field
  9. The nurse is admitting a patient who has tuberculosis to the hospital. What tier of precautions must the nurse institute when caring for this patient?
    - a. droplet contact
    - b. airborne contact
    - c. direct contact
    - d. indirect contact
  10. What is the first step in protocol for a nurse who has been stuck by a needle?
    - a. Report to the emergency department.
    - b. Place the needle in a biohazard bag.
    - c. Call an infectious disease doctor.
    - d. Wash the area thoroughly with soap and water.
  11. The nurse is speaking with a patient about their new diagnosis of *Clostridioides difficile*, highlighting that his infection is no longer impacted by antibiotics. How is this type of infection categorized?
    - a. hospital-specific organism
    - b. multifactor-resistant infection
    - c. hospital-created infection
    - d. multidrug-resistant organism

### Check Your Understanding Questions

1. Discuss the chain of infection and how the chain can be broken.
2. How will the treatment of a bacterial infection differ from the treatment of a viral infection?
3. Why is it important for a healthcare worker to know what type of precautions a patient is on before donning PPE?
4. When opening a sterile package, which part of the package is considered nonsterile?
5. What precautions should be implemented for a patient on contact precautions?
6. What steps can a nurse take to prevent needlesticks?

## Reflection Questions

1. A patient in an outpatient clinic states that they have not been feeling well since yesterday and their temperature has been 100.2°F (37.9°C) since earlier that morning. The patient asks the nurse if they should take Tylenol for the fever. What education should the nurse provide to the patient about infection and fever?
2. Two patients present to the outpatient clinic with different complaints. Patient A has a 100.2°F (37.9°C) temperature since early this morning and reports that he got the influenza vaccine yesterday. Patient B has a 98.5°F (36.9°C) degree temperature and complains that his right arm is swollen and red near an elevated area “that looks like a little hill.” Explain the differences in the patient’s symptoms based on the principles of immunity and the inflammatory response.
3. Discuss the role nurses play in the prevention of healthcare-associated infections.
4. A nurse observes an unlicensed healthcare worker preparing to enter a contact precaution room. They observe the worker donning gloves first, then the isolation gown. What education can the nurse provide the worker about donning PPE?
5. Discuss the principles of sterile technique and how a nurse can maintain sterility.
6. Why are multidrug-resistant organisms a threat to patient safety?

## Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #2: Part 5](#).  
What is the likely method of transmission of the infection?
2. Refer to [Unfolding Case Study #2: Part 6](#).  
What factors may have increased the patient’s risk for developing hospital-acquired pneumonia?
3. Refer to [Unfolding Case Study #2: Part 7](#).  
What are some strategies the nurse could use to decrease the risk of hospital-acquired infections?

## What Should the Nurse Do?

1. The nurse is assigned a patient who is being treated for RSV and is in droplet precautions. Thinking about the infection chain, the nurse wants to impede the spread of RSV by interrupting this chain with their nurse care. What are two things the nurse can do to interrupt this chain? What step in the chain are they interrupting with each action?
2. The nurse is caring for a patient who is infected with methicillin-resistant *Staphylococcus aureus* (MRSA). The patient is angry that the nurse is always wearing gloves and a gown and asks, “Do you think I’m dirty?” How should the nurse respond?
3. The nurse is speaking with a group of students regarding cleaning protocols on the unit. One of the students asks, “What are examples of items in which we would use disinfectants?” How should the nurse respond?

A nursing student has been assigned to a 75-year-old female patient who has a diagnosis of *Clostridioides difficile*. The patient is incontinent and needs assistance with bathing and hygiene. The charge nurse has requested the nursing student to assist with providing care for the patient.

4. What infection prevention and control precautions should be incorporated into the patient’s care to decrease the risk of spreading infection?
5. What education can the student nurse provide to the patient and family?
6. How can being on isolation precautions impact the patient’s mental health?
7. A new graduate nurse is speaking with an experienced nurse regarding their concern about their known sensitivity to latex. The new graduate nurse is worried about using latex-containing products and fears they will not be able to complete their job duties. How should the experienced nurse respond?

## Competency-Based Assessments

1. Map out the infection chain, labeling each step. Then, identify three ways that this chain can be broken.

2. Create a poster comparing and contrasting medical and surgical asepsis. Share with a peer.
3. Use the internet to find a demonstration of sterile technique for a medical procedure. If possible, replicate this demonstration. If resources are not available, vocalize each step as you simulate the experience.
4. Develop a ten-minute presentation discussing how the nurse can promote patient safety through infection control.

# CHAPTER 11

## Medication Administration

**FIGURE 11.1** Medication administration requires competent and efficient nursing skills. (credit: modification of “Medications” by “freestocks.org”/Flickr, Public Domain)

### CHAPTER OUTLINE

- 11.1 Medication Orders
- 11.2 Fundamental Principles of Medication Administration
- 11.3 The Medication Administration Process

**INTRODUCTION** Medication administration is a key function of the nurse’s role. Given the significant portion of time nurses spend on this task, accuracy and adherence to best practices are paramount. Not only must the nurse administer the right dose of medication to the right patient, via the right route, at the right time, but the nurse must also ensure the appropriate medication administration procedures are in place. As such, nursing students must demonstrate competency and safety regarding medication administration before being able to do so for patients.

Medication orders serve as the foundation for administering treatments. A comprehensive understanding of the types and components of medication orders enables nurses to interpret and execute these directives accurately. The principles of medication administration encompass the core guidelines and best practices that ensure safe and effective delivery of medications. Nurses must be well-versed in these principles to perform their duties with precision and care. The process of medication administration involves multiple steps and checkpoints designed to safeguard patient health. From verifying patient identity to monitoring for adverse reactions, each stage requires meticulous attention to detail.

Medication errors are preventable, and nurses are at the forefront of implementing safety precautions to avoid them. Ensuring medication safety is crucial for individual patient outcomes and for maintaining overall healthcare quality and efficiency. Effective medication administration reduces the incidence of adverse reactions, enhances

patient trust, and supports the seamless functioning of healthcare systems. By mastering the principles and processes outlined in this chapter, nurses can engage in safe medication administration practices, thereby significantly influencing positive patient outcomes and upholding the integrity of nursing practice.

## 11.1 Medication Orders

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe types of medication orders
- Identify components of a medication order

Medication orders are a fundamental aspect of nursing practice, serving as the directives for the safe and effective administration of medications to patients. A thorough understanding of medication orders, including the various types and their components, is crucial for nurses to minimize the risk of medication errors, ensure optimal patient care, and enhance therapeutic outcomes. This section will explore the complexities of medication orders, equipping nurses with the basic knowledge required to accurately interpret, verify, and execute these orders accurately. By mastering this aspect of nursing practice, nurses play a pivotal role in ensuring patient safety and delivering high-quality care.

### Types of Medication Orders

A **medication order** is a prescription ordered within clinical practice. When administering medications, it is important for the nurse to be aware of the various types of medication orders that may be written. Common types of medication orders include routine orders, one-time orders, standing orders, STAT orders (to be completed now), PRN (as needed) orders, and titration orders. Each order type has indications for nursing practice. Identifying the order type helps the nurse to prepare for medication administration by knowing which medications to administer, when to administer them, as well as specific indications for administration.

- A **routine order** is a medication order that is continuously followed until canceled. For example, “Aspirin 81 mg PO Q Day” is a routine order. For the order to be canceled, the provider would need to discontinue the order.
- A **one-time order** is an order for a medication to be administered just one time. An example of a one-time order is “Cefazolin (Ancef) 2 g IV × 1 dose before surgery.”
- A **standing order** is a standardized order that may be implemented under certain circumstances. Standing orders are written to address protocols in which the nurse can intervene in a timely manner without having to wait on the provider to write orders, or there are general guidelines for treating a certain condition. For example, surgical procedures often utilize standing orders that allow the nurse to administer medications for pain, nausea or vomiting, constipation, and venous thrombosis prophylaxis.
- A **STAT order** is a one-time order that is administered as urgently as possible. An example of a STAT order may be to administer “Lorazepam (Ativan) 1 mg IV STAT” when the patient is having a seizure.
- A **PRN order** is a medication order to be administered as needed. PRN medications are commonly ordered for symptoms such as pain, nausea or vomiting, itching, sleep, cough, or fever greater than 101°F (38.3°C). An example of a PRN order is “Diphenhydramine (Benadryl) 25 mg PO Q4 hours PRN itching.” It is important to note that a PRN medication may only be administered for the ordered indication. For instance, an order that reads “Acetaminophen 500 mg PO PRN headache” cannot be administered for mild arthritic pain.
- A **titration order** is an order in which the medication dose is either progressively increased or decreased by the nurse in response to the patient’s status. Titration orders are typically used for patients in critical care as defined by agency policy. An example of a titration order is “Norepinephrine 2–12 mcg/min, start at 2 mcg/min and titrate upward by 1 mcg/min every five minutes with continual blood pressure monitoring until systolic blood pressure > 90 mm Hg.”

### Components of a Medication Order

According to the Centers for Medicare and Medicaid Services (2014), all medication orders must contain the following:

- patient’s full name and date of birth

- name of the drug
- drug dose, route, and frequency
- date and time medication order was written
- name and signature of the prescriber

The following additional requirements must also be included when applicable:

- weight of the patient if dose calculation is based on weight (kilograms for children and adults, grams for newborns)
- dose calculation requirements
- exact strength or concentration of medication
- specific quantity or duration to be administered
- specific instructions for use
- reason for use if medication is ordered PRN

An example of a complete medication order is shown in [Figure 11.2](#).

<b>Patient:</b> Rose Sanchez <b>Age:</b> 40	<b>Date of Birth:</b> 04/18/1983 <b>Room:</b> 366M	<b>Medical Record Number:</b> 008222014
<b>Date/Time</b>	<b>Medication</b>	<b>Prescriber</b>
02/10/2023 Time: 07:54 AM	Enoxaparin (Lovenox) 30 mg SQ Q12 hours	Grace Chen, NP
	Acetaminophen (Tylenol) 500 mg PO Q4 hours PRN mild pain	Grace Chen, NP
	Oxycodone/acetaminophen (Percocet) 5 mg/325 mg PO Q6 hours PRN moderate pain	Grace Chen, NP
02/10/2023 Time: 10:21 AM	Promethazine (Phenergan) 12.5 mg IV Q6 hours PRN nausea and vomiting	Grace Chen, NP

**FIGURE 11.2** A complete medication order includes the patient's information as well as the date, medication and dosage, and prescriber's name. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

When reviewing a medication order, the nurse must ensure all essential components are included in the prescription before administering the medication. If any component of the medication order is missing, the nurse must contact the prescribing provider to clarify and correct the order.

### Drug Name

Drugs are provided with three categories of names: (1) a chemical name, (2) a generic name, and (3) a brand name ([Table 11.1](#)). The chemical name provides a detailed description of the drug's molecular structure and chemical composition. This name is often complex and used primarily by chemists and researchers. The generic name, which is the standard name assigned by the United States Adopted Names (USAN) Council, is universally accepted and provides a simpler, more concise designation for the drug (Merck & Co., 2023). It is typically used by healthcare professionals and is preferred in clinical settings to reduce confusion. The brand name, also known as the trade name, is the proprietary name given by the pharmaceutical company that markets the drug. This name is usually easier to remember and is used in advertising and marketing to the public. Although a single drug may have one chemical and generic name, it can be sold under multiple brand names by different manufacturers.

Chemical Name	Generic Name	Brand Name
<i>N</i> -acetyl-para-aminophenol	Acetaminophen	Tylenol
Dihydroxy monocarboxylic acid	Atorvastatin	Lipitor
3-( $\alpha$ -acetylbenzyl)-4-hydroxycoumarin sodium salt	Warfarin	Coumadin

**TABLE 11.1** Examples of Drug Chemical Names, Generic Names, and Brand Names

The drug name must be clearly specified to prevent errors in medication administration. The name should be written in full and should not be abbreviated in order to avoid confusion with other medications that may have similar abbreviations. Both the generic name and brand name of the drug are often included to ensure clarity, with the generic name being preferred to reduce the risk of errors due to similar-sounding brand names. It is essential for the nurse to be familiar with both names to accurately verify and administer the medication. In cases where the drug name is unclear or misspelled, the nurse must contact the prescribing provider for clarification to ensure patient safety.

### Dose

The dosage of the drug refers to how much of a drug a patient should receive. Drug dosages may be written using three systems of measurements: metric system, household, or apothecary. The **metric system** is the most widely used international system of measurement and is considered to be the most accurate of the three systems of measurement. It is a decimal-based system based on units of ten. The **household system** utilizes everyday household items, such as measuring cups and tablespoons, to serve as measuring devices. Due to variations in the size of household items, it is considered to be the least accurate system of measurement. The **apothecary system** utilizes fractions as a part of the whole to measure weights and volumes.

According to the Institute for Safe Medication Practices (ISMP, 2021), household and apothecary measurements should only be used to provide directions for mixing dry ingredients to prepare a topical product. In all other circumstances, the metric system should be used. Common units of measurement for drug doses include the following:

- gram (g)
- kilogram (kg)
- liter (L)
- microgram (mcg)
- milligram (mg)
- milliliter (mL)
- units

Special care should be given to orders that contain a zero. Drug dosages should not be written with trailing zeros. For example, 1 milligram should be written as 1 mg instead of 1.0 mg to reduce the risk of the dosage being mistaken for 10 mg. However, if the dose is less than one unit, a zero must be included before the decimal point, often called a leading zero. For example, half a milligram should be written as 0.5 mg instead of .5 mg to reduce the risk of the dosage being mistaken for 5 mg.

## REAL RN STORIES

### Ensuring Correct Dosage

**Nurse:** Joseph, BSN

**Clinical setting:** Cardiology unit

**Years in practice:** One month

**Facility location:** The inner city of a small metropolitan area in South Carolina

As a newly graduated nurse on the cardiology unit, I was still becoming familiar with the specific medication

protocols followed by the cardiologists. One busy afternoon, Dr. White approached me and informed me that Mr. Thompson, a patient with a history of atrial fibrillation, was experiencing an irregular heartbeat. Dr. White had just placed a new order for a stat dose of IV digoxin to stabilize Mr. Thompson's heart rate and asked me to administer it immediately.

I opened Mr. Thompson's chart and read the order: "Digoxin 0.25 mg IV STAT." I promptly sent the order to the pharmacy for processing and proceeded with the medication administration by overriding the automated medication dispensing machine to avoid any delay, given the urgency of Mr. Thompson's condition.

As I prepared to retrieve the medication, I noted that Digoxin was available in 0.125 mg vials. Believing the order called for 0.25 mg, I calculated that I needed two vials to meet the required dose. However, as I prepared the medication, I was interrupted by an alert from the dispensing machine, warning that the amount requested was unusually high for this drug.

Feeling uncertain, I decided to consult with my charge nurse before proceeding. We rechecked the chart together and discovered a crucial detail that I had initially overlooked. The actual order read: "Digoxin 0.125 mg IV STAT." The way the order was written, the ".125" had been mistakenly read as ".25" due to poor handwriting and a misalignment on the chart.

Realizing my error, I adjusted the medication dosage to the correct 0.125 mg. Thanks to the alert from the automated system and the verification with my charge nurse, we avoided administering double the intended dose. This incident reminded me of the importance of carefully reviewing and verifying medication orders, especially in emergent situations where overriding the safety mechanisms in the medication dispensing machine may be warranted.

## Route

The route of the drug is the method by which the drug should be administered. Commonly used abbreviations for medication routes can be found in [Table 11.2](#).

Abbreviation	Route
AD	Right ear
AS	Left ear
AU	Each ear; both ears
BU or BUC	Buccal
EPI	Epidural
IA	Intra-arterial
IC	Intracardiac
ID	Intradermal
IM	Intramuscular
INH	Respiratory (inhalation)
IT	Intrathecal

**TABLE 11.2** Abbreviations for Routes of Administration

Abbreviation	Route
IV	Intravenous
IVP	Intravenous push
IVPB	Intravenous piggyback
NAS	Nasal
NG	Nasogastric
NGT	Nasogastric tube
OD	Right eye
OS	Left eye
OU	Each eye; both eyes
PO	Per mouth
PR	Per rectum
SC or SQ	Subcutaneous
SL	Sublingual
TD	Transdermal
TOP	Topical
PV	Per vagina

**TABLE 11.2** Abbreviations for Routes of Administration

A drug may only be administered via the ordered route. In the event the medication cannot be administered via the route ordered, the nurse must notify the provider. The nurse should document the reason for the route change and await further instructions from the provider to ensure patient safety and the effectiveness of the medication. If an alternative route is necessary, it must be clearly specified and approved by the provider before administration.

### Frequency

The frequency of the drug refers to how often or how many times per day the medication should be administered. Examples of drug frequency include Q30 minutes (every thirty minutes), Q4 hours (every four hours), Q12 hours (every twelve hours), Q Day (daily), BID (twice daily), TID (three times daily), QID (four times daily), and QHS (at bedtime). If the frequency is denoted in terms of number of times per day, the frequency can be determined by dividing 24 hours per day by the number of times the drug should be administered. For example, a medication ordered twice daily should be administered every twelve hours (24 hours in a day/2 administrations = every 12 hours), and a medication ordered three times daily should be administered every eight hours (24 hours in a day/3 administrations = every 8 hours).

### Date, Time, and Signature of Provider

For the medication order to be complete, it must include the date and time the order was written, along with the prescriber's signature (electronic or handwritten). Best practice is for the provider to enter the order; however, there

may be times when the provider is not able to do so, and a verbal order is required (Patient Safety Authority, 2006). When taking a verbal order, the nurse must restate the order back to the provider to ensure the message was received correctly. The nurse must immediately document the verbal order in the patient's chart, and the provider must review and sign the order according to the agency's policy. Nurses should be aware that both state and organizational policies will dictate required verbal order components. Be sure to follow the organization's policies.

## 11.2 Fundamental Principles of Medication Administration

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- List safety measures of medication administration
- Verbalize the rights of medication administration

Understanding the safety measures of medication administration and being able to verbalize the rights of medication administration are critical components of nursing practice with profound implications for patient care. These principles serve as fundamental safeguards to protect patients from medication errors and potential harm. It is imperative for nurses to grasp these concepts thoroughly, as medication errors can have severe consequences, including patient injury or even death. By adhering to established safety measures and rights of medication administration, nurses can mitigate risks, ensure accuracy, and promote optimal patient outcomes

### Safety Measures for Medication Administration

Given the risk of medication errors, there are many safety measures that should be implemented when administering medications. These safety measures fall into four categories: ensuring correct identification of the patient, checking the medication order for errors, maintaining a safe environment, and monitoring for adverse reactions. Medication administration safety is a priority; therefore, these safety checks may be confirmed by the nurse, provider, and pharmacist. By using an interdisciplinary team approach, safety measures may be assessed at multiple checkpoints and by several professionals, thereby reducing the opportunity for medication errors to occur.

Several organizations are dedicated to supporting safety measures for medication administration. The Institute for Safe Medication Practices (ISMP), a nonprofit organization renowned for its efforts in preventing medication errors, has created lists of look-alike and sound-alike drugs, advocated for the use of tall man (uppercase) lettering to distinguish between similar drug names, published recommended abbreviations, compiled lists of high-alert medications, and implemented a medication error reporting program (ISMP, n.d.). The Joint Commission (TJC) evaluates and accredits healthcare organizations nationwide, setting practice standards and issuing safety alerts to address concerns. TJC takes proactive steps to enhance patient safety by setting national patient safety goals, issuing sentinel event alerts, and offering evidence-based practice recommendations. Some of these recommendations include a Do Not Use list of abbreviations and requiring accredited healthcare organizations to provide a written processes for managing high-alert and hazardous medications. Additionally, organizations such as the Centers for Disease Control and Prevention (CDC), Poison Control, the National Institutes of Health (NIH), and the Food and Drug Administration (FDA) play vital roles in promoting medication safety through various programs, research initiatives, and regulatory measures. Ensuring safe medication administration involves collaborative efforts across multiple organizations to establish and enforce evidence-based practices and policies.

### LINK TO LEARNING

The Institute for Safe Medication Practices (ISMP) develops safe medication standards. Review the ISMP's [current list of drug names with tall man lettering \(https://openstax.org/r/77TallManLetter\)](https://openstax.org/r/77TallManLetter) that aims to reduce medication errors related to look-alike and sound-alike medications.

#### Patient Identification

According to TJC's National Patient Safety Goals, at least two patient identifiers are required to correctly identify the patient. The two most commonly used identifiers are full name and date of birth. The patient should be asked to state their name and date of birth, while the nurse confirms the stated identifiers on the patient armband and medication administration record (MAR). Other unique patient identifier options include medical record number,

phone number, social security number (if noted in medical record), address, or photo. If a patient is unable to verbalize their identity—for instance, they are unconscious—the nurse should verify the patient’s identity using a photo ID. It is important to note that room number is not a unique identifier and should not be used to confirm the patient’s identity. Although it may seem redundant, it is important to confirm the patient’s identity every time medications are administered (The Joint Commission, 2022).

### Verifying Order for Errors

The nurse must ensure all parts of the medication order are complete prior to administering medication. If any part of the medication order is missing, there are any questions about the order, or the writing is illegible, the nurse must contact the prescriber to clarify and correct the order. When verifying the medication order for errors, assessing patient allergies is a key safety consideration. If the patient has a documented allergy to the drug ordered, the nurse should provide notification of the allergy to the provider, who will consider alternative drugs and/or treatments.

With implementation of the electronic medical record, most medication orders are prescribed electronically. Using **computerized provider order entry (CPOE)**, a provider submits patient orders by electronic means, which has reduced the number of medication errors by offering technical safeguards, such as allergy alerts; drug-drug, drug-food, and drug-disease interaction checks; suggestions for safe medication dose ranges and intervals; evidence-based practice order sets; notice of incorrect transcription of handwritten orders; and hard stops to ensure the order is complete. Additionally, CPOE reduces the risk of erroneously transcribing handwritten medication orders.

### Drug Indication

A drug indication refers to the use of the drug for a particular disease or condition. Drugs often have more than one indication. When a drug is used for an FDA-approved purpose, it is termed a “labeled” indication, whereas using it for an unapproved purpose is considered “off-label.” To have a labeled indication, the drug must have been thoroughly researched and shown to be effective in treating the disease or condition. Drugs ordered for off-label indications must have demonstrated reasonable evidence to support effectiveness in treating the indication (Ogbru, n.d.). For example, megestrol acetate (Megace) is a progestin medication that has a labeled indication for treating advanced breast and endometrial cancer. Due to the side effect of increased hunger, even with small doses, megestrol was used off label as an appetite stimulant. Once researched and thoroughly studied, the medication is now labeled for use as an appetite stimulant. When administering medications, it is important to know and understand what medication the patient is taking, why they are taking it, to question the provider if it is unclear as to why a drug is ordered, and to explain to patients what they are taking and why.

Medication orders may also contain an indication for administration. For example, medications ordered on a PRN basis must contain an indication for when to administer the medication. Common indications for PRN medications include symptoms such as pain, itching, headache, nausea, or fever. If more than one medication is ordered for the same indication, the order must contain additional details to inform the nurse of when the nurse is to administer each medication. For example, if the patient is ordered Percocet and ibuprofen for pain, the order may state to administer “Ibuprofen PRN pain rated 0–5 on numerical rating scale give ii 200 mg tabs PO Q8 hours” and administer “Percocet PRN pain rated 6–10 on numerical rating scale give ii 2.5/325 mg tabs PO Q8 hours.”

### Maintaining a Safe Environment

Maintaining a safe environment is crucial for ensuring the safe administration of medications. Essential practices to maintain a safe environment include the following:

- Secure medications by keeping them in a locked cart or cabinet.
- Avoid leaving medications at the patient’s bedside unless ordered by the provider.
- Store narcotics in a double-locked cabinet or automated dispensing cabinet (Figure 11.3).
- Count narcotics at the beginning and end of each shift and each time they are accessed.
- Restrict access to medications to approved staff only.
- Grant electronic log-on access or keys to medication carts and cabinets only to approved staff.
- Gather medications for one patient at a time.
- Clearly label all prepared medications.
- Immediately administer medications once gathered.
- Return medications to the cabinet if there is a delay in administration.
- Avoid placing patient medications in clothing pockets.

- Minimize distractions and interruptions.
- Label medication preparation zones as “no talking” zones.

**FIGURE 11.3** Automated dispensing cabinets provide an electronic means of controlling medication storage, dispensing, and tracking of drugs. (credit: “Pyxis SupplyStation automated dispensing cabinet at Campbell County Memorial Hospital in Gillette, Wyoming” by Mr. Satterly/Wikimedia Commons, WTF Public License Version 2)

## LINK TO LEARNING

Safeguards must also be in place when administering “high-alert” drugs, which are drugs that can cause significant harm if an error occurs. A complete list of [“high-alert” medications \(https://openstax.org/r/77HighAlertMeds\)](https://openstax.org/r/77HighAlertMeds) is provided by the ISMP. Visual cues such as red text and tall man lettering are used to differentiate similar drug names.

If an actual or potential drug administration error occurs, it is important to report the situation immediately according to the agency’s policy. In the event of an actual error, the patient should be closely monitored for any adverse effects, and the patient’s response should be documented. Potential errors are important to report as evaluating these are a means of education for nurses and understanding potential risks. If addressed, potential errors can allow interventions to be implemented to reduce the risk of the situation becoming an actual error in the future.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### Principles for Maintaining a Safe Medication Administration Environment

Quality and Safety Education for Nurses (QSEN) provides a framework of competencies essential for maintaining a safe environment during medication administration. By integrating these competencies into daily practice, nurses can mitigate the risk of medication errors and promote positive patient outcomes. Here’s how these competencies relate to maintaining a safe environment during medication administration:

- Patient-centered care: Ensure medications are administered with consideration for individual patient needs

and preferences. For example, assess patient allergies before administering medications to prevent adverse reactions tailored to patient-specific risks. Collaborate with patients in shared decision-making regarding their medication regimen.

- **Teamwork and collaboration:** Collaborate with interdisciplinary teams to implement safety protocols. For instance, communicate effectively with pharmacists to clarify medication orders and resolve discrepancies in the medication administration process. Participate in interprofessional rounds to discuss medication plans and ensure coordinated care.
- **Evidence-based practice (EBP):** Implement evidence-based guidelines and protocols for medication administration. Utilize resources such as the ISMP to stay updated on best practices and recommendations for safe medication administration techniques. Incorporate research findings into practice to enhance medication safety and optimize patient outcomes.
- **Quality improvement (QI):** Participate in quality improvement initiatives to enhance medication safety practices. For example, engage in root cause analysis following medication errors to identify system weaknesses and implement corrective actions to prevent future errors. Regularly audit medication administration processes and outcomes to identify areas for improvement.
- **Safety:** Prioritize patient safety by following standardized procedures and safety checks during medication administration. For instance, use barcode scanning technology to verify patient identity and medication accuracy before administering any medications. Implement safety measures such as independent double-checks for high-risk medications to reduce the likelihood of errors.
- **Informatics:** Utilize informatics tools, such as electronic health records (EHRs), to access patient medication profiles and allergy information promptly. Ensure accurate documentation of medication administration and adverse reactions to facilitate communication among healthcare team members. Utilize data analytics to identify trends in medication errors and implement targeted interventions to improve safety.

Incorporating QSEN principles into medication administration practices empowers nurses to uphold the highest standards of safety and quality in patient care. By prioritizing patient-centered care, fostering teamwork and collaboration, embracing evidence-based practice, engaging in quality improvement initiatives, ensuring safety protocols, and leveraging informatics tools, nurses can mitigate risks associated with medication administration and promote optimal patient outcomes.

---

### Adverse Reactions

An unwanted and undesirable effect related to a drug is called an **adverse reaction**. Unlike a **side effect**, which is a predictable undesirable effect related to a drug, adverse reactions are unpredictable. Adverse reactions may occur when starting a new drug, stopping a drug, or changing the dose of the drug (U.S. Food and Drug Administration, 2022). The incidence and severity of adverse drug reactions may be impacted by factors such as age, sex, genetics, underlying conditions, drug type, dose, route of administration, and use of other drugs, vitamins, or supplements (Merck & Co., 2023).

#### Allergic Reactions

An **allergic reaction** occurs when the immune system responds to a substance, including a drug. Symptoms may include rash, hives, fever, itching, wheezing, runny nose, and watery eyes. A serious drug allergy will typically cause symptoms to appear within one hour after taking the drug. The nurse should notify the provider immediately if the patient develops any symptoms of an allergic reaction. Nurses should remember to always follow the organization's protocol for adverse reactions to a medication.

The most severe type of allergic reaction is **anaphylaxis**. Anaphylaxis is a rare, life-threatening reaction that causes symptoms such as difficulty breathing, nausea, vomiting, diarrhea, dizziness, tachycardia, hypotension, seizure, and loss of consciousness. Anaphylaxis is considered a medical emergency. The nurse should discontinue the drug and urgently notify the provider if anaphylaxis is suspected. The nurse will also initiate emergency protocols according to agency policy.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Take Action: Intervening When an Allergic Reaction Occurs

Darlene, a 55-year-old female with a history of hypertension and diabetes, was admitted to the hospital for a routine diagnostic procedure involving a computed tomography (CT) scan with contrast dye. She was prepped for the CT scan, and an intravenous (IV) contrast dye was administered to enhance the imaging. Within ten minutes of the dye administration, Darlene started feeling uneasy and reported an unusual sensation on her back. The nurse noticed Darlene scratching her back and asked her about her symptoms. Darlene reported intense itching and a burning sensation that started shortly after the contrast dye was injected.

The nurse performed a physical assessment and found a red, raised rash covering most of Darlene's back. Recognizing these cues—the timing of the symptom onset, the nature of the itching, and the visible rash—the nurse suspected a possible allergic reaction to the contrast dye. To gather more information, the nurse checked Darlene's vital signs to monitor for any systemic involvement, such as changes in blood pressure or heart rate. The nurse also asked Darlene when the itching started, if she had any other symptoms such as difficulty breathing or swelling, and if she had any known allergies.

Based on the analysis of the cues—the rapid onset of itching and rash following the administration of the contrast dye—the nurse hypothesized that Darlene was experiencing an allergic reaction to the IV contrast dye. The nurse immediately stopped the infusion of the contrast dye and alerted the provider about the suspected allergic reaction. The provider ordered an antihistamine (diphenhydramine) and a corticosteroid to manage the allergic reaction and reduce inflammation. Darlene was placed under close observation to monitor for any progression of the allergic reaction, particularly signs of anaphylaxis, such as difficulty breathing or swelling of the face or throat.

### Toxic Effect

The degree to which a drug can be poisonous or harmful to the body is called **drug toxicity**. It is a serious event that causes the medication to build up in the body and can often cause harm to the body or even death. For example, digoxin has a half-life of thirty to forty hours and is excreted through the kidneys. Patients with impaired kidney function, such as older adults or those with chronic kidney disease, are at a higher risk of developing a buildup of digoxin, potentially leading to toxicity. Signs of digoxin toxicity may include gastrointestinal upset, dyspnea, syncope, palpitations, and the appearance of yellow halos around lights. Drug toxicity can occur for various reasons, including accidental factors such as a dose being too high or slowed metabolism of the drug, or intentional factors such as a suicide attempt. If drug toxicity is suspected, the nurse should immediately notify the provider. Treatment for toxicity may involve withholding the drug until serum blood levels in the body decrease or performing stomach lavage to remove significant amounts of the ingested medication (Merck & Co., 2023).

### Tolerance

A **tolerance** refers to a decrease in the effectiveness of the drug over time due to repeated use. For example, patients on long-term opioid use due to cancer or chronic pain may require higher doses of opioids over time or additional pain relief therapies to be added to their regimen to adequately treat their pain. It is important to note that tolerance is not the same as **dependence**, which is when a patient depends on the drug to function. If a patient becomes tolerant to a drug, the provider may need to increase the dose of the drug or use an alternative drug to achieve the desired effect (Merck & Co., 2023).

### Drug Interaction

A **drug interaction** is when a drug reacts with another drug, food, supplement, or the patient's medical condition. This interaction may affect the action of the drug(s) or result in unwanted adverse effects (Figure 11.4). For example, taking opioids and central nervous system depressants together may increase the risk of respiratory depression, whereas eating leafy greens may decrease the effects of warfarin.

**FIGURE 11.4** A drug interaction is a type of adverse reaction that causes undesirable effects. (credit: data source: National Institutes of Health; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Paradoxical Effect

A **paradoxical effect** occurs when the effect of a drug is opposite from the intended effect. For example, a stimulant causing drowsiness, an antidepressant leading to suicidal thoughts, or a pain relief medication causing increased pain are examples of paradoxical effects of medications. Paradoxical effects should be documented and reported to the provider for consideration.

### Rights of Medication Administration

Nurses are responsible for ensuring patient safety during medication administration. The rights of medication administration are a set of guidelines to adhere to when administering medications in an effort to reduce adverse medication events. The five core “rights” of medication administration include the following: right patient, right drug, right route, right time, and right dose. To enhance safety, the American Nurses Association (2021) recommended the addition of right reason, right documentation, and right response ([Table 11.3](#)).

Medication Rights	Nursing Actions
Right patient	Validate correct patient by confirming two or more patient identifiers (e.g., patient’s full name, date of birth, medical record number). Identifiers must be confirmed verbally by the patient, by the patient armband, or other acceptable means according to the agency’s policy.
Right drug	Compare the medication label to the medication order to ensure correct drug name, note expiration date, and confirm patient allergies.
Right route	Ensure medication is administered via the prescribed method (e.g., oral, sublingual, intravenous). If the route needs to be altered, consult the provider, and obtain a new order.
Right time	Medication is administered according to the prescribed frequency. Confirm when last dose was administered.
Right dose	Confirm dose matches the prescribed dose and is within a safe dosage level. Confirm dosage calculations and question doses outside of the safe dosage range.

**TABLE 11.3** The Rights of Medication Administration

Medication Rights	Nursing Actions
Right reason	Confirm why the patient is taking the medication and ensure the mechanism of action aligns with the indication.
Right documentation	Following administration, document the name of the drug, dose, route, time administered, and patient's response to the drug administered.
Right response	Assess if drug resulted in the desired effect.

**TABLE 11.3** The Rights of Medication Administration

The five core “rights” of medication administration (right patient, right drug, right route, right time, and right dose) should be confirmed at three different checkpoints during the medication administration process. These three checkpoints are when obtaining the medication, when preparing the medication, and when administering the medications at the bedside. At each of the checkpoints, the medication label should be compared to the medication order to confirm the right patient, right drug, right route, right time, and right dose.

Bar Code Medication Administration (BCMA) is an electronic scanning system used to decrease the risk of medication administration errors and confirm the “rights” of medication administration ([Figure 11.5](#)). By scanning barcodes on the patient’s armband and medication labels, the electronic system can confirm that the right patient receives the right dose of the right medication according to the right frequency. BCMA also provides additional alerts, such as when vital signs need to be assessed prior to administering a medication, allergies are present, or a second nurse needs to verify the medication.

**FIGURE 11.5** Nurses use Bar Code Medication Administration to assist with confirming the “rights” of medication administration. (credit: “20130306-OC-RBN-3904 (8575102671)” by Bob Nichols, United States Department of Agriculture-Office of Communications-Photography Services Division/Wikimedia Commons, Public Domain)

In addition to checking the basic rights of medication administration and documenting the administration, it is important for nurses to verify the following information to prevent medication errors:

- Right history and assessment. The nurse should be aware of the patient’s allergies as well as any history of any drug interactions. Additionally, nurses collect appropriate assessment data regarding the patient’s history, current status, and recent laboratory results to identify any contraindications for the patients to receive the prescribed medication.

- Right drug interactions. The patient's history should be reviewed for any potential interactions with medications previously given or with the patient's diet. It is also important to verify the medication's expiration date before administration.
- Right education and information. Information should be provided to the patient about the medication, including the expected therapeutic effects as well as the potential adverse effects. The patient should be encouraged to report suspected side effects to the nurse and/or prescribing provider. If the patient is a minor, the parent may also have a right to know about the medication in many states, depending on the circumstances.
- Right of refusal. After providing education about the medication, the patient has the right to refuse to take medication in accordance with the Code of Ethics for Nurses and respect for individual patient autonomy. If a patient refuses to take the medication after proper education has been performed, the event should be documented in the patient chart and the prescribing provider notified.

## 11.3 The Medication Administration Process

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain medication administration procedures according to route
- Describe the nursing roles and responsibilities of medication administration

Serving as the final checkpoint in the medication process before administration, nurses assume a pivotal role in safeguarding patient safety. As such, the nurse must have demonstrated competency in administering medications via each individual route. Moreover, nurses play pivotal roles in the medication administration process, encompassing assessment, delegation, error reporting, documentation, evaluation, and education. Mastery of these roles and responsibilities is indispensable for nurses to uphold the highest standards of patient care and safety.

### Medication Administration Procedures

Medication administration is a critical component of nursing practice that encompasses a variety of routes to deliver therapeutic agents effectively. This section introduces the procedures for administering medications through different routes, including oral, intradermal, subcutaneous, intramuscular, intravenous, as well as ophthalmic (eye), otic (ear), nasal, inhalation, vaginal, and rectal routes. Each route requires specific techniques and considerations to maximize the intended effects of the medication while minimizing potential adverse reactions. Understanding these procedures is essential for nurses to deliver care effectively and to educate patients on their medication regimens.

#### Oral Medication Administration

Administering medications via the oral route is simple, convenient, and widely accepted, especially in home settings. Medications ordered for oral administration (*per os*, or PO) are taken by mouth. After swallowing, these medications are typically absorbed in the small intestine. Oral medications generally have a slow onset, taking about thirty to sixty minutes to start working.

When administering oral medications, patient safety is paramount. The nurse must assess for contraindications such as **dysphagia** (difficulty swallowing), nasogastric (NG) tube with suctioning, nothing by mouth (NPO) status, or the inability to sit upright. If the patient has difficulty swallowing, a **tablet** (compressed powder or granules) is typically crushed ([Figure 11.6](#)) and placed in a substance such as applesauce or pudding for easier swallowing, based on the patient's prescribed diet. However, it is crucial to verify that a tablet may be crushed by consulting a drug reference or a pharmacist. An **enteric-coated tablet** (a tablet covered in a substance that delays the medication from dissolving), a **capsule** (a powder or granules contained in a gelatin shell), and **timed-release** (slow release of a medication for prolonged action) should never be crushed as this will affect the intended action of the medication. In such cases, the provider must be contacted for a change in the route of administration.

**FIGURE 11.6** Pill crushers may be used to crush certain tablets. The pill crusher typically consists of a container or reservoir where the pill is placed and a grinding mechanism or crusher that helps crush the pill into a powder. (reproduced with permission from Carol Clarkson)

Position the patient in an upright position to decrease the risk of aspiration ([Figure 11.7](#)). Patients should remain in this position for thirty minutes after medication administration if possible. If a patient is unable to sit, assist them into a side-lying position. Offer a glass of water or other oral fluid (that is not contraindicated with the medication) to ease swallowing and improve absorption and dissolution of the medication, taking any fluid restrictions into account. Remain with the patient until all medication has been swallowed before documenting to verify the medication has been administered.

**FIGURE 11.7** The patient should be positioned upright when administering oral medications. (Credit: “Nurse administers oral chemotherapy” by Rhoda Baer, National Cancer Institute/Wikimedia Commons, Public Domain)

Once confirmed that oral medications can be safely administered, the nurse should verify the MAR against the provider’s orders and obtain the medications, confirming the medication rights at each step. After preparing the medications and confirming the rights again, the nurse assists the patient into an upright or side-lying position if necessary, offers a suitable liquid, and ensures all medications are swallowed. The nurse then performs any required post-assessments and documents the patient’s response to the medication.

## LIFE-STAGE CONTEXT

### Administering Oral Medications to Children

Several factors should be kept in mind when administering oral medications to children. Sometimes, children are reluctant to take medications. In these instances, it may be helpful to mix the medication with a soft food (e.g., applesauce) when possible or have the child’s caregiver assist with administering the medication. Medications may need to be prescribed in a liquid or chewable form if the child is unable to swallow medications in a solid form. When administering liquid medications to a child, an oral syringe or medication dropper may be used to provide a precise measurement of the medication. Liquid medications should be squirted between the child’s gum and cheek

to avoid aspiration. It is important for the nurse to be patient when administering medications to children and to try to address the child's and caregiver's fears.

For medications given **sublingually** (under the tongue) or **buccally** (between the cheek and gum), ensure the mouth is moist by offering a drink of water prior to administration, which aids absorption. Instruct the patient to allow the medication to completely dissolve without swallowing or chewing it. Liquid medications should be shaken if they are suspensions and poured with the label in the palm of the hand to prevent blurring from any spills. Measure liquids at eye level to ensure accurate dosing, following specific agency policy and procedure when administering oral medications.

### Intradermal Medication Administration

Injecting medications into the dermis layer of the skin, just below the epidermis, is known as **intradermal (ID)** medication administration. This route is commonly used for skin testing, such as tuberculin skin testing (TST), and for administering small volumes of certain medications, such as local anesthetics and allergy tests. Before administering medication intradermally, the nurse must select an appropriate site for injection, typically the inner aspect of the forearm or the upper back, and cleanse the area with an antiseptic solution to minimize the risk of infection. The nurse should also assess the patient's skin integrity and previous reactions to intradermal injections to ensure safety and efficacy.

When preparing for intradermal medication administration, the nurse should use a small-gauge needle, typically 0.25 to 0.5 in (6.4 to 12.7 mm) and 25 to 27 **gauge** (diameter of the hole in the needle), to minimize tissue trauma and ensure accurate placement of the medication within the dermis. The needle should be inserted at a 10- to 15-degree angle into the skin, creating a small bleb or **wheal** (a small, raised, and usually pale bump that forms at the injection site) that indicates proper placement of the medication ([Figure 11.8](#)) (Indiana Department of Health, n.d.). The nurse should inject the medication slowly to minimize discomfort and prevent leakage or dispersion of the medication into surrounding tissues. After administering the medication, the nurse should cover the injection site with a sterile gauze pad or adhesive bandage to protect the area and prevent contamination.

**FIGURE 11.8** A small medication-filled bubble called a wheal, or a bleb, will appear at the injection site if the intradermal medication is administered correctly. (credit: "ID# 6806" by Greg Knobloch, Centers for Disease Control and Prevention/Public Health Image Library, Public Domain)

Following intradermal medication administration, the nurse should closely monitor the injection site for any signs of adverse reactions, such as redness, swelling, or itching. The nurse should also instruct the patient to avoid scratching or rubbing the injection site to prevent irritation and ensure accurate interpretation of skin test results (Indiana Department of Health, n.d.). Additionally, the nurse should document the medication administration, including the medication name, dose, route, injection site, and any patient responses or adverse reactions.

## LINK TO LEARNING

### Subcutaneous Medication Administration

Delivering medications into the fatty tissue layer just beneath the skin is known as **subcutaneous (SQ)** medication administration. This route is commonly used for medications that require slow and sustained absorption into the bloodstream, such as insulin and certain types of vaccines. Before administering medication via the SQ route, the nurse must assess the patient's suitability for this method, considering factors such as the thickness of the subcutaneous tissue, the volume of medication to be injected, and the type of medication being administered. Common sites for SQ injections include the abdomen, upper arms, thighs, and buttocks, with the abdomen being the preferred site for most injections due to its large surface area and consistent absorption rates ([Figure 11.9](#)).

**FIGURE 11.9** The anatomical sites appropriate for administering SQ injections are shown here. The upper back is another appropriate SQ injection site. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

When preparing for an SQ injection, the nurse must adhere to strict aseptic technique to minimize the risk of infection. This involves washing hands thoroughly, preparing the injection site with an antiseptic solution, and ensuring that all equipment is sterile. Additionally, the nurse should select an appropriate needle length and gauge based on the patient's age (25G–30G needle that is 3/8 to 5/8 in [9.5 to 15.9 mm] long), body size, and the type of medication being administered (Mannheim, 2023). After preparing the medication, the nurse should pinch the skin

at the selected injection site to create a skinfold, which helps facilitate proper needle insertion and medication absorption.

During the injection process, the nurse should use a quick, dart-like motion to insert the needle into the subcutaneous tissue at a 45- to 90-degree angle, depending on the needle length and the patient's body size. Once the needle is inserted, the medication should be injected slowly and steadily to minimize discomfort and reduce the risk of tissue damage. After administering the medication, the nurse should withdraw the needle swiftly and apply gentle pressure to the injection site to minimize bleeding. Finally, the nurse should dispose of the used needle and syringe in a puncture-proof container and document the medication administration, including the site used and any patient responses or adverse reactions (Mannheim, 2023).

## LINK TO LEARNING

### Intramuscular Medication Administration

Injecting medications directly into the muscle tissue is known as **intramuscular (IM)** medication administration. This route is commonly used for medications that require a slow and sustained release into the bloodstream or those that cannot be effectively absorbed through the digestive system. Before administering medication via the IM route, the nurse must assess the patient's suitability for this method, considering factors such as muscle mass, amount of fatty tissue, and the volume of medication to be injected. Common sites for IM injections include the deltoid muscle in the upper arm, the vastus lateralis muscle in the thigh, and the ventrogluteal or dorsogluteal muscles in the buttocks (Figure 11.10) (Polania & Munakomi, 2023). The choice of injection site depends on factors such as the patient's age, the volume of medication, and the type of medication being administered.

**FIGURE 11.10** This illustration demonstrates how to locate the (a) deltoid, (b) vastus lateralis, and (c) ventrogluteal site for IM medication injections. (credit a: modification of “Sept-22-2015.11” by British Columbia Institute of Technology, CC BY 4.0; credit b: modification of “Im-vastus-lateralis” by British Columbia Institute of Technology/Wikimedia Commons, CC BY 4.0; credit c: modification of “Im-ventrogluteal-300x244” by British Columbia Institute of Technology/Wikimedia Commons, CC BY 4.0)

When preparing for an IM injection, the nurse must adhere to strict aseptic technique to minimize the risk of infection. This involves washing hands thoroughly, preparing the injection site with an antiseptic solution, and ensuring that all equipment is sterile. Additionally, the nurse should select an appropriate needle length and gauge based on the patient's age (20G–25G needle that is 5/8–1.5-in [15.9–38.1 mm] long), muscle mass, and the type of medication being administered. After preparing the medication, the nurse should **aspirate** the syringe to check for blood return, which helps confirm that the needle is not in a blood vessel before injecting the medication (Polania & Munakomi, 2023).

## LIFE-STAGE CONTEXT

---

### Administering Intramuscular Medications to Pediatric Patients

When administering intramuscular (IM) medications to pediatric patients, nurses must adapt their approach to ensure safety and minimize discomfort. Selecting the appropriate injection site and needle size is crucial, considering the child's age, size, and muscle development. For infants and small children, a shorter needle length (e.g., 5/8 in [15.8 mm]) and smaller gauge (e.g., 25G–27G) are typically appropriate to minimize tissue trauma and discomfort. The vastus lateralis muscle in the thigh is often preferred for IM injections in infants and toddlers due to its larger size and well-developed muscle mass, providing adequate absorption and reducing the risk of nerve injury. In older children and adolescents, longer needles (up to 1.5 in [38.1 mm]) and slightly larger gauges may be used, depending on the child's muscle development and adipose tissue distribution. Nurses should assess the child's individual characteristics, such as body mass index (BMI) and muscle tone, to determine the most suitable injection technique. By tailoring needle size and injection site selection to the child's age and anatomical features, nurses can enhance the safety and comfort of IM medication administration in pediatric patients.

---

During the injection process, the nurse should use a quick, dart-like motion to insert the needle into the muscle tissue at a 90-degree angle (Polania & Munakomi, 2023). Once the needle is inserted, the medication should be injected slowly and steadily to minimize discomfort and reduce the risk of tissue damage. After administering the medication, the nurse should withdraw the needle swiftly and apply gentle pressure to the injection site to minimize bleeding. Finally, the nurse should dispose of the used needle and syringe in a puncture-proof container and document the medication administration, including the site used and any patient responses or adverse reactions.

### Intravenous Medication Administration

Intravenous (IV) medication administration involves delivering medications directly into the bloodstream via a vein. This route allows for rapid absorption and immediate therapeutic effects, making it suitable for medications that require fast onset of action, such as emergency drugs, fluids, and certain antibiotics. Before administering medication intravenously, the nurse must verify the patient's identity, confirm the medication order against the patient's medical record, and assess the patient's vascular access to ensure the availability of suitable veins for infusion. Common sites for IV access include the veins in the arms, hands, and sometimes the feet, depending on the patient's condition and the type of medication to be administered.

When preparing for IV medication administration, the nurse must follow strict aseptic technique to prevent infection and contamination. This involves washing hands thoroughly, disinfecting the infusion site with an antiseptic solution, and using sterile equipment, including IV catheters (small hollow tube placed in the vein), tubing, and syringes. Additionally, the nurse should select the appropriate size and type of IV **catheter** based on the patient's age, vein size, and the viscosity of the medication being administered. The nurse should also assess the compatibility of the medication with the IV solution to avoid potential incompatibilities and adverse reactions.

During the IV medication administration process, the nurse should carefully insert the IV catheter into the vein using aseptic technique and secure it in place to prevent dislodgement. Once the catheter is in place, the nurse should flush the catheter with a saline solution to ensure **patency** (open and unobstructed line) and confirm proper placement ([Figure 11.11](#)). The nurse should administer the medication slowly and continuously, monitoring the patient for any signs of adverse reactions or complications, such as **infiltration** (occurs when the tip of the catheter slips out of the vein and into the surrounding tissue), **extravasation** (infiltration of damaging IV medications into the extravascular tissue around the site of infusion), or **phlebitis** (inflammation of a vein). After completing the medication infusion, the nurse should flush the catheter again to clear any residual medication and maintain catheter patency. Finally, the nurse should document the medication administration, including the medication

name, dose, route, infusion site, and any patient responses or adverse reactions.

**FIGURE 11.11** Part of a nurse's initial assessment includes flushing a saline lock IV with normal saline to ensure and maintain patency. (credit: "Flush the saline lock" by Glynda Rees Doyle and Jodie Anita McCutcheon/Clinical Procedures for Safer Patient Care, CC BY 4.0)

### Eye Medication Administration

Eye (**ophthalmic**) medication administration involves the instillation of medications into the eye to treat various ocular conditions such as infections, inflammation, and glaucoma. Before administering eye medications, the nurse should perform hand hygiene and gather the necessary supplies, including the prescribed medication, sterile saline or sterile water, tissues, and gloves if indicated. To prevent errors, it is essential to verify the patient's identity and confirm the correct medication, dosage, and eye before proceeding with the administration.

To administer an **eye drop**, liquid medication intended for use in the eye, the nurse should instruct the patient to tilt their head back and look up, or lie down if unable to sit upright. Using one hand, the nurse should gently pull down the lower eyelid to create a pouch for the medication. With the other hand, the nurse should hold the medication dropper or bottle above the eye and instill the prescribed number of drops into the conjunctival sac ([Figure 11.12](#)) (Gudgel, 2023). Avoid touching the bottle tip or touching the bottle to the eye or eyelid, to prevent bacterial contamination (Gudgel, 2023). The patient should then close their eyes gently and apply gentle pressure to the inner corner of the eye for one to two minutes to prevent systemic absorption and promote medication absorption.

**FIGURE 11.12** The provider gently pulls the patient's eyelid downward to form a pocket in the lower lid (i.e., conjunctival sac) where the eye drop is placed. (credit: "Instilling eye medication" by British Columbia Institute of Technology (BCIT)/Wikimedia Commons, CC BY 4.0)

For eye ointments, which are greasy semisolids that melt into tiny drops with body warmth, the nurse should instruct the patient to tilt their head back and look up, or lie down if unable to sit upright. Using one hand, the nurse should gently pull down the lower eyelid to expose the conjunctival sac. With the other hand, the nurse should apply a thin ribbon of **ointment** along the inside of the lower eyelid from the inner to the outer corner, ensuring the tube does not touch the eye or eyelashes. The patient should then close their eyes gently and blink several times to distribute the medication evenly across the eye surface. After administration, the nurse should instruct the patient to keep their eyes closed for one to two minutes to minimize eye irritation and systemic absorption. If the patient is receiving eye drops and eye ointments, eye drops should be instilled before applying eye ointment, as the ointment may affect the absorption of the eye drop (Shaw, 2016).

### Ear Medication Administration

Ear (**otic**) medication administration involves the instillation of medications into the ear canal to treat various ear conditions such as infections, inflammation, and excessive earwax buildup. Before administering ear medications, the nurse should perform hand hygiene and gather the necessary supplies, including the prescribed medication, sterile saline or sterile water, cotton balls or gauze, and gloves if indicated. To prevent errors, it is crucial to verify the patient's identity and confirm the correct medication, dosage, and ear before proceeding with the administration.

To administer an **ear drop**, liquid medication applied into the ear canal, the nurse should instruct the patient to lie on their side with the affected ear facing upward. Using one hand, the nurse should gently pull the earlobe upward and backward (downward and backward for a pediatric patient) to straighten the ear canal and create a pathway for the medication ([Figure 11.13](#)) (Nemours Kids Health, 2022). With the other hand, the nurse should hold the medication dropper or bottle above the ear and instill the prescribed number of drops into the ear canal, taking care not to touch the ear or ear canal with the dropper. The patient should then remain in the side-lying position for two to three minutes to allow the medication to penetrate the ear canal fully (Cleveland Clinic, 2023).

**FIGURE 11.13** When administering ear medications, (a) pull the auricle down and back for children or (b) up and back for adults. (attribution a and b: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### LINK TO LEARNING

Watch this video demonstrating how to [administer ear medications \(https://openstax.org/r/77EarMeds\)](https://openstax.org/r/77EarMeds) to a patient.

#### Nasal Medication Administration

Nose or nostril (**nasal**) medication administration involves the delivery of medications into the nasal passages to treat various nasal conditions such as congestion, allergies, and sinus infections. Before administering nasal medications, the nurse should perform hand hygiene and gather the necessary supplies, including the prescribed medication, tissues, and gloves if indicated. To prevent errors, it is essential to verify the patient's identity and confirm the correct medication, dosage, and route before proceeding with the administration.

Before using a nasal medication for the first time, the nasal spray bottle must be primed. This preparatory step entails expelling a few test sprays to eliminate any air from the nozzle or tubing of the bottle, thereby confirming the initial dose administered to the patient contains the accurate amount of medication as intended by the healthcare provider. To administer nasal medications, the nurse should instruct the patient to blow their nose gently to clear the nasal passages. The patient should then sit upright or tilt their head back slightly. Using one hand, the nurse should support the back of the patient's head, while with the other hand, they should hold the medication bottle or nasal spray device. The nurse should insert the nozzle of the bottle or spray device into one nostril, aiming slightly outward toward the ear, and gently press the bottle or spray device to administer the prescribed number of sprays or drops (Figure 11.14). The patient should inhale gently through the nose while the medication is being administered to ensure proper distribution throughout the nasal passages. The process should then be repeated for the other nostril if indicated. The patient should be instructed to avoid blowing their nose or tilting their head forward for five to ten minutes to prevent the medication from leaking out of the nostrils (Cleveland Clinic, 2022).

**FIGURE 11.14** When administering nasal medication, aim the nasal medication bottle toward the ear, away from the septum. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LINK TO LEARNING

Watch this video demonstrating how to [administer nasal medications \(https://openstax.org/r/77NasalMeds\)](https://openstax.org/r/77NasalMeds) to a patient.

### Inhalation Medication Administration

Inhalation medication administration involves delivering medications directly into the respiratory system through inhalation. This method is commonly used to treat respiratory conditions such as asthma, chronic obstructive pulmonary disease (COPD), and respiratory infections. Before administering inhaled medications, the nurse should perform hand hygiene and gather the necessary supplies, including the prescribed medication, inhalation device (such as a metered-dose inhaler or nebulizer), and a **spacer** (a clear tube that fits between the inhaler and the mouthpiece, allowing the medication to move into the spacer for the patient to inhale more slowly and with control) if indicated. To prevent errors, it is crucial to verify the patient's identity and confirm the correct medication, dosage, and route.

For inhalers (pocket-sized devices that deliver medications into the lungs without the use of electricity) and **metered-dose inhalers (MDIs)** (devices that use electricity to create an aerosolized mist of medication that is inhaled into the lungs), the nurse should instruct the patient to shake the **inhaler** well before each use and remove the cap. The patient should then exhale fully to empty the lungs, place the mouthpiece of the inhaler between their lips, and create a tight seal with their lips around the mouthpiece. While breathing in slowly and deeply, the patient should simultaneously press down on the inhaler to release the medication and continue to inhale until their lungs are full. After inhaling the medication, the patient should hold their breath for ten seconds to allow the medication to deposit in the lungs before exhaling slowly. If multiple doses are prescribed, the patient should wait the specified amount of time between doses as directed (National Heart, Lung, and Blood Institute, 2021a).

## LINK TO LEARNING

---

Watch this video demonstrating how to [administer metered-dose inhaler medications \(https://openstax.org/r/77InhalerMeds\)](https://openstax.org/r/77InhalerMeds) to a patient.

---

Small electric or battery-powered machines that deliver a fine mist of liquid medications, or nebulizers, are another common method for delivering inhaled medications and are particularly useful for patients who have difficulty using MDIs or require higher doses of medication. To administer medication via **nebulizer**, the nurse should assemble the nebulizer according to the manufacturer's instructions and add the prescribed amount of medication to the nebulizer chamber. The patient should then sit upright or in a comfortable position and insert the mouthpiece of the nebulizer into their mouth or use a mask if indicated. The nebulizer should be turned on, and the patient should inhale the medication mist produced by the nebulizer until all the medication is gone, which typically takes about five to ten minutes. After administration, the nebulizer should be cleaned and disinfected according to the manufacturer's instructions to prevent contamination and ensure optimal functioning for future use (National Heart, Lung, and Blood Institute, 2021b).

## LINK TO LEARNING

---

Watch this video demonstrating how to [administer nebulized medications \(https://openstax.org/r/77NebulizedMeds\)](https://openstax.org/r/77NebulizedMeds) to a patient.

---

### Vaginal Medication Administration

The insertion of medication into the vaginal canal, known as **vaginal** medication administration, treats various gynecological conditions such as vaginal infections and hormonal imbalances. It is also used to prepare for certain medical procedures. Before administering vaginal medications, the nurse should ensure privacy for the patient and explain the procedure to alleviate any concerns or anxieties. Hand hygiene should be performed, and appropriate supplies, including the prescribed medication, gloves, lubricant (if needed), and applicator (if provided), should be gathered.

To administer vaginal medications, the patient should be instructed to assume a comfortable position, such as lying on their back with knees bent, standing with one foot elevated on a stool, or a left lateral lying position. The nurse should don gloves and prepare the medication according to the provider's orders and manufacturer's instructions. If an applicator is provided, the medication should be drawn into the applicator barrel. If no applicator is provided, the medication may be applied directly from the container or with the nurse's gloved fingers.

Next, the nurse should gently insert the applicator or fingers containing the medication into the vaginal canal, aiming toward the small of the patient's back ([Figure 11.15](#)). The depth of insertion may vary depending on the specific medication and provider's instructions. Once the medication is deposited into the vagina, the applicator should be slowly withdrawn, or the nurse's fingers should be gently removed. Patients should be advised to remain lying down for a few minutes after administration to allow the medication to distribute evenly within the vaginal canal (Carter, 2024).

**FIGURE 11.15** The filled applicator should be inserted into the full length of the vagina before pushing in the plunger. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

After administering the medication, the nurse should dispose of any used supplies appropriately and provide the patient with any necessary postadministration instructions. These instructions may include avoiding sexual intercourse or vaginal douching for a specified period, as well as any potential side effects or adverse reactions to monitor for.

### LINK TO LEARNING

Watch this video demonstrating how to [administer vaginal medications \(https://openstax.org/r/77VaginalMeds\)](https://openstax.org/r/77VaginalMeds) to a patient.

### Rectal Medication Administration

The insertion of medication into the rectum for local or systemic effects is known as **rectal** medication administration. This route is commonly used when the oral route is not feasible due to patient conditions such as vomiting, unconsciousness, or inability to swallow. Before administering rectal medications, the nurse should ensure the patient's privacy and explain the procedure to alleviate any concerns. Hand hygiene should be performed, and appropriate supplies, including the prescribed medication, gloves, lubricant (if needed), and applicator (if provided), should be gathered.

To administer rectal medications, the patient should be instructed to assume a comfortable position, typically lying on their left side with the right knee bent. The nurse should don gloves and prepare the medication according to the provider's orders and manufacturer's instructions. If an applicator is provided, the medication should be drawn into the applicator barrel. If no applicator is provided, the medication may be applied directly from the container or with the nurse's gloved fingers.

Next, the nurse should gently insert the applicator or fingers containing the medication into the rectum, aiming toward the patient's umbilicus ([Figure 11.16](#)). The depth of insertion may vary depending on the specific medication and provider's instructions. Once the medication is deposited into the rectum, the applicator should be slowly withdrawn, or the nurse's fingers should be gently removed. Patients should be advised to remain lying down for a few minutes after administration to allow the medication to be absorbed (Wilson, 2023).

**FIGURE 11.16** The nurse inserts the suppository into the rectum toward the umbilicus. (credit: modification of “Administering-med-rectally-2” by British Columbia Institute of Technology (BCIT)/Wikipedia, CC BY 4.0)

After administering the medication, the nurse should dispose of any used supplies appropriately and provide the patient with any necessary postadministration instructions. These instructions may include avoiding defecation for a specified period to allow the medication to be absorbed, as well as any potential side effects or adverse reactions to monitor for.

### LINK TO LEARNING

Watch this video demonstrating how to [administer rectal medications \(https://openstax.org/r/77RectalMeds\)](https://openstax.org/r/77RectalMeds) to a patient.

## Nursing Roles and Responsibilities of Medication Administration

Nurses play a pivotal role in the safe and effective administration of medications, encompassing a broad range of responsibilities that ensure optimal patient outcomes. These duties include thorough assessment, careful delegation of tasks, accurate documentation, evaluation of medication efficacy, education of patients and their families, and diligent reporting of any errors. By integrating these key responsibilities into their practice, nurses uphold high standards of care and patient safety in medication administration.

### Assessment

When administering medications, one of the pivotal responsibilities of the nurse is comprehensive patient assessment. This assessment occurs before, during, and after medication administration. Prior to administering medications, nurses assess various aspects of the patient’s condition, such as their ability to swallow, current dietary restrictions such as NPO status, and vital signs if deemed necessary. For instance, cardiac medications may require evaluation of heart rate and blood pressure to ensure patient safety. Similarly, reviewing laboratory results is crucial; administering potassium to a patient with elevated levels may lead to further complications. Additionally, before giving PRN medications, assessments of pain levels or sleep patterns are imperative, with the nurse’s clinical judgment dictating whether administration is appropriate.

During medication administration, nurses conduct ongoing patient safety assessments. This includes verifying patient identity, checking for allergies, reviewing the medication “rights,” and ensuring the patient can safely swallow medications. Any signs of difficulty swallowing, such as coughing or choking, warrant halting administration until further assessment can be made to ensure patient safety.

Following medication administration, nurses continue to assess the patient’s response to the medications. This

entails monitoring tolerance, evaluating whether the intended response occurred, reassessing indications for PRN medications, and vigilantly observing for adverse reactions. These postadministration assessments inform clinical decision-making, guiding the nurse on potential changes to the patient's care plan. For example, persistent pain despite pain medication administration may necessitate alternative interventions or medication adjustments. Adverse reactions may prompt discontinuation of the medication and the need for new orders.

### Delegation

When delegating medication administration to assistive personnel (if permitted in the state of practice), the nurse must ensure the five rights of delegation: right task, right circumstance, right person, right directions and communication, and right supervision and evaluation. In determining the right task, it is important for the nurse to ensure the assistive personnel has received the appropriate training and has been deemed competent in the skill. In determining the right circumstance, the nurse should consider the patient's circumstances before delegating the task. Instances in which the results are unpredictable, risks are involved, or medication administration challenges are predicted should not be delegated to the assistive personnel. The right person involves delegating the right task to the right person. It is important for the nurse to be aware of which assistive personnel have been credentialed to administer medications and correctly identify the patient to receive the medication. In ensuring the right directions and communication, the nurse should provide clear instructions regarding the task that needs to be completed, when it should be completed, as well as any additional expectations associated with the task. The right supervision and evaluation require the nurse to provide appropriate monitoring, evaluation, intervention, and feedback.

### Documentation

Upon completion of administering medications, the nurse is responsible for documenting the medication administration as well as any required postadministration assessments. This step is the one in which the medication administration "rights" of right documentation and right response are verified. To ensure accurate documentation, guidelines have been developed to ensure that only approved abbreviations are used, documentation is timely, and there is adequate evaluation of the patient's response to the medication.

#### Accuracy of Documentation

Thorough and accurate documentation is critical for clinical decision-making and the delivery of high-quality care. The patient's medical record serves as a communication tool for the interdisciplinary team and is crucial for ensuring continuity of care. Not only does accurate documentation inform the care team of the patient's current situation and allow for treatment decisions to be made, but it also provides legal evidence that may be used in the court of law. Therefore, accurate documentation is needed to provide the very best care and to mitigate risks.

#### Approved Abbreviations

When documenting medication administrations, it is essential to use only approved abbreviations to avoid potential errors. Agencies should implement standardized abbreviations to ensure consistency and reduce confusion. The ISMP's National Medication Errors Reporting Program highlights numerous error-prone abbreviations linked to medication errors, which should be avoided. TJC's Do Not Use List must be incorporated into organizational policies. For instance, abbreviations for magnesium sulfate ( $MgSO_4$ ) and morphine sulfate ( $MSO_4$ ) should never be used due to the high risk of significant patient harm. Medication names should typically be spelled out in full to prevent confusion, such as avoiding HCT for hydrocortisone and HCTZ for hydrochlorothiazide.

### LINK TO LEARNING

View The Joint Commission's [Do Not Use List fact sheet \(https://openstax.org/r/77DNUFactSheet\)](https://openstax.org/r/77DNUFactSheet).

Dosages should avoid fractions and Roman numerals, as they can be misinterpreted, and proper spacing between drug names, doses, and units of measurement should be maintained to prevent errors. For example, write "Metoprolol 25 mg" with adequate spacing to avoid it being read as "Metoprolol 125 mg." Use commas for numbers greater than one thousand, and use standard measurement units such as mL for milliliters and mcg for micrograms. Routes of administration should be written out in full, though some agencies may allow abbreviations such as PO for oral and IM for intramuscular. Additionally, documenting the administration site for injections is crucial to avoid confusion.

When expressing medication frequency, writing the frequency in full (e.g., daily, at bedtime) is safest, although abbreviations such as Q for *every* may be used with caution. For instance, QD can denote *daily*, but spelling out *daily* is recommended. Symbols are generally not recommended in medication documentation; instead, spell out terms such as *more than* and *less than* rather than using > and <. Similarly, use words such as *increase* and *decrease* instead of directional arrows, and avoid symbols such as @, &, and +, which can be misinterpreted. Using clear and standardized documentation practices is crucial to ensuring safe medication administration.

## LINK TO LEARNING

View the ICMP's [list of error-prone abbreviations \(https://openstax.org/r/77ErrorAbbrev\)](https://openstax.org/r/77ErrorAbbrev).

### Timing of Documentation

Medications should be documented immediately after administration to reduce potential errors and ensure accuracy. This practice minimizes the risk of duplicate administration and can alert clinicians to any changes in the patient's condition. Documenting medication administration prior to actually administering the medication can lead to errors if the patient's condition changes. For instance, a nurse may document an IV medication before administration, only to discover the IV has infiltrated. Similarly, documenting oral medications before administration may be problematic if the patient cannot safely swallow, or if the patient refuses the medication when it is offered. There is also a risk that the nurse might document the administration of the medication but then forget to actually administer it.

### Evaluation

After administering medications, it is crucial for the nurse to ensure the medication achieved the intended outcome as part of the nursing process. For instance, the nurse should check if the patient's blood pressure decreased after administering blood pressure medication or if a fever reduced after giving a fever reducer. If the medication does not produce the expected outcome, the nurse should report this to the provider and document the response in the patient's chart.

The timing for evaluating the medication's effect depends on its onset. Typically, oral medications should be assessed within thirty minutes to one hour, whereas IV medications should be evaluated much sooner, usually within five to fifteen minutes, depending on the medication. Nurses should follow their agency's policies for evaluation time frames.

In addition to the intended response, the nurse should document any adverse reactions, including allergic responses. For example, if a rash develops thirty minutes after administering a new medication, the nurse should document this reaction in the MAR and write a progress note detailing the response, including that the provider was notified and any additional orders received. PRN medications must also be evaluated, with clear documentation of the indication for the medication and reassessment according to its onset. For instance, pain assessments should be conducted thirty minutes to one hour after administering oral pain medications and within ten to fifteen minutes after administering IV pain medications.

### Education

Educating patients about their medications is crucial for ensuring they understand the purpose, dosage, and potential side effects of their prescribed drugs. Nurses should explain how and when to take the medication, any dietary or activity restrictions, and the importance of adhering to the prescribed regimen.

Nurses should also explain what patients can expect with medication administration. This includes potential immediate effects, how long it might take for the medication to start working, and any common side effects they should watch for. Nurses should inform patients about signs of adverse reactions that would require contacting their healthcare provider. It is also important to teach patients how to administer their medications safely and effectively, demonstrating the proper techniques for the administration route.

Educating patients empowers them to take an active role in their own health care, promotes adherence to treatment plans, and enhances overall health outcomes. Nurses should also assess the patient's understanding and readiness to learn, tailoring their educational approach to meet individual needs and ensuring that the patient or caregiver can

correctly follow the medication regimen independently. Providing written materials or resources can help reinforce this information.

## PATIENT CONVERSATIONS

---

### Educating a Patient on Nasal Sprays

**Nurse:** Good morning, Mrs. Yang. I see here that your provider has prescribed a nasal spray for your congestion. Have you used one before?

**Patient:** Yes, I've used nasal sprays in the past, but it has been a while.

**Nurse:** No problem, I'll walk you through it. Nasal sprays are liquid medications that you spray into your nostrils to help clear congestion and reduce inflammation in your nasal passages.

**Patient:** How many times should I spray it?

**Nurse:** Your prescription indicates that you should administer one spray in each nostril once a day. It's important not to exceed this dosage unless instructed otherwise by your provider.

**Patient:** Got it. How do I use it?

**Nurse:** Before using the nasal spray for the first time, you'll need to prime the bottle. To do this, you'll pump the spray bottle a few times until you see a fine mist. Once it's primed, tilt your head slightly forward, insert the nozzle into one nostril, and point it toward the back of your head, away from the center of your nose. As you spray, inhale gently and then repeat the process for the other nostril.

**Patient:** Should I blow my nose before or after using the spray?

**Nurse:** It's best to blow your nose gently before using the spray to clear any excess mucus. Afterward, try to avoid blowing your nose for a few minutes to allow the medication to be absorbed properly.

**Patient:** Okay, that makes sense. Thank you for your help.

**Nurse:** You're welcome, Mrs. Yang. If you have any other questions or concerns, don't hesitate to ask.

---

### Reporting Errors

Nurses are legally responsible for ensuring safe and accurate administration of medications and may be held liable for medication errors. When a medication error occurs, the nurse's first responsibility is to ensure the patient's safety by immediately monitoring the patient for any adverse effects and providing necessary interventions. Following this, the nurse must notify the appropriate healthcare team members, including the nurse manager (and/or charge nurse) and the prescribing provider, to ensure timely corrective measures are taken. Documentation of the error is also essential, often in the form of an incident report. This report should detail the nature of the error, the patient's response, and any actions taken. The aim of reporting is not to assign blame but to identify and address potential system-wide issues, contributing to a culture of safety within the healthcare environment. By reporting medication errors, nurses play a vital role in preventing future errors, enhancing patient safety, and fostering continuous quality improvement in healthcare settings.

The nurse is also legally responsible for delegated tasks. Some states may allow the nurse to delegate medication administration to unlicensed assistive personnel (UAP) (Carder & O'Keeffe, 2016). In these instances, the nurse is responsible for supervising the UAP throughout the medication administration process. Although some tasks may be delegated to the UAP, the nurse remains responsible for the assessment, planning, teaching, evaluation, and nursing judgment associated with the administration of medications.

## Summary

### 11.1 Medication Orders

Different types of medication orders include routine orders, one-time orders, standing orders, STAT orders, PRN orders, and titration orders, each with specific indications for nursing practice. Routine orders are continuously followed until canceled, whereas one-time orders are for a single dose. Standing orders allow nurses to intervene promptly without waiting for provider orders, and STAT orders are administered urgently. PRN orders are used as needed for specific symptoms, and titration orders involve dose adjustments based on patient status.

The components of a medication order are crucial elements that ensure safe and effective medication administration. They include specific patient identifiers such as name and date of birth; details about the prescribed drug including its name, dosage, and route of administration; and the frequency and timing of administration. Additionally, the order must include the date and time it was written, along with the signature of the prescribing healthcare provider, to authenticate the order and ensure accountability.

### 11.2 Fundamental Principles of Medication Administration

To reduce the risk of medication errors, several safety measures should be implemented during medication administration. These measures include ensuring correct patient identification, checking medication orders for errors, maintaining a safe environment, and monitoring for adverse reactions. Adverse reactions are unwanted and unpredictable effects of drugs that can be influenced by various factors, including age, sex, genetics, and underlying conditions. Severe allergic reactions, such as anaphylaxis, require immediate medical attention. Drug toxicity, resulting from an accumulation of a drug in the body, can cause significant harm and must be promptly addressed. Tolerance, drug interactions, and paradoxical effects also play a crucial role in medication safety, necessitating thorough monitoring and appropriate interventions. An interdisciplinary approach involving nurses, providers, and pharmacists can further minimize errors by verifying safety at multiple checkpoints. Organizations such as the ISMP and TJC provide guidelines and standards to support these measures, including lists of high-alert medications and recommended abbreviations.

Nurses play a crucial role in ensuring patient safety during medication administration by adhering to the rights of medication administration, including confirming the right patient, drug, route, time, and dose. Additional rights recommended by the American Nurses Association (ANA), such as right reason, documentation, and response, further enhance safety and accountability. Bar Code Medication Administration (BCMA) is utilized to minimize errors by electronically confirming medication administration rights through barcode scanning. Nurses must also verify patient history, assess for drug interactions, provide education, and respect the patient's right to refuse medication, ensuring comprehensive medication safety and adherence to ethical standards.

### 11.3 The Medication Administration Process

The practice of medication administration in nursing involves various routes such as oral, intradermal, subcutaneous, intramuscular, intravenous, ophthalmic, otic, nasal, inhalation, vaginal, and rectal, each requiring specific techniques for effective delivery while minimizing adverse reactions. Oral medication administration, typically via tablets or liquids, involves assessing patient safety, verifying medication orders, positioning the patient, and ensuring proper swallowing and absorption. Intradermal injections, used for skin testing and local medications, require careful site selection, skin assessment, and slow injection to create a wheal. Subcutaneous injections, commonly used for insulin and vaccines, demand aseptic technique, proper site selection, skin pinching, and slow, steady injection. Intramuscular injections, for slow drug release or digestive system bypass, necessitate aseptic technique, appropriate needle selection, muscle assessment, and aspiration to avoid blood vessels. Intravenous administration delivers medications directly into the bloodstream, requiring meticulous asepsis, vascular assessment, and monitoring for adverse reactions. Ophthalmic, otic, nasal, inhalation, vaginal, and rectal routes demand similar attention to hygiene, patient positioning, medication preparation, and administration techniques to ensure safety and efficacy, emphasizing patient education and comfort throughout the process.

Nurses are integral to the safe and effective administration of medications, ensuring optimal patient outcomes through thorough assessment, careful delegation, accurate documentation, evaluation of medication efficacy, patient education, and diligent error reporting. Assessment is conducted before, during, and after medication

administration, encompassing aspects such as the patient’s ability to swallow, vital signs, and allergy checks. Delegation involves ensuring the right task, person, circumstance, communication, and supervision. Documentation is crucial for verifying medication administration “rights” and ensuring accurate records of patient responses. Nurses also play a vital role in evaluating medication efficacy and educating patients while actively reporting errors to promote patient safety and continuous quality improvement.

## Key Terms

- adverse reaction** an unwanted and undesirable effect of a drug
- allergic reaction** an immune system response to a drug
- anaphylaxis** a rare, life-threatening reaction to a drug
- apothecary system** a system of measurement that utilizes fractions as a part of the whole to measure weights and volumes
- aspirate** to pull back on the plunger to assess for blood return
- buccally** between the cheek and gum
- capsule** a powder or granules contained in a gelatin shell
- catheter** a small hollow tube placed in a vein
- computerized provider order entry (CPOE)** a patient order that the provider submits electronically
- dependence** a condition in which a patient depends on the drug in order to function
- drug interaction** a drug reaction with another drug, food, supplement, or medical condition
- drug toxicity** the degree to which a drug can be poisonous or harmful to the body
- dysphagia** difficulty swallowing
- ear drop** liquid medication applied into the ear canal
- enteric-coated tablet** a tablet covered in a substance that delays the medication from dissolving
- extravasation** the infiltration of damaging IV medications into the extravascular tissue around the site of infusion
- eye drop** liquid medication intended for use in the eye
- gauge** the diameter of the hole in a needle
- household system** a system of measurement utilizes everyday household items, such as measuring cups and tablespoons, to serve as the measuring device
- infiltration** the leakage of IV fluid into surrounding tissue as a result of the tip of the catheter slipping out of the vein.
- inhaler** a pocket-sized device that delivers medications into the lungs without the use of electricity
- intra-dermal (ID)** occurring within the dermis layer of the skin, just below the epidermis
- intra-muscular (IM)** occurring within the muscle tissue
- medication order** a prescription ordered within clinical practice
- metered-dose inhaler (MDI)** a device that uses electricity to create an aerosolized mist of medication that is inhaled into the lungs
- metric system** a decimal-based system based on units of ten
- nasal** relating to the nose or nostrils
- nebulizer** a small electric or battery-powered machine that delivers a fine mist of liquid medications
- ointment** greasy semisolid that uses body warmth to melt into tiny drops
- one-time order** medication to be administered just one time
- ophthalmic** relating to the eye
- otic** relating to or located near the ear
- paradoxical effect** an effect of a drug that is opposite from the intended effect
- patency** the state of being open and unobstructed
- phlebitis** inflammation of a vein
- PRN order** a medication order that is administered as needed
- rectal** relating to or affecting the rectum
- routine order** a medication order that is continuously followed until canceled
- side effect** a predictable, undesirable effect related to a drug
- spacer** a clear tube that fits between the inhaler and the mouthpiece, allowing the medication to move into the spacer for the patient to inhale more slowly and with control
- standing order** a standardized order that may be implemented under certain circumstances

**STAT order** a medication order that is urgent or requires immediate action

**subcutaneous (SQ)** relating to or affecting the fatty tissue layer just beneath the skin

**sublingually** under the tongue

**tablet** powder or granules compressed into a pill shape

**timed-release** consisting of or containing medication that is released in small amounts over time for prolonged action

**titration order** a medication dose that is either progressively increased or decreased by the nurse in response to the patient's status

**tolerance** a decrease in the effectiveness of a drug over time due to repeated use

**vaginal** relating to or affecting the vagina

**wheal** a small, raised, and usually pale bump that forms at an injection site

## Assessments

### Review Questions

1. What medication order type allows the nurse to administer medications for pain, nausea, or vomiting without waiting for a provider's order?
  - a. one-time order
  - b. standing order
  - c. PRN order
  - d. STAT order
2. The provider has requested a medication to be given as quickly as possible. What medication order type would the nurse expect to be ordered?
  - a. one-time order
  - b. standing order
  - c. PRN order
  - d. STAT order
3. The nurse receives an order for "Ibuprofen (Advil) 400 mg every four hours." What action should the nurse take?
  - a. Administer the medication to the patient.
  - b. Call the pharmacy to clarify the order.
  - c. Call the provider to clarify the order.
  - d. Assess if the patient has a headache.
4. The provider writes an order for "Amoxicillin 500 mg PO QID." What is the correct interpretation of "QID"?
  - a. once daily
  - b. every four hours
  - c. every hour
  - d. four times daily
5. During medication administration, how should the nurse confirm the medications are for the right patient?
  - a. Ask the patient to state their full name and compare the name given to the name on the patient's armband.
  - b. Ask the patient to state their full name and birth date, comparing the information to the MAR and the patient's armband.
  - c. Ask the patient to state their full name and room number, comparing the information to the MAR and the patient's armband.
  - d. Ask the patient to state their last name and birth date, comparing the information to the MAR and the patient's armband.
6. The patient is prescribed warfarin (Coumadin) to prevent blood clots and is instructed not to consume large amounts of green leafy vegetables. These instructions are provided to prevent which potential adverse

reactions?

- a. allergic reaction
  - b. drug interaction
  - c. paradoxical effect
  - d. toxic effect
- 7.** The five core “rights” of medication administration should be checked at three different checkpoints during the medication administration process. What are the three medication checkpoints?
- a. when obtaining, preparing, and documenting the medication
  - b. when preparing, administering, and disposing of the medication
  - c. when obtaining, preparing, and administering the medication
  - d. when preparing, administering, and documenting the medication
- 8.** A new medication order is placed by the provider. Upon verifying the order, the nurse realizes the patient is allergic to the drug. Which patient “right” is the nurse concerned about in this scenario?
- a. right patient
  - b. right drug
  - c. right dose
  - d. right route
- 9.** What does a “paradoxical effect” mean in medication administration?
- a. The drug has no effect at all.
  - b. The drug causes the opposite of the intended effect.
  - c. The drug causes an allergic reaction.
  - d. The drug’s effect is exactly as intended.
- 10.** The nurse is preparing to administer eye drops. What is the appropriate procedure for administering eye drops?
- a. Instruct the patient to keep their eyes closed for thirty seconds.
  - b. Place the eye drop in the inner canthus of the eye.
  - c. Press one finger against the inner canthus of the eye after administering the eye drop.
  - d. Wipe dirt and debris away from the eye from the outer canthus to the inner canthus.
- 11.** The nurse is preparing to administer a nasal medication. How should the patient be positioned?
- a. lying down with the head tilted toward the affected side
  - b. lying down with the head tilted toward the unaffected side
  - c. sitting with the head tilted backward
  - d. sitting with the head tilted forward
- 12.** The nurse is administering an intradermal injection. What is the proper technique for administering ID injections?
- a. Hold the syringe at a 10- to 20-degree angle from the site.
  - b. Administer using a 22- to 24-gauge needle.
  - c. Hold the syringe at a 10- to 15-degree angle from the site.
  - d. Administer using a 20- to 22-gauge needle.
- 13.** A patient is ordered an enteric-coated medication PO (by mouth) TID (three times a day); however, the patient is having difficulty swallowing the tablet. What action should the nurse take?
- a. Contact the prescribing provider to discuss alternatives.
  - b. Divide the tablet in half using a pill splitter.
  - c. Dissolve the tablet in a small amount of liquid.
  - d. Crush the tablet and place it in applesauce.

## Check Your Understanding Questions

1. What are the required components of a complete medication order?
2. What three systems of measurement are commonly used for medication dosing? Which system of measurement is the most accurate?
3. What are the eight rights of medication administration as recommended by the ANA?
4. List three safety measures that should be implemented when administering medications.
5. What is the purpose of using tall man lettering in medication names?
6. What is the appropriate needle gauge and length to use for an SQ injection?
7. A medication is ordered sublingual. How should the nurse administer the medication?
8. Describe the process for administering oral medications.
9. Explain the importance of using approved abbreviations in medication documentation.

## Reflection Questions

1. Consider the importance of understanding different types of medication orders in your nursing practice. How does this knowledge contribute to patient safety?
2. Imagine a patient had an adverse reaction to a medication you administered. How would you respond?
3. Why should the patient's room number not be used for identification purposes?
4. While opening the package, the medication falls on the floor. What should the nurse do?
5. Discuss the challenges you might face when delegating medication administration tasks to UAP.

## What Should the Nurse Do?

1. You are in the exam room with the patient and provider and hear the provider mention placing an order for an antibiotic. When you review the medication order, you notice the route is missing. What should you do?
2. You come across a medication order with an abbreviation that is not recognized and is not listed in any medication reference guide. What should be your next course of action?

Mr. Hammad, a 65-year-old male, complains of a headache. Upon looking at his chart, you notice the medication orders:

- Ibuprofen 800 mg PO Q6 hours PRN pain
- Tylenol 500 mg PO Q6 hours PRN pain

3. Which medication should the nurse administer?
4. What should the nurse do if the medication label does not match the medication order?
5. What steps should the nurse take if the patient refuses to take the prescribed medication?
6. While administering ophthalmic medications, the nurse drops the lid to the eye drop medication bottle on the floor. What should the nurse do?
7. What should the nurse do if a patient experiences difficulty swallowing during medication administration?
8. What should the nurse do if a medication error occurs?

## Competency-Based Assessments

1. Create a table that outlines the various types of medication orders (routine orders, one-time orders, standing orders, STAT orders, PRN orders, and titration orders). Provide a description of the order type, when it may be used, and examples for each order type.
2. Outline how you would confirm the "right patient" before medication administration.

3. Create a presentation describing the nurse's role in assessing a patient before, during, and after medication administration.
4. Draw a diagram displaying the appropriate angles for intradermal, subcutaneous, intramuscular, and intravenous medication administration.

## CHAPTER 12

# Assessment: Recognizing Cues

**FIGURE 12.1** Nursing assessments are the foundation for efficient and effective patient-centered care. (credit: “Combat Nurses” by Tech. Sgt. D. Clare/U.S. Air Force, Public Domain)

### CHAPTER OUTLINE

- 12.1 The Nurse’s Role in Assessment
- 12.2 Types of Assessment
- 12.3 Collection of Assessment Data
- 12.4 Cognitive Process for Analyzing Assessment Data

**INTRODUCTION** It is a familiar scene that happens countless times each day: a nurse assesses a patient. The information collected about the patient’s health will enable the care team to identify potential problems, diagnose the likely causes, and plan appropriate treatments. At one moment, the nurse may use a specific tool to assess a specific part of a patient’s body, for example, an otoscope to check this patient’s ears. However, the exam room contains numerous other assessment tools and sources of important information that the nurse needs to pay attention to, including the patient and family members or caretakers who have accompanied them. This chapter explores assessment, from the patient’s initial examination to the diverse skills nurses use in gathering data and determining care priorities.

## 12.1 The Nurse’s Role in Assessment

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the primary focus of a nursing assessment
- Explain the domains of the nursing assessment
- Identify how to conduct assessments with clinical reasoning

The systematic and dynamic process of collecting and analyzing data about a patient's health is called **assessment**, and it forms the cornerstone of patient care (American Nurses Association, n.d.). In essence, the nursing assessment is a comprehensive approach to understanding a patient's health status. The process aims to identify the needs and concerns of patients, serving as the foundation for subsequent nursing care plans. A nursing assessment is not just an evaluation of physical symptoms—it encompasses a broader perspective that includes psychological, sociocultural, and environmental factors influencing a patient's well-being.

In every assessment, nurses must decipher a complex array of information. They must sift through various data points, from clinical signs and laboratory results to the patient's expressed concerns and behaviors. This process requires technical knowledge, expertise, and a keen sense of empathy and intuition. The goal is to create a holistic picture of the patient's health, enabling nurses to prioritize care and interventions effectively.

### Primary Focus of a Nursing Assessment

The primary focus of nursing assessment is to gather comprehensive and accurate information about a patient's health status, including physical, psychological, social, and environmental factors. First, nurses gather detailed health histories encompassing past illnesses, surgeries, medications, allergies, and family medical backgrounds. Subsequently, a thorough physical examination is performed to evaluate vital signs, general appearance, skin condition, cardiovascular and respiratory functions, neurological status, and body systems. Psychosocial assessment is crucial, revealing a patient's mental health status, emotional well-being, coping mechanisms, support systems, cultural beliefs, and socioeconomic factors. Functional assessment evaluates the patient's ability to perform daily activities and mobility, while nutritional assessment delves into dietary habits, nutritional status, and related concerns. Pain assessment is fundamental, examining pain presence, intensity, duration, and impact. Medication review ensures accurate reconciliation and identifies potential drug interactions. Risk assessment aims to pinpoint safety concerns, and collaboration with the healthcare team facilitates comprehensive care planning. The nursing assessment is the foundation for developing an individualized care plan and effective nursing care.

To conduct a thorough and accurate assessment, nurses must recognize the signs of apparent physical health issues, such as high blood pressure or mottled skin, as well as the more subtle indicators that may suggest underlying problems. For example, a patient might mention specific sources of stress or allude to a family history of a particular condition. It is essential to recognize that assessment is an ongoing, dynamic process. Nurses continuously collect data, assess patient responses, and adapt care plans as the patient's condition progresses. This proactive approach ensures that care remains responsive and tailored to evolving patient needs.

### Evaluate Patient's Response to Impaired Health

When evaluating a patient's response to impaired health, nurses consider the effect of health issues on the patient's overall well-being. The nurse must look at physical symptoms and assess how these symptoms affect the patient's mental and emotional health. For example, a patient recovering from surgery might show signs of depression or anxiety. A patient with chronic arthritis might experience reduced mobility, leading to feelings of frustration or dependency; they may experience social isolation or financial strain due to an inability to work. All these concerns are as important to address as the physical aspects of recovery.

A critical component of this evaluation is understanding the patient's resilience and coping mechanisms. This part of the assessment might include identifying a patient's support networks, such as family or community resources, or the use of coping strategies like meditation or exercise to manage pain. Nurses assess these factors to provide holistic care, which encompasses the physical, psychological, emotional, and spiritual dimensions of an individual patient.

### Evaluate Basic Human Needs

Evaluating basic human needs is a fundamental component of the nursing assessment. This concept, rooted in theories such as Maslow's hierarchy of needs, suggests there are fundamental needs that must be met for a person to achieve optimal health. These needs include physiological requirements, safety and security, love and belonging, self-esteem, and self-actualization (McLeod, 2018). Maslow's hierarchy is discussed in greater detail in [12.3 Collection of Assessment Data](#).

Nurses primarily concentrate on assessing their patients' physiological needs, particularly in the initial stages of the assessment. They must thoroughly review factors such as nutrition, hydration, breathing, circulation, sleep patterns,

and pain management. Nurses assess these factors to ensure that a patient's fundamental health requirements are being met, which is crucial for recovery and stability. For example, a patient with diabetes requires careful monitoring of dietary intake and blood sugar levels, addressing their physiological need for homeostasis.

Safety and security also play a role in assessment. In particular, nurses seek to identify environmental or personal factors that might pose risks to a patient's health. For instance, in cases of malnutrition, nurses must address the patient's immediate dietary needs as well as explore potential causes like food insecurity or disordered eating. If these significant contributors are not addressed, the patient will continue to struggle with malnutrition.

## REAL RN STORIES

### Assessing Basic Human Needs as Part of the Nursing Assessment

**Nurse:** Leonard, RN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 11

**Facility location:** Las Vegas, Nevada

I was working on a busy medical-surgical unit when I encountered a patient admitted for exacerbation of congestive heart failure. Upon initial assessment, it was evident the patient was experiencing significant difficulty breathing. They also exhibited anxiety and appeared fatigued. Since assessing basic human needs is important, I began my assessment by prioritizing the patient's physiological needs.

First, I made sure the patient's airway was clear and that oxygen therapy was initiated to improve oxygenation. While addressing the physiological aspect, I also recognized the patient's psychological needs, as evidenced by their anxious demeanor. I engaged in therapeutic communication with the patient, offering reassurance and support to alleviate their anxiety. I also assessed the patient's nutritional status and hydration, recognizing the importance of meeting these basic needs for their overall well-being and recovery. I collaborated with the dietitian to ensure the patient received dietary modifications and adequate hydration as appropriate for their medical condition. I also considered the patient's sociocultural needs, acknowledging their religious beliefs and preferences regarding care. I facilitated spiritual support by arranging for a visit from the hospital chaplain, who provided emotional and spiritual guidance to the patient and their family.

Throughout the patient's hospital stay, I continually reassessed their basic human needs, adjusting interventions as needed to promote healing and comfort. By holistically addressing the patient's physiological, psychological, and sociocultural needs, I provided comprehensive care that contributed to their recovery and well-being.

### Actual Problems

In the context of nursing assessment, an **actual problem** refers to current health issues that are identifiable through a patient's symptoms or clinical evidence. They are the immediate concerns that the patient presents with and require prompt attention. The nurse's role is to accurately assess these concerns, document them, and initiate appropriate interventions (Ajibade, 2021).

Accurate identification of actual problems is crucial, as it forms the basis of the care plan and interventions. For example, when assessing a patient with respiratory distress, the nurse would note symptoms like shortness of breath, then check the patient's oxygen saturation levels and respiratory rate and listen to their lung sounds. This thorough evaluation allows the nurse to determine the severity of the problem and the urgency of the required care.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Analyze Cues: Assessing a Patient's Pain Level

The nurse is providing care to a patient who is recovering from a recent surgery. When conducting an assessment, the nurse would gather data through observation and patient communication, noting the presence of pain behaviors such as grimacing, guarding of the surgical site, and verbal expressions of discomfort. The nurse would also assess the patient's pain level using a standardized pain scale.

On assessment, the nurse notes the presence of redness, swelling, and tenderness at the surgical incision site. The patient reports pain intensity of eight out of ten on the numerical pain scale. The pain significantly affects their ability to perform activities of daily living and rest comfortably.

Based on this assessment data, the nurse identifies “Acute Pain related to surgical incision” as an actual problem requiring nursing intervention.

### Potential Problems

A **potential problem** includes a risk or condition a patient is susceptible to but is not currently manifesting symptoms of. A nurse’s ability to foresee these issues is critical to preventive care. If not properly monitored and addressed, potential problems could become actual problems (Gaines, 2023). For example, a bedridden patient is at risk of developing pressure ulcers. Even if the ulcers are not present at the time of assessment, the nurse must recognize the risk and implement preventive measures like regular repositioning and skin assessments. Similarly, a patient with a history of falls requires a thorough assessment to identify any risk factors present, such as medication side effects or environmental hazards, to prevent future incidents. Identifying and addressing potential problems is a key aspect of proactive nursing care.

## CULTURAL CONTEXT

### Ethnicity and Genetic Predisposition in Nursing Assessments

Ethnicity and genetic factors can significantly impact a patient’s risk for certain health conditions. However, nurses should always remain sensitive to individual variations and avoid stereotyping, ensuring that each patient’s care is informed by their unique health profile and needs. Nurses must be aware of the predispositions common to their patients, otherwise assessments might miss potential problems. Here are a few examples:

- Individuals of Black ancestry are known to have a higher risk of hypertension, stroke, and type 2 diabetes. Tailoring assessments to these risks involves closely monitoring blood pressure and blood sugar levels and educating patients about the importance of lifestyle factors in managing these conditions (American Heart Association, n.d.).
- Individuals of South Asian descent often have an increased risk of heart disease, including myocardial infarction, at a younger age. Nurses should consider early cardiovascular screenings and discussions about heart health for patients in this demographic (Purnani & Merchant, 2020).
- Individuals of Ashkenazi Jewish descent are more susceptible to certain genetic conditions, such as Tay-Sachs disease, and certain types of breast cancer (*BRCA1* and *BRCA2* mutations). Nurses should be aware of these risks when assessing symptoms and collecting family health histories (Levy, 2023).
- There is a heightened prevalence of type 2 diabetes in individuals of Hispanic and Latin American descent. Nurses should prioritize diabetes screening and provide culturally appropriate dietary and lifestyle education (Centers for Disease Control and Prevention, 2022).
- Individuals of American Indian descent have higher rates of death from several diseases, including heart disease, liver disease, and stroke. Assessments should include screenings for these conditions and discussions about preventive health measures (Indian Health Service, 2019).

By incorporating knowledge of specific predispositions into assessments, nurses can more effectively identify potential health risks within specific patient populations. This approach enables early intervention and personalized care planning, improving health outcomes for diverse patient populations.

### Domains of the Nursing Assessment

To provide holistic care, the nurse must give each patient a comprehensive assessment covering all health domains, including physical, psychosocial, emotional, and spiritual (American Nurses Association, n.d.). These domains represent different aspects of a patient’s well-being, and each plays a crucial role in determining how best to address their needs. Consider a patient with a history of cardiovascular disease who is complaining of shortness of breath and chest pains. A thorough assessment would likely begin by noting these physical symptoms, but the nurse would then need to assess the other domains to get a complete picture of the patient’s health.

## Physical

The physical domain of the nursing assessment involves a systematic examination of the body. To thoroughly assess a patient's physical health status, the nurse will focus on various aspects of the patient's anatomy, physiology, and functioning. Nurses begin by measuring vital signs, such as temperature, blood pressure, pulse rate, and respiratory rate, to assess the patient's physiological status. They observe the patient's general appearance, including skin color, hydration status, body posture, and grooming, which may provide valuable insights into overall health. A head-to-toe assessment follows, with nurses examining each body system, assessing the skin for abnormalities, auscultating heart and breath sounds, evaluating neurological status, and assessing musculoskeletal function. Additionally, they thoroughly examine the gastrointestinal (GI) and genitourinary (GU) systems, along with the lymphatic and endocrine systems, for any signs of dysfunction or irregularities. This comprehensive assessment allows nurses to identify any abnormalities or areas of concern, guiding interventions to promote optimal health and well-being. By focusing on the physical domain of assessment, nurses gather essential data to inform diagnosis, treatment planning, and ongoing patient care, ensuring holistic and individualized care delivery.

For example, a physical assessment for a patient with signs of cardiovascular disease would include measuring blood pressure, heart rate, and oxygen saturation. The nurse would also perform a cardiac examination, listen to the heartbeat to detect murmurs or irregularities, and inspect the patient's extremities for signs of poor circulation, such as edema or cyanosis. The nurse might also review the results of diagnostic tests, such as electrocardiograms (ECGs) or lipid profiles, to corroborate physical findings and obtain information that will help them determine the severity and specific characteristics of the patient's condition.

## Psychosocial

The psychosocial domain includes both psychological and social components of mental health. This domain of nursing assessment delves into the patient's mental, emotional, and social well-being, recognizing the interconnectedness between psychological and social factors and how they affect health.

Nurses employ a holistic approach to gathering information about a patient's mental health status, emotional state, coping mechanisms, social support network, and cultural beliefs and values. Again, therapeutic communication and active listening help nurses establish rapport with patients, creating a safe and supportive environment for open expression of thoughts and feelings. The nurse comes to understand the patient's perception of their illness, their level of distress or anxiety, and their ability to cope with stressors. Additionally, nurses consider the patient's social context, including family dynamics, living situation, and socioeconomic factors, which may influence their health and treatment outcomes. By addressing psychosocial factors in nursing assessment, nurses can identify potential barriers to care, provide emotional support and counseling, and facilitate referrals to appropriate resources such as social services or mental health professionals.

To continue the previous example, the nurse would likely assess the patient's understanding of their condition, mental state, and any stressors that might exacerbate their symptoms of cardiovascular disease. Assessment questions might explore the patient's support network, occupation, lifestyle, and coping mechanisms. For example, a patient experiencing high stress at work or lacking a reliable support network may be at increased risk for a heart attack. The nurse might use validated tools such as the **Holmes-Rahe Life Stress Inventory** to measure the stress level experienced by an individual based on the occurrence of certain life events within a specified period, to quantify the patient's stress levels and guide interventions, such as educating them about stress management techniques or connecting them with support groups (American Institute of Stress, 2023).

## LINK TO LEARNING

The [Holmes-Rahe Life Stress Inventory \(https://openstax.org/r/77holmesrahe\)](https://openstax.org/r/77holmesrahe) instructs patients to identify potentially stressful life events they have experienced in the past year, such as the death of a family member, a pregnancy, a vacation, or a legal problem. Each event is assigned a certain number of points. Patients who score higher on the inventory are experiencing more stress and are therefore more likely to experience a health problem in the near term.

### Emotional

The emotional domain of the nursing assessment requires the nurse to observe the patient's demeanor and emotional responses regarding their health condition. Distinguishing between psychological and emotional needs, psychological needs encompass broader aspects of mental well-being such as cognition, behavior, and self-perception, while emotional needs focus specifically on feelings and expressions associated with experiences, including the need for validation, support, and empathy in response to emotional states. To elicit these responses, the nurse typically asks open-ended questions. The nurse will also employ empathetic communication and active listening skills to create a supportive environment where patients feel comfortable expressing their emotions and concerns. Through therapeutic interactions, the nurse can assess the patient's emotional responses to their illness or injury, including fear, anxiety, sadness, or frustration.

Another tool in the nurse's arsenal is screening for common mental health disorders, such as depression and anxiety, for which they can use standardized assessment tools as available and appropriate. Conducting screenings helps nurses identify patients who may require further evaluation or intervention from mental health professionals.

To continue with the example, the nurse might ask how the patient feels about their risk of heart attack and listen for signs of anxiety, depression, or other emotional responses. The nurse would also observe nonverbal cues, such as body language or facial expressions, to gauge emotional state. Tools such as the **Beck Depression Inventory**, a widely used self-report questionnaire designed to assess the severity of depression symptoms, may be used for more structured emotional assessment (American Psychological Association, 2020).

### LINK TO LEARNING

The [Beck Depression Inventory \(https://openstax.org/r/77beckdepress\)](https://openstax.org/r/77beckdepress) consists of twenty-one questions relevant to the patient's feelings of optimism and self-esteem.

Effective communication skills help nurses encourage patients to express their concerns and fears. For instance, a patient who is anxious about their condition may need reassurance and information about their treatment plan, and providing that information can alleviate anxiety and improve compliance with medical recommendations.

### Spiritual

The nurse also needs to assess a patient's spiritual needs, which involves understanding their religious practices, if any. It also explores their beliefs and values concerning their place in the universe, as well as the fundamental meaning and purpose of their life. These beliefs may shape the patient's approach to their health care and preferences about treatment.

The nurse should approach the spiritual assessment with sensitivity and respect for the diverse spiritual and religious backgrounds of patients. It is important to use open and nonjudgmental communication to explore a patient's spiritual beliefs, including their faith traditions, rituals, and sources of spiritual strength or comfort. The nurse will specifically ask about a patient's spiritual needs, such as the desire for prayer, religious rituals, or pastoral support, to ensure that these aspects of care are incorporated into the patient's treatment plan, if desired. The nurse will also need to understand how the patient's spiritual beliefs influence their coping mechanisms, resilience, and sense of meaning and purpose in life.

The nurse could start this conversation by asking the patient open-ended questions, such as the following:

- Please tell me about your spiritual and religious preferences.
- Please tell me about your religious practices that may impact your health care.
- How does your faith or spirituality help you cope with challenges?
- How important is your faith in your health and healing process?
- How would you describe your connection to a religious or spiritual community?
- How does your community support you during difficult times?

The **Faith, Importance and Influence, Community, and Address (FICA) tool**, a tool used by healthcare professionals to assess patients' spiritual and religious beliefs and practices, provides a more structured approach to understanding a patient's spirituality (GW Institute for Spirituality and Health, 2024).

## LINK TO LEARNING

---

The FICA tool is a framework used by healthcare professionals, including nurses, to assess and address the spiritual needs of patients. FICA stands for the following:

- faith, belief, meaning
- importance and influence
- community
- address/action in care

More [information about FICA \(https://openstax.org/r/77infoFICA\)](https://openstax.org/r/77infoFICA) is provided at this website, including a free download of the tool.

---

## Conducting Assessments

Nursing assessment is a critical skill that requires **clinical reasoning**, a structured, thoughtful approach that synthesizes a nurse's knowledge and experience with patient data to determine an appropriate response to a medical problem (Gruppen, 2017). An effective assessment is not just about collecting data; it involves collecting the right data in the right way. Data should be purposeful, prioritized, complete, systematic, accurate, and significant, and the nurse should ensure that documentation follows established standards and guidelines. We explore each of these aspects in the context of a patient presenting with signs of cardiovascular disease.

### Purposeful

A purposeful assessment involves conducting evaluations with specific goals in mind. Before beginning an assessment, nurses clearly define the objectives they aim to achieve, such as identifying symptoms, assessing responses to treatment, or evaluating progress toward therapeutic goals.

Purposeful assessments help focus attention on relevant information, leading to more efficient use of time and resources. For example, when caring for a patient with potential heart disease, the nursing assessment would be specifically tailored to look at the function of the patient's cardiovascular system. In addition to physical tests, the nurse would take the patient's personal and family history of previous heart conditions and identify any relevant lifestyle factors, such as smoking or exercise habits. This targeted approach ensures that the information gathered is directly relevant to the patient's current health concerns.

### Prioritized

Prioritizing assessments is how the nurse arranges for the most urgent and essential aspects of a patient's condition to be addressed first. Nurses must triage assessments based on the patient's immediate needs, severity of symptoms, and potential risks. For a patient with cardiovascular risk, priority might be given to evaluating the intensity of their chest pain, asking about shortness of breath, and identifying other signs of an imminent heart attack, such as lightheadedness or nausea. Such prioritization is critical in acute settings where timely interventions can be lifesaving.

### Complete

A complete assessment covers relevant aspects of the patient's health. This includes gathering information about physical, psychological, social, and environmental factors that may affect the patient's well-being. Nurses must consider the patient's medical history, current symptoms, functional status, and risk factors during assessments. For a patient with chest pain, the nurse would assess related systems and risk factors, such as blood pressure, lipid profiles, and glucose levels, to create a more comprehensive picture of the patient's current health status.

### Systematic

Systematic assessments follow a structured and organized approach, ensuring consistency and reliability in data collection. Nurses should use standardized assessment tools and protocols, when possible, to guide their evaluations. By following a systematic process, healthcare professionals can methodically gather information, identify patterns or trends, and track changes over time. When assessing a patient for cardiovascular disease, for instance, the nurse would follow a set sequence, typically starting with a health history, then a physical examination, and a review of diagnostic tests. This systematic approach promotes thoroughness and reduces the likelihood of

assessment errors or omissions.

### Accurate

Accuracy in assessments involves collecting reliable and precise data that reflect the patient's true health status, which is crucial for correct diagnosis and treatment planning. Nurses should use validated assessment techniques and reliable, evidence-based measurement tools to ensure the accuracy of their observations. They should also critically evaluate the quality of information gathered, considering factors such as source credibility, relevance, and consistency. For example, assessing a cardiac patient involves using precise techniques for measuring blood pressure, accurately interpreting heart sounds, and correctly reading diagnostic tests like ECGs. Each nursing assessment needs to be original and not just copied from the previous nurse's assessment to ensure that any changes in the patient's condition are accurately identified. Accuracy ensures the reliability of the assessment data.

### Significant

Significance in assessment refers to the importance and relevance of the data collected. The nurse must ascertain the most relevant information for a patient's condition and care plan. Significant assessments help healthcare professionals identify priorities, set goals, and tailor interventions to meet each patient's unique needs. For example, a cardiovascular assessment of a patient may provide the nurse with a wealth of important data, including a history of myocardial infarction or the presence of risk factors like hypertension. Identifying a smoking history would be relevant and significant to the cardiac patient as well as even learning that the patient's favorite snack is a salty food, which may increase fluid retention.

### Documentation Follows Standards and Guidelines

Proper documentation in nursing assessments is critical for ensuring effective patient care and legal compliance. It involves adhering to established protocols and regulations that govern how patient information is recorded and shared. Key aspects of these standards and guidelines include the following:

- **Accuracy and completeness:** Documentation must accurately and completely reflect the nursing assessment. This means recording all relevant findings, including the patient's statements, observations made during the physical examination, and results from diagnostic tests. Documenting both normal and abnormal findings is essential to provide a full picture of the patient's health status.
- **Timeliness:** Entries should be made as soon as possible after an assessment to ensure the information is current and accurate. Timely documentation is crucial when a patient's condition changes rapidly, as it can significantly impact subsequent care decisions.
- **Confidentiality and privacy:** Throughout an assessment, the nurse must adhere to laws and regulations related to patient confidentiality, such as the Health Insurance Portability and Accountability Act (HIPAA), a U.S. law protecting identifiable patient health information and preventing its disclosure without patient consent. These regulations dictate how patient information can be shared and stored, emphasizing the need to protect patient privacy.
- **Standardized format:** Many healthcare facilities have standardized formats for documenting information, including an electronic health record (EHR), a digital version of a patient's comprehensive medical history. These systems often include templates or checklists that guide nurses in recording specific information, ensuring consistency and completeness in the documentation process, and enabling all members of a patient's care team, including the patient, to easily access the information.
- **Legibility and professional language:** Documentation should be legible and use professional, nonbiased language. In the case of electronic records, this includes ensuring that entries are typed accurately. Standardized medical terminology and abbreviations are necessary for clear communication among healthcare professionals.
- **Legal and ethical considerations:** Nurses must be aware of the legal implications of nursing documentation. Inaccurate or incomplete documentation may violate federal or state laws and negatively affect the quality of patient care. Ethically, nurses are responsible for ensuring their documentation reflects an honest and accurate account of the assessment. This documentation also serves as proof of care when legal issues arise.

By following these protocols and regulations, nurses ensure that their documentation is a reliable and useful tool in the patient care continuum. Well-documented assessments aid in clinical decision-making, ensure continuity of care, and provide legal protections for both the patient and the healthcare providers (American Nurses Association, 2010).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Enhancing Nursing Assessment Documentation with QSEN Competencies

Streamlining nursing assessment documentation while adhering to Quality and Safety Education for Nurses (QSEN) competencies ensures high-quality patient care. By integrating QSEN competencies into documentation practices, nurses can enhance patient safety, improve care coordination, and promote evidence-based practice. The following is how key QSEN competencies align with effective documentation of nursing assessments:

#### Patient-centered care:

- Ensure that documentation reflects a patient-centered approach, emphasizing the patient's preferences, values, and goals.
- Include patient-reported outcomes and concerns in the assessment documentation to ensure care plans are tailored to individual needs.
- Document communication with patients and families, including education provided, shared decision-making, and care preferences.

#### Teamwork and collaboration:

- Document interdisciplinary communication and collaboration regarding assessment findings, care plans, and patient progress.
- Clearly communicate assessment findings and care priorities to other members of the healthcare team through comprehensive documentation.
- Document interprofessional care conferences, consultations, and recommendations to facilitate coordinated care delivery.

#### Evidence-based practice:

- Ensure assessment documentation is based on evidence-based guidelines, protocols, and best practices.
- Document the rationale behind assessment decisions, interventions, and care plans, referencing current evidence to support clinical decisions.
- Use standardized assessment tools and validated measures to gather and document data systematically and accurately.

#### Quality improvement:

- Document outcomes of nursing assessments and interventions, tracking progress over time and identifying areas for improvement.
- Use documentation data to identify trends, patterns, and opportunities for enhancing the quality and effectiveness of nursing assessments.

#### Safety:

- Document safety measures implemented during assessments to prevent adverse events and ensure patient safety.
- Document patient identifiers, allergies, and precautions to prevent medication errors, falls, and other safety incidents.
- Use documentation to report and follow up on safety concerns, near misses, and adverse events, contributing to a culture of safety within the healthcare organization.

#### Informatics:

- Utilize EHR systems to streamline documentation.
- Leverage telehealth platforms and remote monitoring devices to conduct virtual assessments and monitor patients' vital signs remotely.
- Incorporate mobile health applications and patient portals to empower patients in self-assessment, symptom tracking, and health management.

By aligning documentation practices with these competencies, nurses can enhance the accuracy, efficiency, and effectiveness of nursing assessments, ultimately improving patient outcomes and experiences.

## 12.2 Types of Assessment

### LEARNING OBJECTIVE

By the end of this section, you will be able to:

- Explain the key differences in the types of nursing assessments and when to use each type

Nursing practice demands a dynamic and adaptable approach to patient assessments, as these are not one-size-fits-all tools for data collection. Assessments vary depending on a patient's condition, the clinical setting, and the specific point in the care process. Understanding the different types of assessments is fundamental for nurses, as each type serves a unique and vital purpose in patient care.

This section explores the nuances of various types of assessments and explains when and why each would be appropriate. This knowledge ensures procedural competence as a nurse and enhances critical-thinking and decision-making skills. By understanding the purpose and application of different assessments, nurses are better equipped to respond to the diverse needs of patients, ensuring high-quality care tailored to each individual's situation.

### Different Types of Nursing Assessments

At the heart of nursing is the goal of providing patient-centered care. To achieve this goal, nurses utilize a spectrum of assessment techniques tailored to meet the diverse needs of their patients ([Table 12.1](#)). These assessments range from initial evaluations, which provide a comprehensive view of the patient's health, to more focused assessments targeting specific health problems. Rapid and targeted assessments are crucial in emergencies to address immediate and life-threatening concerns. In contrast, ongoing and time-lapsed assessments help monitor a patient's progress over time and adjust care plans accordingly (Lloyd-Davies, 2024; Verve College, n.d.).

Type of Assessment	Description	Example of When to Use
Initial	Comprehensive assessment performed on admission or entry	When a patient is admitted to a hospital or clinic
Problem-focused	Assessment focused on a specific problem or complaint	When a patient complains of chest pain or nausea
Ongoing	Continuous assessment performed at regular intervals	During routine rounds or shift changes
Emergency	Rapid assessment conducted in critical or life-threatening situations	When a patient experiences cardiac arrest or trauma
Time-lapsed	Assessment performed after a longer period to compare changes over time	When checking progress after a week of treatment

**TABLE 12.1** Types of Assessments

#### Initial Assessment

The **initial assessment** is the first extensive evaluation of a patient's overall health status. This type of assessment is typically conducted on a patient's admission to a healthcare facility or at the time the patient begins receiving care. The primary goal of the initial nursing assessment is to establish a baseline understanding of the patient's health condition so that any immediate health concerns or problems can be identified. It involves a comprehensive evaluation of the patient's physical condition, medical history, and current symptoms.

Typically, an initial assessment begins with collecting basic demographic information, followed by conducting an in-

depth review of the patient's medical and surgical history. This includes any chronic conditions, medications, allergies, past hospitalizations, and surgeries, as well as the patient's perspective on the issues that brought them to the facility. The nurse also inquires about the patient's lifestyle choices, such as diet, exercise habits, and tobacco or alcohol use, which can significantly impact health. The nurse also investigates social determinants of health (societal and environmental conditions in which individuals live and work), encompassing factors like housing stability, socioeconomic status, access to health care, and social support networks, to gain a comprehensive understanding of the patient's health needs within the context of their environment.

Physical examination forms a significant part of the initial assessment. The nurse conducts a head-to-toe exam to systematically evaluate each body system. This examination includes assessing vital signs such as blood pressure, heart rate, and temperature. The nurse will also observe the patient for signs of distress or discomfort (Nightingale College, 2022).

## LINK TO LEARNING

---

A checklist is a useful tool for ensuring the nurse conducts a comprehensive physical examination. This [sample checklist \(https://openstax.org/r/77checklist\)](https://openstax.org/r/77checklist) provided by Nightingale College details the steps in a typical head-to-toe assessment.

---

The initial assessment sets the stage for all future healthcare interactions and decisions for the patient. It provides a comprehensive view of the patient's health and helps identify any immediate health concerns that need addressing. Even for patients who are healthy and well, this assessment serves as a baseline to which future assessments can be compared to monitor for changes. Effective communication skills are essential, as establishing trust and rapport with the patient is necessary for obtaining accurate and complete information. During this process, the nurse must be attentive, empathetic, and sensitive to the patient's needs and concerns.

### Establishing a Complete Database

The initial assessment is also an opportunity to begin compiling a complete database for the patient. This database serves as the cornerstone for all subsequent nursing care and interventions. It includes detailed information about the patient's physical, psychological, and emotional status, which form the basis for developing an individualized care plan.

The process of creating a patient database involves gathering both subjective and objective data. The patient's descriptions of their symptoms, feelings, and perceptions are known as **subjective data**. Subjective data may also include relevant descriptions from friends or family members. The measurable and observable information collected during a physical examination, such as blood pressure, heart sounds, and lung sounds, and any data obtained from lab results are called **objective data** (Lukey, 2023).

In addition to health-related information, a comprehensive dataset includes an assessment of the patient's social and environmental factors, which encompasses family health history, social relationships, cultural background, and environmental factors like living conditions, financial circumstances, and occupational hazards. These elements are crucial in understanding the broader context of the patient's health and wellness.

## PATIENT CONVERSATIONS

---

### Conducting an Initial Assessment

**Scenario:** Mrs. Sanchez, a 64-year-old Mexican American female, has come to a neighborhood clinic complaining of chest pain. After checking the patient's vital signs, Nurse Jordan proceeds with the initial examination.

**Nurse:** Mrs. Sanchez, you mentioned you were experiencing some chest discomfort. How would you describe the pain you are feeling?

**Patient:** It's like a heavy pressure, especially when I'm walking.

**Nurse:** When did you first notice this discomfort?

**Patient:** About two days ago.

**Nurse:** Do you have any other symptoms, like shortness of breath, dizziness, or nausea?

**Patient:** I've felt a little short of breath, but no dizziness or nausea.

**Nurse:** Thank you for sharing that. It's important information. Have you ever experienced anything like this before?

**Patient:** No, this is the first time.

**Nurse:** I see. Let's talk about your medical history. Do you have any chronic conditions like hypertension or diabetes?

**Patient:** I've had high blood pressure for years. I take medication for it.

**Nurse:** Tell me the name of your medication, and are you taking it as prescribed?

**Patient:** It's lisinopril, I think. I take it most days, but sometimes I forget.

**Nurse:** Forgetting can happen. Is there someone in your household who could support you in remembering to take your medication?

**Patient:** Actually, I have lived alone since my partner passed away last year. So, there's no one around to remind me.

**Nurse:** I'm sorry to hear that. It's important to manage your hypertension, especially with your current symptoms. Let's talk about some strategies that could help you remember to take your medication. Some patients find setting a daily alarm on their phone or using a pill organizer helpful. What do you think about these options?

**Patient:** An alarm might work. I do have a smartphone.

**Nurse:** Great! Setting an alarm can be a simple, yet effective reminder. Now, about your support network: do you have family, friends, or neighbors who check in on you? Or someone you feel comfortable reaching out to if you need to?

**Patient:** My daughter lives out of state, but we talk on the phone. My neighbor, Mrs. Omar, has been kind enough to check on me sometimes.

**Nurse:** It's good to have someone to talk to and check in on you. I would encourage you to keep in regular contact with your daughter and perhaps inform Mrs. Omar about your current health condition, just so she's aware. Having a support system, even if it's not in-house, can be very beneficial.

---

### Problem-Focused Assessment

A **problem-focused assessment** is a targeted examination conducted to assess a specific health issue or symptom identified in a patient. This type of assessment is narrower in scope than an initial assessment and is crucial when a patient presents with new or worsening symptoms. It allows nurses to quickly and efficiently address and monitor specific health concerns.

For example, if a patient complains of acute abdominal pain, a problem-focused assessment would involve evaluating the abdomen, including noting the location, nature, and severity of the pain, as well as any accompanying symptoms like nausea or vomiting. The nurse would also review relevant aspects of the patient's medical history, such as recent surgeries or digestive issues, and check for any changes in vital signs that might indicate a serious underlying problem.

This type of assessment is also key for managing chronic conditions, where it can monitor specific aspects of the patient's health. For example, in patients with heart failure, regular, problem-focused assessments can be used to monitor fluid status and heart function, ensuring that any changes to the patient's condition are caught and treated promptly.

### Ongoing Assessments

An **ongoing assessment** is a fundamental subset of problem-focused assessments that involve continuous monitoring and evaluation of the patient's health status, their response to treatment, and any changes in their condition over time. Unlike the initial assessment, which provides a comprehensive snapshot of the patient's health

at a specific point, ongoing assessment is dynamic and occurs over time. Nurses regularly collect and analyze data, including vital signs, laboratory results, and observations of the patient’s physical, psychosocial, and emotional status. Ongoing surveillance allows nurses to detect subtle changes or deterioration in the patient’s condition promptly, intervene as necessary, and modify care plans to address evolving needs.

When planned at specific intervals, ongoing assessments are critical for patients when regular monitoring is essential for managing a condition, for example, when a patient is recovering from an acute illness or surgery or is living with chronic illness. In a postoperative context, for example, ongoing assessments might include frequent monitoring of wound healing, pain levels, nausea and vomiting, vital signs, and signs of infection.

In acute care settings, such as emergency departments, ongoing assessments ensure timely interventions for patients with rapidly changing conditions. In chronic disease management, such as diabetes, scheduled assessments may include regular monitoring of blood glucose levels, foot examinations, and review of medication adherence. These assessments facilitate the early identification of complications and adjustments in the management plan.

## PATIENT CONVERSATIONS

### Focused Assessment for Feet in Patients with Diabetes

**Scenario:** Keiko, an emergency room nurse, is caring for Mr. Strout, who presented with hyperglycemia. Mr. Strout has poorly controlled diabetes mellitus and has not seen a healthcare provider for follow-up for several years because he does not have health insurance. The nurse is assessing the patient and is ready to move on to the foot examination.

**Nurse:** Mr. Strout, I’d like to take a look at your feet next. Can you take your shoes off, or would you like some help?

**Patient:** My feet? What do you want to look at them for? I’m here ‘cause my sugars are bad.

**Nurse:** Your feet can actually be affected by diabetes. Is it okay with you if I take a look at them? I’ll explain as I go along.

**Patient:** Well, I guess, if you say so. Could you give me a hand . . . with my feet? Ha!

**Nurse:** Sure thing.

[The nurse helps Mr. Strout remove his shoes and socks and proceeds with the assessment.]

**Nurse:** So, what I’m going to look for are signs that there is damage to your feet that could be related to your high blood sugar levels. If there’s damage, you may not be getting enough blood and oxygen flowing to your feet. This can lead to things like discoloration or even ulcers. Have you noticed anything like that?

**Patient:** No, but I don’t look at my feet very much, honestly.

**Nurse:** Do you have any pain or feelings like tingling or numbness?

**Patient:** Well...now that you mention it, they do feel funny sometimes.

[The nurse continues to closely examine Mr. Strout’s feet, looking at the skin and nails for any signs of discoloration, poor healing, or infection. Feeling the feet and pulses gives the nurse an idea of blood flow, and noting any other signs, like an odor, will also be an important part of the assessment. At the same time, the nurse continues to engage with the patient and answer questions and elicit more information about the patient’s foot health.]

**Nurse:** Can you tell me more about what “funny” feels like?

**Patient:** You know, like TV static in your foot. Like it falls asleep.

**Nurse:** How often does that happen?

**Patient:** I don’t know, exactly. Once in a while.

**Nurse:** That feeling comes from your nerves. Sometimes, nerves can get damaged by diabetes too. We call that

neuropathy. And that can be dangerous in any part of your body, but especially in your feet. Please be sure to tell the provider about those feelings in your feet, and I'll make a note in your chart.

**Patient:** Okay . . . sorry I didn't trim my toenails, didn't think I'd be getting a pedicure today.

**Nurse:** Do you trim your nails regularly?

**Patient:** Yup, if I don't, they get all ingrown and hurt.

**Nurse:** Great habit to get into. Foot hygiene is very important, things like keeping them nice and clean and dry, and trimming your nails, making sure you don't get any fungus . . . that all helps keep them healthy.

**Patient:** If my sugars don't get better, could I not be able to walk?

**Nurse:** Diabetic foot problems can be very serious, Mr. Strout. In severe cases, people are in a lot of pain and can't walk. When they get bad infections, they may even need to have a foot amputated.

**Patient:** Yikes! Well, how do they look? My feet?

**Nurse:** I don't see any wounds, which is great. But I want you to tell the provider about those tingling feelings. They'll talk to you more about how you can take care of your feet and work on getting those blood sugars under control.

[The nurse will document the findings and make sure to answer any further questions from the patient before completing the assessment.]

### Emergency Assessment

An **emergency assessment** is conducted when a patient presents with life-threatening or potentially life-threatening conditions. The goal of emergency nursing assessment is to swiftly identify and address immediate threats to the patient's life or health, initiating appropriate interventions to optimize outcomes and promote patient survival. This type of assessment has a rapid and focused nature and is aimed at identifying and addressing critical health issues promptly. In emergency settings, time is of the essence, and the accuracy of these assessments can have significant implications for patient outcomes.

In critical moments, nurses prioritize the assessment of vital signs and airway, breathing, and circulation (ABCs) to quickly determine a patient's stability and the need for urgent interventions. This assessment may involve assessing the patient's level of consciousness, oxygen saturation, heart rate, blood pressure, and respiratory rate. For example, if a patient exhibits signs of a stroke, the nurse quickly assesses for balance, vision changes, facial drooping, arm weakness, and speech difficulties in a timely manner. Following the primary survey, a secondary survey is conducted to gather more detailed information about the patient's condition and history.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Form a Hypothesis: Emergency Pain Assessment

**Identifying cues:** John, a 62-year-old male, is brought into the emergency department by ambulance after collapsing at home. On arrival, he is unconscious and unresponsive. His wife, who accompanied him, informs the medical team that John has a history of hypertension and diabetes, for which he takes medications regularly. She reports he has been complaining of severe headaches and dizziness for the past week but attributed it to stress from work. She also mentions that he has been increasingly fatigued and has experienced episodes of confusion and blurred vision.

#### Analyzing cues:

- unconsciousness and unresponsiveness upon arrival
- history of hypertension and diabetes
- complaints of severe headaches and dizziness for the past week
- increased fatigue and episodes of confusion and blurred vision

**Forming a hypothesis:** Given John's medical history, symptoms, and recent complaints, a hypothesis could be

that he is experiencing a hypertensive crisis or a diabetic emergency, such as diabetic ketoacidosis or hyperosmolar hyperglycemic state. These conditions are characterized by severe fluctuations in blood pressure or glucose levels, which can lead to neurological symptoms and loss of consciousness if left untreated.

The nurse's role in an emergency assessment is to swiftly collect critical data and initiate necessary interventions, such as administering oxygen or initiating CPR if required. The ability to make quick, informed decisions is crucial in these high-stakes scenarios. Although nurses can formulate nursing diagnoses and intervene based on their assessments, it is important to acknowledge that the formal medical diagnosis is the responsibility of the healthcare provider.

### Physiological Crisis

In emergency nursing assessment, a **physiological crisis** refers to a critical situation where the patient's physiological functions are severely compromised, posing an immediate threat to life or health. Conditions such as heart attacks, severe respiratory distress, or major trauma would all fall under this category. When encountering a physiological crisis, nurses must act quickly and decisively to stabilize the patient's condition and prevent further deterioration. A crisis may manifest in various ways, such as respiratory distress, cardiac arrest, severe bleeding, or neurological deterioration.

Assessment during a physiological crisis typically begins with a rapid evaluation of the patient's ABCs, which are vital for sustaining life. Nurses assess the patency of the airway, the adequacy of breathing, and the presence of a pulse to determine the patient's immediate needs. This assessment may involve interventions such as administering oxygen, initiating cardiopulmonary resuscitation (CPR), or controlling severe bleeding. For example, in a patient experiencing a severe asthma attack, the assessment would include evaluating respiratory rate, oxygen saturation, and the presence of wheezing or other abnormal breath sounds. Immediate interventions might include administering bronchodilators or corticosteroids.

In addition to the ABCs, nurses gather pertinent information about the circumstances leading to the crisis, the patient's medical history, allergies, and medications. This information helps guide the assessment and subsequent interventions. Vital signs such as heart rate, blood pressure, respiratory rate, and oxygen saturation, are closely monitored to assess the patient's physiological status and response to treatment.

The ultimate goal of the emergency nursing assessment during a physiological crisis is to stabilize the patient's condition, restore physiological function, and initiate appropriate interventions to prevent further harm. During a physiological crisis, nurses must maintain clear communication with other members of the healthcare team and prioritize interventions based on the patient's condition and the resources available. Multidisciplinary collaboration is crucial for delivering timely and effective care, especially in high-stakes situations.

### Psychological Crisis

A **psychological crisis** refers to a state of acute emotional or mental distress that significantly impairs an individual's ability to cope with their current circumstances. These crises may arise due to various factors such as trauma, acute stress, psychiatric disorders, substance abuse, or suicidal ideation. In such cases, the emergency assessment focuses on evaluating the patient's mental status, ensuring their safety, and identifying immediate psychological needs. Key components include assessing the patient's level of consciousness, cognition, thought processes, mood, and affect.

When encountering a psychological crisis, nurses must employ compassionate and effective assessment techniques to ensure the safety and well-being of the patient. Nurses utilize active listening skills to allow patients to express their feelings and concerns openly. To ensure a safe environment, the nurse may need to implement measures like constant observation if the patient poses a risk to themselves or others. Recommending a referral to mental health specialists and initiating crisis intervention protocols are often part of the response in such situations.

### Time-Lapsed Assessment

A **time-lapsed assessment** is a systematic process for evaluating a patient's health status and progress over time, usually every few months. Unlike initial assessments performed on admission or during the early stages of care, time-lapsed assessments occur at regular intervals throughout a patient's treatment trajectory, allowing nurses to monitor changes, track trends, and adjust care plans accordingly. These assessments serve several purposes,

including assessing the effectiveness of interventions, detecting new health issues or complications, evaluating the patient's response to treatment, and promoting continuity of care.

The frequency and timing of time-lapsed assessments vary depending on factors such as the patient's acuity level, the nature of their health condition, the goals of care, and institutional protocols. For patients with chronic conditions or complex medical histories, time-lapsed assessments may occur weekly, monthly, or at other predetermined intervals. In contrast, patients with acute conditions or undergoing rapid changes in status may require more frequent assessments.

This type of assessment is common in all settings but is particularly important in chronic disease management and long-term care. For example, in a patient with hypertension, a time-lapsed assessment might include reviewing changes in blood pressure readings over several months, assessing medication effectiveness, and making necessary adjustments in the treatment plan. It also includes reevaluating the patient's lifestyle changes and the impact of these changes on health outcomes.

Documentation plays a critical role in time-lapsed assessments because it allows nurses to document changes in the patient's condition, track progress toward goals, and communicate findings with other members of the healthcare team. As they help providers track the improvement or worsening of a condition, time-lapsed assessments support timely interventions and modifications in the care plan. They are integral to ensuring continuity of care and adapting care strategies to meet the evolving needs of the patient.

## 12.3 Collection of Assessment Data

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Verbalize primary sources to collect data during an assessment
- Recognize the importance of establishing priorities during the assessment
- Recall how the nurse will analyze data collected during the assessment

The information nurses gather about a patient's health status is referred to as **data**. This information guides clinical decision-making and is essential in developing a personalized approach to care. Data collected during nursing assessments can be categorized into two types: objective and subjective (Lukey, 2023).

- Objective data are quantifiable and measurable aspects of a patient's condition, such as vital signs, laboratory test results, and physical examination findings. These observable facts provide concrete evidence about the patient's health.
- Subjective data consist of information provided directly by the patient or their caretakers, including their personal experiences, feelings, and perceptions of their health and symptoms. These data offer invaluable insights into the patient's personal view of their health status and contribute to a holistic understanding of their needs.

Both types of data are indispensable in nursing assessments, complementing each other to create a full picture of a patient's health.

This module explores the various data sources, discusses how nurses set priorities during the assessment process, and explains how nurses analyze the data they collect. Mastering these skills is integral to becoming a proficient and compassionate nursing professional.

### Sources of Data

Nurses gather assessment data from a variety of sources, including the patients themselves and their family members or other caretakers. Information that comes directly from the patient is **primary data**, while **secondary data** comes from another source, such as a patient's family member or medical record. Nurses also utilize their clinical skills and observations. Each data source provides unique insights, contributing to a comprehensive understanding of the patient's health status.

#### The Patient

The patient is often the most important source of data in nursing assessments. Through direct communication with patients, nurses gather subjective data by asking open-ended questions, actively listening to their concerns, and

exploring their perspectives on their health condition.

Subjective data gathered from the patient include their personal experiences, symptoms, feelings, beliefs, past medical history, medication history, and perceptions of their health. For example, a patient's description of their pain—its location, intensity, and character—provides indispensable information that cannot be obtained through objective means alone. Patients can also offer key information about their lifestyle, such as dietary habits, exercise routines, and substance use, which are critical to understanding their overall health and well-being.

In addition to verbal communication, nonverbal cues from the patient, such as facial expressions, body language, and overall demeanor, offer valuable data. For instance, a patient's posture and facial expressions can indicate pain or discomfort, even if they have not verbally expressed it. Effective communication skills, including active listening and empathetic engagement, are essential for nurses to interpret and utilize the data provided by the patient accurately.

### The Family

Family members and significant others can also be key sources of data on a patient, especially in situations where the patient is unable to communicate effectively. Such may be the case for many pediatric, geriatric, or critically ill patients. Family members can provide historical information, corroborate patient reports, and offer insights into the patient's normal behavior and daily functioning. For example, when assessing a patient with Alzheimer disease, family members can provide crucial information about the patient's baseline cognitive function and recent changes in behavior or memory.

Family-provided data also extend to understanding the patient's home environment and social support system, which are significant in planning postdischarge care. In pediatric care, the observations of parents and guardians when discussing a child's symptoms, eating habits, and developmental milestones are invaluable in forming a complete assessment. It is also important for nurses to consider cultural and familial dynamics, as these influences determine the information provided by family members and the patient's health practices and beliefs.

## CULTURAL CONTEXT

---

### Cultural Diversity and the Collection of Data

Understanding and respecting cultural diversity is essential in nursing assessments. Nurses often encounter patients from various cultural backgrounds, and recognizing how cultural factors influence health beliefs and practices is crucial for collecting accurate data. Here are some examples illustrating the importance of cultural awareness (U.S. Department of Health and Human Services, 2004):

- **Communication styles:** In some cultures, direct eye contact might be considered disrespectful, while in others, it is a sign of honesty and engagement. For instance, patients from certain Asian cultures may avoid direct eye contact with healthcare providers as a sign of respect, which should not be misinterpreted as disinterest or noncompliance.
- **Pain expression:** Cultural norms can influence how patients express pain. Some cultures encourage vocal expression of pain, while others may value stoicism. Nurses must realize that a patient who does not outwardly seem to be in pain might nevertheless be hurting.
- **Family involvement:** In many cultures, family plays a central role in healthcare decisions. In Hispanic and South Asian cultures, for example, family members, including extended family, often participate actively in care discussions and decision-making. Understanding these dynamics is important for communicating effectively and obtaining accurate health histories.
- **Health beliefs and practices:** Traditional health practices and beliefs can significantly influence a patient's approach to illness and treatment. Many people that immigrate to the United States may use traditional healing practices alongside or in place of conventional medicine. Being open to these practices and respectfully discussing them can enhance trust and rapport.
- **Dietary considerations:** Dietary habits rooted in cultural practices can impact health and treatment plans. For example, certain religious practices, like fasting during Ramadan for Muslims or dietary restrictions in Hinduism, can affect medication schedules and nutritional needs.

By incorporating cultural awareness into the data collection process, nurses can ensure they are gathering complete and accurate information while also respecting each patient's cultural background. This approach contributes to more holistic and patient-centered assessments, a crucial component of quality health care.

---

### Nursing Skills

Nursing skills play a fundamental role in the collection of assessment data. These skills encompass a range of techniques and methods that nurses use to gather information about a patient's health status. From observational skills to specific physical examination techniques, each skill contributes uniquely to the overall assessment. Proficiency in these skills enables nurses to collect both subjective and objective data effectively, forming the basis for accurate diagnoses and care planning (American Nurses Association, n.d.).

### LINK TO LEARNING

An overview of [nursing skills for data collection \(https://openstax.org/r/77nurskdata\)](https://openstax.org/r/77nurskdata) is provided in this video.

---

### Observational Skills

Observational skills in nursing involve the use of all senses to gather data about a patient. This includes noticing changes in skin color, body posture, facial expressions, and behaviors that might indicate pain or discomfort. For example, observing a patient's gait can reveal a lot about their physical condition. A shuffling gait might indicate fear of falling, possibly due to balance issues or muscle weakness. A patient with a limp may be experiencing pain in the hip, knee, or foot, or they could have a muscular or skeletal abnormality. Alternatively, an unsteady or irregular gait might suggest neurological issues, such as those seen in patients with stroke history or Parkinson disease. By noting these specifics, a nurse can tailor the assessment and care plan to address mobility concerns.

Observational skills also extend to monitoring changes over time, such as tracking the progression of a wound's healing or changes in a patient's response to treatment. These skills are critical for identifying subtle changes that might not be explicitly communicated by the patient. Consider a patient who has reported feeling fine for several days but appears to wince when moving in bed one morning. This apparent contradiction between the patient's words and behavior, caught through keen observation, can lead the nurse to uncover an issue that might otherwise have been overlooked.

### Communication Skills

Effective communication skills are vital in nursing assessments to elicit subjective data from the patient. These skills include active listening, open-ended questioning, and empathetic responses that encourage patients to share concerns and symptoms. For instance, asking a patient to describe their pain in their own words and following up with open-ended questions can provide valuable information about the location, quality, and severity of the pain. A patient might initially complain of pain in their chest, but a skilled nurse can guide them to provide a more detailed description, such as "a squeezing sensation that radiates to my left arm." A more specific description can be crucial for accurate diagnosis and timely intervention.

Communication skills also involve educating and informing patients about their condition and the assessment process, which can alleviate anxiety and build trust. Consider a patient who is hesitant to discuss their mental health and initially downplays their anxiety levels. Through empathetic and nonjudgmental communication, a nurse can create a safe space for the patient to open up about ongoing stressors. With this knowledge, specific strategies for alleviating stress can be incorporated into the patient's care plan.

### Inspection

A fundamental nursing skill known as **inspection** is when the nurse visually examines the patient's body for normal and abnormal findings (Burke, 2023). It is often the first step in the physical examination process and can provide immediate clues about the patient's health status. During inspection, nurses observe the patient's overall appearance, noting factors such as skin color, posture, hygiene, and level of consciousness. Skin inspection allows nurses to assess for abnormalities such as pallor (pale color), cyanosis (blue color), jaundice (yellow color), rashes, bruises, lesions, or signs of inflammation, which may indicate underlying health conditions or injuries. For example, a nurse might inspect a patient's skin for rashes, lesions, or signs of infection or a patient's throat for redness or

swelling. Posture and body alignment provide insights into musculoskeletal function and potential mobility limitations, while personal hygiene reflects the patient's self-care abilities and overall health practices. For example, a patient with COPD may present with barrel chest and use of accessory muscles to breathe.

Inspection also extends to the patient's behavior and affect, including facial expressions, gestures, speech patterns, and interactions with others. Observing for signs of distress, agitation, lethargy, or confusion helps nurses evaluate the patient's cognitive and emotional status, detect changes in mental functioning, and assess their ability to communicate effectively. For example, a nurse caring for an older patient may assess cognitive function before and after a procedure to watch for any concerning changes from baseline.

Additionally, nurses may observe for nonverbal cues of pain or discomfort, such as grimacing, guarding, or restlessness, which inform pain assessment and management strategies. A common example would be observing a postoperative patient who has not yet fully recovered from anesthesia and sedation for nonverbal signs of discomfort.

### Palpation

The technique of using one's hands to feel the body for abnormalities during a physical examination is called palpation ([Figure 12.2](#)) (Burke, 2023). It assesses the texture, temperature, moisture, and size of organs and tissues. For example, during an abdominal assessment, the nurse may feel a pulsating mass in the midabdominal area, raising suspicion of an abdominal aortic aneurysm. Such a finding would warrant urgent medical evaluation.

Palpation can be light to assess surface characteristics or deep to assess organs or other structures within the body. This skill is crucial for obtaining information that cannot be gained through inspection alone.

**FIGURE 12.2** The nurse is palpating the child's abdomen to check for abnormalities. (credit: "Abdominal palpitation of a boy" by Cohen A. Young, U.S. Air Force/Wikimedia Commons, Public Domain)

### Percussion

Tapping on the body to assess underlying structures is known in the healthcare field as **percussion** (Burke, 2023). The sound produced can indicate the presence of fluid, air, or solid tissue and is useful in assessing the size and density of organs. Percussion is commonly performed in respiratory and abdominal assessments. For instance, in respiratory assessments, percussion can help detect areas of lung consolidation or fluid accumulation; dull sounds over the lung fields, instead of the expected resonance (echoing sound), might indicate pneumonia. When percussing the abdomen, a shift in sound from the expected tympany (hollow sound) to dullness can confirm the presence of ascitic fluid, guiding further diagnostic testing and management. This technique requires skill to elicit and interpret the sounds correctly.

## LINK TO LEARNING

Learn the proper techniques for [conducting a physical assessment \(https://openstax.org/r/77physassess\)](https://openstax.org/r/77physassess) in this video.

### Auscultation

Listening to the sounds produced within the body, typically using a stethoscope, is called **auscultation** (Figure 12.3) (Burke, 2023). This technique is essential for assessing the function of the heart, lungs, and abdomen. For instance, when auscultating a patient's heart, a nurse listens for abnormalities such as murmurs, which could indicate valvular heart disease. On the other hand, a high-pitched, whooshing sound heard at the heart's apex could signify mitral regurgitation. Identifying specific sounds such as these is crucial for early intervention and referral to cardiology.

**FIGURE 12.3** Healthcare providers typically use a stethoscope to auscultate (or listen to) the sounds made by a patient's heart, lungs, bowels, and other organs. (credit: "Standardized-Patient-Program-examining-t he-abdomen" by University of Michigan Medical School Information Services/Wikimedia Commons, CC BY 2.0)

Auscultation of the lungs involves listening to breath sounds, including inspiratory and expiratory sounds, and any adventitious (unusual) sounds, such as crackles, wheezes, or rhonchi. These lung sounds provide information about the patency of the airways, ventilation-perfusion ratios, and the presence of conditions such as pneumonia, bronchitis, or pulmonary edema. For example, a patient with heart failure may present with crackles in the lung bases, indicative of fluid accumulation. Recognizing these abnormal breath sounds can prompt immediate interventions such as diuretic therapy to manage heart failure more effectively.

In addition to cardiac and respiratory auscultation, nurses may also perform auscultation of the gastrointestinal system to assess bowel sounds. Normal bowel sounds indicate the presence of peristalsis (digestive movement) and normal gastrointestinal motility, while changes in bowel sounds may signify conditions such as bowel obstruction (intestinal blockage), ileus (intestinal paralysis), or intestinal inflammation. Auscultating the abdomen allows nurses to monitor gastrointestinal function, assess for signs of bowel obstruction or impaction, and evaluate the effectiveness of interventions such as bowel rest or nasogastric tube decompression.

### Establishing Priorities during Assessment

When assessing a patient to collect data, prioritization is usually necessary. Nurses often face complex situations

and multiple health issues that need attention. They must quickly identify the most critical needs to address to ensure patient safety and well-being. This approach is particularly vital in emergency settings or with patients who have multiple chronic conditions of varying immediacy and severity. Prioritizing ensures that the most urgent conditions are treated promptly while still allowing other important health needs to be addressed in a systematic manner. Even for routine assessments, it is important to prioritize, as not every piece of data is relevant to a patient's care.

### ABCs

The **ABC framework** is a fundamental approach nurses use to establish priorities during an assessment, especially in emergency and acute care settings. This system uses the letters A (airway), B (breathing), and C (circulation) to remind providers to assess these components of health (Marymount University, 2022):

- **Airway:** An obstructed airway can rapidly lead to respiratory arrest. Therefore, the priority is to ensure the patient's airway is open and clear. For example, in cases of trauma, swelling or foreign objects can obstruct the airway, necessitating quick intervention.
- **Breathing:** Once the airway is secured, the nurse assesses the patient's breathing. This includes checking the rate, depth, and effort of breaths and observing for signs of respiratory distress. For instance, assessing for wheezing and use of accessory muscles is critical to managing the breathing of a patient with asthma.
- **Circulation:** The third priority is circulation. The nurse should assess the patient's heart rate, blood pressure, and perfusion. Any signs of circulatory compromise, such as weak pulse, hypotension, or cyanosis, require immediate attention. For example, in a cardiac arrest scenario, restoring circulation through CPR is a priority.

### Maslow's Hierarchy

Another framework used by nurses to establish priorities, particularly for patients in less acute settings, is Maslow's hierarchy of needs. Based on the work of the American psychologist Abraham Maslow, the hierarchy uses a triangle to organize human needs from the most basic (at the bottom) to the most complex (at the top) ([Figure 12.4](#)) (McLeod, 2018). Before humans can focus on meeting any particular need, they must have met the needs lower in the hierarchy (Marymount University, 2022).

**FIGURE 12.4** According to Maslow's hierarchy of needs, the most basic needs are physiological (including food, water, and sleep) and safety. Once these needs are met, humans can seek to meet their needs for love and belonging, self-esteem, and ultimately, self-actualization—the state of having reached one's full potential. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

- The hierarchy begins with physiological needs, which include basic requirements such as air, food, water, and shelter. In nursing, this means ensuring that a patient's basic health needs, such as nutrition, hydration, and pain management, are met. For instance, a diabetic patient's need for blood sugar regulation is a primary physiological concern.
- Safety and security needs come next, encompassing both a patient's physical safety and psychological security. In a healthcare setting, this might involve reducing the risk of falls in older adult patients or reassuring anxious patients about their care and treatment.
- The hierarchy also includes psychological and self-fulfillment needs, such as love and belongingness, self-esteem, and self-actualization, which are more relevant in long-term care and holistic patient well-being. For example, addressing a patient's social interactions and self-esteem issues is essential in mental healthcare and rehabilitation settings.

### Nursing Process

The nursing process is a systematic method nurses use to provide individualized patient care. It consists of five steps: assessment, diagnosis, planning, implementation, and evaluation. Each step involves prioritizing patient needs and ensuring that the most critical issues are addressed effectively. [Table 12.2](#) illustrates this process using the example of a patient, Mrs. Smith, who has been admitted with congestive heart failure.

Step	Explanation	Connection to Prioritization
Assessment	The first step in the nursing process involves gathering relevant data about the patient, including medical history, medication regimen, and lifestyle factors.	The nurse should focus on Mrs. Smith's most pressing symptoms, such as difficulty breathing and fluid retention.
Diagnosis	Based on the assessment, the provider determines the cause of the health issue. This step helps in setting clear goals for the patient's treatment.	For Mrs. Smith, a primary nursing diagnosis might be "impaired gas exchange related to congestive heart failure." This issue should take precedence over less urgent ones.
Planning	The planning phase involves setting short-term (e.g., can be achieved within hours to days) and long-term (e.g., can be achieved over weeks to months) goals and determining the course of action for treating the issue.	The plan should be tailored to address the most critical needs first. For Mrs. Smith, high-priority goals include stabilizing her breathing and managing her heart function. Lower-priority goals might involve education about lifestyle modifications and long-term management of her condition.
Implementation	During this phase, the prioritized care plan is put into action.	High-priority interventions for Mrs. Smith might include administering diuretics to manage fluid retention and providing oxygen therapy to improve her breathing. Secondary interventions could involve nutritional counseling and mobilization strategies as her condition stabilizes.
Evaluation	In the final step, the nurse evaluates the patient's response to the treatment plan. The care team can then determine whether the plan needs to be adjusted.	Prioritizing in this step involves assessing whether the high-priority goals for Mrs. Smith, such as improved breathing and reduced edema, have been achieved.

**TABLE 12.2** Prioritization and the Nursing Process

The **Clinical Judgment Measurement Model (CJMM)**, a framework designed to assess and evaluate the clinical judgment skills of nurses, intersects with each phase of the nursing process (Figure 12.5), enriching and refining nurses' clinical decision-making skills. During the assessment phase, CJMM emphasizes gathering thorough patient data and recognizing subtle cues to inform subsequent clinical judgments and interventions. In the diagnosis phase, CJMM guides nurses in formulating precise nursing diagnoses, integrating assessment data and evidence-based practice. The CJMM supports nurses in developing holistic care plans in the planning phase, prioritizing interventions, and collaborating with interdisciplinary teams. During implementation, CJMM assists in executing care plans with adaptability and incorporating evidence-based interventions. In the evaluation phase, CJMM facilitates a comprehensive review of patient responses, enabling critical analysis and continuous quality improvement. Integrating CJMM enhances nurses' ability to promote patient safety, deliver high-quality care, and make informed clinical judgments throughout patient care delivery.

Comparing the Clinical Judgment Measurement Model (CJMM)						
Nursing Process	Assessment	Analysis		Planning	Implementation	Evaluation
CJMM	Recognize cues	Analyze cues	Prioritize hypotheses	Generate solutions	Take actions	Evaluate outcomes

**FIGURE 12.5** The alignment between the Clinical Judgment Measurement Model (CJMM) and the nursing process is evident in how CJMM principles guide each step of the nursing process to facilitate informed clinical judgments and improve patient outcomes. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## Analyzing Data Collected during the Assessment

Analyzing the data collected during a nursing assessment is a critical step in the nursing process. It involves interpreting the gathered information to make informed decisions about patient care. This analytical process requires nurses to identify significant clues, make inferences, recognize patterns, and apply both inductive and deductive reasoning. These skills enable nurses to translate assessment data into actionable insights, forming the basis for accurate nursing diagnoses and effective care plans.

### Clues and Inferences

Clues are pieces of observable, measurable, and factual information obtained during the assessment process. These may include vital signs, physical examination findings, patient statements, and laboratory results. For example, if a patient reports increased shortness of breath and the nurse observes swelling in the legs, these clues might suggest heart failure.

Inferences are the conclusions drawn from these clues. Nurses use critical-thinking skills to analyze the data, recognize patterns, identify deviations from the norm, and consider the significance of each finding in the context of the patient's overall health. In this case, the nurse might infer that the patient's heart failure is worsening. Making accurate inferences based on observed clues is crucial for identifying a patient's health issues and planning appropriate interventions.

### Patterns

Recognizing patterns in the assessment data is another crucial aspect of analysis. Patterns refer to recurring themes, trends, or relationships observed across various aspects of the assessment. To analyze patterns effectively, nurses compare and contrast data points collected over time or across different assessment parameters. They look for consistency or inconsistency in the findings, noting any deviations from the expected or normal range. For instance, a pattern of increasing blood pressure readings over several visits might indicate poorly controlled hypertension. Recognizing these patterns helps nurses anticipate and prevent complications, adjust treatments, and advocate for changes in the care plan.

### Inductive Reasoning

Making generalizations based on specific observations is known as **inductive reasoning** (Burke, 2023). For example, if a nurse observes a patient's wound is not healing despite standard care and knows that similar cases have improved with a different treatment, then the nurse may conclude that their patient may benefit from an alternative treatment. This form of reasoning allows nurses to formulate hypotheses about a patient's condition and potential

responses to treatment based on observed trends and outcomes.

### Deductive Reasoning

In **deductive reasoning**, general principles are applied to make conclusions about specific cases (Burke, 2023). For instance, knowing that immobility increases the risk of pressure ulcers, a nurse caring for a bedridden patient will deduce the need for regular repositioning and skin assessments. This type of reasoning allows nurses to apply established knowledge and guidelines to individual patient scenarios, ensuring evidence-based and personalized care.

## REAL RN STORIES

---

### Reasoning in Action: A Complex Case of Diabetes Management

**Nurse:** Maria, RN, BSN

**Clinical setting:** Endocrinology unit

**Years in practice:** 12

**Facility location:** San Antonio, Texas

As a nurse in the endocrinology unit, I encounter many patients with complex cases of diabetes. One such case that stands out involved a patient, Mr. Hernandez, who was admitted with poorly controlled type 2 diabetes and recurrent foot ulcers.

From the initial assessment, it was clear that Mr. Hernandez's situation was multifaceted. He reported being diligent with his medication, yet his blood glucose levels were consistently high. Through careful observation, I noticed his reluctance to discuss dietary habits and a general lack of knowledge about diabetes management. This was my first clue that there might be more to his condition than medication adherence.

Using my communication skills, I gently probed into his daily routine and eating habits. This revealed a pattern of sporadic mealtimes and consumption of high-carbohydrate foods despite his medication regimen. It became evident that Mr. Hernandez's understanding of diabetes management was limited, impacting his ability to control his condition effectively.

Applying inductive reasoning, I hypothesized that a lack of education about diabetes and inadequate nutritional guidance were contributing to Mr. Hernandez's poor health outcomes. This was further supported by the pattern of his uncontrolled blood glucose readings in relation to his eating habits.

Using deductive reasoning based on the general principles of diabetes management, I concluded that comprehensive patient education was crucial. I worked with the diabetes education team to develop a tailored education plan for Mr. Hernandez, focusing on nutrition, medication management, and foot care.

The integration of in-depth assessment, inductive and deductive reasoning, and a focus on patient education led to significant improvements in Mr. Hernandez's condition. His experience is a testament to the impact of holistic nursing care and the importance of collecting and analyzing a wide range of data when managing complex health conditions.

---

## 12.4 Cognitive Process for Analyzing Assessment Data

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify ways a nurse will analyze data collected from health assessment
- Describe the skills needed for effective critical thinking, clinical reasoning, and clinical judgment
- Define steps needed to successfully implement critical thinking, clinical reasoning, and clinical judgment

In the dynamic healthcare environment, a nurse's role extends beyond collecting patient data. Nurses rely on cognitive processes to interpret and make sense of the information gathered during patient assessments, diagnostic tests, and monitoring. Cognitive processes are the mental activities people use to acquire, process, store, and use information. For the nurse analyzing healthcare data, these mental processes play a vital role in understanding the patient's condition, identifying potential problems or risks, and formulating appropriate interventions or treatment

plans.

Here is an example case: A 60-year-old patient who underwent surgery two days ago to remove an infected appendix has developed a fever. The nurse providing care for the patient needs to analyze the myriad of data collected during the patient's stay in the hospital—his vital signs, physical examination findings, patient history, and subjective descriptions of his symptoms. To navigate this complex information, the nurse must employ a structured approach, integrating nursing knowledge, observational insights, and experiential understanding. This involves not just identifying the apparent symptoms but also interpreting underlying patterns, making inferences, and ultimately, formulating a clinical judgment that will guide the patient's care plan.

This section explores how nurses can use various cognitive skills to sift through and make sense of patient data, apply critical thinking to identify key health concerns, use clinical reasoning to understand the implications of data, and exercise clinical judgment to make informed decisions. By mastering these cognitive processes, nurses ensure that their assessments lead to effective and individualized patient care.

### Analyzing Knowledge

Analyzing knowledge in nursing is a multifaceted process that involves clinical reasoning, critical thinking, and clinical judgment. These skills are essential for transforming the raw data collected from patient assessments into meaningful, actionable information. They enable nurses to understand the implications of the data, anticipate patient needs, and make informed decisions about care and treatment ([Figure 12.6](#)).

**FIGURE 12.6** The nurse must analyze what they know and observe about a patient to appropriately diagnose and treat them. (credit: “U.S. Navy Doctors, Nurses and Corpsmen Treat COVID Patients in the ICU Aboard USN Comfort” by Navy Medicine/Flickr, Public Domain)

### Clinical Reasoning

As learned in [Conducting Assessments](#), clinical reasoning is the process by which a healthcare provider combines their knowledge and experience with data obtained through various patient assessments to generate hypotheses about a patient's condition and determine an appropriate response (Hong et al., 2021). The nurse will consider observable and subjective data on the patient gleaned from a current assessment and use the medical record to review the patient's history. Once they have processed the information at hand, the nurse will formulate a hypothesis that will guide examination and potential interventions.

### Critical Thinking

The disciplined, systematic process of applying skillful reasoning to guide belief or action is **critical thinking**. It involves questioning assumptions, considering alternative perspectives, and weighing evidence to make informed clinical judgments. It encompasses skills such as logical reasoning, analysis, reflection, and skepticism, enabling healthcare professionals to assess the validity and reliability of information and apply sound reasoning in clinical practice (Falcó-Pegueroles et al., 2021).

### Clinical Judgment

The nurse's ability to synthesize information, draw conclusions, and make decisions about patient care based on clinical reasoning and critical-thinking skills is **clinical judgment**. It involves assessing the significance of patient data, recognizing patterns or trends, and predicting potential outcomes to guide clinical actions and interventions. Clinical judgment integrates knowledge, experience, intuition, and evidence-based practice to make informed decisions that promote positive patient outcomes and ensure safe and effective care delivery. It is the culmination of the assessment process when the nurse decides on a course of action based on the data and their analysis (Conner et al., 2023).

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Form a Hypothesis: Using Clinical Judgment to Formulate Hypotheses

Imagine a scenario in which a nurse is conducting a health assessment on a patient who presents with shortness of breath and chest pain. The patient, a 55-year-old male, arrives at the emergency department clutching his chest and is visibly distressed. He reports a sudden onset of chest pain that radiates to his left arm and is accompanied by difficulty breathing. The nurse quickly ushers the patient into a private examination room and begins the assessment.

- **Identifying cues:** The nurse gathers relevant data by asking the patient about their medical history, current symptoms, and any precipitating factors. The patient mentions a history of hypertension and smoking, as well as recent travel by plane. Additionally, the nurse performs a physical examination and reviews vital signs, noting the patient's elevated blood pressure (160/90 mm Hg), tachycardia (heart rate of 110 bpm), and respiratory rate of 24 breaths per minute. Auscultation reveals diminished breath sounds on the left side of the chest.
- **Analyzing cues:** When collecting data, the nurse meticulously analyzes the cues to identify patterns, trends, and deviations from the norm. The nurse recognizes that the patient's shortness of breath and chest pain, especially when accompanied by radiation to the left arm and risk factors such as hypertension and recent air travel, could be indicative of various underlying conditions, such as a heart attack or a pulmonary embolism.
- **Forming hypotheses:** Based on the analyzed cues, the nurse forms hypotheses about the possible causes of the patient's symptoms. The nurse considers potential conditions, weighing the likelihood of each condition based on the patient's clinical presentation, risk factors, and relevant diagnostic tests. Hypotheses may include pulmonary embolism due to recent surgery or prolonged immobility, myocardial infarction due to cardiovascular risk factors and typical symptoms, or pneumonia due to a recent respiratory infection or compromised immune status.

## Nursing Skills Needed for Critical Thinking, Clinical Reasoning, and Clinical Judgment

The application of critical thinking, clinical reasoning, and clinical judgment is underpinned by a set of core skills nurses must have. These skills, which include observation, knowledge, experience, reflection, and interpretation, are essential for nurses to analyze patient data effectively and make informed decisions.

### Observation

Observation is a crucial skill for effective critical thinking, clinical reasoning, and clinical judgment in health care. Through careful observation, healthcare professionals meticulously attend to details, nuances, and subtle cues in a patient's presentation, history, and physical examination. This attention to detail enables the collection of accurate and comprehensive information, laying a solid foundation for critical thinking.

Moreover, observation facilitates the identification of patterns, trends, and relationships within the data gathered, thereby fostering deeper analysis and synthesis of information critical for problem-solving. In clinical reasoning, observation serves as the primary data collection method, observing the patient's appearance, behavior, vital signs, and physical signs and symptoms to gather information about their health status.

It is through observation that healthcare professionals interpret findings, identify potential health issues, and formulate hypotheses to guide clinical decision-making. For clinical judgment, observation is pivotal in assessing the patient's condition and determining the appropriate course of action. Vigilant observation enables nurses to detect subtle changes in the patient's condition, facilitating timely adjustments to treatment plans and interventions.

### Knowledge

Effective critical thinking, clinical reasoning, and clinical judgment in nursing rely heavily on a solid knowledge foundation spanning many domains. First, nurses must possess a comprehensive understanding of anatomy, physiology, and pathophysiology to grasp the human body's complexities and recognize deviations from normal functioning. This knowledge allows for accurate interpretation of clinical data and identification of underlying health issues.

Second, proficiency in medical terminology and pharmacology is crucial for effective communication and medication management. Nurses must be able to accurately document patient assessments, communicate with interdisciplinary team members, and administer medications safely.

Third, familiarity with evidence-based practice guidelines, clinical protocols, and healthcare policies is essential for making informed decisions and providing quality care. Healthcare professionals need to stay updated on the latest research findings and clinical guidelines to ensure that their practice aligns with best practices and standards of care.

Last, but certainly not least, a solid understanding of cultural competence and ethical principles is vital for delivering patient-centered care and respecting patients' autonomy and rights.

### Experience

A nurse's experience complements their knowledge by providing practical insights they have gained over time. Nurses need proficiency in patient assessment techniques, including history-taking, physical examination, and diagnostic interpretation. This hands-on experience enables nurses to gather accurate and relevant data from patients, laying the foundation for informed decision-making.

Exposure to diverse clinical scenarios and patient populations enhances adaptability and flexibility in problem-solving. By encountering a variety of cases and situations, nurses develop the ability to recognize patterns, anticipate potential complications, and tailor care plans to meet individual patient needs. Practical experience fosters the development of intuition and clinical judgment, allowing healthcare professionals to make rapid yet thorough assessments of complex situations. Through exposure to real-world challenges, nurses refine their ability to prioritize tasks, identify red flags, and navigate ethical dilemmas.

### Reflection

Reflection involves reflecting on one's own experiences and learning from them. Nurses must be able to reflect on their own experiences, actions, and decisions to identify strengths, weaknesses, and areas for improvement.

Through self-reflection, nurses can critically evaluate their clinical practice, identifying patterns of success and areas where they may have made errors or faced challenges. This introspective process enables nurses to continuously refine their clinical skills and enhance their ability to make informed decisions in future patient encounters.

Reflection skills encourage healthcare professionals to consider the perspectives and experiences of others, including patients, colleagues, and interdisciplinary team members. By reflecting on interactions with patients and colleagues, nurses can gain insights into different communication styles, cultural perspectives, and professional dynamics.

### Interpretation

Interpretation is the ability to make sense of all the gathered information. Interpretation skills involve synthesizing

complex information from multiple sources, including patient histories, physical examination findings, laboratory results, and diagnostic imaging studies, to develop a comprehensive understanding of the patient's health status.

Nurses must be able to integrate the data they gather, critically analyze it, and derive meaningful insights to inform their clinical reasoning and decision-making. This process requires recognizing connections between different pieces of information and drawing logical conclusions based on the available evidence.

## PATIENT CONVERSATIONS

---

### Managing Migraines

**Scenario:** Ms. Chang, a 50-year-old Chinese American female, is seeing her primary care provider, Nurse Patel, a board-certified nurse practitioner, for a routine wellness visit. Note how Nurse Patel utilizes the five core skills you just read about.

**Nurse:** Good morning, Ms. Chang. How have you been since our last visit?

**Patient:** Good morning, Nurse Patel. It's been tough. The migraines are more frequent now.

#### **OBSERVATION**

**Nurse:** I see you're rubbing your temples. Are you experiencing a headache right now?

**Patient:** Yes, it started this morning. It's quite intense.

**Nurse:** I noticed you seemed sensitive to the light when you walked in. Light sensitivity is common with migraines. Have you experienced any nausea or other symptoms?

#### **KNOWLEDGE**

**Patient:** I feel a bit nauseous, yes.

**Nurse:** Nausea often accompanies migraines. Are there any activities or foods you've noticed that seem to trigger these episodes?

**Patient:** I think stress and maybe certain foods. I'm not sure which ones, though.

**Nurse:** It's helpful to track your diet and activities. Sometimes, aged cheeses, processed foods, or even skipping meals can trigger migraines.

#### **EXPERIENCE**

**Patient:** Skipping meals? I didn't know that.

**Nurse:** Yes, maintaining a regular eating schedule can sometimes help. In my years of working with migraine patients, I've also seen stress management techniques make a significant difference. Have you tried any relaxation methods?

**Patient:** I used to meditate, but I haven't found the time recently.

**Nurse:** Rediscovering those helpful habits could be beneficial. Many patients find that resuming meditation helps manage their stress levels and reduce migraine frequency.

#### **REFLECTION**

**Patient:** Maybe I should give that a try again.

**Nurse:** Reflecting on what has worked for you in the past is a great approach. In addition to meditation, do you recall any other activities or treatments that brought relief?

**Patient:** I remember feeling better when I used to exercise regularly.

**Nurse:** Exercise can be an effective way to manage stress and potentially reduce migraine occurrences. Incorporating regular physical activity into your routine might be something to consider.

## INTERPRETATION

**Patient:** I could start with some light exercise, maybe walking or yoga.

**Nurse:** That sounds like an excellent idea. Based on our conversation and your symptoms, it seems managing stress and maintaining a healthy lifestyle could play a key role in your migraine treatment plan. We can explore this further and adjust your care plan accordingly.

---

## Implementation of Critical Thinking, Clinical Judgment, and Reasoning

The implementation of critical thinking, clinical judgment, and reasoning in nursing practice is a dynamic and multifaceted process. It requires the nurse to move beyond data collection, employing a structured approach to conceptualize, apply, analyze, synthesize, and evaluate information as they make informed decisions about patient care. This process is crucial to ensuring that care is effective and tailored to each patient's unique needs.

### Conceptualizing

Forming an initial understanding of the patient's situation based on the data collected is called **conceptualizing**. The nurse must be able to synthesize complex information, identify relationships between concepts, and construct mental models that represent the underlying principles or mechanisms governing clinical phenomena. Nurses conceptualize concepts such as pathophysiology, pharmacology, and anatomy to understand the underlying mechanisms of disease processes and treatment modalities.

By conceptualizing these concepts, clinicians can analyze clinical scenarios, anticipate potential outcomes, and devise effective interventions or management strategies. When a nurse understands the implications of different clinical scenarios and considers the broader context of patient care, they can prioritize interventions, anticipate potential complications, and optimize patient outcomes.

### Applying

The practical implementation of knowledge, skills, and strategies to address clinical challenges, solve problems, and make informed decisions in healthcare settings is called **applying**. It involves putting theoretical concepts into practice and translating abstract ideas into concrete actions that impact patient care and outcomes. By translating knowledge and skills into action, healthcare professionals can effectively address the multifaceted challenges of patient care, promote evidence-based practice, and ensure the delivery of safe, high-quality care that meets the needs of diverse patient populations.

### Analyzing

The systematic examination and evaluation of information, data, or evidence to derive meaning, identify patterns, and draw conclusions is called **analyzing**. Analyzing is the breaking down of information into smaller parts to understand the significance of each part and the relationships among them. This step is critical in moving from having a general understanding of a patient's health status to having more specific insight into it.

### Synthesizing

The process of integrating, combining, or organizing diverse pieces of information, data, or evidence to develop a coherent understanding, formulate hypotheses, or generate solutions is called **synthesizing**. It involves drawing connections between different sources of information, identifying patterns or relationships, and synthesizing findings to inform decision-making and problem-solving processes.

As they become skilled at integrating diverse sources of information, nurses develop nuanced understandings of complex clinical scenarios, make informed decisions, and provide high-quality, patient-centered care that optimizes patient outcomes and enhances the quality and safety of healthcare delivery.

### Evaluating

Assessing, appraising, or judging the quality, relevance, and effectiveness of information, data, or evidence to make informed decisions, solve problems, or improve outcomes is called evaluating. The process involves critically examining the strengths and weaknesses of various options, interventions, or approaches and determining their suitability or appropriateness based on established criteria or standards.

Through systematically assessing and appraising information, data, and decisions, nurses can make informed

judgments, optimize patient outcomes, and continuously improve the quality and safety of healthcare delivery.

## Summary

### 12.1 The Nurse's Role in Assessment

Nursing assessment is a systematic process of gathering comprehensive and accurate information about a patient's health status. A comprehensive nursing assessment includes physical signs as well as psychosocial, emotional, and spiritual factors to ensure holistic care.

Using the information gathered, the nurse can tailor care and treatment to a specific patient's needs. The process starts with examining a patient's current condition, identifying changes or risks, and prioritizing health needs for intervention. An accurate assessment is essential for a correct diagnosis and appropriate planning and emphasizes the significance of the data collected.

Nurses use clinical reasoning skills to perform focused assessments to address immediate concerns while covering all necessary health aspects using a systemic approach. Proper documentation that adheres to confidentiality requirements and standardized formats is necessary not only for legal compliance but also for ensuring effective communication among healthcare providers who are part of the patient's care team.

### 12.2 Types of Assessment

There are several types of nursing assessments, each tailored to meet specific patient needs and clinical situations. Understanding when and how to employ each type is a key skill for nurses, enabling them to provide effective, patient-centered care across a range of healthcare settings.

An initial assessment is the most comprehensive. It is typically conducted on admission to a healthcare setting and includes a complete evaluation of the patient's physical condition, medical history, lifestyle, and current symptoms. This type of assessment provides a baseline of a patient's health. It is also an opportunity to establish a complete database on which future care and decisions are based.

In contrast, problem-focused assessments are more specific, targeting particular health issues or symptoms. These are often shorter, scheduled, and ongoing, with the focus on monitoring a specific problem or chronic condition. Emergency assessments are rapid and focused, aimed at addressing life-threatening crises and stabilizing the patient's condition.

Time-lapsed assessments are conducted when several months have passed since the previous assessment. They are crucial for evaluating a patient's progress over time, particularly in chronic disease management and long-term care. Ongoing assessments also allow the nurse to track a patient's well-being and function over time and observe for any concerning deviations from their established baseline. These assessments also play an important role in evaluating treatments and informing how care may evolve for a patient as time and other life factors change their healthcare needs.

### 12.3 Collection of Assessment Data

Nurses gather assessment data from various sources, including the patient and their family, as well as their observations and skills. The information gathered during an assessment informs patient care and is crucial to providing care that is tailored to a patient's individual needs. Obtaining information requires the nurse to use techniques like observation and physical examination (observation, communication, inspection, auscultation, palpation, and percussion), to get a "big picture" sense of a patient's physical state and needs.

Once the nurse has acquired the patient data, they need to decide the most important need that must be met before all others. A patient's most basic needs, like safety, must be addressed before other, broader needs can be tackled.

Prioritization frameworks like ABCs (airway, breathing, circulation) and Maslow's hierarchy help nurses focus on the most urgent needs first. The nurse will then analyze assessment data through pattern recognition, inductive/deductive reasoning, and identification of clues. This skilled analysis allows nurses to interpret the information accurately and make informed clinical decisions, ensuring that the interventions align with and support a patient's unique needs.

## 12.4 Cognitive Process for Analyzing Assessment Data

The cognitive process of analyzing patient data is a critical component of patient care. The nurse will take a structured approach to apply a variety of skills to interpret information collected during health assessments. Nurses must integrate their knowledge, observations, and experiences to produce meaningful, actionable patient information. The nurse achieves this by interpreting underlying patterns, making inferences, and formulating a clinical judgment that informs a patient's care.

Critical thinking, clinical reasoning, and clinical judgment are three essential skills that facilitate the process. Critical thinking involves systematically questioning and evaluating information to form a reasoned judgment. The skill enables nurses to consider various possibilities and outcomes based on patient data. Clinical reasoning is the process of collecting cues, processing the information, and understanding the patient's health problem. It guides nurses in planning and implementing interventions, evaluating outcomes, and learning from the process. This reasoning requires the nurse to move beyond data collection and use a structured approach to conceptualize, apply, analyze, synthesize, and evaluate information to make informed decisions about patient care.

The culmination of these efforts is clinical judgment, through which nurses make informed decisions based on the analyzed data. They must synthesize all gathered information, including observations, patient history, and clinical knowledge, to arrive at a conclusion and action plan.

All the nurse's cognitive skills are called on to ensure that care is thorough, evidence based, and tailored to individual patient needs. The successful implementation of these skills requires ongoing practice and reflection, making them fundamental to the role of the nurse in patient care and treatment.

### Key Terms

**ABC framework** a system that uses letters as reminders to establish three fundamental priorities during a nursing assessment: airway, breathing, and circulation

**actual problem** current health issues that are identifiable through symptoms or clinical evidence

**analyzing** the systematic examination and evaluation of information, data, or evidence to derive meaning, identify patterns, and draw conclusions

**applying** the practical implementation of knowledge, skills, and strategies to address clinical challenges, solve problems, and make informed decisions in healthcare settings

**assessment** the systematic and dynamic process of collecting and analyzing data about a patient's health

**auscultation** the technique of listening to the sounds produced within the body, typically using a stethoscope

**Beck Depression Inventory** a widely used self-report questionnaire designed to assess the severity of depression symptoms experienced by an individual

**clinical judgment** utilizing nursing knowledge, critical thinking, and clinical reasoning, drawing from evidence, theories, and interdisciplinary insights to make informed and patient-centered decisions

**Clinical Judgment Measurement Model (CJMM)** the latest framework developed by the National Council of State Boards of Nursing (NCSBN) to aid in identifying nursing-focused clinical problems

**clinical reasoning** the process by which a healthcare provider combines their own knowledge and experience with data obtained through various patient assessments to diagnose a medical problem and determine an appropriate response

**conceptualizing** forming an initial understanding of the patient's situation based on the data collected

**critical thinking** the disciplined, systematic process of applying skillful reasoning as a guide to belief or action

**data** information that nurses gather about a patient's health status

**deductive reasoning** the process of applying general principles to draw conclusions about specific cases

**emergency assessment** an assessment conducted when a patient presents with life-threatening or potentially life-threatening conditions

**Faith, Importance and Influence, Community, and Address (FICA) tool** a tool used by healthcare professionals to assess patients' spiritual and religious beliefs and practices

**Holmes-Rahe Life Stress Inventory** a tool used to measure the stress level experienced by an individual based on the occurrence of certain life events within a specified period

**inductive reasoning** the process of making generalizations based on specific observations

**initial assessment** the first extensive evaluation of a patient's overall health status, including their physical

condition, medical history, and current symptoms; typically conducted on a patient's admission to a healthcare facility

**inspection** a fundamental nursing skill by which the nurse visually examines the patient's body for normal and abnormal findings

**objective data** measurable and observable information collected by the healthcare provider

**ongoing assessment** assessment conducted continuously, often in response to changes in the patient's condition

**percussion** the technique of assessing the body's underlying structures based on the sound they make when tapped

**physiological crisis** a critical situation where the patient's physiological functions are severely compromised, posing an immediate threat to life or health

**potential problem** risk or condition that a patient is susceptible to but not currently manifesting symptoms of

**primary data** information provided directly by the patient

**problem-focused assessment** a targeted examination conducted to assess a specific health issue or symptom identified in a patient

**psychological crisis** a state of acute emotional or mental distress that significantly impairs an individual's ability to cope with their current circumstances

**secondary data** information collected from a family member, chart, or other source

**subjective data** descriptions provided by the patient or family members of the patient's symptoms, feelings, and perceptions

**synthesizing** the process of integrating, combining, or organizing diverse pieces of information, data, or evidence to develop a coherent understanding, formulate hypotheses, or generate solutions

**time-lapsed assessment** an assessment conducted when several months have passed since the previous assessment to evaluate the progress of a patient's health over time

## Assessments

### Review Questions

- What is the primary focus of a nursing assessment?
  - to ensure a patient is comfortable and pain free
  - to refer a patient to the most appropriate specialist
  - to systematically identify and prioritize a patient's health concerns
  - to prescribe appropriate medications based on a patient's symptoms
- A nurse asks a patient questions to determine the strength of their support network. These questions address what domain of a nursing assessment?
  - emotional
  - physical
  - psychosocial
  - spiritual
- What action will the nurse take to use clinical reasoning while assessing a patient?
  - focus solely on medical history and current symptoms
  - follow a systematic approach that elicits significant data
  - rely primarily on the patient's self-diagnosis and perception of illness
  - limit the assessment to what the patient finds comfortable and convenient
- Addressing the physical, psychological, emotional, and spiritual dimensions of an individual patient's needs is practicing what kind of care?
  - homeopathic
  - heuristic
  - holistic
  - hospice
- What type of comprehensive assessment allows the nurse to check for abnormalities in each body system?

- a. cultural/spiritual
  - b. head-to-toe
  - c. focused
  - d. psychosocial
6. What type of nursing assessment is typically conducted upon a patient's admission to a healthcare facility?
- a. emergency
  - b. initial
  - c. problem focused
  - d. time lapsed
7. How does a problem-focused assessment differ from an initial assessment?
- a. It covers the patient's complete medical history.
  - b. It is only conducted when a patient has an emergency.
  - c. It targets a specific health issue identified in the patient.
  - d. It involves monitoring the patient's progress over several months.
8. When is a time-lapsed assessment most appropriately conducted?
- a. immediately before issuing a referral to a specialist
  - b. immediately after the patient is admitted to the hospital
  - c. when the patient presents with a life-threatening condition
  - d. when several months have passed since the previous assessment
9. In emergency nursing assessment, what type of crisis refers to a critical situation where the patient's cardiovascular and respiratory functions are severely compromised, posing an immediate threat to life or health?
- a. physiological
  - b. psychological
  - c. pathological
  - d. prelogical
10. What assessment is the nurse using when evaluating progress in a patient who is newly diagnosed with type 2 diabetes and learning how to manage their blood sugars with an insulin pump and glucose checks?
- a. emergency
  - b. initial
  - c. problem focused
  - d. ongoing
11. What is a primary source of data during a nursing assessment for a patient who is unable to communicate verbally?
- a. medical textbooks
  - b. the patient's caretakers
  - c. pharmaceutical guidelines
  - d. online medical databases
12. The nurse is providing care for a patient who is recovering from surgery. At 0900, the nurse needs to assess the patient's pain level and do a wound check. As the nurse enters the room, they observe the patient trying to get out of bed unassisted, stating, "I need to use the bathroom." The nurse notes the patient is short of breath when speaking and looks pale. What should the nurse prioritize for this patient?
- a. oxygen levels
  - b. assisting to the bathroom
  - c. pain level
  - d. wound check

- 13.** When a nurse applies general principles to draw a conclusion about a specific patient case, they are using which nursing skill?
- palpation
  - auscultation
  - inductive reasoning
  - deductive reasoning
- 14.** The nurse is assessing a patient in the emergency room who was brought in after a motor vehicle accident. What is an example of subjective patient data collected by the nurse?
- pain level
  - heart rate
  - temperature
  - blood alcohol level
- 15.** The nurse is assessing a newly admitted patient. When the nurse asks about any dietary needs, the patient states they are allergic to eggs. What step will the nurse take next?
- tell kitchen about patient's food allergy
  - document patient food allergy
  - notify provider of patient food allergy
  - confirm patient food allergy with family
- 16.** What three skills do nurses need to transform raw data collected from their patients into meaningful, actionable information?
- clinical judgment, clinical reasoning, critical thinking
  - initial assessment, problem-focused assessment, ongoing assessment
  - checking a patient's airway, breathing, and circulation
  - prioritizing between physiological, psychological, and social needs
- 17.** To effectively engage in critical thinking about patient data, what must the nurse be able to do?
- Administer a wide range of medications.
  - Follow hospital protocols without deviation.
  - Accurately document vital signs in medical records.
  - Systematically analyze and evaluate patient information.
- 18.** What process allows nurses to turn details collected from patient assessments into meaningful, actionable information?
- clinical judgment
  - analyzing knowledge
  - observation
  - clinical reasoning
- 19.** What step allows the nurse to think about their own experiences, actions, and decisions and learn from them?
- conceptualizing
  - observing
  - interpreting
  - reflecting
- 20.** The nurse is assessing a patient and looking at details about the person's appearance and behavior. What skill is the nurse using?
- evaluating
  - analyzing
  - observation
  - judgment

## Check Your Understanding Questions

1. Why is a nursing assessment important in patient care?
2. Consider the four domains of a nursing assessment. How does each domain contribute to a holistic understanding of a patient's health?
3. Choose two key principles of conducting an assessment with clinical reasoning. Why is each principle important in the assessment process?
4. What is the primary purpose of an emergency assessment?
5. How does a time-lapsed assessment differ from a problem-focused assessment in terms of its timing and objectives?
6. Consider a patient scheduled for surgery. When would the patient likely undergo an initial assessment, and when would they likely undergo a problem-focused assessment? Explain why each type is important in this context.
7. Explain how nurses use their observational skills as a source of data during patient assessments. Provide an example of what a nurse might observe and how it contributes to the assessment.
8. Discuss how a nurse might use Maslow's hierarchy of needs to prioritize care for a patient who has both physiological and psychological needs. Which needs should be addressed first, and why?
9. Describe a situation where a nurse would use inductive reasoning to analyze patient data. How does this reasoning help in formulating a nursing diagnosis or care plan?
10. What is the difference between clinical reasoning, critical thinking, and clinical judgment?
11. Describe how a nurse might use clinical reasoning to determine the cause of a postoperative fever in a patient.
12. How do reflection and interpretation contribute to a nurse's critical-thinking skills when addressing a complex patient case?
13. Explain the steps a nurse should take to effectively implement clinical judgment in managing a patient with severe asthma exacerbation. Describe how the nurse would evaluate the effectiveness of the care plan.

## Reflection Questions

1. Imagine you are assessing a patient who has just been diagnosed with a chronic illness. Reflect on how you would address each domain of the nursing assessment (physical, psychosocial, emotional, spiritual) for this patient. How might the approach differ from an assessment for an acute condition? Consider the long-term implications of a chronic illness on each domain and how this would influence your nursing care plan.
2. Reflect on a clinical experience or a case study in which a comprehensive assessment was crucial in identifying and treating a patient's health issue. How did principles of clinical reasoning influence the assessment? Evaluate which principles were the most critical in this scenario and explain how they contributed to patient care and outcomes.
3. Reflect on a clinical scenario where you might encounter a patient with a chronic condition, such as diabetes. How would you use different types of nursing assessments throughout the continuum of this patient's care? Explain how each assessment type would contribute to the patient's overall treatment and care plan, highlighting the importance of each type at different stages of the patient's healthcare journey.
4. Reflect on a clinical scenario in which you had to rely on multiple sources of data to assess a patient. How did you integrate information from the patient, their family, and your nursing skills to form a comprehensive assessment? Which needs and issues did you prioritize during the assessment, and why?
5. Think of a patient case in which you had to analyze a complex set of data. Describe how you used both inductive and deductive reasoning to interpret the data and formulate a plan of care. What patterns did you identify, and how did they influence your clinical decisions?

6. What strategies can nurses employ to systematically analyze patient data and identify relevant clinical findings?

### What Should the Nurse Do?

Mr. Thompson, a 65-year-old male with a history of type 2 diabetes, presents to a clinic with complaints of increased fatigue, shortness of breath, and occasional dizziness over the past two weeks. He states that these symptoms have become more pronounced while climbing stairs. His medical history includes hypertension and a recent diagnosis of arthritis. He lives alone and admits to occasionally forgetting to take his medications. Mr. Thompson has a family history of heart disease.

1. Given the primary focus of a nursing assessment, what should be the initial step in assessing Mr. Thompson's condition?
2. How should the nurse evaluate Mr. Thompson's psychosocial and emotional states?
3. What approach should the nurse take to ensure the assessment is complete and systematic? Why is this approach important in Mr. Thompson's case?
4. After conducting the assessment, what are the key considerations for the nurse in terms of clinical reasoning and planning Mr. Thompson's care?

Mr. Lee, a 72-year-old male with a history of COPD, presents to the clinic for a routine follow-up. He mentions feeling shorter of breath than usual over the past week. He also reports a persistent cough and increased fatigue. Mr. Lee lives alone and admits to struggling with his inhaler technique. His last full assessment was six months ago.

5. Identify the type of nursing assessment most appropriate for Mr. Lee at the beginning of this clinic visit. Explain your reasoning.
6. Considering Mr. Lee's history and current symptoms, how should you approach his care differently now than if you were performing an initial assessment?
7. If Mr. Lee's condition were to suddenly worsen during the visit, necessitating an emergency assessment, describe what immediate actions should be taken.

Lena, a 32-year-old teacher, arrives at the emergency department experiencing an acute asthma attack. She is struggling to breathe, is using accessory muscles, and appears anxious. She is accompanied by her partner, who reports that Lena's usual inhaler has not been effective, and she has been experiencing increased stress at work due to her school district's new testing requirements for students.

8. What primary sources of data should the nurse use in Lena's assessment, and why are they significant?
9. Considering Lena's presentation, how should the nurse prioritize her needs during the assessment?
10. How should the nurse analyze the collected data to develop a care plan for Lena? Describe the application of inductive and deductive reasoning in this process.

Nurse Rivera is caring for Mr. Nguyen, a 70-year-old patient who has been hospitalized due to COPD exacerbation. Mr. Nguyen, a long-term smoker, is struggling with severe shortness of breath, experiencing coughing fits, and feeling increasingly anxious about his breathing difficulties. Nurse Rivera is tasked with managing his immediate respiratory needs while also considering his long-term care and lifestyle changes.

11. How should Nurse Rivera use clinical reasoning to assess and prioritize Mr. Nguyen's immediate and long-term care needs?
12. Describe how Nurse Rivera can apply critical-thinking skills in developing a comprehensive care plan for Mr. Nguyen.
13. What steps should Nurse Rivera take to implement and evaluate her clinical judgments in Mr. Nguyen's care?

### Competency-Based Assessments

1. Mrs. Rodriguez, a 45-year-old female, was brought to the emergency department by ambulance. Mrs. Rodriguez presents with complaints of severe abdominal pain, nausea, and vomiting for the past twenty-four hours. She reports a history of gallstones and has undergone cholecystectomy (gallbladder removal) surgery five years ago. On initial assessment, Mrs. Rodriguez appears pale and diaphoretic and is in severe pain. Her vital signs include a heart rate of 110 bpm, blood pressure of 140/90 mm Hg, respiratory rate of 22 breaths per minute, and oxygen saturation of 95 percent on room air. What are the actual and potential problems identified in this scenario?

2. Mrs. Smith, a 68-year-old female, has been admitted for exacerbation of chronic obstructive pulmonary disease (COPD). She presents with increased dyspnea, productive cough with purulent sputum, and generalized weakness. Mrs. Smith has a history of smoking for forty years and lives alone in a small apartment. She has been feeling increasingly isolated since her husband passed away three years ago. Explain how the nurse should assess the patient's physical, psychosocial, emotional, and spiritual health.

Nurse Emily is working in a primary care clinic. She is assigned to conduct assessments on three different patients with varying health concerns. Patient A is a 70-year-old male with a history of diabetes and hypertension who presents with complaints of dizziness and shortness of breath. Patient B is a 35-year-old female who recently underwent knee surgery and is experiencing postoperative pain. Patient C is a 45-year-old male who is seeking advice for smoking cessation.

3. For patient A, what type of nursing assessment would be most appropriate, and why?
4. What specific assessments would Nurse Emily prioritize for patient A's complaints of dizziness and shortness of breath?
5. Considering patient B's recent knee surgery, what type of nursing assessment would Nurse Emily conduct for postoperative pain management?
6. What assessments would be included in the problem-focused assessment for patient B?
7. For patient C, what type of nursing assessment would be beneficial in addressing his smoking cessation needs?
8. How would Nurse Emily approach the initial assessment for patient C to gather relevant information for smoking cessation counseling?

You are working as a nurse in the emergency department of a hospital. It is a busy Friday night, and the department is filled with patients requiring urgent care. Suddenly, the emergency alarm rings, signaling the arrival of a critically injured patient. The paramedics rush in with a middle-aged male who was involved in a high-speed car accident. The patient is unconscious and bleeding profusely from a head injury. Vital signs reveal a weak pulse and shallow breathing. The patient's family informs you that the patient has a history of hypertension and diabetes, but they are unsure of any other medical conditions.

9. How would you apply the ABCs framework in prioritizing patient care during this emergency situation?
10. Explain how Maslow's hierarchy of needs can guide your prioritization of care for patients with complex healthcare needs.
11. Provide examples of clues that may indicate underlying health issues during a patient assessment.
12. Discuss the difference between inductive and deductive reasoning and how each can be applied in analyzing assessment data to formulate a care plan.

## CHAPTER 13

# Diagnosis and Planning: Analyzing, Prioritizing, and Generating Solutions

**FIGURE 13.1** Diagnosis and planning are the second and third phases in the nursing process, following the assessment phase. A thorough assessment is essential to identify a diagnosis and plan for care correctly. (credit: Jason W. Edwards/NARA & DVIDS Public Domain Archive, Public Domain)

### CHAPTER OUTLINE

- 13.1 Evolution of Nursing Diagnosis
- 13.2 Focus of Nursing Diagnosis
- 13.3 Categories of Nursing Diagnosis
- 13.4 Focus of the Planning Phase

**INTRODUCTION** A fundamental part of working as a nurse is formulating a nursing diagnosis, which guides outcomes and corresponding interventions to achieve patient care goals. It is a dynamic method of assessment and data aggregation that encompasses the depth and breadth of the nurses' scope of practice and, in many situations, serves as a tool to aid in critical thinking. To write and apply an appropriate nursing diagnosis, the nurse must gather patient data incorporating the scientific, physiological, and medical aspects of a patient's situation. The critical thinking skills necessary for this process enable nurses to make clinical judgments based on evidence and experience.

How do nurses learn to do this? How does a nurse learn to think in a way that leads to the appropriate decisions and conclusions? It is one thing to learn clinical knowledge—facts, figures, anatomy, and physiology—but how do nurses learn to go a step further to think critically and apply clinical judgment? The nurse acquires these key skills by creating a systematic method of gathering data, assessing, forming a hypothesis, creating a plan, putting the plan into action, and reevaluating.

This chapter begins with the evolution of nursing diagnoses and a discussion of the nursing process, which is the basis for developing nursing thought. Then, the chapter goes through the various thinkers and theories that moved the development of nursing diagnoses to the newest process in place, the Clinical Judgment Measurement Model (CJMM) developed by the National Council of State Boards of Nursing (NCSBN). The section ends with a discussion on the role nursing diagnosis plays in clinical decision-making, the different categories of nursing diagnosis, and how to formulate the diagnosis from the tools available. Understanding nursing diagnosis is an important part of nursing.

## 13.1 Evolution of Nursing Diagnosis

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the development and evolution of a nursing diagnosis
- Explain how a nursing diagnosis is used as a problem-solving approach for planning patient care
- Understand the rationale for transitioning to the clinical judgment measurement model

Most people have heard of medical diagnoses, but few outside the healthcare profession know about nursing diagnosis or what its purpose is. The role of nursing has evolved in health care, and in today's healthcare world, it is often up to nurses to facilitate a patient's entry into the healthcare system. There must be a systematic and structured method of obtaining the necessary data to achieve that outcome. The development of nursing diagnosis began with the need for a common language to communicate across the profession.

In carefully constructed, concise statements, the nursing diagnosis identifies patient issues (clinical and psychosocial) and articulates potential causes of the problem. Using this statement structure and medical terminology as part of this system allows a patient with diabetes to go from being described as “a diabetic” or “a person with type 2 diabetes mellitus” to the more detailed and descriptive statement of “risk for unstable blood glucose levels related to insufficient diabetes management.” Changing the medical diagnosis to the nursing diagnosis allows the nurse to identify a patient's specific needs—which, in the case of a patient who has diabetes, may be unstable glucose levels. Now, the nurse can develop a plan of care to help the patient manage the identified problem.

Given the many factors involved in caring for complex patients, a common and concise form of communication was essential for the growth of the nursing profession. This problem-solving approach to articulating patient problems or needs is the basis for planning care and interventions, as it lays the foundation for critical thinking.

### Development of Nursing Diagnosis

Nursing diagnosis began in the 1960s, first as the nursing process. The **nursing process** is a five-step method of guiding decision-making for nurses:

- assessment
- diagnosis
- planning
- implementation
- evaluation

These five steps of the nursing process are also named by the American Nurses Association (ANA) as the approved Standards of Practice to designate a “competent level of nursing care . . . and forms the foundation of the nurse's decision-making” (American Nurses Association [ANA], 2015a). However, more standardization and commonality were needed to develop this process further. In the 1970s, the North American Nursing Diagnosis Association (NANDA) developed a list of nursing diagnoses, which were delineated, patient-focused statements formed through this nursing process and selected through patient assessment.

A methodical way to provide and evaluate appropriate patient care is called **nursing diagnosis**. These diagnoses were updated and modified several times throughout the next four decades, with the last update in 2024 of *NANDA-I International Nursing Diagnoses: Definitions & Classification, 2024–2026*, 13th edition by T. Heather Herdman, Shigemi Kamitsuru, and Camila Lopes.

The NANDA diagnosis list utilizes a problem-solving approach that helps provide individualized nursing care to

patients. In short, it provides a framework for decision-making based on collected data related to the patient's condition. Articulating these nursing-focused problems as diagnoses created a way for nurses to begin their patient care in a planned and organized fashion, and using the NANDA-approved diagnoses gave nurses the common language to understand these interventions across the profession.

Nursing diagnosis became the foundation of what makes nursing a distinct and autonomous profession in health care. The dynamic ability of nursing diagnoses enables nurses to address multiple facets of their patients' healthcare needs, including clinical, pathophysiological, psychosocial, and environmental.

Nursing diagnosis is a step-by-step way to gather patient data and to create, deploy, and evaluate a plan for patient care. It helps nurses conduct research and drives quality initiatives in clinical and outpatient settings. Most importantly, it provides a common language and decision-making framework that enable nurse educators to teach future generations of nurses.

## LINK TO LEARNING

This quick video explains [how to write a nursing diagnosis \(https://openstax.org/r/77nursediag\)](https://openstax.org/r/77nursediag) when developing patient plans of care.

### ANA Standards of Practice

The **Standards of Practice** designed by the ANA and based on the nursing process provided a problem-solving-focused approach to nursing practice. The Standards of Practice was the beginning of the definition of nursing as a clinically, technically rigorous, and autonomous profession. Within the Standards of Practice, the ANA defines the job of the nurse as including “the diagnosis and treatment of human responses to actual or potential health problems” (ANA, 2015b). This statement and these standards bolster the strength of nursing diagnosis as a decision-making tool of an autonomous profession. These standards outline the level of care that should be provided by a competent level nurse modeling the nursing process as a critical thinking model.

### ANA Competencies for Nursing Diagnosis

The nursing process has six competencies that nurses use as part of their critical thinking process and decision-making (ANA, 2015a). As you learned in [12.4 Cognitive Process for Analyzing Assessment Data](#), critical thinking describes a process of thought that uses structured methods of observation, reasoning, and thought to make educated and rational decisions. Critical thinking sets nurses apart from those who simply “follow orders.” Steps in the nursing-specific critical thinking process include the following:

1. **Assessment:** The nurse gathers data from the patient's history and physical symptoms and compares them to normal values. Refer back to [Chapter 12 Assessment: Recognizing Cues](#) for a recap on nursing assessment.
2. **Diagnosis:** The nurse groups the data and uses them to focus on one or more patient problems. These problems can then be prioritized.
3. **Identifying expected outcomes:** The nurse focuses on one problem and then thinks about the best end result or desired outcome for this specific patient.
4. **Creating a plan to achieve these expected outcomes:** The nurse will decide on planned activities the patient must complete to meet the determined result or desired outcome. These are tasks that the patient must be able to do alone or collaboratively with healthcare professionals.
5. **Implementing the plan:** This is the phase in which the patient completes the planned activities. This step is where the action happens.
6. **Evaluating the plan's effectiveness:** The nurse reviews the patient's progress toward the desired outcome or intended results. Was the goal met—fully, partially, or not at all? Is the patient making progress toward the intended results? Does anything about the plan need to be changed? Or can it continue as planned? Or, perhaps, more time is needed for the patient to achieve the goal? The answers to these questions will determine if the plan is continued, modified, or discontinued completely.

It is important to note when engaging in this process that nurses do not only consider the patient themselves but all those involved in providing care. Families, significant others, loved ones, and perhaps even friends can all be part of the patient's support network. Therefore, each of them has a collaborative part in this process alongside the patient.

## Problem-Solving Approach

The problem-solving approach to planning patient care nursing began with the development of a diagnosis and identifying the relevant problems. To pinpoint those, the nurse must conduct an assessment. The nurse's assessment is focused on the collection and analysis of clinical data.

The first data point is the patient's problem. The nurse must start by identifying the patient's chief complaint. Using collected data referred to as the patient's signs and symptoms, the nurse will determine if the identified problem is currently happening or at risk of happening. The problem-solving approach to care planning gives the nurse a clear starting point to assign interventions and evaluate their effectiveness.

Methods to complete the problem-solving approach have evolved over time and consist of three tactics. The first was NANDA-I, followed by Tanner's Clinical Judgement Model (CJM), which transitioned into the Clinical Judgement Measurement Model (CJMM). Research states that no one tactic is better than the other; rather, nurses should be able to incorporate a combination of all three.

### NANDA International (NANDA-I)

In 2002, NANDA officially became NANDA International. The name changed again in 2011, to NANDA International, Inc., after considering the significant growth of membership outside North America. The organization continues to use "NANDA" as part of its name due to its familiarity (NANDA-I, 2024). However, "NANDA" is no longer the appropriate acronym. The organization is now known as **NANDA-I**, whose purpose is still to facilitate the development, modification, distribution, and use of standardized nursing diagnostic terminology.

NANDA-I nursing diagnoses are easily identified as clear statements written and developed by the evidence-based organization. The terminology gives nurses a starting point for the problem-solving approach used to develop a nursing diagnosis. For clarity, the organization created a taxonomy, or classification system, for arranging or listing the patient's identified problem. In 2002, the work of Dr. Mary Gordon's Functional Health Assessment Patterns was used as the framework to develop what is known as Taxonomy II. **Taxonomy II**, the current classification method for listing nursing diagnoses, has three levels: domains, classes, and nursing diagnosis ([Figure 13.2](#)).

<b>TAXONOMY II Classification Method for Nursing Diagnosis</b>	
<p><b>DOMAIN 1 • Health promotion</b>  <b>Class 1:</b> Health awareness  <b>Class 2:</b> Health management</p> <p><b>DOMAIN 2 • Nutrition</b>  <b>Class 1:</b> Ingestion  <b>Class 2:</b> Digestion  <b>Class 3:</b> Absorption  <b>Class 4:</b> Metabolism  <b>Class 5:</b> Hydration</p> <p><b>DOMAIN 3 • Elimination/Exchange</b>  <b>Class 1:</b> Urinary function  <b>Class 2:</b> Gastrointestinal function  <b>Class 3:</b> Integumentary function  <b>Class 4:</b> Respiratory function</p> <p><b>DOMAIN 4 • Activity/Rest</b>  <b>Class 1:</b> Sleep/Rest  <b>Class 2:</b> Activity/Exercise  <b>Class 3:</b> Energy balance  <b>Class 4:</b> Cardio-vascular/Pulmonary responses  <b>Class 5:</b> Self-care</p> <p><b>DOMAIN 5 • Perception/Cognition</b>  <b>Class 1:</b> Attention  <b>Class 2:</b> Orientation  <b>Class 3:</b> Sensation/Perception  <b>Class 4:</b> Cognition  <b>Class 5:</b> Communication</p> <p><b>DOMAIN 6 • Self-perception</b>  <b>Class 1:</b> Self-concept  <b>Class 2:</b> Self-esteem  <b>Class 3:</b> Body image</p>	<p><b>DOMAIN 7 • Role relationship</b>  <b>Class 1:</b> Caregiving roles  <b>Class 2:</b> Family relationships  <b>Class 3:</b> Role performance</p> <p><b>DOMAIN 8 • Sexuality</b>  <b>Class 1:</b> Sexual identity  <b>Class 2:</b> Sexual function  <b>Class 3:</b> Reproduction</p> <p><b>DOMAIN 9 • Coping/Stress tolerance</b>  <b>Class 1:</b> Post-trauma responses  <b>Class 2:</b> Coping responses  <b>Class 3:</b> Neuro-behavioral stress</p> <p><b>DOMAIN 10 • Life principles</b>  <b>Class 1:</b> Values  <b>Class 2:</b> Beliefs  <b>Class 3:</b> Value/Belief/Action congruence</p> <p><b>DOMAIN 11 • Safety/Protection</b>  <b>Class 1:</b> Infection  <b>Class 2:</b> Physical injury  <b>Class 3:</b> Violence  <b>Class 4:</b> Environmental hazards  <b>Class 5:</b> Defensive processes  <b>Class 6:</b> Thermo-regulation</p> <p><b>DOMAIN 12 • Comfort</b>  <b>Class 1:</b> Physical comfort  <b>Class 2:</b> Environmental comfort  <b>Class 3:</b> Social comfort</p> <p><b>DOMAIN 13 • Growth/Development</b>  <b>Class 1:</b> Growth  <b>Class 2:</b> Development</p>

**FIGURE 13.2** Taxonomy II is a classification system used to organize, define, and list nursing diagnoses according to domains of care. This system allows nurses to use a problem-solving approach to planning patient care. (data source: Herdman & Kamitsuru, 2018; attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The domains are broken out into thirteen groups. The domains consist of topics such as health promotion, activity, comfort, and safety. The domains are further organized into forty-seven classes directly related to each domain. For instance, the domain of health promotion has two classes: health awareness and health management. The domain of comfort has three classes: physical comfort, social comfort, and environmental comfort. The nursing diagnoses are coded according to seven different criteria and include the diagnostic concept, time, unit of care, age, health status, descriptor, and topology.

In addition, nursing diagnoses are listed alphabetically by their concept, not by the first word in the diagnosis. NANDA-I and Taxonomy II are both used today in clinical practice as a problem-solving approach to clinical decision-making.

### Tanner's Clinical Judgment Model (CJM)

After years of growing the nursing profession to one that is based on evidence and research, nurses started to realize that only those experienced in the profession could truly understand how to incorporate NANDA-I and the development of a nursing diagnosis into the patient's plan of care accurately and efficiently. New nurses were

struggling with not knowing what they didn't know.

In 2006, a nursing educator, Christine Tanner, published a researched model of clinical judgment, which was the product of extensive research and synthesis used to identify the essential themes of how new nurses develop strong clinical judgment skills (Tanner, 2006). **Tanner's Clinical Judgement Model (CJM)** is a helpful framework that offers a different articulated perspective to the problem-solving approach for developing nursing diagnoses. Tanner's model consists of four steps (Tanner, 2006):

- **Noticing:** What are the clinical cues, and why are they relevant? The key to effective nursing and safe patient care begins with the ability to recognize when the data are relevant and important.
- **Interpreting:** What do the data mean? Understanding the data and processing them in terms of the patient's pathophysiology is essential to interpreting the data correctly.
- **Responding:** Now that the nurse has recognized necessary data and has interpreted them correctly, what is the course of action taken by the nurse? Knowing the appropriate response is key to planning and implementing an intervention.
- **Reflecting:** Once the plan is implemented and the intervention accomplished, it is time to reassess and see if the patient's response to the intervention was as expected. Tanner elaborates on this last step by identifying two methods of reflection:
  - Reflection *in* action—decisions that are made to the plan of care immediately and in the moment.
  - Reflection *on* action—thinking done after the care is provided to determine if the decisions made were the right ones, and if not, what could be done differently going forward (Rischer, 2020).

## PATIENT CONVERSATIONS

---

### A Therapeutic Conversation: Responding

**Scenario:** A patient is in the medical-surgical floor and is complaining of pain. The nurse was called to the room to assess the situation.

**Nurse:** Good morning, Levi. How are you feeling today?

**Patient:** Not so good, the pain in my back is still bothering me.

**Nurse:** I'm sorry to hear that. Can you tell me more about your pain?

**Patient:** It's a sharp pain in my lower back, and it gets worse when I try to move. Right now, it's a 9 out of 10.

**Nurse:** I see you have been taking your pain medication the doctor ordered. Does the medication seem to help your pain?

**Patient:** Not really, even when I take the pain medication it only comes down to a 7 out of 10. They helped for a little while, but the pain comes back so strong, well before my next does is available.

**Nurse:** I understand. I am going to call your provider to discuss possible options to help with your pain.

**Patient:** Thank you. I appreciate you listening and responding to my needs.

---

Tanner's model is important because of what sets it apart from the nursing process. Its focus was to help develop the beginning nurse's clinical judgment skills, as they have no prior nursing experience. The realistic assumption is that nurses need to be taught through a combination of education and clinical experience. The model reframes the thought processes that are needed for clinical judgment.

### Transition to the Clinical Judgment Measurement Model (CJMM)

However, healthcare technology continues to evolve, and patient populations are becoming increasingly complex with both clinical and psychosocial demands. It has now become clear that while North American Nursing Diagnosis Association (NANDA) provided a good framework for developing nursing diagnoses, it does not always work well with the complexities of today's patient needs.

For example, unexpected changes in patient conditions require immediate changes to the plan of care. Many of

these unexpected changes do not fit into a ready-made diagnosis. Nurses started having trouble thinking outside the box.

As a profession, nurses realized they needed to develop critical thinking and clinical judgment skills that are required to dynamically revise nursing diagnoses as needed. This need led to the development of a more flexible and focused method of learning how to think and develop clinical judgment skills, the Clinical Judgment Measure Model.

The Clinical Judgment Measurement Model (CJMM) is the latest framework developed by the National Council of State Boards of Nursing (NCSBN) to aid in identifying nursing-focused clinical problems. The CJMM is based on the most current research and literature in nursing pedagogy, nursing science, and psychology (NCSBN, 2020) ([Figure 13.3](#)).

Comparing the Clinical Judgment Measurement Model (CJMM)						
Tanner	Noticing	Interpreting		Responding	Reflecting	
Nursing Process	Assessment	Analysis		Implementation	Evaluation	
CJMM	Recognize cues	Analyze cues	Prioritize hypotheses	Generate solutions	Take actions	Evaluate outcomes
<b>Example</b>	<i>A patient is breathing 22 times a minute and states, "I can't catch my breath. My head hurts."</i>	<i>The nurse recognizes that the patient is in respiratory distress.</i>		<i>The nurse raises the head of the bed, and tells the patient to take deep breaths and breathes with them while making eye contact. A nasal cannula is also applied to give supplementary oxygen to the patient.</i>	<i>The nurse observes the patient and looks for signs of improvement or deterioration. If the patient is doing well then the nurse will make sure the situation is safe and then notify the healthcare provider about the incident and document it in the chart.</i>	

**FIGURE 13.3** Understanding that the basis of the CJMM lies in the frameworks of the nursing process and Tanner's model of clinical judgment. Although the three types of clinical judgment models are interrelated, the Clinical Judgment Measurement Model refines the methodology and improves decision-making by adding two levels of modeling thought that help build complexity into decision-making. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LINK TO LEARNING

The NCSBN created the [Clinical Judgment Measurement Model \(CJMM\)](https://openstax.org/r/77CJMM) (<https://openstax.org/r/77CJMM>) to explore new ways of testing clinical judgment in nursing as part of the National Council Licensure Examination (NCLEX). The diagram at this site shows the layers of the model.

The CJMM incorporates elements of the nursing process and Tanner's model of clinical judgment with two additional levels of modeling thought that help build complexity into decision-making. Understanding the components of this framework provides yet another method of clinical decision-making.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Prioritize a Hypothesis: Developing a Nursing Diagnosis

A nurse hears a patient's vital sign monitor go off. She walks into the room and sees several things at once: the patient looks very uncomfortable—they are grimacing, their eyes are wide, their skin is pale, and they are diaphoretic (sweaty). The patient's respirations are 22 breaths a minute, and he is saying, "I can't catch my breath, and my chest hurts." His blood pressure is elevated at 160/90 mm Hg, heart rate is 128 beats per minute, and the patient is sitting up in bed in a tripod position. The nurse quickly asks how the patient is feeling, and they respond with, "I can't catch my breath, and I don't feel good at all."

- **Recognizing cues:** The nurse swiftly identifies alarming cues, including the patient's grimacing, diaphoresis, and complaints of difficulty breathing and chest pain. These cues prompt immediate attention and further assessment.
- **Analyzing cues:** Through rapid analysis, the nurse interprets the patient's symptoms as indicative of distress. Recognizing the urgency, the nurse correlates the respiratory distress with elevated vital signs, indicating a potential critical condition.
- **Prioritizing a hypothesis:** Prioritization comes from Airway, Breathing, and Circulation (ABCs) in acute or emergent situations. ABCs is an effective priority framework that focuses on lifesaving interventions. Understanding the gravity of the situation, the nurse prioritizes hypotheses focused on acute respiratory distress or cardiac compromise, recognizing the patient has a potential breathing and circulation issue. This prioritization will guide subsequent interventions and decision-making.

Based on the presented scenario, a potential nursing diagnosis for the patient could be "impaired gas exchange related to inadequate ventilation secondary to respiratory distress as evidenced by tachypnea (22 breaths per minute), dyspnea ("I can't catch my breath"), elevated blood pressure (160/90 mm Hg), elevated heart rate (128 beats per minute), diaphoresis, and the patient's inability to lie flat (sitting up in bed in a tripod position)."

### Six Cognitive Skills

The CJMM includes six cognitive skills each nurse must master to think critically through a patient care situation. The cognitive skills needed to implement the CJMM are as follows:

- **Recognize Cues** can be defined as identifying relevant clinical data using multiple sources available to the nurse, including the presenting scenario, medical history, vital signs, nursing assessment, and laboratory values, then extracting important clinical data from these sources.
- **Analyze Cues** can be defined as taking the data that have been collected and interpreting it using an existing knowledge base. It also includes organizing the clinical data, recognizing patterns, and generating hypotheses regarding the clinical cues collected.
- **Prioritize a Hypothesis** is described as using the data articulated as hypotheses, narrowing down what the most pressing problem is, and thus identifying which is the priority.
- **Generate Solutions** is determining the expected outcomes or goals for the patient. This skill also includes developing a plan of care and identifying nursing interventions that need to be in place to bring about the expected outcome.
- **Take Action** can be described as implementing the solutions generated that will address the identified priority hypothesis as well as subsequent priorities as they exist. This requires nurses to determine which interventions are the most appropriate and to implement them in order of importance to the patient's health and well-being.
- **Evaluate Outcomes** is determining whether patient outcomes were met. They can be either fully or partially met and may require revision to continuously work toward achieving the expected outcome. They can also be marked as complete if it is determined that the outcome has been achieved.

 **LINK TO LEARNING**

Read this [evidence-based research article on the importance of critical skills in nursing \(https://openstax.org/r/77critskills\)](https://openstax.org/r/77critskills) to learn how they are used to develop critical thinking.

The six cognitive steps are needed to incorporate the CJMM into developing accurate and efficient critical thinking skills. As nurses transition from school to clinical settings, they will understand the six cognitive skills and how practicing nurses really think when determining the best possible care for their patients.

## 13.2 Focus of Nursing Diagnosis

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the foundational steps for clinical decision-making
- Recognize the difference between a nursing diagnosis and a medical diagnosis
- Identify how the nursing diagnosis can promote expected patient care outcomes

This section discusses the focus of nursing diagnosis. Just as the focus of each role for different healthcare clinicians varies, so does the focus of the nursing diagnoses. The primary focus is for the nurse to explain why the patient needs nursing care versus medical care. The diagnosis identifies nursing care that treats a patient's problem or concern and can be performed independently by the nurse instead of the provider.

This section analyzes foundational steps for clinical decision-making using a model that focuses on preventing problems or issues. It also discusses the differences between nursing and medical diagnoses and explores how these differences highlight the uniqueness of each profession. This section also demonstrates how nursing diagnosis promotes the desired patient outcome.

### Foundation for Clinical Decision-Making

Before the evolution of nursing diagnosis and the autonomy of the profession, the healthcare mindset was to have providers diagnose while nurses treat and care for patients. Hence, the foundation of the nursing profession is to care for those in need. Since the evolution of an autonomous profession that collaborates with other healthcare clinicians, the trend has shifted to place more value on the nurse, basing patient care on evidence-based research and incorporation of clinical decision-making.

The foundational steps for incorporating clinical decision-making for patient care are to predict, prevent, manage, and promote (PPMP). Through evidence-based interventions, nurses can address their patients' needs by predicting potential problems, preventing problems before they start, managing problems when they do arise, and providing health promotion strategies.

#### Predict

In the presence of known problems, nurses must predict the most common and dangerous complications associated with each problem. This involves looking at the big picture and thinking about the best and worst possible outcomes. The best outcome will show signs and symptoms of the patient's progress toward recovery. In contrast, the worst outcome will represent signs of patient deterioration and decompensation.

The nurse must always be thinking two steps ahead. While it sounds daunting, most people use this thinking in daily life without realizing it. For example, most people wouldn't just hit the open roads on a road trip without thinking first about their destination or plan to get there. It takes a plan to make sure the trip is enjoyable and goes off without a hitch.

#### Prevent

The nurse has a primary role in keeping the patient safe. This responsibility means nurses are constantly looking for potential problems and determining how to prevent them from happening. Think of the road trip example again. Getting the car's oil and tires checked, mapping out the route, and packing extra snacks and water in case of a breakdown on the road are all steps that can be taken ahead of time.

The same planning applies when using thinking skills in clinical decision-making. Nurses must think through the many possible scenarios that could happen to a patient and carefully put measures in place to prevent the worst scenarios from taking place. Nurses must be ready to take immediate action when a potential problem becomes an actual problem.

### Manage

If a potential problem cannot be prevented, the nurse will initiate the management phase. This step includes managing the problem through interventions such as involving the patient in decision-making, using evidence-based sources and protocols, and asking other interdisciplinary team members to collaborate on care if needed. The nurse will organize monitoring of the patient to be watchful for signal changes in a patient's condition or deterioration.

The road trip example applies here, too. What if a car's tire blows out? Some people may change the tire themselves, while others would call a rescue service such as a tow truck company or a local mechanic. What they would *not* do is sit on the side of the road and wait for the tire to fix itself. The same goes for nursing care for identified patient problems. The nurse must manage the situation to prevent the patient's situation from getting worse.

### Promote

The nurse always ensures that the safety and learning needs of the patient are being met by promoting peak functioning and independence. Patients will not need nurses forever. The nurse will actively encourage a patient to heal and self-manage their disease or condition. Often, the most natural way to promote health is to include the patient in their care. A patient will become empowered to protect their own well-being by learning to identify the signs and symptoms of potential problems. While the nurse has knowledge about disease management, the patient has a front-row seat to the actual problem and the effects it has on their quality of life.

Just like a driver would promote their own safety and the safety of their passengers while on a road trip, safety is at the forefront of all nursing interventions regardless of outcome. The knowledge and experience gained from a specific patient scenario informs future scenarios and provides information for how to plan for, prevent, and manage any complications.

As the nurse starts interpreting and analyzing data to predict, prevent, manage, and promote, they may identify the need for collaborative care to ensure the best possible outcomes for a patient. For example, perhaps the provider will need to re-evaluate the patient's medical diagnosis or order new diagnostics. Maybe other interdisciplinary team members need to initiate interventions such as wound care, physical therapy, or respiratory therapy. In such situations, the nurse is responsible for reporting their findings and working collaboratively with each discipline to resolve the identified patient problem.

## Nursing Diagnosis versus Medical Diagnosis

A **medical diagnosis** identifies a disease or a condition and describes a problem toward which providers direct the treatment plan. Treatment plans focus on the **etiology**, the cause (or causes) of a specific disease state. A nursing diagnosis identifies a patient's response to health and illness-related problems. The diagnosis process is performed independently within the nurse's professional scope of practice. It is also fluid and ever-changing based on the patient's response to interventions. These key distinctions reflect the differences between medical and nursing diagnoses ([Table 13.1](#)).

	<b>Nursing Diagnosis (Care-Focused)</b>	<b>Medical Diagnosis (Etiology-Focused)</b>
Definition	Identifies the signs and symptoms of the disease stated by the patient and their caregiver(s)	Identifies the clinical process behind the disease itself and the pathophysiology responsible for its cause
Focus	Emphasis is on the person and their physiological and/or psychological response to the illness	Emphasis is on the illness or condition
Example 1	Ineffective cardiac tissue perfusion related to reduced coronary blood flow	Myocardial infarction (heart attack)
Example 2	Risk for aspiration related to altered sensory perception	Cerebrovascular accident (stroke)
Example 3	Risk of deficient fluid volume related to gastrointestinal losses and NPO status	Small bowel obstruction

**TABLE 13.1** Nursing Diagnosis versus Medical Diagnosis

It is important to remember that a nursing diagnosis is based on the patient as a whole person and includes physical, mental, and social factors. The patient’s response to the disease process affects all of these domains of their life, so they must be part of the plan of care. The nurse considers actual responses and potential risks. They also look at how areas of concern could affect psychosocial factors, such as family or community support, access to resources, healthcare access in general, and financial barriers to care.

The nurse must also be aware of their own potential biases when doing assessments. These biases can present with preconceived notions about particular groups or situations and may ultimately affect how nurses provide care. Poor outcomes could look like inadequate patient assessment, inappropriate diagnosis and treatment plans, or the lack of education and follow-up for the patient and family.

### Actual Problems

Another important consideration is that disease processes do not affect all patients in the same way. As such, the same nursing diagnosis will not fit every patient with the same medical diagnosis. The nurse must ensure the diagnosis chosen is an actual problem or a problem the individual patient is or could potentially experience. Actual problems are discussed in the context of nursing assessment in [\[link to: Chapter 12, section 12.1 H4\]Actual Problems\[/link\]](#).

A common example of this would be the medical diagnosis of diabetes in two different patients. One patient goes home and asks their entire family for help, changes their diet, and begins to exercise every day. The second patient internalizes the medical diagnosis, feels depressed and ashamed, and keeps the diagnosis a secret from their family and friends. The patient goes for walks occasionally but gives up when the weather gets hot in the summer.

The first patient was energized and ready to learn how to manage the disease and change their life in response to it. Their plan of care might start with a nursing diagnosis, such as “readiness for enhanced knowledge.” The nurse could provide education related to disease management. The second patient is not coping well with the new diagnosis. They have isolated themselves by not involving family and will have less-than-optimum outcomes if they do not change their mindset. The patient’s response to the diagnosis must be addressed before the nurse can start to educate the patient on how to manage the disease. This patient’s plan of care might start with a nursing diagnosis of “ineffective coping.” The nurse would need to provide the patient with education on healthy coping mechanisms and how they affect disease progression. The nurse may connect the patient with community support and resources.

## Nursing Diagnosis versus Collaborative Problem

A nursing diagnosis is also different from a **collaborative problem**. Collaborative problems require interdisciplinary team members to complete. Response to these problems can be initiated by the provider, the nurse, or another discipline, but the responsibility of ensuring the task is completed falls on the nurse.

When the nurse identifies an expected outcome or goal, if it cannot be initiated without a medical order, then it is not a nursing diagnosis. Rather, it is a collaborative problem. For example, perhaps the nurse is planning care for a patient who has just undergone a knee replacement. The nurse recognizes the patient has “impaired physical mobility” and recommends a goal of “the patient will walk to the nurses’ station and back without assistance before discharge.” This task cannot be completed without the provider writing an order for physical therapy (PT) to evaluate and treat the patient. Therefore, it is a collaborative problem and not a nursing diagnosis. If the patient reports severe pain and cannot tolerate PT, the nurses could write a nursing diagnosis of “impaired physical mobility related to pain” and would need to administer medication before physical therapists can work with the patient.

Collaborative problems and nursing diagnoses are often intertwined. Therefore, it is imperative that collaborative problems are identified early within the treatment plan so that preventive nursing care can be initiated sooner rather than later.

Another way to think of collaborative problems is as interdisciplinary problems. See [Table 13.2](#) for a side-by-side comparison of nursing and medical diagnoses with collaborative problems. Any time another interdisciplinary team member is involved in a patient’s plan of care, it is a collaborative problem. Nurses can use nursing-prescribed actions within the scope of their license and skill set to carry out provider-prescribed orders. The focus of collaborative problem-solving is monitoring patients for changes in clinical status, understanding who can best address the identified problem, and recommending new interventions. Nurses not only utilize appropriate nursing interventions but can also implement treatments as prescribed by providers.

Nursing Diagnosis	Collaborative Problem	Medical Diagnosis
Disturbed body image	Need for prosthetic: rehabilitation therapist to fit for prosthetic device	Amputation
Ineffective airway clearance	Need for chest physical therapy (CPT): respiratory therapist to perform chest physiotherapy	Pneumonia
Imbalanced nutrition	Need for specialized diet: dietician to evaluate and treat	Malnutrition: failure to thrive
Ineffective activity tolerance	Potential complications related to respiratory failure: cardiopulmonary rehabilitation	Chronic obstructive pulmonary disease (COPD)
Total self-care deficit	Potential complications related to deconditioning: occupational therapy (OT)/speech therapy (ST)/physical therapy (PT) to assist with activities of daily living	Cerebrovascular accident (stroke)

**TABLE 13.2** Nursing Diagnoses, Medical Diagnoses, and Collaborative Problems

### Potential Complications

It is important to remember that a nursing diagnosis is not based on a medical diagnosis—it’s based on a patient’s response or reaction to their condition or disease. Nurses use information gathered during the assessment process and analyze the data collected. Determining a healthy response from a nonhealthy response is not as easy as it sounds. To avoid making a **diagnostic error** or failing to identify a response as unhealthy, the nurse must incorporate common evidence-based comparative standards when interpreting and analyzing data.

Recognizing which data are significant data is an important first step in preventing potential complications. For example, a blood pressure of 136/88 mm Hg may be considered elevated for a patient without a history of high blood pressure. However, the same blood pressure could be considered normal for a patient with a medical diagnosis of hypertension. According to the National Institutes of Health (NIH), some common comparative standards to use when analyzing patient data include the following:

- Unexplained changes in normal health patterns such as growth and development.
  - Example: A 7-year-old child suddenly develops an inability to control their bladder.
  - Rationale: Most 7-year-old children have bladder control.
- A marked change from what is considered a population norm.
  - Example: A previously social teenager suddenly becomes withdrawn and isolates themselves from peer interactions.
  - Rationale: Depression is linked to a sudden change in social habits.
- Personal behavior that is described as nonproductive to the body as a whole (Young et al., 2023).
  - Example: A college student suddenly loses weight and is seen bingeing food after being accepted to the cheerleading team.
  - Rationale: Unhealthy nutritional habits and a negative self-perception are dysfunctional and have negative implications for one's health.

## REAL RN STORIES

---

### Patient Education to Prevent Potential Complications

**Nurse:** Marilyn, RN

**Clinical setting:** Primary care office

**Years in practice:** 2

**Facility location:** Southern Indiana

One day when I was working, a mom brought her 11-year-old daughter in for her yearly well-child visit. The mom said things are going great, the only thing she has been having an issue with is difficulty getting her daughter to drink milk or eat any dairy products. The mom reported, “I do not really see it as a problem because I do not like milk or dairy, either.” I asked if the daughter’s diet consisted of other sources of calcium. The mom said, “No, not really, we like snack-style foods like pastries and pizza.” I educated the mom on the importance of a well-balanced diet, but especially the need for calcium in her daughter’s diet as well as in her own diet. I discussed bone formation at this age in growth and development, and talked about how her daughter was in her formative years. I got some supplemental printouts to help the mom select some foods rich in calcium that the daughter might like. After reviewing the list of foods, the mom said, “Oh, we love walnuts and almonds. I will make sure to keep a good supply of those on hand. We can try to incorporate some of these other options, too.”

---

### Promotion of Expected Outcomes

Articulating outcomes is similar to goal setting when conducting patient and family education. Like planning goals, planning nursing outcomes from interventions should be clear, focused, and SMART—specific, measurable, achievable, relatable, and timely. The difference is that the outcomes are not measured solely on achieving a goal—rather, they are based on the progress toward attaining the desired outcomes.

## LINK TO LEARNING

---

This article outlines [SMART goals \(https://openstax.org/r/77SMARTgoals\)](https://openstax.org/r/77SMARTgoals) in nursing practice.

---

Many times, nurses will see several problems occurring for a patient at the same time. This means that one patient can have several nursing diagnoses. For example, they may have problems with pain, a wound, and a cough. The nurse must formulate these diagnoses and think about the common threads between them. It's necessary to consider how the diagnoses are related and, subsequently, how interventions can be planned and implemented to

address multiple diagnoses.

## 13.3 Categories of Nursing Diagnosis

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify how to determine the category for the nursing diagnosis
- Describe how to validate the nursing diagnosis
- Explain how to refine the nursing diagnosis

To make safe and effective clinical judgments using nursing diagnoses, nurses need to understand how the diagnoses are categorized. The categories also differentiate nursing diagnoses from medical diagnoses.

This section discusses the different nursing diagnosis categories and explains how to identify a valid and appropriate diagnosis for a patient's condition. The discussion also covers how nurses refine a nursing diagnosis to make it more specific and beneficial, thereby promoting positive outcomes for patients.

### Determine the Category

Throughout the evolution of nursing diagnosis and the formation of NANDA-I, the organization of categories has been simplified to accommodate the simultaneous progression to an electronic database.

NANDA-I developed a structure that allowed for the expansion of the classification structure without having to change codes when new diagnoses, refinements, and revisions are added (NANDA-I, 2020). This is accomplished through a five-digit code. The code structure is compliant with recommendations from the National Library of Medicine concerning healthcare terminology codes.

The categories for nursing diagnosis can be broken down into problem-focused, risk, health promotion, and syndrome (Figure 13.4). Knowing in which category a diagnosis belongs helps the nurse direct their thought process when planning care and strengthens their critical thinking skills.

**FIGURE 13.4** These are examples of nursing diagnosis categories. Having a solid understanding of each category allows nurses to provide effective patient care through proper identification and application of diagnoses to each individual patient. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### LINK TO LEARNING

This [tutorial provides NANDA-I-approved nursing diagnoses \(https://openstax.org/r/77NANDAI\)](https://openstax.org/r/77NANDAI) to help students develop an understanding of grouping nursing diagnoses.

#### Problem-Focused Diagnosis

An actual problem identified or recognized during the assessment process falls into the problem-focused category of nursing diagnoses. Unwanted responses to a health condition would be a **problem-focused diagnosis**. They are identified or based on the presence of clinical signs and/or symptoms and are the foundation for nursing diagnosis selection.

A problem-focused nursing diagnosis has four components: label, definition, defining characteristics, and related

factors. These components will be discussed further in this section. Examples of problem-focused nursing diagnoses include

- impaired mobility related to musculoskeletal injury as evidenced by limited range of motion and difficulty ambulating;
- ineffective breathing pattern related to chronic obstructive pulmonary disease (COPD) as evidenced by shortness of breath and use of accessory muscles for breathing;
- impaired skin integrity related to pressure ulcer on sacrum as evidenced by erythema and skin breakdown; and
- ineffective coping related to the recent loss of a loved one as evidenced by tearfulness and social withdrawal.

### Risk Diagnosis

A **risk diagnosis** is developed through clinical judgment based on the vulnerability of the patient's individualized situation. A risk diagnosis is recognized when the nurse identifies a potential problem that can/will develop if no intervention is initiated. This is in direct contrast to a problem-focused diagnosis, which is based on the actual presence of signs and symptoms rather than the potential for a problem's development. Risk diagnoses are broader and used to cover the "what if" situations that could occur. For example, consider an older adult living alone with vertigo. In this patient's case, the risk diagnosis would be "risk for falls." The patient has not yet fallen, but their situation lends itself to putting them at risk for this outcome.

Examples of risk nursing diagnoses include

- risk for falls related to history of falls, impaired mobility, and use of sedative medications;
- risk for infection related to compromised immune system secondary to chemotherapy treatment;
- risk for aspiration related to dysphagia and impaired gag reflex; and
- risk for impaired skin integrity related to immobility and prolonged bed rest.

### Health Promotion Diagnosis

A **health promotion diagnosis** can help promote and improve a patient's overall well-being and health, as well as their family/support structure/community. The diagnoses are not about identified problems or potential risks but about potential benefits based on the patient's current situation. This category of nursing diagnosis is more concerned with the patient's motivation and desire to improve their overall well-being and increased quality of life.

Examples of health promotion nursing diagnoses include

- readiness for regular exercise related to expressed interest in starting a fitness program;
- readiness for health literacy enhancement related to limited understanding of medication management;
- readiness for enhanced nutrition related to expressed desire to improve dietary habits and increase intake of fruits and vegetables; and
- readiness for smoking cessation related to acknowledgment of health risks associated with smoking and expressed willingness to quit.

### Syndrome Diagnosis

The last category, according to NANDA-I, is syndrome diagnosis. A **syndrome diagnosis** occurs when a group or cluster of nursing diagnoses can be utilized based on certain life events or situations. The diagnosis can be actual, risk, or health promotion, but all are commonly used for the patient's situation.

Evidence-based research shows that most people who experience trauma will go through certain phases of healing and experience many of the same signs and symptoms. A syndrome diagnosis is not a "one-and-done" tactic, meaning that the nurse must ensure a diagnosis still relates to the individual patient. That said, it is a helpful way to identify several potential nursing diagnoses based on a specific life event.

Examples of syndrome nursing diagnoses include

- chronic pain syndrome related to neuropathic pain secondary to diabetic neuropathy as evidenced by reports of persistent pain and altered sleep patterns;
- chronic fatigue syndrome related to chronic illness and sleep disturbances, as evidenced by reports of profound fatigue despite adequate rest;
- post-traumatic stress syndrome related to a traumatic event as evidenced by flashbacks and hypervigilance;

and

- disorganized infant feeding syndrome related to maternal anxiety and lack of breastfeeding support.

## Validate the Nursing Diagnosis

The validation stage comes after the identification of a nursing diagnosis. To **validate** means confirming the chosen diagnosis is appropriate for the individual patient using evidence to support it. While NANDA-I has developed a database that transitioned to digital format seamlessly (and it makes the identification of nursing diagnosis easier, based on the data collected and documented in the electronic health record), it is still crucial for the nurse to take the extra step to manually validate the diagnosis. There are several key factors used to prove validity. The following are a few questions the nurse can use to help validate the chosen diagnosis:

- Are the collected assessment data appropriate, accurate, and supported by nursing research?
- Did I use the data to identify the existence of a pattern?
- Is the identified pattern characteristic of the defined health problem?
- Does the nursing diagnosis use scientific nursing knowledge and evidence-based practice standards as the basis for selection?
- Can the nursing diagnosis be reduced or resolved by independent nursing action or interventions?
- Would other qualified clinicians formulate the same nursing diagnosis based on my data?

It is important at this stage to actively encourage, rather than ignore, the patient's ongoing participation in the process. Ask, "What are the patient's perceptions of the problem?" "What do they think will help resolve the problem?" "How do these perceptions and thoughts compare with the nursing interventions, plans, and expected outcomes?"

For example, the identified nursing diagnosis of "activity intolerance" can be validated and confirmed by the patient through expressed statements such as, "I am unable to complete the assigned tasks due to weakness."

### Related Factors

Related factors are derived from the etiology or pathophysiology of the disease process or condition. Simply put, a **related factor** is the reason behind the signs and symptoms the patient is experiencing.

For example, if the chosen nursing diagnosis is "ineffective breathing patterns," the related factors, expressed as a "related to" statement, could be described as "related to decreased lung expansion." The identified problem or negative response is ineffective breathing, and the related factor used to explain the presence of the problem is decreased lung expansion.

Some related factors are easily identified, while others may stem from different origins. It is important for the nurse to identify which factors are related to the individual patient being in a specific situation. For example, consider the nursing diagnosis of pain. The related factors for pain could range from sources of physical, psychological, psychosocial, or even spiritual and cultural factors. The nurse needs good clinical judgment to determine the exact cause of the patient's pain and correctly associate the related factor for the formal nursing diagnosis.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Analyze Cues: Asking Specific Questions

As the nurse enters the room, the patient complains of pain at the surgical site. During inspection of the site, the nurse notices that the patient's skin is red, swollen, and hot to the touch. The nurse is using clinical signs to begin the process of formulating the hypothesis—the patient has an infection. Upon further data collection, the nurse identifies abnormal vital signs that include elevated heart rate and increased temperature. Using analysis, the nurse determines these cues are not related to the nursing diagnosis of pain but to a possible change in the patient's condition.

### Defining Characteristics

The **defining characteristic** of a nursing diagnosis are the actual signs and symptoms being exhibited by the problem. The phrase used to write defining characteristics is "as evidenced by." To continue with the example of "ineffective breathing pattern," the defining characteristics are the signs and symptoms exhibited or expressed by

the patient during data collection. The nurse noticed signs and symptoms such as dyspnea (shortness of breath), coughing, and difficulty breathing.

Putting all of these elements together, the nursing diagnosis would be “ineffective breathing pattern (category) related to decreased lung expansion (related factors) as evidenced by dyspnea, coughing, and difficulty breathing (defining characteristics).”

### Refine the Nursing Diagnosis

After validating and applying the nursing diagnosis, the nurse may need to refine it. This can be considered the evaluation phase of formulating a nursing diagnosis. To **refine the nursing diagnosis**, the nurse may need to select a new diagnosis or narrow it down more specifically to assign new interventions based on outcomes. Think of this as the application of patient care. What worked? What did not work?

Sometimes social or environmental factors and disease progression require that the diagnosis be reassessed and the care plan altered. Take the previous nursing diagnosis of “ineffective breathing patterns related to decreased lung expansion as evidenced by dyspnea, coughing, and difficulty breathing” and assume the following interventions were implemented:

- The nurse will encourage the use of incentive spirometry.
- Respiratory therapy will administer breathing treatments as needed per provider’s orders.
- The nurse will assist the patient into semi-Fowler’s position (head of the bed is elevated at an angle of approximately 30 to 45 degrees) to help increase lung expansion.

Now, let’s assume the patient continued to display signs and symptoms of dyspnea, coughing, and difficulty breathing even after the interventions were implemented. This situation would warrant redefining the nursing diagnosis. Things to consider would be the recommendation of further diagnostic tests to determine a more specific underlying cause of the problem, such as impaired gas exchange or possible lung infection. At this point, the nurse would recommend an order for an ABG (arterial blood gas) to help identify ineffective gas exchange or possible sputum analysis to identify any infections.

## PATIENT CONVERSATIONS

### Refining a Nursing Diagnosis

**Scenario:** Mrs. Winters is an 80-year-old female diagnosed with heart failure and is now being discharged home with a new prescription of furosemide. Currently, Mrs. Winters’s nursing diagnosis is risk for fluid volume overload. The nurse, Samuel, goes into the room to provide discharge instructions to Mrs. Winters.

**Nurse:** Okay, Mrs. Winters, do you have any other questions for me?

**Patient:** Yes, I have questions about that water pill.

**Nurse:** The new diuretic your provider ordered is called furosemide. This is a diuretic that will help you urinate excess fluid, which will help reduce strain on your heart. What questions do you have?

**Patient:** Well, I live alone. There are two bathrooms in my house, but the only one that works is downstairs. If I am going to pee more than normal, I’m worried I won’t be able to make it to the bathroom in time.

**Nurse:** Just to make sure I understand—you have two bathrooms, but the one upstairs located near your bedroom doesn’t work? Only the bathroom on the main floor is functioning. Is that right?

**Patient:** Yes, that’s right. I really don’t want to pee my pants, but I’m scared about running up and down those stairs at my age!

**Nurse:** I completely understand, and those are valid concerns. We want to keep you safe, and rushing up and down the stairs at night would be considered a fall risk. Let me talk to the social worker. She may be able to get you a bedside commode for you to use at night, and then when the home health aide comes in the daytime, they can empty and clean it for you.

**Patient:** That sounds pretty good. Let's see if we can make that work. Thank you!

**Scenario follow-up:** Samuel refines the nursing diagnosis to include risk for falls in addition to risk for fluid volume overload.

---

## 13.4 Focus of the Planning Phase

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define the need to research evidence to support the plan of care
- Recognize how to establish priorities during the implementation of care
- Analyze the importance of outcome identification
- Explain the nurse's role in the planning phase

The primary focus of the outcome identification and planning phases is to develop with the patient a plan of care for the patient. This section discusses creating a plan of care and the nurse's role in implementing that plan. To create a plan, first consider what research the plan is based on and what evidence is available to support positive patient outcomes. Once those questions are answered, the nurse can determine how to establish priorities while implementing a care plan. Finally, the nurse must identify outcomes and evaluate the effectiveness of the plan.

The nurse is involved in every step of the planning phase, from the first stage of identifying the needs to thinking through the priorities, designing the plan, and putting the plan into action. To perform their role in the planning process, nurses must understand the importance of developing interpersonal competence, recognize the stages of comprehensive planning, and understand their role as care coordinators in the implementation phase.

### Research Evidence to Support Plan of Care

An evidence-based practice (EBP) is the responsible and thoughtful use of current and best evidence to guide the implementation of patient care. Everything nurses say and do must be supported and validated by evidence-based research. Nursing research provides the evidence needed to support the implementation of specific nursing actions to facilitate patient recovery.

EBP has freed nurses from relying on anecdotal or historical healthcare practices that may have been based on less-than-favorable conditions, such as the availability of supplies. Nursing care that is based on evidence provides a more solid foundation for manageable and predictable outcomes. This section will discuss the most common EBP guidelines, including clinical pathways and core measures set forth by government bodies and widely known healthcare organizations.

#### Clinical Pathways

A **clinical pathway** is an evidence-based practice guideline used to develop plans of care. A clinical pathway is an example of a multidisciplinary care plan that translates policy, guidelines, and/or evidence into a standardized structure ([Figure 13.5](#)). Examples of clinical pathways include algorithms or hospital protocols for commonly treated conditions. Utilization of a common set of standard guidelines or protocols allows more research to be conducted on effective treatment plans. The overall aim of clinical pathways is to translate research into practice.

**FIGURE 13.5** This example of early mobilization protocol for patients in ICU shows how the process works as a flowchart with all the necessary decisions laid out. (credit: Agency for Healthcare Research and Quality, Public Domain)

Clinical pathways are designed based on clinical research and evidence. Another widely known example of a clinical pathway is the advanced cardiac life support (ACLS) algorithm. The ACLS pathway outlines the multiple steps to treat patients who need advanced cardiac life support (ACLS). Specific medication and identified steps are implemented based on the patient's response to treatment.

### Core Measures

A **core measure** is an evidence-based standard of care or practice guidelines established by The Joint Commission (TJC) and the Centers for Medicare & Medicaid Services (CMS), agencies that aim to improve healthcare quality and patient safety by establishing evidence-based standards of care.

Core measures incorporate EBP guidelines to care for specific conditions or diagnoses. Examples include stroke protocols or acute coronary system (ACS) protocols associated with signs and symptoms that point to a particular clinical situation. In these scenarios, core measures help the nurse articulate what to do, what else to look for, what might be causing the problem, and even what diagnostic tests to consider. Particularly important is the relationship between core measure protocols and clear standards of performance guidelines set forth by the accrediting agencies.

The CMS primarily oversees the organization of most core measures. This responsibility stems from CMS's pivotal role in establishing and enforcing healthcare quality benchmarks, ensuring that healthcare providers participating in Medicare and Medicaid adhere to these standards. According to CMS (2021), core measures are quality guidelines that healthcare providers are to follow, such as

- promotion of measurement that is evidence-based and generates valuable information for quality improvement;
- consumer decision-making;
- value-based payment and purchasing;
- reduction in the variability in measure selection; and
- decreased provider's collection burden and cost.

### Establishing Priorities

The means of identifying what steps need to be implemented first and why is called **establishing priorities**.

Prioritization in nursing is a decision-making process in which a nurse considers the determined patient's care needs, applies decision-making guidelines, and determines an order of importance for the patient's health and well-being. Commonly used formats for clinical reasoning when establishing priorities include ABCs, Maslow's hierarchy (see [4.2 Models of Health](#) for more information), and the identification of actual versus potential problems, acute versus chronic problems, patient preferences, and anticipation of future problems. The importance of establishing priorities during assessment are detailed in [Establishing Priorities during Assessment](#).)

### ABCs

In the clinical setting, steps needed for life are considered the most important and should be considered above all else. Patient ABCs—airway, breathing, and circulation—are the highest priorities. The nurse must ensure a patient has an effective and functioning airway, is breathing efficiently, and is adequately circulating or has sufficient cardiac perfusion. If the ABCs are identified as a need, protocols such as basic or advanced life support should be initiated.

### Actual versus Potential Problem

When prioritizing interventions or steps of care, the nurse must consider whether the problem they are addressing is an actual or potential problem. The nurse will prioritize an actual problem over a potential one.

Consider the following scenario: The nurse enters a room and finds the patient sitting in bed crying, emotionally distraught over an argument they've had with their significant other. The patient states, "I may not even be able to eat lunch today because I am too upset to think about food." Applying the priority decision tree to the patient's situation, the nurse can rule out an ABC problem. However, the patient's problem does fall within Maslow's hierarchy of needs. First, the nurse considers the patient's emotional well-being, as the patient is crying and visibly upset. Second, the nurse considers the patient's statement that they "might not be able to eat lunch today." According to Maslow, eating is the priority—but the nurse will consider it a potential problem for now. The priority in this situation is what is happening right now—the patient's emotional state.

### Acute versus Chronic Problem

If the application of ABC, Maslow's, and actual versus potential problems do not apply, the next step is to consider whether the problem is acute or chronic. Acute or chronic problems depend on what is going on with the patient. The nurse needs to determine which interventions or applied care should take priority.

As nurses come to understand disease processes, they will learn that certain conditions or problems are associated with specific signs and symptoms. For example, an acute episode of rheumatoid arthritis is more of a priority than a patient's chronic constipation problem. Acute problems will take precedence over chronic problems when prioritizing care.

### Expected versus Unexpected Problem

Finally, the nurse will apply the prioritization of expected versus unexpected related to identified problems or needs. Consider a patient with chronic asthma. The nurse realizes it is expected that the patient will have wheezing even with minimal exertion or activity. It is not expected, however, that a patient without a chronic lung disease will experience wheezing with minimal activity or exertion of activity.

Another example of applying prioritization is when patients are prescribed certain treatments by the provider. For example, the nurse knows that a patient prescribed a diuretic is going to produce more urine and will need to go to the bathroom more often. The nurse expects the outcome and plans the patient's care accordingly. The nurse also knows that the patient should not experience increased heart rate, hives, and shortness of breath after administration of the medicine. These would be unexpected outcomes and would take priority over other interventions when planning care.

### Outcome Identification

An **outcome** is the desired result or goal after the implementation of the patient's individualized plan of care. Identified outcomes may be long-term or short-term goals and should all follow the SMART goal format. The nurse considers several factors related to outcome identification. These factors include

- specific measurements to determine the success of outcomes;
- relevance of the outcomes for the specific patient with their unique qualities and needs; and
- attainability of the outcome based on the outlined timeline.

### Realistic Outcomes

The nurse will determine whether the outcome identified is realistic, meaning reasonable and attainable for this specific patient. For example, it is expected that patients undergoing minor surgical procedures will begin to move and possibly walk within a day (or even the same day) as the surgery. However, this would not be realistic for all patients. Consider a patient who is paraplegic who undergoes a minor surgical procedure—they could not walk before the surgery, so it is not realistic to expect them to walk after the surgery.

Another example is a patient who has been prescribed physical therapy to gain muscle coordination and strength training. On the day of therapy, it is realistic and attainable to expect the patient to walk a few steps in the room with therapy assistance. However, it is not realistic or attainable to expect the patient to walk 500 feet (150 meters) to the nurse's station and back without assistance. While common sense helps with outcome identification, a strong use of critical thinking is also needed.

### Expected Time Frame for Completion

As with any goal or expectation, a time frame for completion must be set. Having a set time frame enables the nurse to implement the interventions and evaluate the effectiveness of the intervention at the end of the time frame. The identified outcome time frame is set by the nurse and the healthcare team, as well as the patient's input, when possible. There are two types of outcome identification regarding time frames: short-term and long-term.

## PATIENT CONVERSATIONS

### Setting Short-Term and Long-Term Goals

**Scenario:** Luisa is being discharged from the hospital with a new diagnosis of type 2 diabetes. She is a bit overwhelmed with her diagnosis, but she is very motivated to stay well for the sake of her children and grandchildren. Minh is the nurse doing her discharge teaching.

**Nurse:** Luisa, let's talk about setting some short- and long-term goals for your diabetes care. That might help you focus on what you need to do to stay well.

**Patient:** Yes! My short-term goals are to eat better and exercise more, and my long-term goal is to lose thirty pounds (fourteen kilograms) in six months.

**Nurse:** Those are ambitious goals! Let's plan on how you're going to go about achieving them.

**Patient:** Well, that's where I get worried because thirty pounds is a lot of weight, and I really don't know how to change my diet. When my family gets together, we love to make food and eat and it's going to be hard. Plus, I don't live near a gym, and I couldn't afford one even if I did. Can I still achieve these goals?

**Nurse:** I think if we look at your goals more closely and maybe modify them to better suit your life and resources it might be a bit easier to approach. What if we change the long-term goal to five pounds (two kilograms) in one month? That is a realistic amount of weight to lose in a month, and you won't need a gym. Do you live near any parks?

**Patient:** Yes, there's a park about half a mile from my house where I take my grandchildren to play.

**Nurse:** That's great! Let's set a short-term goal of walking to the park and back once a day, five days a week. Does that sound doable?

**Patient:** Yes. My grandchildren will be so happy!

**Nurse:** (laughs) I'm so glad! Now let's talk about diet goals.

**Scenario follow-up:** By helping Luisa modify her long-term goal into a more realistic one, she has helped her get a plan in place for living a healthier lifestyle.

### Short-Term Goals

Short-term goals have a time frame of days to a week—some are even within the nurse's assigned shift. Most short-term goals are to be achieved before the patient is discharged. This allows the healthcare team to evaluate the

effectiveness of a newly prescribed treatment, medication, or specific intervention. For example, a patient with an indwelling Foley catheter may have a goal or outcome identified as “The patient will void (urinate) within two hours after removal of the Foley catheter.” This outcome allows the healthcare team to ensure the patient regains bladder function.

Another example of a short-term goal might be a patient who has recently been diagnosed with diabetes. The outcome identified would be “The patient will demonstrate how to check their own blood sugar using the return demonstration method before discharge.” This allows the healthcare team to ensure the patient can self-monitor their blood sugar upon discharge.

### Long-Term Goals

Long-term goals generally have time frames longer than a few days and can be several weeks or even months. These goals often involve ongoing activities or interventions that continue long after the patient is discharged. Examples of long-term goals include cardiac, respiratory, or physical rehabilitation as well as wound care and long-term medication protocols. Long-term goals often are set to improve a patient’s quality of life.

## The Nurse’s Role in Planning

The nurse has an integral role in the planning phase. Nurses are responsible for tasks that start with identifying the patient’s needs through establishing priorities, implementing the plan, and evaluating the outcomes. To execute their role effectively and efficiently, the nurse must understand the importance of developing interpersonal competence, the steps involved in comprehensive planning, and the role of being a care coordinator.

### Interpersonal Competence

The nurse’s interpersonal competence is a crucial step that starts with their very first interaction with a patient. If the patient perceives the nurse as unknowledgeable or lacking the skills needed to provide care, they may not trust the entire team—especially if they are new to the healthcare environment. Patients may judge all nurses by that one encounter and be resistant to any future attempts at education or treatments performed by nurses.

There are several things the nurse can do to promote and demonstrate interpersonal competence. Techniques the nurse can utilize to accomplish effective communication and display personal competence include active listening, clear verbal communication, patience, and a teamwork mentality. The nurse must display knowledge and professionalism when speaking with the patient. They should use evidence to support communication, not opinion. Nurses must establish a trusting relationship with patients to facilitate active participation and cooperation with the plan of care. Nurses need effective communication with patients and their families, as well as the skills to communicate clearly and effectively with other members of the healthcare team.

A multitude of factors contribute to patient needs, and nurses must develop a strong sense of interpersonal competence to recognize them. Nurses use their clinical knowledge, experience, and social and cultural awareness to assess patients. They also need to understand how patient needs differ from family needs. Aspects such as a patient’s culture, age, and family dynamics need to be considered as the nurse develops competence.

Nurses must understand that patients and families may find it difficult to manage the expectations placed on them. Clear communication and asking direct questions about expectations help the nurse identify needs and lead to more competent decision-making.

At every stage, the nurse’s interpersonal competence drives their decision-making. The nurse needs to recognize the patient may have fears associated with the healthcare process and should plan accordingly. Addressing patient and family fears in the planning phase of care is an essential part of the process. Ensuring the patient and family are as well-educated and prepared as possible allays fears and provides a solid starting place. However, the nurse should avoid focusing too much on fears, as it can halt progress.

## REAL RN STORIES

### Assessing and Addressing Patient Fears

**Nurse:** Gigi, RN

**Clinical setting:** Large acute-care hospital in the cardiovascular intensive care unit

**Years in practice:** 7

**Facility location:** Chicago, Illinois

I was once caring for a 44-year-old male who had been admitted with a myocardial infarction (heart attack) and had coronary artery bypass grafting (CABG). The surgery was successful, and he was getting ready for discharge in the next day or two. He and his family were very shaken by the whole experience and had a lot of concerns about going home. Much of his plan of care was based on lifestyle changes. These included topics such as a low-sodium, heart-healthy diet and at least an hour of exercise a day. The patient and family were asking many questions. They had so many questions, but they were clearly willing and motivated to learn, so I did what I could to ease their concerns. I put in a nutrition consultant and had the cardiac nutrition specialist speak with the family; she gave them a lot of ideas on changing their favorite family recipes to make them healthier, including fried chicken. I found hospital-approved pamphlets about post-surgical care for the surgical incision, and I emailed several links I had found about healthy eating and exercise to the patient and his wife. I made sure they had the hospital/clinic app downloaded onto their phone and showed them how to use the messaging and chat functions so they could message their doctor if they had further concerns or questions. The resources and information I shared helped the patient go home feeling less nervous about his lifestyle changes going forward.

### Comprehensive Planning

The planning stage of the nursing process is defined by the ANA as developing a “collaborative plan” in conjunction with the healthcare consumer, family, significant others, and the interprofessional team. A plan is termed comprehensive because it includes all relevant and affected parties. The planning phase can be broken into three main categories: initial planning, ongoing planning, and discharge planning ([Table 13.3](#)).

Type	Description
Initial planning	Addresses each problem in a nursing diagnosis format, prioritizes interventions in order of implementation, and identifies patient outcomes
Ongoing planning	Addresses the patient’s ongoing needs, identifying which parts of the plan of care need revision, are marked as completed, or need new areas developed based on condition changes
Discharge planning	Addressed by the entire interdisciplinary team but implemented by the nurse, the discharge plan identifies what will happen after the patient is discharged from the facility. It can include identification of community resources or need for further health care such as home health.

**TABLE 13.3** Types of Planning

### Nurse’s Role as Care Coordinator

Nurses are in the unique position of being at the center of the patient’s care. They see the patient the most frequently and get to know them and their family the best. So, when it comes to coordinating what the patient needs, the nurse is usually the one to make that happen. Almost like a manager or a quarterback of a football team, the nurse sees the whole picture for the patient and helps organize the different team members.

As a coordinator of care, the nurse plays many roles, including communicator, educator, counselor, and interdisciplinary team member ([Table 13.4](#)).

Role	Description	Example
Communicator	Uses clear, concise, and therapeutic communication techniques with the patient, family and other healthcare team members	The nurse explains to the patient that based on their current lab results, the provider would like to start checking their blood glucose levels before each meal.
Educator	Uses knowledge, skill, or competency to help facilitate someone else's learning	The nurse teaches the patient how to perform a blood glucose test.
Counselor	Assists the patient with making decisions that promote overall health and well-being, and provides encouragement and support for patient-centered care	The nurse listens as the patient decides which foods from a list are appropriate for their diagnosis of diabetes. Then the nurse offers praise when the patient selects the correct foods.
Interdisciplinary team member	Identifies and meets the needs of the patient by performing as an active team member	The nurse recognizes the patient's blood sugar is above the normal range (264). Then the nurse notifies the provider and receives new medication (insulin) and diet orders (diabetic). The nurse then notifies the pharmacy and nutritionist of the newly received orders and communicates the newly developed plan to the patient.

**TABLE 13.4** Roles of the Nurse in Care Coordination

## PATIENT CONVERSATIONS

### Nurse as a Care Coordinator

**Scenario:** Augusto has been admitted to the cardiac unit to be worked up for an aortic valve replacement. He has never been hospitalized before this and didn't even know that anything could be wrong with his heart valves. Augusto was admitted at 6:00 a.m. Max is his day shift nurse.

**Nurse:** Good morning, Augusto. My name is Max, and I'll be your nurse today. How are you feeling?

**Patient:** Freaked out, man. I've never been in the hospital before, and this place is crazy busy.

**Nurse:** I understand, there is a lot going on here. I know it can all seem overwhelming.

**Patient:** They say that I need a valve replaced. What are "valves" in my heart, and why does mine need to be replaced? Is this why I've been having more and more trouble walking without getting out of breath?

**Nurse:** Those are all good questions. Your heart valve is the source of your shortness of breath when walking. I've got some info for you at the nurse's station regarding the normal anatomy of the heart, and about heart valve replacement surgery. I also have an informational video the hospital made. I can show you it on your TV screen. There are a lot of reasons why a heart valve needs to be replaced. I will ask the doctor when he comes by on rounds shortly to come in and discuss your reasons for needing the surgery.

**Patient:** Wow, thanks! I had no idea there were so many resources to help teach me about what's going on. Yeah, I think I'd prefer to watch a video first before getting into any reading material. This way I'll know questions to ask the doctor too.

**Nurse:** No problem, Augusto. I'll do my morning assessment right now, and I'll pull up the video for you to watch while I'm getting your morning medications.

**Scenario follow-up:** Max got the patient to talk about their concerns and found out how the patient likes to learn. He has developed a positive therapeutic relationship with Augusto and has started an important discussion about his disease process that allows Augusto to ask questions. Max can coordinate with the doctor or other members as Augusto's questions and needs arise.

---

## Summary

### 13.1 Evolution of Nursing Diagnosis

Nursing diagnosis is a defining characteristic of the nursing profession. The breadth and depth of patient problems that fall under the umbrella of this concept are the basis of nursing practice. The ANA Standards of Practice and the ANA Competencies for Nursing Diagnosis both support the autonomy of the profession. The decision was founded on the nursing profession exhibiting strong clinical judgment. The nursing profession deemed a problem-solving approach the best way to achieve patient care outcomes.

NANDA-I supports nursing diagnosis through taxonomy and classification. Taxonomy for clinicians is used to communicate in a clear, efficient, and standardized manner. NANDA-I and Tanner's Clinical Judgment Model (CJM) both provide a framework for clinical decision-making using a problem-solving approach.

As patient needs become more complex, the need for nurses to think critically evolves as well. The most current evolution of clinical decision-making is the Clinical Judgment and Measurement Model (CJMM). The CJMM uses six cognitive skills to develop critical thinking that can be aligned with both the nursing process and Tanner's CJM.

While all the processes look very similar, each requires a slightly different way of thinking and incorporating progressive levels of knowledge to provide patient care. Ultimately, the goal is to provide all patients with the best possible care and help them achieve the best possible outcomes.

### 13.2 Focus of Nursing Diagnosis

The foundational steps for clinical decision-making are to predict, prevent, manage, and promote. Using this as a framework for thought processes helps beginning and experienced nurses alike form appropriate nursing diagnoses and understand the steps they took to reach those diagnoses. It is important to differentiate between nursing and medical diagnoses.

As mentioned previously, medical diagnosis focuses on the actual disease or condition, while nursing diagnosis focuses on the patient's response to that disease or condition. Once a decision has been made, the planning process gets underway. The nurse must keep the focus on the patient's expected versus actual outcomes, which includes using the nursing diagnosis to promote the best possible outcomes for the patient. Using SMART goals is one proven tool for the nurse to keep sight of patient outcomes. The evidence-based tool can ensure the outcomes remain attainable and reasonable for the patient to achieve and allow the nurse to adjust the nursing diagnosis as necessary.

### 13.3 Categories of Nursing Diagnosis

Understanding how nursing diagnoses are categorized is the first step in determining how to select one for a patient. The four NANDA-I approved categories are problem-focused, risk for, health promotion, and syndrome-based. Once a category is chosen, the nurse can identify which diagnosis best suits an individual patient's needs. After assigning, the nurse must then validate the selected diagnosis. Validating the nursing diagnosis is based on evidence. Re-examining the signs and symptoms discovered during data collection and comparing them to current evidence-based practice standards are two ways the nurse will validate the selected diagnosis. The nurse needs a plan in case the identified nursing diagnosis does not produce the desired outcomes or the patient's condition changes. In this situation, redefining the diagnosis may be warranted. Redefining the diagnosis is narrowing it down or creating a new one based on current needs. Sometimes, associated interventions are unsuccessful, and the addition or revision of a nursing diagnosis allows for new interventions to be applied to the plan of care.

### 13.4 Focus of the Planning Phase

The planning phase utilizes research and resources to organize and prioritize a patient's needs. Using evidence-based resources such as clinical pathways and core measures ensures that best practice standards are incorporated into the patient's plan of care. Prioritizing patient care is also initiated during the planning phase when the nurse systematically determines which of a patient's needs should be addressed first. This process is called prioritizing care. The decision process can utilize frameworks such as ABCs, Maslow's hierarchy, acute versus chronic problems, expected versus unexpected problems, and actual versus potential problems. The importance of outcome identification cannot be overstated; nurses must ensure that patient outcomes or goals are realistic,

attainable, and time-specific. Goals can be short- or long-term goals. Nurses have a crucial role in the planning phase where they serve as care coordinator and team player, provide education, and communicate efficiently.

## Key Terms

**clinical pathway** evidence-based practice guideline used to develop plans of care

**collaborative problem** a problem that requires interdisciplinary team members to complete

**core measure** evidence-based standard of care or practice guideline established by The Joint Commission (TJC) and the Centers for Medicare & Medicaid Services (CMS)

**defining characteristic** the actual sign or symptom being exhibited by the problem

**diagnostic error** a failure to identify a response as unhealthy

**establishing priorities** the means of identifying what steps need to be implemented first and why

**etiology** the cause (or causes) of a specific disease state

**health promotion diagnosis** a diagnosis that can help promote and improve the overall well-being and health of a patient and/or their family/support structure/community

**medical diagnosis** identification of a disease or a condition and a description of a problem toward which providers direct the treatment plan

**NANDA-I** an organization whose purpose is to facilitate the development, modification, distribution, and use of standardized nursing diagnostic terminology

**nursing diagnosis** a method to provide and evaluate appropriate patient care

**nursing process** a five-step method to guide decision-making for nurses

**outcome** the desired result or goal after implementation of the patient's individualized plan of care

**problem-focused diagnosis** an unwanted response to a health condition

**refine the nursing diagnosis** to select a new diagnosis, or narrow an existing diagnosis down more specifically, to assign new interventions based on outcomes

**related factor** the reason derived from the etiology or pathophysiology of the disease process or condition

**risk diagnosis** a diagnosis behind the signs and symptoms the patient is experiencing; developed through clinical judgment based on the vulnerability of the patient's individualized situation

**Standards of Practice** standards designed by the ANA and based on the nursing process that provides a problem-solving-focused approach to nursing practice

**syndrome diagnosis** a diagnosis that occurs when a group or cluster of nursing diagnoses can all be utilized based on certain life events or situations

**Tanner's Clinical Judgement Model (CJM)** a framework that offers a different articulated perspective to the problem-solving approach of developing nursing diagnosis

**taxonomy** a system of classification

**Taxonomy II** the current classification method for listing nursing diagnosis; it has three levels: domains, classes, and nursing diagnosis

**validate** to confirm the chosen diagnosis is appropriate for the individual patient using evidence to support the diagnosis

## Assessments

### Review Questions

1. What clinical decision framework includes these five steps: assessment, analysis, planning, implementation, and evaluation?
  - a. Tanner model
  - b. nursing process
  - c. Clinical Judgment Measurement Model (CJMM)
  - d. NANDA model
2. What is the term for designated words and phrases that make up a common system of classification, such as the NANDA nursing diagnoses?
  - a. dictionary
  - b. reference

- c. taxonomy
  - d. glossary
3. When a nurse is determining whether an outcome was met, partially met, or not met, which one of the six cognitive skills are they utilizing?
    - a. taking action
    - b. evaluating outcomes
    - c. recognizing cues
    - d. analyzing cues
  4. Step three of Tanner's Clinical Judgement Model is responding. With what step of the Clinical Judgment Measurement Model (CJMM) does responding correlate?
    - a. recognizing cues
    - b. analyzing cues
    - c. interpreting cues
    - d. taking action
  5. Step one of Tanner's Clinical Judgement Model is noticing. With what step of the Clinical Judgment Measurement Model (CJMM) does noticing correlate?
    - a. recognizing cues
    - b. analyzing cues
    - c. interpreting cues
    - d. observing cues
  6. How do nursing diagnoses differ from medical diagnoses?
    - a. Nursing diagnoses are concerned with bodily functions such as ingestion and elimination.
    - b. Nursing diagnoses are concerned with the physical aspect of caring for patients.
    - c. Nursing diagnoses are concerned with the human response to health conditions.
    - d. Nursing diagnoses are a subset of medical diagnoses.
  7. To avoid making a diagnostic error or fail to identify a response as unhealthy, what must the nurse incorporate when interpreting and analyzing data?
    - a. the nurses' opinion
    - b. evidence-based comparative standards
    - c. the patient's opinion
    - d. the least expensive option
  8. What term is not included when developing SMART goals?
    - a. achievable
    - b. specific
    - c. realistic
    - d. untimed
  9. The foundational steps for incorporating clinical decision-making for patient care are to predict, prevent, manage, and promote (PPMP). What is an example of the "promote" step?
    - a. monitoring vital signs every four hours as ordered
    - b. administering a yearly flu vaccine
    - c. placing the call light within the patient's reach before leaving the room
    - d. providing the patient with a list of condition-appropriate foods to enhance knowledge
  10. Using the following information, what NANDA-I-approved category should the nurse consider when developing a nursing diagnosis for the following patient?

The patient comes to the emergency department with signs and symptoms of an MI (heart attack).

- a. problem-focused
- b. risk for
- c. health promotion
- d. syndrome-based

- 11.** Using the following information, what NANDA-I-approved category should the nurse consider when developing a nursing diagnosis for the following patient?

The patient is planning to be discharged home and wants to practice changing their wound care dressing one more time to make sure they fully understand.

- a. problem-focused
- b. risk for
- c. health promotion
- d. syndrome-based

- 12.** Using the following information, what NANDA-I-approved category should the nurse consider when developing a nursing diagnosis for the following patient?

The patient is 86 years old with macular degeneration. His wife must go home tonight to rest, and this will be his first time being alone in the hospital at night.

- a. problem-focused
- b. risk for
- c. health promotion
- d. syndrome-based

- 13.** Using this information, what NANDA-I-approved category should the nurse consider when developing a nursing diagnosis for the following patient?

The patient is a young woman attending college and goes to see the campus clinic because she was raped the evening before.

- a. problem-focused
- b. risk for
- c. health promotion
- d. syndrome-based

- 14.** What is the highest priority according to the ABCs of nursing?

- a. emotional support
- b. social interaction
- c. airway maintenance
- d. pain management

- 15.** How does a nurse differentiate between actual and potential problems?

- a. by assessing the severity of symptoms
- b. by considering patient preferences
- c. by focusing on chronic conditions
- d. by analyzing the patient's emotional state

### Check Your Understanding Questions

1. Why was the transition to the Clinical Judgment Measurement Model (CJMM) necessary in nursing practice?
2. What are the four components of the nursing diagnosis?

3. Why is it important for nurses to validate nursing diagnoses?
4. Name two ways to incorporate evidence-based nursing practice (EBP) when planning patient care.
5. Discuss how the nurse can be a counselor when a patient expresses the need to leave an abusive partner.
6. Discuss how the nurse can determine the difference of expected versus unexpected problems in patient care planning.
7. Describe the difference between a short-term and long-term goal and include attributes all goals must include.

### Reflection Questions

1. How do you think the development of nursing diagnosis has impacted the autonomy and professionalism of nurses?
2. How can nurses ensure that nursing diagnoses accurately reflect the holistic needs of patients, considering physical, psychosocial, and environmental factors?
3. How can understanding the categories of nursing diagnoses aid in critical thinking and clinical decision-making for nurses?

### What Should the Nurse Do?

A nurse sees a patient's call light go off and goes into the room. The patient is sitting at the side of the bed with his eyes closed, holding onto the blankets. The nurse asks the patient what he needs, and he says he feels dizzy. The nurse knows that the patient has heart failure and is on a diuretic, or water pill, to rid his body of excess fluid. The nurse also knows that they increased the dose of the diuretic yesterday. The nurse wonders if the dose is now too high and the patient is losing too much fluid. When the nurse checks the patient's blood pressure and looks at the patient's chart, they notice the patient has urinated eight times over the past twelve hours, the total output is 1.5 L of urine, and that their dry weight is 2 lbs (1 kg) lighter than yesterday. The patient's blood pressure is 100/65 mm Hg, which is lower than he usually trends around 120/70 mm Hg. The nurse guesses that the patient may have lost too much fluid and contacts the provider, who agrees. The provider instructs the nurse to hold the patient's afternoon dose of the diuretic. The nurse does and charts the medication hold, then ensures the patient's safety by assisting him back into bed in a supine position. The nurse ensures he has his call light and urinal close by; she explains that his dizziness may be due to the water pill and that if he wants to get up, he must call for help before doing so. The patient thanks the nurse and falls asleep. About five hours later, the patient wakes up and tells the nurse he feels much better. He has urinated once in the past five hours and put out 65 mL. The nurse checks his blood pressure and sees it is 118/70 mm Hg. The nurse concludes that holding the medication has helped the patient retain some fluid.

1. Which cues did the nurse recognize in the patient that indicated something was amiss?
2. How did the nurse analyze the cues?
3. What hypothesis did the nurse form after analyzing the cues?
4. What was the nurse's solution to the patient's problem?
5. What actions did the nurse take to address the problem?
6. How did the nurse know the interventions worked?

### Competency-Based Assessments

1. Sarah, a registered nurse, is working in the emergency department (ED) when a new patient is brought in by ambulance. Mr. Johnson is a 65-year-old male who presents with severe chest pain and shortness of breath. Upon arrival, he appears diaphoretic and anxious. His vital signs show a blood pressure of 180/100 mm Hg, a heart rate of 120 beats per minute, a respiratory rate of 26 breaths per minute, and oxygen saturation of 92 percent on room air. Apply the Clinical Judgment Measurement Model (CJMM) to outline how Sarah will assess and manage the patient's condition. Break down the approach into the key components of recognizing cues, analyzing cues, prioritizing hypotheses, generating solutions, taking action, and evaluating outcomes.
2. Consider the following diagnoses and label whether it is a nursing or a medical diagnosis.

- a. risk for electrolyte imbalance
  - b. impaired urinary elimination
  - c. essential hypertension
  - d. impaired gas exchange
  - e. hyperlipidemia
  - f. chronic obstructive pulmonary disease
  - g. decreased cardiac output
  - h. ineffective tissue perfusion
  - i. urinary tract infection, site not specified
  - j. neoplasm (malignant) related fatigue
3. A 65-year-old patient with a history of chronic obstructive pulmonary disease (COPD) is admitted to the medical-surgical unit with exacerbation of symptoms, including increased dyspnea, productive cough with thick yellow sputum, and decreased oxygen saturation levels. The patient reports difficulty performing activities of daily living due to shortness of breath and fatigue. Upon assessment, crackles are auscultated bilaterally in the lower lung fields, and the patient appears anxious and restless. Based on the scenario provided, formulate a nursing diagnosis for the patient.

Sarah, a 65-year-old female, was admitted to the hospital due to a fall at home. She fractured her hip and underwent surgery for hip replacement. During the assessment, the nurse observed that Sarah is experiencing shortness of breath, coughing, and difficulty breathing. Vital signs indicate an elevated heart rate and increased blood pressure. Sarah reports feeling anxious and worried about her recovery.

- 4. Based on the scenario provided, formulate a nursing diagnosis for the patient.
- 5. How would the nurse validate the nursing diagnosis?
- 6. Scenario update: After implementing interventions such as administering breathing treatments and encouraging the use of incentive spirometry, Sarah's symptoms of dyspnea and coughing persist. Despite these interventions, she continues to experience difficulty breathing and reports ongoing anxiety. Based on the scenario update, refine the nursing diagnosis for this patient.

## CHAPTER 14

# Implementation and Evaluation: Taking Action, Evaluating Outcomes, and Documentation

**FIGURE 14.1** In some ways, the nursing process is like any other plan for achieving a goal. You need a training plan to prepare to run a marathon, and only by putting your plan into action and assessing the outcome can you determine its effectiveness. (modification of “A Midsummer Night’s Run 2011” by “V.L.”/Flickr, Public Domain)

### CHAPTER OUTLINE

- 14.1 The Nurse’s Role in Implementation
- 14.2 Types of Interventions
- 14.3 The Nurse’s Role in Evaluation
- 14.4 Evaluation Methods
- 14.5 Guidelines for Effective Documentation

**INTRODUCTION** Imagine you’ve set a goal for yourself: to run a marathon. It’s a challenging objective, requiring determination and a strategic approach. Your plan will likely include a detailed training schedule, a nutritious and balanced diet, and regular health checkups to monitor your fitness levels. The next crucial step is implementation: putting your plan into action by sticking to a training schedule, eating a nutritious diet, and consistently monitoring your health.

The final, critical phase is evaluation. Imagine that on the day of the marathon, despite your best efforts, you are unable to complete the 26.2 mi (42.2 km). Did you train sufficiently? Were there nutritional gaps in your diet? Did you give your body enough time to recover between training sessions? Addressing these questions will help you understand the shortcomings of your initial plan and make the necessary adjustments for your next attempt.

This process of planning, implementing, and evaluating is a fundamental approach in various professional fields, including nursing. In this chapter, you will explore how nurses implement care plans, evaluate outcomes, and

document each step of the process, ensuring that patient care is continuously improved and adapted to achieve the best possible results.

## 14.1 The Nurse's Role in Implementation

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the nurse's role during the implementation phase
- Describe the goals of the implementation phase
- Identify the skills needed to complete the implementation phase

In this unit, the process of providing nursing care will be explained in detail. This process begins with assessment, as nurses collect comprehensive data about the patient, followed by the diagnosis when data are analyzed to identify the causes of health problems. Based on the diagnosis, the care team and patient collaborate to identify desired health outcomes, then develop a plan of care for achieving these goals through various **interventions** (any action intended to stop a harmful outcome or promote a healthful one). Each step in the nursing process is crucial and builds on the previous ones, all to ensure a holistic approach to patient care (American Nurses Association [ANA], n.d.).

The next phase of the nursing process is the **implementation** phase, when the plans and strategies formulated in earlier steps are put into action. The specifics of implementation describe how nurses translate care plans into practical, patient-centered actions. This section also covers the importance of effectively carrying out care plans, adapting interventions to patient responses, and ensuring continuity of care. Implementation is where theory meets practice, and the nurse's skills, knowledge, and judgment come to the forefront to positively affect patient health.

### Emphasis during the Implementation Phase

During the implementation phase of nursing care, nurses play a crucial role in translating the established plan of care into action, applying evidence-based practices, and ensuring continuity of care. This phase involves actively executing the plan, monitoring patient responses to interventions, and maintaining consistent care delivery—particularly when the patient transitions out of the facility.

#### Putting the Plan into Action

Nurses translate a patient's established plan of care into action by delivering interventions, treatments, and therapies as outlined. This requires following evidence-based practices, adhering to protocols, and utilizing critical-thinking skills to adapt the plan to meet the patient's immediate needs and changing conditions. By applying their clinical knowledge and critical-thinking skills, nurses adapt the plan to meet the unique needs of each patient, striving to achieve optimal outcomes and promote recovery.

#### Gauging Patient Response

Gauging the patient's response to interventions is a critical aspect of the implementation phase. It involves continuously observing and interpreting how the patient physically, mentally, and emotionally reacts to the care plan. This process is essential for ensuring that interventions are effective and align with the patient's needs and comfort levels.

Nurses assess responses through various means, including direct feedback from the patient, clinical observations, and monitoring vital signs or other relevant health indicators. This ongoing assessment allows the nurse to make timely adjustments to the care plan, ensuring it remains responsive and patient-centered. The implementation phase focuses on actively carrying out the established care plan, making real-time adjustments based on patient feedback, and ensuring that interventions are administered in a way that promotes the patient's immediate well-being. In contrast, the evaluation phase systematically assesses the overall effectiveness of the care plan after interventions have been administered. It involves reviewing patient data and outcomes to determine if the goals and objectives of the care plan were met, making long-term adjustments based on a thorough analysis, and documenting the results for continuous improvement of future care plans.

## REAL RN STORIES

---

### Quick Response and Adaptation in Postoperative Care

**Nurse:** Emily, RN, BSN

**Clinical setting:** Ophthalmology unit in a metropolitan hospital

**Years in practice:** 5

**Facility location:** Seattle, Washington

As a nurse in the ophthalmology unit, I've seen a variety of postoperative cases, but one patient, Mr. Henderson, taught me the importance of swift adaptation during the implementation phase. Mr. Henderson, a 68-year-old retiree, had just undergone cataract surgery. Initially, his recovery seemed textbook perfect: he was alert, and his initial vision checks were promising. However, during a routine check the morning after his surgery, I noticed he was unusually quiet and seemed hesitant to open his operated eye.

Upon gently inquiring, Mr. Henderson admitted to experiencing “a bit of discomfort” in his eye, which he initially thought was normal after surgery. As I assessed his condition, it became clear that his discomfort was more than typical postoperative irritation. His eye was slightly redder and more swollen than expected, and he reported a sensation of “pressure” in his eye.

Recognizing these as potential signs of postoperative complications, possibly an infection or increased intraocular pressure, I immediately informed the ophthalmologist. We adjusted Mr. Henderson's care plan, increasing the frequency of eye drops to manage potential inflammation and scheduling an urgent follow-up examination.

The quick response was crucial. The ophthalmologist confirmed the early signs of infection and adjusted Mr. Henderson's medication accordingly. This intervention prevented what could have escalated into a severe complication, potentially jeopardizing his vision recovery.

This experience reinforced how critical it is to gauge patient responses meticulously during the implementation phase. Even seemingly minor complaints or changes in condition can be indicative of significant issues. It's a reminder that, as nurses, our vigilance and ability to adapt care plans can profoundly affect patient outcomes.

---

### Providing Continuity of Care

Providing continuity of care is pivotal in the implementation phase, particularly as the patient prepares to transition from the hospital to home or another care setting. This aspect of care ensures that the patient receives consistent and uninterrupted support throughout their recovery. Continuity of care requires effective communication, thorough documentation, and coordinated handoffs among healthcare professionals. It also involves preparing the patient and their family for what to expect after discharge, which may include education on medication management, physical therapy exercises, and wound care (Regis College, 2023).

### Goals of the Implementation Phase

The implementation phase in nursing is driven by specific goals tailored to each patient's care plan. These goals are derived from the patient's diagnosis and desired outcomes, which are determined in earlier steps of the nursing process. Achieving goals requires a strategic approach, ensuring that each action by nursing staff contributes meaningfully to a patient's recovery and overall well-being.

### Ongoing Assessment

Ongoing assessments, discussed in [Chapter 12 Assessment: Recognizing Cues](#), are a vital, continuous part of the implementation phase. They involve regular monitoring and evaluation of a patient's condition and responses to interventions. Through these assessments, nurses can detect subtle changes in the patient's status that may indicate either improvement or deterioration. As a result, care remains dynamic and responsive, adjusting to the patient's evolving needs. For nurses, ongoing assessment encompasses an array of activities, from measuring physiological parameters to observing behavioral responses, all contributing to a comprehensive understanding of the patient's health (Lloyd-Davies, n.d.). Through diligent ongoing assessment, the care team can ensure the patient's care plan is continuously aligned with their needs, making modifications as necessary to optimize outcomes.

### Establishing Priorities

Establishing priorities is deciding which patient needs are the most urgent and addressing them first (Marymount University, 2022). Prioritizing is especially important when resources are limited or when a patient has multiple needs. It's always vital for effective and efficient care delivery. Priority setting is often guided by frameworks such as Maslow's hierarchy of needs or specific clinical guidelines, helping nurses focus their attention and resources where they are most needed. Review [Establishing Priorities during Assessment](#) for more information about priorities and assessment. By continually evaluating and establishing priorities, the nursing team can ensure that a patient's care is streamlined and targeted and that their needs are addressed in a logical, effective order.

### Resource Allocation

Resource allocation involves strategically distributing and utilizing available resources to ensure optimal patient outcomes. Careful planning and organization are required to ensure that every aspect of patient care is adequately supported. Effective resource allocation means that the right personnel, equipment, and materials are available when needed, ensuring that the patient's care proceeds smoothly and without unnecessary delays. This process includes both tangible resources such as medical supplies and staffing and intangible resources such as time and information.

### Required Nursing Skills during the Implementation Phase

The implementation phase of the nursing process demands a specific set of skills to ensure effective and patient-centered care. These skills include clinical knowledge, critical thinking, and clinical judgment ([Table 14.1](#)), as well as psychomotor, interpersonal, and cognitive skills. Each skill plays a crucial role in translating a care plan into practical action and adapting it to the patient's evolving needs. In nursing, these skills are not isolated competencies but interrelated aspects of a nurse's ability to provide high-quality care.

	Definition	Description	Example
Clinical knowledge	Understanding of health, disease processes, treatments, and nursing interventions	Foundation for care plans and informed decisions; gained through education and experience	Knowing the signs of hypoglycemia and how to respond to a patient with diabetes showing signs and symptoms of hypoglycemia
Critical thinking	Skillful reasoning to guide belief or action	Analyzing information, evaluating evidence, and making decisions; crucial in assessing situations and adapting care plans	Deciding to elevate a patient's legs if they exhibit signs of fluid overload, even if the care plan does not explicitly mention this intervention
Clinical judgment	Using reasoning and thinking to draw conclusions and make decisions	Synthesizing information from various sources to prioritize interventions and make timely decisions based on patient needs and responses	Consulting with a wound care specialist on how to modify a patient's care plan when treatment has not improved the surgical site infection

**TABLE 14.1** Definitions and Examples of Clinical Knowledge, Critical Thinking, and Clinical Judgment

#### Clinical Knowledge

A nurse's understanding of health and disease processes, treatments, and nursing interventions is referred to as **clinical knowledge**. It is the foundation upon which nurses build their care plans and make informed decisions. Clinical knowledge is gained through education and experience and is vital in understanding the implications of different health conditions and how to manage them effectively. It is also a key component of clinical reasoning, the process by which a healthcare provider combines their knowledge and experience with data obtained through various patient assessments to diagnose a medical problem and determine an appropriate response (Gruppen,

2017).

## **CLINICAL SAFETY AND PROCEDURES (QSEN)**

---

### Using Clinical Knowledge to Develop Nursing Interventions

The Quality and Safety Education for Nurses (QSEN) competencies provide a framework for nursing education and practice, emphasizing key areas necessary for improving the quality and safety of patient care. Clinical knowledge is used to formulate nursing interventions using the QSEN competencies:

- **Patient-centered care:** Clinical knowledge enables nurses to develop nursing interventions tailored to each patient's unique clinical presentation, medical history, and personal circumstances. By understanding the underlying pathophysiology of the patient's condition, nurses can design interventions that address specific symptoms, promote healing, and enhance the patient's overall well-being.
- **Evidence-based practice (EBP):** Clinical knowledge plays a crucial role in EBP by providing nurses with a solid foundation of understanding regarding the latest research findings, treatment modalities, and clinical guidelines relevant to their practice. Nurses use this knowledge to select and implement nursing interventions that are supported by evidence, ensuring that patients receive care that is both effective and safe.
- **Quality improvement (QI):** Clinical knowledge helps nurses identify areas for improvement within their practice settings by recognizing patterns of patient outcomes, adverse events, or system inefficiencies. By leveraging their understanding of disease processes, pharmacology, and best practices in nursing care, nurses can develop and implement targeted interventions to address identified areas of concern and optimize patient outcomes over time.
- **Safety:** Clinical knowledge is essential for identifying and mitigating potential risks to patient safety. Nurses draw upon their understanding of anatomy, physiology, pharmacology, and patient assessment techniques to anticipate and prevent adverse events while implementing nursing interventions. This may involve ensuring correct medication dosages and administration routes, implementing fall prevention strategies, or monitoring patients for signs of deterioration following interventions.
- **Teamwork and collaboration:** Clinical knowledge enables nurses to communicate effectively with interdisciplinary team members, such as physicians, pharmacists, and allied health professionals, by articulating rationales for nursing interventions based on sound clinical principles. By collaborating with other healthcare providers, nurses can ensure that interventions are implemented seamlessly and that patient care is well-coordinated across the continuum.
- **Informatics:** Clinical knowledge enables nurses to effectively utilize informatics tools, such as electronic health records (EHRs), clinical decision support systems, and telehealth platforms, to inform nursing interventions. By accessing patient data and evidence-based resources, nurses can make informed decisions about care delivery, monitor patient progress, and communicate effectively with interdisciplinary team members. Additionally, nurses use informatics to track outcomes, analyze trends, and identify opportunities for quality improvement, ultimately enhancing the safety, efficiency, and effectiveness of nursing interventions.

By integrating clinical knowledge into their practice, nurses uphold the core principles of the QSEN competencies and deliver high-quality, safe, patient-centered care (PCC).

---

### Critical Thinking

When implementing a care plan, nurses should not simply “follow orders” without concern for how circumstances may change. Instead, they inform and reflect on decisions using critical thinking, the disciplined, systematic process of applying skillful reasoning to guide belief or action. Analyzing information, evaluating the available evidence, and making reasoned decisions is known as critical thinking (ANA, 2024). It is crucial in the implementation phase, as it allows nurses to assess situations, consider various options, and make decisions that best suit the patient's needs. This process also ensures patients receive the most appropriate and effective care for their situation.

### Clinical Judgment

Using clinical reasoning and critical thinking to draw conclusions or make decisions about a case is referred to as clinical judgment. It involves synthesizing information from various sources, including patient assessments, clinical

knowledge, and the nurse's experience (Tanner, 2006). Nurses utilize clinical judgment to prioritize nursing interventions, considering factors such as the patient's condition, preferences, and response to treatment. By drawing upon their clinical knowledge and experience, nurses make timely and appropriate decisions regarding selecting and implementing interventions to promote optimal patient outcomes. The nurse's clinical judgment will guide the decision to modify the treatment plan or consult with other healthcare professionals for further management.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Using Clinical Judgment to Initiate Nursing Interventions

Sarai, a registered nurse working in the emergency department, receives a new patient, Mr. Smith, a 63-year-old male presenting with chest pain and shortness of breath. Sarai begins by noticing the cues presented by Mr. Smith, including his chief complaint of chest pain and shortness of breath, as well as his pallor and diaphoresis. Sarai interprets the significance of the cues she has noticed, considering Mr. Smith's age, medical history, and presenting symptoms. She recognizes that chest pain and shortness of breath could indicate a myocardial infarction (heart attack) and understands the urgency of the situation. Based on her interpretation of the cues, Sarai responds promptly by initiating appropriate nursing interventions per standing orders. She ensures that Mr. Smith is placed on continuous cardiac monitoring, administers oxygen therapy to improve his oxygenation, and establishes intravenous access for medication administration and fluid resuscitation.

#### Psychomotor Skills

The practical, hands-on abilities required to implement interventions effectively in nursing are known as **psychomotor skills**. These skills range from basic tasks such as taking vital signs to more complex procedures such as administering injections or performing wound care (University of San Francisco School of Nursing, 2011). Proficient psychomotor skills are essential for ensuring that physical interventions are carried out safely and correctly and with minimal patient discomfort. The precise execution of psychomotor skills contributes significantly to effectively implementing a patient's care plan and their overall recovery experience.

#### Interpersonal Skills

Effective communication and interaction with patients, their families, and other healthcare professionals comprise **interpersonal skills** in nursing. These skills are crucial for building trust through open communication and mutual respect to build relationships and partnerships. They provide emotional support through empathy and compassion to acknowledge patients' emotions and alleviate distress, promoting a sense of comfort and reassurance. Interpersonal skills also facilitate the exchange of information through active listening techniques to understand patients' perspectives, preferences, and needs, allowing nurses to tailor interventions accordingly. These skills also involve collaboration—nurses collaborate with patients, families, and interdisciplinary team members to coordinate care, share information, and achieve common goals. Interpersonal skills must also encompass **cultural sensitivity**, which means being aware of and respecting a patient's cultural background and beliefs. Nurses create a supportive environment that encourages patients to voice their concerns, ask questions, and express their preferences, ultimately enhancing the success of nursing interventions and promoting positive patient outcomes (ANA, 2023). Effective interpersonal skills help nurses better understand their patients' needs and concerns, enabling more personalized care. By establishing a rapport and maintaining clear communication, the nurse can build trust and keep the patient and family informed and involved in care, enhancing the overall experience and adherence to the care plan.

#### Cognitive Skills

The mental processes involved in understanding patient needs, planning care, problem-solving, and decision-making in nursing are collectively known as **cognitive skills**. These skills are fundamental to processing patient information, applying clinical knowledge, and adapting care plans to meet individual patient needs. Cognitive skills enable nurses to think critically and apply clinical reasoning and judgment in practice. The nurse's ability to process and integrate various pieces of information is key to adapting a patient's care plan in response to changing needs, ensuring a smooth and effective recovery process.

## PATIENT CONVERSATIONS

---

### A Skillful Conversation

**Scenario:** Nurse Ali is paying a home visit to Mrs. Dewi, who has been struggling with irritable bowel syndrome (IBS). Note how Nurse Ali utilizes the various nursing skills throughout the conversation.

**Nurse:** Good morning, Mrs. Dewi.

**Mrs. Dewi:** Good morning, Ali.

### **INTERPERSONAL SKILLS**

**Nurse:** I see another beautiful drawing on your wall. Your grandchildren really keep your spirits up, don't they?

**Mrs. Dewi:** Oh, yes. It's from Lily. Her drawings are my little pieces of joy. She came over last night for dinner and made that one.

**Nurse:** How nice. What did you eat?

**Mrs. Dewi:** Don't worry, I was good!

**Nurse:** I have no doubt.

### **CLINICAL KNOWLEDGE**

**Mrs. Dewi:** I've been avoiding those high-fiber foods you mentioned. There's been less bloating, but the discomfort is still there sometimes.

**Nurse:** That's good to hear about the bloating. Remember, with irritable bowel syndrome, it can take some time to see the full benefits of dietary changes. Let's keep monitoring this.

**Mrs. Dewi:** All right.

### **CRITICAL THINKING**

**Nurse:** Besides diet, other factors such as stress can impact IBS. Have you noticed any patterns or specific times when the discomfort increases?

**Mrs. Dewi:** Now that you mention it, evenings are tougher. I tend to worry about things at night.

**Nurse:** That's a helpful observation. Stress management can be a key part of managing IBS symptoms. Let's explore some options to help you relax in the evenings.

**Mrs. Dewi:** I know, I should probably stay off the internet.

### **CLINICAL JUDGMENT**

**Nurse:** Definitely before bed. But I'd recommend trying some relaxation techniques as well, such as guided imagery or deep-breathing exercises. It could help ease your symptoms.

**Mrs. Dewi:** I haven't tried those before. How do they work?

**Nurse:** I can show you some techniques and provide resources. We can practice a few together to get you started.

### **PSYCHOMOTOR SKILLS**

**Nurse:** Now, let's do a quick abdominal check. Please let me know if you feel any discomfort.

*Nurse Ali performs a gentle abdominal examination.*

**Mrs. Dewi:** It's a little tender but not painful.

**Nurse:** That's normal. I'm checking for any unusual signs.

**Mrs. Dewi:** Nothing unusual?

### COGNITIVE SKILLS

**Nurse:** Nothing unusual. You know, your feedback is important. Have we talked about keeping a symptom diary? You can note down your meals, stress levels, and when you experience discomfort.

**Mrs. Dewi:** That sounds like a plan. I can track what I eat and how I feel each day.

**Nurse:** Exactly. This diary will help us both see the bigger picture and adjust your care plan more effectively.

---

## 14.2 Types of Interventions

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the categories of patient care used in the implementation phase
- Compare different interventions used to implement care
- Recall the focus of interventions based on nursing diagnosis
- Describe how to effectively prioritize nursing interventions
- Define delegation rules regarding assigning interventions

A well-structured care plan is pivotal to ensuring patient well-being and recovery. At the heart of this plan are interventions—actions designed to either mitigate harmful outcomes or promote beneficial health results. More than tasks or procedures, interventions are the active components of nursing care that are tailored to address specific patient needs and health goals.

This module will cover the diverse range of interventions, which may be dependent, independent, and interdependent. It will explain how various interventions are employed during the implementation phase of the nursing process. It will also explore how to align interventions with nursing diagnoses, ensuring that each action taken is purposeful and grounded in clinical reasoning, and identify how to prioritize and delegate interventions as needed. These topics highlight the importance of understanding the scope of practice and the dynamics of working within an interdisciplinary team. First, the section takes a closer look at the categories of patient care.

### Categories of Patient Care

During the implementation phase of patient care, different categories of interventions are used to address the patient's needs effectively. Medical interventions are treatments and procedures that are performed by healthcare providers, such as administering medications or conducting diagnostic tests. Nursing interventions encompass a broad range of actions that are performed by nurses to meet their patients' physical, emotional, and psychosocial needs. These interventions may include administering prescribed medications, providing wound care, assisting with activities of daily living (ADLs), and educating patients and families about self-care techniques.

Imagine following a nurse through a typical shift in the hospital. The nurse's day begins with a handover from the previous shift, during which they review patient notes and plan their schedule. Then, the nurse heads to patient rooms for the beginning of shift assessments, checking vital signs, administering medications, and chatting with each patient about how they feel. The nurse updates care plans based on observations and discussions with patients to ensure their needs are met.

Throughout the shift, the nurse performs various tasks—from changing dressings on a postsurgical wound and assisting a patient with mobility exercises to providing patient education on managing conditions. Between these activities, the nurse coordinates care by consulting with providers about changes in a patient's condition, coordinating diagnostic tests, and participating in multidisciplinary team meetings to discuss patient care strategies. Think about how the nurse might categorize the activities they do ([Figure 14.2](#)). Some actions involve direct interaction with patients, addressing their immediate needs and providing comfort. Actions not performed at bedside are equally important for patient care and require coordination and planning behind the scenes. Direct care and indirect care are two categories that form the basic dichotomy during the implementation phase of the nursing process (FVI School of Nursing and Technology, n.d.).

**FIGURE 14.2** Nursing tasks can involve (a) direct interactions with patients or (b) take place behind the scenes. (credit a: modification of “World Breastfeeding Week spotlights lifelong benefits of nursing final version” by U.S. Navy Petty Officer 1st Class James Stenberg/Health.mil, Public Domain; credit b: modification of “Technology (5815873138)” by Medill DC/Wikimedia Commons, CC BY 2.0)

### Direct Care

Interventions that involve personal contact or interaction with patients, whether in person, over the phone, or digitally, are known as **direct care**. This type of care is a key component of the implementation phase, as it allows nurses to assess patients’ conditions firsthand, respond to their needs, and provide immediate comfort and support. Examples of direct care interventions include administering medications, performing physical assessments, assisting with daily living activities, treating wounds, and educating patients about their health conditions. These interactions are essential for the physical aspects of patient care and building rapport and trust—two essential elements in the therapeutic relationship between a nurse and a patient.

### Indirect Care

Tasks and interventions that are performed away from the patient but are still vital to their overall care are called **indirect care**. This type of care is crucial for the successful implementation of a patient’s care plan, and it requires organizing, managing, and coordinating healthcare services. Indirect care interventions may include documentation, collaborating with other healthcare professionals, arranging referrals or follow-up care, and managing resources. For example, the nurse’s consultations with providers and participation in care planning meetings are forms of indirect care. These activities, though not always visible to patients, significantly affect the quality and efficacy of the care provided.

## LIFE-STAGE CONTEXT

### Tailoring Direct and Indirect Care for Different Age Groups

Both direct and indirect nursing care needs to be adapted according to the age of the patient to ensure it is appropriate and effective. Understanding these variations is crucial for nursing students as they prepare to cater to a diverse patient population.

- **Neonatal patients:** In neonatal care, direct care involves delicate handling, as these patients are extremely vulnerable. Tasks such as bathing, feeding, and physical assessments require gentle and precise techniques. Indirect care includes coordinating with pediatricians and lactation consultants and educating parents about neonatal care. The focus is on providing a safe, nurturing environment conducive to growth and development.
- **Pediatric patients:** With older children, direct care includes age-appropriate communication to explain procedures and engage them in their care. This might involve using play therapy for assessments or distraction techniques during uncomfortable procedures. Indirect care includes collaborating with family members and school officials to support the child’s health needs, both in the hospital and upon their return to school.

- **Adult patients:** Direct care for adults involves a more collaborative approach, encouraging patient autonomy and informed decision-making. This might include teaching self-care skills for chronic disease management. Indirect care involves coordinating care transitions, such as from hospital to home or rehabilitation facilities. It could also include arranging for home health services or occupational therapy.
- **Older adult patients:** In care for older adults, direct care often requires understanding the complexities of aging, such as managing multiple chronic conditions or addressing mobility issues. Indirect care includes working with multidisciplinary teams to coordinate care, considering factors such as home safety assessments and support systems to ensure a safe living environment.

In each age group, the nuances of direct and indirect care reflect the unique needs and challenges of the patients. Adapting these care approaches based on age is essential for providing holistic and effective nursing care.

## Types of Interventions

In healthcare settings, nurses employ various interventions to implement care plans that cater to the diverse needs of patients. These interventions are categorized as dependent, independent, or interdependent. Each type of intervention plays a distinct role in promoting patient well-being and facilitating recovery. Understanding the differences between these intervention types is essential for nurses, as it allows them to deliver comprehensive and effective care tailored to individual patient needs.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Implementing Various Types of Nursing Interventions

Jarrell, a registered nurse working in a busy medical-surgical unit, is assigned to care for Mr. Johnson, a 65-year-old patient admitted with exacerbation of heart failure. During his assessment, Jarrell notices that Mr. Johnson is experiencing shortness of breath, has crackles in his lungs upon auscultation, and his oxygen saturation levels are below the target range. Interpreting these cues, Jarrell determines that Mr. Johnson requires immediate interventions to address his respiratory distress and manage his heart failure exacerbation.

Responding to the situation, Jarrell implements a variety of interventions tailored to Mr. Johnson's needs. For dependent interventions, Jarrell contacts the healthcare provider to request orders for supplemental oxygen therapy and intravenous diuretics to reduce fluid overload and improve Mr. Johnson's respiratory status. Additionally, he administers prescribed medications such as angiotensin-converting enzyme (ACE) inhibitors and beta blockers as ordered to optimize cardiac function and alleviate symptoms.

For independent interventions, Jarrell provides emotional support to reassure Mr. Johnson and alleviate anxiety associated with his breathing difficulties. He also assists him with ADLs, such as positioning for optimal respiratory function and facilitating mobility to prevent complications associated with immobility. Furthermore, Jarrell educates Mr. Johnson about dietary restrictions, fluid management, and medication adherence to empower him in managing his heart failure at home.

Recognizing the complexity of Mr. Johnson's condition and the importance of interdisciplinary collaboration, Jarrell engages in interdependent interventions. He communicates with the respiratory therapist to initiate respiratory treatments, such as nebulizer therapy or chest physiotherapy, to improve Mr. Johnson's ventilation and oxygenation. Jarrell also collaborates with the physical therapist to develop a plan for progressive mobility exercises and with the dietitian to optimize Mr. Johnson's nutrition and fluid intake while adhering to his dietary restrictions.

There are also other ways to categorize the activities a nurse performs ([Table 14.2](#)). During a shift, the nurse performs many tasks on their own without input from providers (**independent intervention**). The nurse also performs some tasks only after getting instructions from a provider (**dependent intervention**). The nurse may also perform tasks as part of a collaborative, multidisciplinary team (**interdependent intervention**).

Nursing Intervention	Description	Rationale	Examples
Independent	Actions initiated and carried out by the nurse based on their clinical judgment, without instructions from others	Addresses immediate patient needs promptly, proactively enhances comfort and well-being, and empowers nurses to use their clinical judgment	Providing emotional support, assisting with ADLs, educating patients on self-care, implementing preventive measures (e.g., pressure-relieving cushions, fall prevention)
Dependent	Actions carried out under the orders or direction of a healthcare provider (e.g., physician, nurse practitioner)	Ensures that medically essential treatments are delivered safely and effectively according to the provider's orders	Administering medications, performing prescribed treatments or procedures (e.g., wound care, dressing changes), preparing patients for surgery
Interdependent	Collaborative actions that require coordination with other members of the healthcare team	Leverages the expertise and resources of the entire healthcare team to provide comprehensive, holistic care that addresses the patient's physical, emotional, and social needs	Interdisciplinary rounds to discuss patient progress, coordinating transitions of care (e.g., discharge planning), participating in multidisciplinary meetings for complex case management (e.g., diabetes management with a dietitian, physical therapist, and social worker)

**TABLE 14.2** Types of Nursing Interventions

### Focus of Interventions Based on Nursing Diagnosis

Healthcare providers design interventions to solve or reduce the risk of health problems. Just as there are different types of interventions, there are different patient problems ([Table 14.3](#)). A nurse may start their shift in one patient's room, administering medication to help lower high blood pressure—which is an immediate and observable health issue. In another room, the nurse may identify that a patient is at risk of developing pressure ulcers due to limited mobility. In a third room, the nurse collaborates with other healthcare professionals to manage a patient with complex diabetic needs—a situation that often includes a variety of problems, some immediate, some distant, some serious, and some minor.

Problem Type	Definition	Focus of Interventions	Example
Actual	An immediate, identified issue currently affecting a patient	Resolving existing health problems and improving the patient's current condition	Treating high blood pressure with medication, monitoring, and lifestyle education
Potential	A risk or condition a patient is susceptible to but is not currently manifesting	Preventing the potential problem from becoming an actual problem; implementing preventive measures	Identifying a patient with limited mobility as being at risk for pressure ulcers and implementing regular repositioning and pressure-relieving devices
Collaborative	A complex issue requiring the coordinated efforts of multiple healthcare professionals	Addressing complex care needs that require a multidisciplinary approach	Managing a patient with diabetes by collaborating with a dietitian, endocrinologist, and diabetes educator

**TABLE 14.3** Types of Patient Problems

### Prioritizing Nursing Interventions

In nursing practice, prioritizing interventions is a crucial skill that ensures efficient and effective patient care. This process is similar to prioritizing assessments, as discussed in [Establishing Priorities During Assessment](#). Nurses often utilize tools such as the ABC framework (airway, breathing, circulation) ([Figure 14.3](#)) and Maslow's hierarchy of needs to determine the order of their interventions ([Figure 12.4](#)). These frameworks remind nurses to address life-threatening problems first, then basic needs next, before proceeding to less critical issues. Prioritizing helps ensure a systematic approach to patient care (Marymount University, 2022).

**FIGURE 14.3** The ABC framework directs nurses to prioritize issues involving the airway, breathing, and circulation. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

For instance, if a patient is experiencing breathing difficulties and has a long-term mobility issue, the nurse should address the breathing problem first, as it poses an immediate risk to the patient's life. Once stabilized, the nurse can

focus on interventions for the patient’s mobility. By prioritizing interventions, nurses can efficiently manage their time and resources to focus on the most pressing issues first and then address other important (but less critical) aspects of patient care.

## REAL RN STORIES

---

### Quick Decision-Making in a High-Stakes Environment

**Nurse:** Ife, RN, BSN

**Clinical setting:** Emergency department

**Years in practice:** 5

**Facility location:** Savannah, Georgia

During a particularly busy shift in the Emergency Department, I encountered a situation that tested my ability to prioritize under pressure. A young man, around 25 years old, was rushed in following a motorbike accident. He was conscious but visibly in pain and disoriented.

Upon initial assessment, I noticed he had a compound fracture in his leg and was bleeding, but he was also struggling to breathe. Remembering the ABC framework, I immediately recognized that his airway and breathing were at risk, which took precedence over his leg injury despite the visible trauma.

Working swiftly, I called for respiratory support and ensured his airway was clear. Once his breathing stabilized and oxygen was administered, I turned my attention to his leg. The bleeding needed to be controlled quickly to prevent shock. I applied pressure to the wound and called for assistance from the trauma team.

In that moment, my years of training in prioritizing patient care based on immediate threats to life came into play. Although the fracture was severe, addressing his respiratory distress first was crucial for his survival. After stabilizing his breathing and controlling the bleeding, he was taken for surgery to address his leg injury.

Reflecting on this experience, I realize how critical our role as nurses is in making quick, life-saving decisions. Prioritizing patient needs isn’t just a part of our job; it’s a responsibility that can mean the difference between life and death.

---

### Assessing Patient Safety

Ensuring patient safety is a primary concern during the implementation phase and is integral to prioritizing nursing interventions. Nurses continually assess potential threats to patient safety, such as fall risks, medication errors, or complications from immobility. They must prioritize interventions that mitigate these risks for patients. For example, when administering medications, nurses must carefully follow protocols to prevent errors, considering risk factors such as correct dosages, patient allergies, and medication interactions. In direct patient care, a nurse may prioritize interventions that prevent falls for a patient with mobility issues, such as ensuring the environment is safe, assisting with ambulation, and educating the patient and their family about fall-prevention strategies. For a postoperative patient, a nurse typically prioritizes wound care and monitors for signs of infection to prevent complications. These actions, focused on maintaining patient safety, highlight the nurse’s role in identifying and addressing potential hazards, ensuring that care delivery is effective and safe.

### Delegating Interventions

Delegation in nursing is a crucial skill involving the transfer of responsibility for certain tasks while retaining accountability for the outcome. Nurses delegate tasks to manage time effectively and ensure patient care is delivered efficiently. However, not every task can be delegated, and not every staff member can accept a request for delegation. Understanding when and why to delegate involves considering the “five rights” of delegation, which are listed in [Table 14.4](#) (National Council of State Boards of Nursing & American Nurses Association [NCSBN & ANA], 2019). Delegation is discussed further in [15.4 Nursing Standards of Delegation](#).

Right	What It Means	Example
Right Task	The task must be appropriate for delegation.	Delegate the monitoring of routine vital signs to a nursing assistant, a task within their competency.
Right Circumstance	The circumstances must be appropriate for delegation.	Ensuring the patient's condition is stable and appropriate for delegation.
Right Person	The individual must be able to perform the task delegated to them.	Selecting a qualified and competent team member to perform a task, such as a licensed practical nurse for administering oral medications.
Right Communication	The instructions regarding the task must be clear.	Providing clear, specific instructions on the task.
Right Supervision	The individual performing the task must be properly supervised.	Requires the nurse to monitor the delegated task and intervene if necessary, ensuring patient safety and quality of care.

**TABLE 14.4** Rights of Nursing Delegation

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Delegating Nursing Interventions

Taylor is a registered nurse working in a medical-surgical unit. She is responsible for caring for several patients, including Mr. Martinez, a 70-year-old patient admitted for pneumonia. During her morning rounds, Taylor notices several cues indicating a change in Mr. Martinez's condition.

- **Recognize Cues:** Mr. Martinez appears more fatigued than usual, with increased respiratory effort. His oxygen saturation levels have dropped to 88% on room air. Mr. Martinez is coughing more frequently and producing thicker sputum. There is new-onset confusion and restlessness noted in his behavior.
- **Analyze Cues:** Based on these cues, Taylor analyzes the situation and considers possible reasons for the changes in Mr. Martinez's condition. She recognizes that the decreased oxygen saturation levels, increased respiratory effort, and changes in mental status could indicate worsening pneumonia and respiratory distress. The thicker sputum production suggests a potential airway obstruction or worsening infection.
- **Form a Hypothesis:** Taylor forms a hypothesis that Mr. Martinez's pneumonia may be progressing, leading to respiratory compromise and altered mental status. She suspects that prompt interventions are necessary to improve his oxygenation, clear his airway, and address the underlying infection to prevent further deterioration.
- **Take Action:** Taylor decides to delegate certain interventions to the certified nursing assistant (CNA) assigned to assist her. She instructs the CNA to assist Mr. Martinez with positioning to optimize his respiratory mechanics, such as elevating the head of the bed. While the CNA helps to reposition Mr. Martinez, Taylor gathers the necessary supplies and initiates supplemental oxygen therapy as prescribed by the healthcare provider to improve oxygenation.

#### Scope of Practice

As discussed in [Scope of Practice](#), the nursing scope of practice refers to the defined limits and parameters within which nurses are authorized to work, make decisions, and provide services. Scope is established by regulatory bodies, licensing boards, and professional organizations such as the American Nurses Association (ANA).

The nursing scope of practice is a critical factor when making delegation decisions. It dictates what nurses are legally permitted to do and informs which tasks can be delegated to other team members. For instance, although registered nurses (RNs) can delegate noninvasive procedures such as bed bathing to nursing aides, they cannot delegate tasks that require clinical judgment, such as patient assessments (NCSBN & ANA, 2019). Understanding

the scope of practice ensures that delegation aligns with legal and professional standards, safeguarding the patient and the healthcare provider.

## LINK TO LEARNING

The ANA maintains [a web page on the nursing scope of practice \(https://openstax.org/r/77ANAScope\)](https://openstax.org/r/77ANAScope) that includes an option to purchase the complete resource, currently in its fourth edition.

### Interdisciplinary Team

Delegating interventions within an interdisciplinary team requires a thorough understanding of each team member's scope of practice to ensure safe, effective, and comprehensive patient care. The scope of practice for each healthcare professional is defined by their education, training, certification, and licensure, which determines the specific tasks they are qualified to perform. When delegating interventions, it is crucial for healthcare providers to clearly communicate and collaborate, assigning tasks that match each team member's expertise and skills. For instance, a nurse may delegate tasks such as vital signs monitoring, assisting with ADLs, and collecting specimens to a certified nursing assistant (CNA). Meanwhile, licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) might be assigned more complex tasks, including administering oral medications and performing basic wound care. However, interventions that require advanced clinical judgment, such as creating and implementing care plans, performing initial health assessments, and developing treatment plans, should be reserved for registered nurses (RNs).

By adhering to the defined scopes of practice and leveraging the unique strengths of each team member, interdisciplinary delegation fosters an environment of teamwork and ensures that patient care is delivered efficiently and effectively. Effective interdisciplinary delegation requires clear communication and collaboration among team members, with a focus on patient-centered care (PCC) where decisions prioritize the patient's needs and preferences.

Nurses also play a pivotal role in making referrals to the interdisciplinary team. They assess the patient's condition and needs, identify when specialized care or expertise is required, and initiate or suggest referrals to other healthcare professionals (dependent upon agency policies). For example, a nurse might refer a patient to a physical therapist for mobility issues, a dietitian for nutritional counseling, or a social worker for support with discharge planning and community resources. These referrals are based on comprehensive patient assessments and the nurse's clinical judgment, ensuring that the patient receives holistic and coordinated care. By making appropriate referrals that reflect defined scopes of practice, nurses help foster a collaborative environment that enhances the quality and efficiency of patient care.

In the context of an interdisciplinary care team, delegation fosters collaboration and maximizes the expertise of various professionals working together to care for patients. Effective delegation within an interdisciplinary team promotes comprehensive patient care, with each member bringing their specific skills and knowledge to support optimal patient outcomes.

## 14.3 The Nurse's Role in Evaluation

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain how the evaluation phase reveals a patient's progress
- Recognize how the evaluation phase provides a system for nurses to define, explain, and measure patient care
- Identify the evaluation phase's role in promoting continuity of care
- Identify ways the nurse evaluates the plan of care
- Recognize how the nurse analyzes conclusions during the evaluation phase

In the nursing process, the evaluation phase follows the implementation phase, marking the final step. The systematic determination of a patient's progress toward achieving the outcomes and goals set during the care-planning process is called **evaluation**. It is a dynamic and ongoing activity in which nurses assess whether the

patient's health status is improving, staying the same, or worsening in response to the nursing interventions. This phase is crucial because it determines the effectiveness of the nursing care provided, informs necessary changes to the care plan, and ensures that the patient's health needs are adequately met (ANA, n.d.).

### Determine the Patient's Progress

Determining the patient's progress is a fundamental step in the evaluation phase. In this phase, nurses compare the patient's current status to the baseline data collected during the assessment phase and the expected outcomes established during the planning phase. Through careful analysis of data, nurses can determine whether the patient's condition has improved, remained stable, or deteriorated since the initiation of care. They assess whether the patient is meeting the expected outcomes outlined in the care plan and identify any discrepancies or areas where adjustments may be needed.

The nurse will perform a comprehensive review of a patient's current health status compared to the expected outcomes outlined in the care plan. They will assess various factors to gain insight into how well the interventions have worked and whether a patient is on track to meet goals. However, it is not just about noting improvements—the nurse also identifies areas where progress might be lagging or complications have developed.

#### Analyze Current Data

As described in [Chapter 12 Assessment: Recognizing Cues](#), nurses are continually obtaining and analyzing data from their patients, and this includes during the evaluation phase (Lukey, 2023). To analyze current data, nurses review various sources of information, including objective data such as vital signs, laboratory results, and physical assessments, as well as subjective data provided by the patient or their family members regarding symptoms, comfort level, and overall well-being. Although tasks such as obtaining updated vital signs can be delegated to unlicensed assistive personnel (e.g., CNA), physical assessment and evaluating the data remain the responsibility of the nurse.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Analyze Cues: Using Current Data to Determine Effectiveness of Interventions

Janieh, a registered nurse working in a pediatric unit, is caring for a 5-year-old child, Emily, who was admitted with a severe asthma exacerbation. Emily has been receiving nebulized bronchodilators and corticosteroids as prescribed, but her respiratory distress persists despite treatment. Janieh is tasked with assessing Emily's response to the interventions and determining the next course of action.

- Recognize cues: Emily continues to exhibit audible wheezing and retractions, indicating ongoing respiratory distress. Emily's respiratory rate remains elevated at thirty breaths per minute. Emily appears restless and irritable, with increased work of breathing noted.
- Analyze cues: Based on the cues observed, Janieh analyzes Emily's response to the nursing interventions implemented thus far. Despite receiving nebulized bronchodilators and corticosteroids, Emily's respiratory distress persists, as evidenced by the continued presence of wheezing, retractions, and elevated respiratory rate. Additionally, Emily's restlessness and irritability suggest that she is experiencing discomfort and difficulty breathing, further highlighting the inadequate response to treatment.

Janieh concludes the current nursing interventions have not been effective in alleviating Emily's respiratory distress. Despite receiving appropriate medications, Emily's condition has not improved, and she continues to exhibit signs of respiratory compromise. By recognizing cues that suggest inadequate improvement in Emily's condition despite treatment, Janieh can take proactive steps to reassess and modify the care plan to promote optimal patient outcomes.

To analyze current data, the nurse will utilize the patient's medical records since the start of the implementation phase, including vital signs and other objective data that provide observable and measurable evidence of progress. Subjective data, such as a patient's reports of pain and feelings about progress, are also crucial as they give the nurse a holistic view of the patient's experience and recovery.

The team also evaluates the effectiveness of patient education by assessing a patient's understanding and

adherence to the care plan. This comprehensive analysis helps the nursing team make informed decisions about necessary adjustments to the care plan, ensuring it remains aligned with a patient's health needs and goals.

### System for Nurses to Define, Explain, and Measure

The evaluation stage in the nursing process is a systematic approach for nurses to define, explain, and measure the effectiveness of patient care. This stage enables nurses to concretely define the outcomes of their interventions, explain the reasons behind the success or failure of these interventions, and measure the extent to which patient care goals have been met. By defining specific criteria for success and measuring a patient's progress against these benchmarks, the team can objectively evaluate the quality and efficacy of the care provided.

#### Verify the Quality of Nursing Care

Nurses assess the quality of care provided to patients by comparing actual outcomes to predetermined standards and benchmarks. Verifying the quality of nursing care involves a detailed assessment of the care provided against established standards and guidelines. They must confirm that interventions were implemented correctly, adherence to evidence-based practice guidelines was maintained, and patient outcomes met the established criteria for success. By verifying quality, nurses ensure that patients receive safe, effective care aligned with best practices.

#### Analyze Nursing Interventions

Nurses analyze the effectiveness of interventions implemented during the care process to determine their effect on patient outcomes. They examine the patient's response to treatment, assess changes in their condition over time, and identify any factors that may have influenced the effectiveness of interventions. Through this analysis, nurses gain valuable insights into which interventions are most beneficial for specific patient populations, allowing for continuous improvement in care delivery. In analyzing the nursing interventions, the nursing team critically evaluates each action and its outcome. This detailed analysis can involve both objective and subjective data from the patient.

## PATIENT CONVERSATIONS

### Discussing Intervention Effectiveness

**Nurse:** Good morning, Mr. Silva. How are you feeling today?

**Patient:** Morning, Nurse. I'm feeling okay, just a bit sore from the surgery.

**Nurse:** That's understandable after knee replacement surgery. Let's talk about how you're doing with the interventions we've implemented. First, let's discuss your pain management. How has your pain management been since we started administering medication every four hours?

**Patient:** It's not as bad. The pain is much more manageable now.

**Nurse:** I'm glad to hear that. It's important that we keep your pain at a tolerable level so you can participate in rehabilitation exercises. Have you experienced any side effects from the medication, or is there anything else you're experiencing?

**Patient:** Not really, no. I've been a bit drowsy, but that's about it.

**Nurse:** Good to know. Now, let's talk about your mobility. How have you been finding the physical therapy sessions?

**Patient:** They're challenging, but I can already feel some improvement in my knee's flexibility.

**Nurse:** That's great progress. What has been your experience with the at-home exercises? Are the exercises we showed you for at-home practice clear and manageable?

**Patient:** Yes, I've been doing them every day. They help with the stiffness.

**Nurse:** Excellent. How are you feeling about the self-care instructions we went over, such as wound care and the signs of infection to watch for? Is there anything you're unsure about?

**Patient:** Yes, those instructions are clear. The wound seems to be healing well, no redness or swelling.

**Nurse:** Perfect. It's crucial to monitor the wound for any changes.

**Patient:** I understand.

**Nurse:** That's great. Your feedback is valuable in helping us evaluate and adjust our care plan. Is there anything else you'd like to discuss or any questions you have about your ongoing care or what we've talked about today?

**Patient:** No, I think I'm good for now. Thank you for taking the time to go through everything with me.

**Nurse:** Of course, Mr. Silva. We're here to support you every step of the way. Keep up the good work with your recovery!

---

### Promote Accountability among Nurses

Nurses hold themselves and other members of the healthcare team accountable for the care provided to patients. They ensure that interventions are documented accurately, responsibilities are fulfilled, and communication among team members is clear and effective. By promoting accountability, nurses foster a culture of transparency, professionalism, and collaboration, ultimately enhancing the quality and safety of patient care. Promoting accountability in a patient's care requires each nurse to reflect on their individual contributions and understand their effect on the patient's experience and outcomes. This self-assessment and accountability ensure that each nurse takes ownership of their part in a patient's care, fostering a responsible and reflective practice environment that prioritizes patient well-being.

### Promote Continuity of Care

As discussed earlier in this chapter in [Providing Continuity of Care](#), continuity of care is a vital aspect of the nursing process, ensuring patients receive consistent, uninterrupted support throughout their healthcare journey (Regis College, 2023). During the evaluation phase, nurses play a crucial role in promoting continuity of care, especially as patients transition between various stages of recovery. The nurse continuously assesses a patient's progress and adjusts the care plan based on these evaluations. These coordinated efforts may occur between hospital staff, home healthcare providers, and the patient's family, all with the overall goal of maintaining the quality and effectiveness of care across each setting.

### Establish Patterns of Continuous Care

Establishing patterns of continuous care is essential for patients transitioning between healthcare settings. This process involves meticulous planning to ensure each care setting is equipped to meet the diverse needs of patients. For instance, a patient moving from a hospital to home care may require arrangements for home healthcare services, whereas a patient transitioning to a rehabilitation facility might need specialized rehabilitation plans. Nurses coordinate care transitions by preparing detailed discharge plans, facilitating communication between healthcare providers, and ensuring seamless access to a patient's medical history. This coordinated approach aims to maintain the quality of care, regardless of the setting—whether it's a patient's home, another hospital, or a long-term care facility.

### Patient and Family Involvement

Involving patients and their families (if the patient permits) in the continuity of care process is crucial for successful health outcomes. Educating patients and families about postdischarge care, such as medication management, wound care, and the importance of follow-up appointments, is a key responsibility of the nursing team. This education empowers family members to actively participate in a patient's care and decision-making. Encouraging family members' input in care planning ensures that their preferences and concerns are considered and fosters a collaborative approach to health management. This supportive involvement enhances adherence to treatment plans and provides emotional support, as patients and their families feel more in control and informed about their healthcare journey (Agency for Healthcare Research and Quality, 2012).

### Evaluate Data

Evaluating data is a pivotal aspect of the nursing evaluation phase. Nurses systematically review collected data to assess the effectiveness of nursing interventions and the patient's overall progress. This process involves examining various types of data, including vital signs, lab results, pain assessments, and patient feedback. By examining data, nurses can determine whether the patient's health outcomes align with the goals set in the care plan. The

evaluation of data is also crucial for ensuring high-quality patient care, as it informs any necessary changes or adjustments to the care plan. It helps the nurse identify trends, understand the patient's response to treatment, and make evidence-based decisions. Thorough evaluation ensures that care remains patient-centered and is continuously adapted to meet the patient's evolving needs.

### Compare Activities to Identified Outcomes

When comparing activities to identified outcomes, nurses carefully assess the interventions implemented during patient care and evaluate their contribution to achieving the desired goals and outcomes. They review the care plan to identify specific objectives and measurable criteria established for each patient's condition or situation.

Then, nurses systematically compare the activities performed during care delivery to the identified outcomes to determine whether progress has been made toward achieving the desired goals. For example, if the goal is to improve mobility in a postoperative patient, the nurse will assess whether interventions, such as ambulation exercises and physical therapy sessions, have led to increased mobility and independence. Comparing provides nurses with valuable insights into the effectiveness of interventions, helps them identify areas for improvement, and empowers them to make informed decisions about modifying the care plan to better meet a patient's needs and goals.

### Analyze Conclusions

The final part of the evaluation phase involves analyzing the conclusions drawn from the data assessment ([Table 14.5](#)). This crucial step determines the future course of the patient's care plan. Nurses analyze whether the care provided has achieved the desired outcomes or if there are areas where the goals have not been met.

Evaluation	When to Make the Decision	Actions to Take	Rationale
Goal met	Patient's condition or situation aligns with expected outcomes defined in the care plan.	Continue with current plan of care.	Interventions are effective and patient is progressing toward desired outcomes. No need to modify current strategies unless the patient's condition changes or new goals emerge.
Goal unmet	Patient's condition does not improve as expected, new issues arise, or goals are not met.	Reassess patient's condition, review interventions, consult with healthcare professionals, and revise the care plan.	Current interventions may not be fully effective, patient's condition may have changed, or new challenges may have arisen. Modifying interventions, setting new goals, or exploring alternative approaches can optimize care delivery and improve outcomes.
Terminate	Interventions are no longer relevant, feasible, or effective in achieving desired outcomes.	Discontinue specific interventions, focus on other interventions, or adjust the care plan to remove irrelevant aspects.	Terminating interventions can be appropriate when specific goals are not met, certain treatments are no longer beneficial, or the patient's condition or preferences have changed.

**TABLE 14.5** Analyzing Conclusions

This analysis is foundational in deciding whether to continue with the current care plan, make revisions for better

outcomes, or terminate interventions that are no longer necessary. The ability to make these determinations is a key component of nursing judgment and ensures that patient care is both effective and adaptable.

## REAL RN STORIES

---

### Flexibility and Adaptation in Managing High Cholesterol

**Nurse:** Junot, RN, BSN

**Clinical setting:** Community health clinic

**Years in practice:** 6

**Facility location:** San Diego, California

In my six years as a registered nurse, particularly in a community health setting, I've learned the importance of being adaptable and responsive to patient care plans. A memorable case that highlights this was with Mr. Jacobs, a 52-year-old patient with a diagnosis of high cholesterol.

Initially, we developed a care plan focusing on lifestyle modifications: diet changes, increased physical activity, and regular health monitoring. Despite our efforts, Mr. Jacobs's cholesterol levels remained high during subsequent checkups. This was a clear indication that our initial plan was not as effective as we had hoped.

Acknowledging this, we revised Mr. Jacobs's care plan. We introduced a more structured diet program and the provider added a cholesterol-lowering medication. We also involved a dietitian for more personalized dietary guidance and scheduled more frequent follow-ups to closely monitor his progress.

The revised plan showed significant improvement in Mr. Jacobs's cholesterol levels. He became more engaged in his care, often sharing his new recipes and exercise routines with us. His dedication and our collaborative approach paid off, and over time, his cholesterol levels stabilized to a point where we could gradually reduce and eventually terminate the medication.

This experience with Mr. Jacobs reinforced the dynamic nature of nursing care. It highlighted the necessity of continually evaluating and adjusting our care plans, staying patient-centric in our approach, and being open to changing strategies when initial plans don't yield the expected results. The success of this case was a testament to the power of collaboration, patient involvement, and the willingness to adapt for the betterment of patient health.

---

## 14.4 Evaluation Methods

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe quality assurance programs used in the evaluation phase
- Recognize how quality improvement programs guide patient care
- Identify how patient satisfaction programs influence quality of care
- Recognize how nursing-specific patient safety and quality initiative programs are incorporated into the evaluation phase

In nursing, quality is the cornerstone of effective patient care and positive health outcomes. Quality can be defined as the degree to which nursing services for healthcare consumers, families, groups, communities, and populations increase the likelihood of desirable outcomes and are consistent with evolving nursing knowledge (Agency for Healthcare Research and Quality, 2020). This definition underscores the dynamic nature of nursing, highlighting the necessity for services to achieve desired outcomes and evolve in tandem with expanding knowledge and practices in the field.

Quality in nursing is a multifaceted concept, encompassing patient safety, effectiveness, efficiency, equity, timeliness, and patient-centeredness. More information about quality is provided in [Chapter 15 Evidence-Based Research, Quality Improvement, and Collaborative Practice](#).

This module focuses on the connection between quality and the evaluation phase of the nursing process. As discussed in earlier chapters, evaluation in nursing is not just an endpoint—it's a vital component of a continuous cycle of improvement. Through evaluation, nurses ensure that their practice is based on the best available evidence

and is responsive to the unique needs and preferences of each patient.

## Quality Assurance Programs

As a crucial part of many industries and professions, **quality assurance (QA)** is oversight that ensures current quality standards are met and that staff receive the education and infrastructure support to maintain quality (Selvi, 2018). In nursing, quality encompasses behaviors or processes that result in **quality health care**. Such actions utilize practices that are consistent with current evidence and knowledge to improve the chances of preferred patient outcomes and decrease the chances of negative outcomes, such as errors.

QA programs in nursing range widely, reflecting the diversity of the healthcare field. Infection control protocols, patient safety measures, staff competency assessments, and performance reviews of clinical procedures are all examples of QA. A common theme among the programs is that they use systematic assessments, audits, and reviews to monitor performance, identify areas for improvement, and implement strategies to enhance the quality of patient care.

By integrating QA programs into the evaluation phase, healthcare organizations can proactively address issues, optimize care-delivery processes, and improve patient outcomes and satisfaction. In an inpatient setting, a QA program might focus on reducing hospital-acquired infections through rigorous hygiene practices and patient monitoring. In a community health setting, QA could involve ensuring home health nurses have up-to-date training in the latest home-care techniques and technologies. Regardless of their particular focus, QA programs typically involve a systematic process of oversight to ensure that all relevant aspects of patient care are continuously monitored and improved. The aim is to maintain quality care and ensure that healthcare staff, including nurses, are equipped with the necessary education, skills, and support infrastructure to uphold these standards.

The **Donabedian model** is a widely used framework for evaluating the quality of healthcare delivery. It is a well-known model for thinking about QA that identifies three dimensions of care ([Figure 14.4](#)) (ACT Academy, n.d.). Each component of the model has an important role:

- **Structure:** Pertains to the organizational and environmental factors that shape healthcare services, including the physical resources, staffing levels, and policies in place.
- **Process:** Includes the activities and interactions involved in delivering care, such as clinical procedures and communication among healthcare team members.
- **Outcomes:** Refers to the results or effects of healthcare services on patient health and satisfaction. It emphasizes the importance of evaluating the technical aspects of care delivery and its influence on patient outcomes and experiences.

**FIGURE 14.4** Many QA programs focus on three dimensions: the structures within which care occurs, the processes through which care is delivered, and the outcomes of patients and populations who receive care. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Structure Evaluation

A **structure evaluation** is an assessment of the characteristics of a healthcare system or provider. These include the facilities, equipment, staffing qualifications and levels (e.g., the ratio of providers to patients), and other aspects of the physical and organizational infrastructure (ACT Academy, n.d.). A structure evaluation can provide a foundational understanding of a healthcare entity's capability to deliver quality care, enabling healthcare providers and administrators to identify areas needing improvement.

For example, hospital leadership might perform a structure evaluation to assess the adequacy and up-to-dateness of medical equipment, the physical layout of patient care areas, and the availability of necessary resources such as intensive care units or specialized labs. Staffing patterns could also be evaluated to determine whether there are enough qualified healthcare professionals to meet patient needs. The evaluation might reveal the need for more specialized nurses in a neonatal unit or for updated magnetic resonance imaging (MRI) machines to enhance diagnostic capabilities.

### Process Evaluation

A **process evaluation** assesses how a system or provider delivers health care. It focuses on the procedures, protocols, and interactions involved in patient care. This type of evaluation sheds light on the actual practices and methods used in patient care, which directly affect patient outcomes. Through process evaluation, healthcare providers can identify inefficiencies or shortcomings in their care-delivery methods and make necessary adjustments to overcome them (ACT Academy, n.d.).

In a hospital setting, a process evaluation might examine how patient care is managed from admission to discharge, including how efficiently patients are triaged in the emergency room, whether best practices and protocols are followed for surgical procedures, and how effectively patient education and follow-up care is conducted. For instance, the evaluation might find that improving communication between different departments, such as surgery and postoperative care, could enhance overall patient care efficiency and outcomes.

### Outcome Evaluation

An **outcome evaluation** is the assessment of healthcare outcomes on patients and populations. It measures the effectiveness of healthcare interventions and services by looking at metrics such as recovery rates, complication rates, and patient satisfaction. This evaluation provides concrete data on the effects of healthcare services, informing decisions on how to improve care quality and patient experiences (ACT Academy, n.d.). By focusing on tangible results, outcome evaluation helps hospitals identify successful practices and areas needing improvement, ultimately guiding strategic decisions to enhance patient care quality and safety.

Within a hospital, outcome evaluations might focus on specific departments or treatments. For example, evaluating the outcomes of a cardiology department might involve analyzing patient recovery rates after cardiac surgeries, the incidence of postoperative complications, and patient satisfaction with the care received. This evaluation could reveal trends such as a higher-than-average readmission rate, prompting a review of discharge procedures and postdischarge follow-up care.

Outcome evaluations can also extend to broader health outcomes, such as assessing the impact of a hospital's diabetes management program on the overall health and quality of life of patients with diabetes in the community. By examining factors such as blood sugar control, complication rates, and patient adherence to treatment plans, hospitals can gauge the effectiveness of their care protocols and patient education efforts, leading to more tailored and effective patient care strategies.

### Quality Improvement Programs

The aim of a QA program is to ensure providers are meeting quality standards. But what happens if evaluations determine they are not or that standards are inadequate? In these cases, the question shifts from how to assess and assure quality to how to *improve* quality.

In health care, **quality improvement (QI)** is a systematic framework for enhancing patient care and outcomes (Kelly, 2022). Central to QI is the continuous process of identifying areas for improvement and implementing strategies to achieve better patient outcomes, efficiency, and service quality. Healthcare organizations typically have QI programs in place, and providers, including nurses, can become certified in QI. The certification allows them to showcase their expertise and commitment to improving care quality. A quality improvement nurse plays a pivotal role in QI programs, often leading initiatives and guiding implementation.

### Systems and Processes

QI systems and processes vary across healthcare organizations. In a hospital, QI might focus on reducing patient readmission rates or enhancing surgical outcomes. In private practice, QI efforts could center on improving patient wait times and enhancing the patient-provider communication process. Assisted living facilities might implement QI processes to improve resident safety measures and medication management protocols. Each setting requires a unique approach to QI, tailored to its specific patient population and care-delivery model. However, most QI programs include several areas of focus, including the experiences of patients and team members and the usage of data to reveal issues and guide solutions.

### Focus on Patients

The patient-focused aspect of QI programs centers on enhancing the patient experience and outcomes. This

approach involves tailoring healthcare services to meet the specific needs and preferences of patients, ensuring their involvement in care decisions, and regularly gathering and responding to patient feedback.

In diverse healthcare settings, focusing on patients manifests in different ways. In outpatient clinics, patient-focused QI might involve reducing waiting times and improving systems for scheduling appointments. In hospitals, it could include creating initiatives to improve patient-provider communication and developing more effective pain management protocols. Assisted living facilities may implement QI projects that enhance the personalization of care plans, ensuring that residents' preferences and life histories are considered in daily care activities. Across all settings, the emphasis is on recognizing and addressing the unique needs and experiences of patients to improve their overall healthcare journey.

## PATIENT CONVERSATIONS

---

### Addressing Patient Concerns for Quality Improvement

Crucial to patient-centered care is providing patients with an opportunity to give feedback on their experience. This is especially important when the patient is dissatisfied with an aspect of their care, as in the following conversation between a nurse and a patient prior to their discharge.

**Nurse:** Good afternoon, Ms. Smith. I'm glad to hear your treatment went well. I'm sure you're looking forward to going home.

**Patient:** Yes, I can't wait.

**Nurse:** We're continuously working to improve our care, and your feedback is vital. Can you share how you felt about your experience with us?

**Patient:** Well, the treatment was fine, but I felt rushed whenever I had questions for the staff. It made me a bit uncomfortable.

**Nurse:** I'm sorry to hear that you felt rushed, Ms. Smith. It's important to us that our patients feel heard and understood. Can you tell me more about when this happened?

**Patient:** Mostly during the morning rounds. The staff seemed very busy, and I didn't want to bother them, but I had questions about my medications and aftercare.

**Nurse:** Thank you for sharing that. We do have busy moments, but that shouldn't prevent us from addressing your concerns thoroughly. I'll bring this up with our team so we can improve our communication, especially during busy times. We might need to adjust our morning routine or provide additional support during peak hours.

**Patient:** That would be great. I just wanted a bit more time to understand my care plan and what I needed to do after going home.

**Nurse:** Absolutely, Ms. Smith. Understanding your care plan is crucial for your recovery. Maybe we could explore options such as designated Q&A time during rounds. I'll also make sure that a member of the team gives you a follow-up call tomorrow. Would that be helpful?

**Patient:** Yes, a follow-up call sounds like a good idea. I also think having a set time for questions would have eased my concerns.

**Nurse:** I'm glad to hear that, and I appreciate your feedback. We'll work on implementing these changes to improve our patients' experiences. Your insights are invaluable in helping us provide better care. If you have any more suggestions or concerns, please feel free to share them.

---

### Focus on the Team

The team-focused aspect of QI in health care emphasizes the importance of collaboration, communication, and professional development among healthcare workers. This approach recognizes that high-quality patient care results from coordinated efforts among various healthcare professionals, each contributing their expertise to help solve problems.

For example, in hospital settings, team-focused QI might involve interdisciplinary rounds where providers, nurses, and other healthcare professionals collaboratively discuss patient care plans, ensuring comprehensive and coordinated care. In a primary care clinic, QI could be focused on enhancing team communication and coordination, particularly in managing patients with complex care needs and multiple chronic conditions. In home health care, QI initiatives may emphasize training and developing a cohesive team approach, with nurses, therapists, and caregivers working together to provide consistent and effective care in the patient's home environment. These initiatives foster a culture of teamwork and continuous learning, which are key to improving patient outcomes and staff satisfaction.

### Focus on the Use of Data

The data focus in QI programs includes systematically collecting, analyzing, and applying healthcare data to inform and improve care practices. This approach leverages data to identify trends, measure the effectiveness of interventions, and guide decision-making processes.

In hospital environments, data might be used to track patient outcomes and identify patterns in readmissions or hospital-acquired infections, leading to targeted improvement strategies. In a community health center, data analysis could focus on tailoring public health initiatives and outreach programs to health trends in the local population. In a mental health facility, data might be used to evaluate the effectiveness of different therapeutic interventions, guiding improvements in treatment approaches. Across a range of settings, the strategic use of data enables healthcare providers to make evidence-based decisions, enhancing the quality and efficiency of the care they deliver.

### Patient Satisfaction Programs

Patient satisfaction programs in health care are designed to gauge and improve the experience of patients during their interaction with healthcare systems. These programs vary in scope and method but aim to collect feedback from patients about their care, which can then be used to improve service delivery.

Satisfaction measurement often uses data collected through patient surveys, suggestion boxes, or direct interviews. These tools capture the patient's perspective on various aspects of care, such as the quality of communication with healthcare providers, the level of comfort and cleanliness in the facility, the adequacy of information provided about treatments, and overall satisfaction with the care received. Some programs invite patients and families to participate in policy-making and program development. For example, patient advisory councils collaborate with providers to improve the healthcare experience (Boissy & Lloyd, 2024). This approach is increasingly relevant as healthcare institutions aim to enhance patient satisfaction, a key metric under the Affordable Care Act (ACA), which ties patient experience to reimbursement rates.

### Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS)

The **Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS)** is a standardized survey instrument and data collection methodology for measuring patient perspectives on hospital care (Centers for Medicare & Medicaid Services, 2023). HCAHPS (pronounced "H-caps") was developed by the Centers for Medicare & Medicaid Services (CMS) in partnership with the Agency for Healthcare Research and Quality (AHRQ) to provide a standardized measurement of patient satisfaction across all hospitals in the United States. HCAHPS was implemented in October 2006, and the first results were publicly reported in March 2008.

The rationale behind HCAHPS is to provide objective and comparable information about patients' perspectives on hospital care, which can be used to improve the quality of healthcare services. The survey consists of twenty-nine questions, nineteen of which cover critical aspects of the hospital experience, such as the communication and responsiveness of the staff, the cleanliness of the facilities, and the usefulness of discharge information; patients are also asked to give the hospital an overall rating and to say whether they would recommend it to others.

The administration of the HCAHPS survey is strictly regulated to ensure consistency and reliability. Hospitals can administer the survey through mail, telephone, or a combination of methods. The survey is given to a random sample of adult patients between forty-eight hours and six weeks after discharge, excluding those with psychiatric diagnoses. The results are publicly reported, allowing for comparison across hospitals and fostering transparency in healthcare quality.

The effect of HCAHPS is significant, leading hospitals to focus more on patient-centered care (PCC), enhance efforts at transparency and accountability, and prioritize improvements in areas directly affecting patient satisfaction. For

example, many hospitals have developed specific initiatives to improve communication skills of healthcare providers, enhance the hospital environment for patient comfort, and streamline discharge processes for better patient understanding of posthospital care. These initiatives are not only aimed at improving patient satisfaction scores but also at enhancing the overall quality of care and patient outcomes. HCAHPS has also influenced reimbursement rates under CMS policies. Hospitals with better patient satisfaction scores may receive higher reimbursement, creating a financial incentive to improve patient experience.

### Nursing-Specific Patient Safety and Quality Initiatives

Patient safety and quality initiatives are critical components of health care that focus on minimizing risks, errors, and harm to patients during the delivery of care. These initiatives encompass a broad range of practices, from ensuring basic patient safety standards, such as hygiene and infection control, to implementing complex clinical protocols designed to improve the quality of care. Central to these efforts is the commitment to creating a healthcare environment that prioritizes patient well-being, safety, and the delivery of high-standard healthcare services. Modern nurses have important roles in these initiatives, which foster a culture of continuous improvement and accountability within healthcare organizations.

#### Nursing-Sensitive Quality Indicators

Specific metrics, called **nursing-sensitive quality indicators**, influence nursing behaviors that reflect the quality of nursing care (Phillips et al., 2021). Nurses who provide quality care can be identified by looking at desirable patient outcomes such as low fall rates, few instances of pressure ulcers and hospital-acquired infections, and high patient satisfaction scores. These indicators also cover structural and process factors such as nurse staffing levels, turnover rates, and care coordination ([Table 14.6](#)).

Nursing-Sensitive Quality Indicator	Structure	Process	Outcome
Nursing hours per patient day	X		
Patient falls		X	X
Patient falls with injury		X	X
Pediatric pain assessment, intervention, and reassessment (AIR) cycle		X	
Pediatric peripheral intravenous infiltration rate			X
Pressure ulcer prevalence		X	X
Psychiatric physical/sexual assault rate			X
Restraint prevalence			X
RN satisfaction survey options		X	X
Nursing education and training	X		
Nurse staffing levels	X		
Availability of nursing supplies	X		
Nurse-to-patient ratio	X		
Nursing certification	X		

**TABLE 14.6** Nursing Sensitive Quality Indicators (Source: Oner et al., 2021.)

Nursing-Sensitive Quality Indicator	Structure	Process	Outcome
Skill mix	X		
Voluntary nurse turnover	X		
Nurse vacancy rate	X		
Nosocomial infections			X

**TABLE 14.6** Nursing Sensitive Quality Indicators (Source: Oner et al., 2021.)

Nursing-sensitive quality indicators are essential to QA and QI programs. They are vital to highlighting areas where nursing care directly affects patient outcomes. For example, in assessing patient fall rates, hospitals can identify the effectiveness of their fall prevention protocols. By monitoring pressure ulcer prevalence, healthcare facilities can evaluate the adequacy of patient mobility and skin care regimens provided by nurses. These indicators help pinpoint areas for improvement as well as recognize and replicate successful nursing practices across different settings.

### National Database of Nursing Quality Indicators (NDNQI)

The **National Database of Nursing Quality Indicators (NDNQI)** is a comprehensive database that provides standardized monitoring of nursing-sensitive quality indicators (Madaris, 2023). Developed by the ANA, the NDNQI allows healthcare organizations to compare their performance against national and regional benchmarks in key areas of nursing care and patient outcomes. The data collected in NDNQI encompass a range of indicators, such as patient falls, pressure ulcers, nursing care hours, staff turnover, and patient satisfaction levels.

NDNQI is a valuable tool for healthcare organizations that want to identify areas of strength and areas needing improvement. A hospital can use NDNQI data to benchmark its pressure ulcer rates against similar institutions and develop targeted interventions to reduce these incidents. The database also aids with tracking the effectiveness of implemented changes over time, allowing hospitals to see the tangible effects of their quality improvement efforts.

NDNQI also provides insights to guide staffing decisions, which helps hospitals ensure they have the appropriate nurse-to-patient ratios and skill mixes to deliver optimal care. By analyzing trends and patterns from the NDNQI, healthcare administrators and nursing leaders can make evidence-based decisions to enhance patient safety and care quality. The database is also instrumental in supporting research and policy development in nursing care, contributing to advancing the nursing profession and healthcare delivery as a whole.

### LINK TO LEARNING

The National Database of Nursing Quality Indicators (NDNQI) is managed by Press Ganey, a healthcare company that also distributes a popular survey on outpatient satisfaction. Read this [Press Ganey blog \(https://openstax.org/r/77PressGaneyBlg\)](https://openstax.org/r/77PressGaneyBlg) to learn more about the purpose, content, and uses of the NDNQI.

## 14.5 Guidelines for Effective Documentation

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify how to document data collected during the implementation phase
- Describe requirements for documentation of risk management
- Define how to document evaluation of interventions
- Describe the importance of accuracy when documenting
- Identify appropriate terminology to use when documenting
- Recognize types of source-oriented documentation
- Describe different problem-oriented types of documentation

Nurses document a wide range of data—including vital signs, medication administration, results of assessments,

and responses to treatment and other interventions—for a variety of purposes. Documenting information accurately and comprehensively ensures continuity of care, supports clinical decision-making, manages risk, and aids in evaluating the effectiveness of interventions.

The ANA has articulated six principles for high-quality documentation by nurses ([Table 14.7](#)) (ANA, 2010). This module demonstrates how these principles apply to documentation in the real world, as well as the various purposes and components of high-quality documentation.

Principle	Explanation
1. Documentation characteristics	High-quality documentation has several identifiable characteristics, including accessibility, completeness, legibility, and timeliness.
2. Education and training	Nurses must receive sufficient education and training to ensure they are capable of performing high-quality documentation.
3. Policies and procedures	Nurses must know and apply all of their organization's policies and procedures relevant to documentation.
4. Protection systems	Documentation must happen in systems that have been designed to ensure patient security and confidentiality.
5. Documentation entries	Each documented entry must be authenticated and made in a standardized manner, with an accurate date and time stamp.
6. Standardized terminologies	All nurses must use a standardized, agreed-upon terminology to describe the steps in the nursing process and patient symptoms and conditions.

**TABLE 14.7** ANA Nursing Documentation Principles

## LINK TO LEARNING

The ANA's six principles for nursing documentation are explained in [this pamphlet \(https://openstax.org/r/77ANA6Principle\)](https://openstax.org/r/77ANA6Principle) along with a variety of recommendations for effective documentation.

## Documenting Data Collected

As discussed in [12.3 Collection of Assessment Data](#), data consist of information that nurses gather about a patient's health status. Baseline and ongoing assessments of the patient's health status, including the recording of vital signs such as blood pressure, heart rate, temperature, and respiratory rate are among the most critical aspects of nursing documentation. Nurses also meticulously document specific assessments related to the patient's condition, such as pain levels, mobility, nutritional status, and mental health assessments. These data form the foundation upon which treatment plans are developed and adjusted.

Another crucial aspect of nursing documentation is the administration of medications and treatments, which must include the time, dosage, route, and any patient reactions or side effects. This information is vital for managing the patient's treatment and ensuring other healthcare providers are aware of the patient's current interventions.

Documentation extends to patient education and understanding, with nurses recording the information provided to patients and their families, including instructions for care, explanations of procedures, and any educational materials. This aspect ensures that patient education is integrated into the care plan and that there is a record of the patient's understanding and consent for various aspects of that care.

## Changes in Patient Condition

Documenting changes in a patient's condition, whether improvements or deteriorations, is a fundamental

responsibility of nursing practice. Changes in patient condition can range from subtle shifts in vital signs to more significant clinical changes, such as adverse reactions to medications, improvement or worsening of symptoms, or positive responses to treatment interventions.

There are two main reasons why documenting changes is an essential part of patient care:

1. It guides clinical decisions by helping the care team recognize patterns or trends in a patient's condition, which is crucial for early intervention if adverse developments arise.
2. It ensures effective communication within the healthcare team, keeping all members aware of the patient's current status and recent changes, even those without direct contact with the patient. Lastly, it provides a clear and objective record that can be referenced in future care planning and evaluation.

In the Clinical Judgment Measurement Model (CJMM), documenting changes in a patient's condition aligns with the steps of Recognizing Cues and Analyzing Cues. By systematically recording changes, nurses gather crucial information (cues), which is then analyzed to inform clinical judgments and interventions, ensuring that patient care is responsive, timely, and based on the most current and accurate information available. (Next Generation NCLEX, n.d.).

## LIFE-STAGE CONTEXT

---

### Changes in Patient Condition across Different Age Groups

Nurses must consider the unique physiological and developmental characteristics associated with different life stages when documenting changes in a patient's condition. This attention to age-specific details is crucial in accurately interpreting and responding to changes in patient condition.

- **Neonates and infants:** In neonatal and infant patients, subtle changes can be significant. For example, a slight change in feeding patterns, activity level, or cry pitch may indicate discomfort or illness, as infants cannot verbally communicate their symptoms. Nurses should closely monitor and document parameters such as feeding tolerance, stool and urine output, and skin color, as these can be early indicators of changes in condition.
- **Children:** With pediatric patients, especially those with limited communication skills, changes in behavior or play can be important cues. A child who is usually active but becomes withdrawn or shows changes in eating and sleeping patterns may be experiencing discomfort or illness. Documenting these behavioral changes alongside physical symptoms is vital in assessing the child's overall condition.
- **Adolescents:** Adolescents may be more capable of expressing their symptoms, but they can also be reluctant to share concerns about their health. Nurses should document both the verbalized symptoms and observed behaviors, such as changes in social interaction or school performance, which can be indicators of underlying health issues.
- **Adults and older adults:** In adults, especially older patients, nurses should be vigilant about documenting even minor changes in condition, as they can be early signs of more serious health concerns. For example, slight confusion or memory lapses in an older adult patient might be the first signs of a urinary tract infection or other systemic issue. In these age groups, it's also important to document baseline cognitive function to recognize any deviations.

Across all life stages, effective documentation of changes in a patient's condition includes noting physical symptoms and observing and recording behavioral and cognitive changes. This comprehensive approach ensures that care is tailored to the specific needs of each age group, enhancing patient safety and care quality.

---

### Documenting Risk Management

Risk management in nursing involves identifying, assessing, and taking steps to minimize risks that might harm patients or healthcare providers. Documentation provides a detailed record of potential risks and the measures taken to manage them. Effective documentation in risk management promotes patient safety, enhances the quality of care, and serves as a legal record. It also enables healthcare providers to track the effectiveness of interventions designed to mitigate these risks.

### Potential Safety Concerns

Nurses are often the first to identify situations that may pose a risk to patient safety, such as environmental hazards, the potential for medication errors, or risks associated with patient mobility. For example, a nurse might document observations of a cluttered room that could increase the risk of falls for an older adult patient. This documentation is vital for initiating immediate actions to remove the hazard and informing the broader healthcare team about the risk. Another example is the documentation of potential allergic reactions to medications. If a nurse observes signs of an allergy, such as a rash or difficulty breathing, after medication administration, this information should be documented immediately. It is crucial for healthcare providers to make informed decisions about medication adjustments and to monitor for similar risks in the future.

### Development of New Problems

Nurses also document the development of new problems or complications in patient care, which is essential for effective risk management. For instance, if a patient develops bedsores due to limited mobility, this must be documented as a new problem. The nurse would record the location, size, and appearance of the bedsores, along with any interventions applied, such as repositioning the patient or wound care. This documentation facilitates appropriate ongoing care and serves as a record for evaluating the effectiveness of the interventions and adjusting care plans as needed.

## REAL RN STORIES

---

### Proactive Documentation in Risk Management

**Nurse:** Jasmine, RN, BSN

**Clinical setting:** Postsurgical unit

**Years in practice:** 6

**Facility location:** Billings, Montana

During my years as a nurse on the postsurgical unit, I've seen firsthand how proactive documentation can significantly impact patient outcomes, especially in risk management. One experience in particular stands out to me, emphasizing the importance of detailed observation and timely documentation in identifying and managing risks.

I was caring for Miss McGregor, who had undergone abdominal surgery. During my routine postoperative checks, I noticed a slight redness and swelling around her incision site. Although these postsurgical symptoms can be normal, my intuition told me to monitor this closely. I documented my observations, including the size and appearance of the redness, and informed the surgical team.

Over the next few hours, I continued to document any changes I observed in Miss McGregor's condition, noting an increase in swelling and the onset of a mild fever. Because of this detailed and timely documentation, the surgical team decided to reassess her wound sooner than the scheduled time. It turned out Miss McGregor was developing an infection, and due to the early detection, we were able to initiate antibiotic therapy promptly.

This incident reinforced to me the critical role of documentation in managing patient risks. By accurately recording even the subtle changes in Miss McGregor's condition, I was able to provide the surgical team with the necessary information to make a timely and informed decision. Our prompt action prevented further complications and expedited Miss McGregor's recovery. It was a clear reminder of how our vigilance and records as nurses can make a real difference in patient outcomes.

---

### Documenting Evaluation of Intervention

Evaluating the results of nursing interventions is a critical component of the nursing process, allowing healthcare professionals to assess the effectiveness of their actions and make necessary adjustments to patient care. Documentation plays a crucial role in this evaluation phase, as it provides a detailed record of the interventions implemented and their outcomes. Through meticulous documentation, nurses can track the progress of a patient's condition, analyze the effectiveness of treatments, and provide a basis for future care decisions. This process is integral to ensuring that patient care is evidence-based, patient-centered, and continuously evolving to meet the individual needs of each patient.

In the context of the CJMM, documenting the evaluation of interventions aligns with the steps of Generate Solutions, Take Action, and Evaluate Outcomes. Accurate and comprehensive documentation allows for an informed evaluation of the care provided and supports the ongoing process of clinical judgment and decision-making (Next Generation NCLEX, n.d.).

### Outcome Achievement

When documenting the evaluation of interventions, one key aspect is to record whether the intervention has achieved its intended outcome. For example, if a patient is experiencing postsurgical pain, a nurse might administer pain medication as an intervention. Documenting the patient's pain level before and after medication administration provides clear evidence of whether the intervention was effective. If the pain level decreases significantly, it indicates the success of the intervention. Conversely, if there is no change or an increase in pain, it may signal the need for reevaluation and potential changes in the pain management plan. Similarly, in cases of chronic conditions such as hypertension, nurses document the patient's blood pressure readings before and after implementing lifestyle changes or medication adjustments. This ongoing documentation helps assess the long-term effectiveness of the intervention and guides future care planning.

### Document Education Provided

Another essential aspect of documentation in the evaluation phase is recording the education provided to patients and their families. Educating patients about their condition, treatment plans, and self-care is one of the most important aspects of nursing care. Documenting educational interventions, including the topics covered, the materials used, and the patient's response, is necessary for several reasons.

First, it ensures continuity of care. If a patient is transferred to another unit or readmitted later, the next care team can see what education the patient has already received and build upon it. Second, it serves as evidence of patient teaching, which is often required for compliance and accreditation purposes. For example, if the nurse teaches a patient with diabetes how to manage their blood sugar levels through diet and medication, documenting the education session records what was taught and demonstrates the patient's understanding and engagement with their care plan.

### Accurate Description of Care

Accurate documentation of care is essential in nursing, serving both medical and legal purposes. It ensures continuity of care by providing subsequent caregivers with a comprehensive understanding of a patient's history, current condition, and the care they have received. Accurately describing care also protects nurses and healthcare facilities legally, as medical records can serve as evidence in cases of disputes or litigation. The legal role of these documents emphasizes the necessity for precise, clear, and complete documentation of all elements of patient care.

It can be helpful to see how the components of accurate documentation would look in the context of a specific patient. The following is an example to consider that will be revisited throughout the chapter to help demonstrate key concepts: Mr. Ahmed is a 70-year-old patient admitted to the hospital with congestive heart failure (CHF). His condition requires careful monitoring, medication management, and patient education regarding lifestyle changes to manage his CHF effectively (Cleveland Clinic, 2023).

### What You Did

The nurse must accurately document actions taken as part of patient care to establish a clear record of all interventions, treatments, and procedures performed. This information enables the patient's healthcare providers to track the progress of care, evaluate the effectiveness of interventions, and identify deviations from the planned course of treatment. Accurate documentation also supports accountability by clearly documenting the responsibilities of each healthcare provider involved in the patient's care.

In Mr. Ahmed's case, documenting "what you did" would require the nurse to record all actions taken as part of providing his care. For example, if the nurse administered a diuretic to manage his fluid retention, the documentation should include the name of the medication, dosage, route of administration, and time given. See

[Table 14.8](#) for an example of how what you do may be documented.

- Nursing note: 0800
- Administered furosemide 40 mg orally

---

**TABLE 14.8** Documentation of Treatment, Part 1

### What You Observed

Documenting “what you observed” focuses on the nurse’s assessments and observations about Mr. Ahmed’s condition. This includes changes in his symptoms, responses to treatments, and any side effects observed. See [Table 14.9](#) for an example of how what you observe may be documented.

- Nursing note: 0800
- Administered furosemide 40 mg orally
- Nursing note: 1000
- Mr. Ahmed reports a decrease in shortness of breath. Slight edema reduction noted in bilateral lower extremities.

---

**TABLE 14.9** Documentation of Treatment, Part 2

### Chart in Real Time

Charting in real time is necessary for maintaining accurate and up-to-date patient records. In Mr. Ahmed’s case, this would mean documenting assessments, interventions, and observations as soon as they occur. See [Table 14.10](#) for an example of how the nurse may chart medication administration in real time.

- Nursing note: 0800
- Administered furosemide 40 mg orally. Patient educated about potential side effects, such as dizziness, and the importance of monitoring output. Patient verbalized understanding of education.

---

**TABLE 14.10** Documentation of Treatment, Part 3

### Chart Precautions and Preventative Measures

Documenting precautions and preventative measures is key in managing Mr. Ahmed’s CHF. This could involve noting the implementation of low-salt diet instructions, fluid restriction guidelines, and daily weight monitoring to track fluid status. See [Table 14.11](#) for an example of how the nurse may chart precautions and preventative measures.

- Nursing note: 0800
- Administered furosemide 40 mg orally. Patient educated about potential side effects, such as dizziness, and the importance of monitoring output. Provided written instructions for a low-sodium diet. Advised to limit fluid intake to 1.5 liters per day. Set up daily morning weight monitoring to track fluid changes. Patient verbalized understanding of education.

---

**TABLE 14.11** Documentation of Treatment, Part 4

In each documentation aspect within Mr. Ahmed’s chart, the focus is on providing a detailed and accurate account of the care provided to the patient, ensuring that all healthcare team members are informed and aligned in their approach to managing his CHF. This comprehensive documentation approach is integral to delivering high-quality, patient-centered care.

### Appropriate Terminology

In nursing documentation, using appropriate terminology is essential for clear and effective communication among healthcare providers. Appropriate terminology ensures that documented information is accurately conveyed and universally understood in the healthcare setting. This includes documenting with medically accepted terms, approved abbreviations, and providing complete descriptions. It also requires a focus on documenting care provided, rather than conflicts or interpersonal issues, to maintain professionalism and a patient-centered approach.

### Use Approved Abbreviations

Using approved abbreviations in medical documentation is necessary, but the nurse must only use widely recognized and accepted abbreviations within the healthcare community. For example, “BID” is a commonly accepted abbreviation meaning “twice daily.” The term comes from the Latin phrase *bis in die*. A sample documentation might read, “Administered 5 mg of metoprolol PO BID,” which is clear and concise (Mennonite College of Nursing, n.d.). Using lesser-known or outdated abbreviations can cause misunderstandings and lead to errors in patient care. Nurses should always refer to their facility’s approved abbreviation list and avoid using nonstandard abbreviations to prevent confusion or mistakes.

### LINK TO LEARNING

This comprehensive [guide to nursing abbreviations and acronyms \(https://openstax.org/r/77NursingAbbrev\)](https://openstax.org/r/77NursingAbbrev) is maintained by the Mennonite College of Nursing.

### Chart with Complete Descriptions

Although abbreviations are useful for efficiency, it’s equally important to provide complete descriptions when necessary, especially for complex or unusual situations. For instance, instead of simply documenting “wound care performed,” a more descriptive entry would be, “Cleaned wound with saline, applied new dressing, no signs of infection noted, patient reports pain level 2/10.” This level of detail ensures that anyone who reads the chart understands the care provided and the patient’s current condition. This level of detail is especially helpful when a patient’s condition is changing, or there is something out of the ordinary about their care—for example, an uncommon treatment.

### Chart Care, Not Conflicts

When documenting in patient charts, the focus should always be on the care provided and the patient’s response to that care, not conflicts or interpersonal issues that may arise. If there’s a disagreement with a patient about a treatment plan, the nurse’s documentation should include the facts of the situation rather than the disagreement. The nurse should stick to objective information and avoid opinions. This approach maintains professionalism and ensures that a patient’s chart is a factual record of care and responses, not a subjective log of disagreements or conflicts.

### PATIENT CONVERSATIONS

#### Handling Argumentative Patients

After reading this conversation between a nurse and a patient who has been prescribed a new medication, decide what the nurse should document and what does not need to be documented.

**Nurse:** Mr. Lee, this medication is important for managing your condition. It can significantly reduce your symptoms.

**Patient:** But I read about all these side effects online and I’m really worried about them.

**Nurse:** It’s good to be informed. However, the benefits of this medication are significant for your long-term health—

**Patient:** (*interrupting*): But what about the risks? I heard it can even cause liver problems.

**Nurse:** Mr. Lee, please let me finish explaining. These benefits include improved blood pressure and reduced risk of heart-related issues. Yes, there are potential side effects, like with any medication, but they are relatively rare. We monitor your health closely to mitigate these risks.

**Patient:** I just don’t want to risk more health problems. Can’t we try something else?

**Nurse:** I understand your concerns. There are alternatives, but they may not be as effective for your specific condition. Let’s go through them together and discuss with your provider. We want to ensure you’re comfortable and well-informed about your treatment.

**Patient:** Okay, I'm willing to listen, but I'm still not sure about this.

**Nurse:** That's perfectly fine, Mr. Lee. Let's explore all your options and find a solution that works best for you. Your comfort and health are our top priorities.

**Scenario follow-up:** The nurse should document this conversation by focusing on the care aspects: for example, "Discussed treatment options with Mr. Lee, who expressed concerns about potential side effects of the prescribed medication. Reviewed benefits and risks. Patient hesitant about starting medication due to side effect concerns. Arranged for consultation with the provider to discuss alternative treatments and ensure patient comfort with the plan." This style of documentation maintains professionalism, focusing on the care and treatment decisions rather than the tension in the conversation.

## Source-Oriented Documentation

A traditional method of recording healthcare information is known as **source-oriented documentation** (Table 14.12). Each healthcare professional, such as nurses, providers, therapists, and others, documents their findings and interventions in separate sections or forms. This approach makes it easy to identify the source of each piece of data. The advantage of source-oriented documentation is the clear delineation of information by discipline, making it faster and more efficient to locate specific data. It provides a detailed and chronological account of the patient's healthcare journey from various professional perspectives. However, a drawback is that it can lead to fragmented information, as separate documentation by different providers can make it challenging to get a comprehensive view of the patient's overall status. Additionally, redundancy and repetition may occur when multiple providers document similar information (Almasi et al., 2019).

Documentation Type	Purpose	Advantages	Disadvantages	Tips for Effective Use
An <b>admission sheet</b>	Initial record upon admission; includes medical history, medications, allergies, reason for admission	Baseline for patient condition; crucial reference throughout hospital stay	Can become outdated if not regularly updated	Ensure accuracy and completeness; note changes promptly
A <b>flow sheet</b>	Brief form with essential patient information	Efficient tracking of specific data over time; easy-to-spot trends	Can miss important details if not concise	Focus on key information; update frequently
A <b>narrative note</b>	Detailed account of patient's condition, care, and response in paragraph form	Provides context and detailed explanations; allows for more in-depth documentation	Time-consuming to write and read; important information can be buried	Be clear, concise, and focus on significant events; organize chronologically; use clear language and avoid medical jargon

**TABLE 14.12** Types of Source-Oriented Documentation

## Problem-Oriented Documentation

An organized approach to recording patient care that focuses on the individual problems a patient may have is called **problem-oriented documentation**. It differs from source-oriented documentation because it organizes information around patient issues rather than the source of information. This method enhances the coherence and focus of patient records, allowing healthcare providers to track the progress of each problem, the interventions implemented, and the outcomes (Altman et al., 2023). Problem-oriented documentation typically leads to better communication among healthcare team members because it provides a clear, concise overview of patient issues,

interventions, and outcomes. However, it also requires a thorough understanding of patient problems and consistent documentation practices to maintain effectiveness.

Problem-oriented documentation also comes in different forms, including the SOAP and PIE methods, **focused charting**, charting by exception, and the case management model.

## LINK TO LEARNING

In this video by Mometrix Nursing, you can learn some [tips for creating SOAP notes \(https://openstax.org/r/77SOAPnotes\)](https://openstax.org/r/77SOAPnotes).

### SOAP Method

The **SOAP method** is a widely used form of problem-oriented documentation, structured into four components: Subjective, Objective, Assessment, and Plan (Sindhu, 2020).

- Subjective: This section records the patient’s perspective, including symptoms and feelings.
- Objective: This section documents objective data, such as vital signs, physical exam findings, and lab results.
- Assessment: This section documents the nurse’s clinical judgment about the patient’s condition based on subjective and objective information.
- Plan: This section outlines the plan of care or interventions to address the patient’s problem.

The SOAP method is beneficial for its structured and comprehensive approach to documenting patient care; however, it requires careful attention to ensure all aspects of the patient’s condition are accurately captured. An example SOAP note could look like [Table 14.13](#).

Subjective	Patient reports worsening SOB and fatigue over the last forty-eight hours.
Objective	Vital signs: BP 150/95, HR 110, RR 28, O <sub>2</sub> sat 89 percent on room air. Auscultation reveals bilateral crackles in lung bases.
Assessment	CHF exacerbation
Plan	Notify provider, stat chest x-ray, supplement oxygen via nasal cannula

**TABLE 14.13** SOAP Method

Sometimes, the SOAP method will be expanded to the SOAPIER method. The SOAPIER method extends the traditional SOAP format to enhance documentation by integrating ongoing evaluation and revision, ensuring a dynamic approach to patient care management.

- Intervention: Documents specific actions taken as part of the plan, including procedures performed, medications administered, and therapeutic interventions.
- Evaluation: Describes the patient’s response to interventions, assessing their effectiveness and any changes in the patient’s condition.
- Revision: Documents any adjustments made to the plan based on evaluation findings or changes in the patient’s status.

An example SOAPIER note could look like [Table 14.14](#).

Subjective	Patient reports worsening SOB and fatigue over the last forty-eight hours.
Objective	Vital signs: BP 150/95, HR 110, RR 28, O <sub>2</sub> sat 89 percent on room air. Auscultation reveals bilateral crackles in lung bases.
Assessment	CHF exacerbation

**TABLE 14.14** SOAPIER Note

Plan	Notify provider, stat chest x-ray, supplement oxygen via nasal cannula
Intervention	Administered supplemental oxygen at 2 L/min via nasal cannula.
Evaluation	After one hour, patient's O <sub>2</sub> saturation improved to 94 percent, with decreased respiratory distress noted.
Revision	Revised plan to continue oxygen therapy at 2 L/min and monitor closely for further improvement.

**TABLE 14.14** SOAPIER Note

### PIE Method

The **PIE method** involves another acronym, with each letter representing a component of the documentation (Almasi et al., 2019):

- Problem: The nurse identifies the patient's problem.
- Intervention: The nurse documents the actions taken to address the problem.
- Evaluation: The nurse describes the patient's response to the intervention.

This method ensures a direct link between identified problems and the care provided. Its focus on ongoing evaluation makes it helpful when adapting the care plan, but it can be time-consuming due to the level of detail required. An example of a PIE method note could look like [Table 14.15](#).

Problem	Uncontrolled hypertension
Intervention	Education on the importance of medication adherence and compliance with lifestyle change recommendations.
Evaluation	After two weeks of intervention, patient BP still elevated at 160/98. Medication adjustment may be necessary.

**TABLE 14.15** PIE Method

### Focused Charting

Focused charting involves documenting care and observations based on specific patient concerns or behaviors. A note typically includes four parts, which form the acronym F-DAR (Magbanua, 2024).

- Focus: Briefly note the main purpose of the note or patient concern.
- Data: Information about the patient's condition or behavior.
- Action: The interventions or care provided.
- Response: The patient's response to the action(s) taken.

Focused charting is beneficial for its patient-centered approach and flexibility, allowing nurses to adapt the documentation to the specific needs and issues of each patient. A note using the F-DAR format could look like [Table 14.16](#).

Focus	Patient reports pain at incision.
Data	Patient rates pain at 8/10. Incision site is red, warm, and there is a small amount of purulent drainage.
Action	Wound cleaned and dressed, antibiotics administered per provider order.
Response	Reassessed one hour later, patient reports pain 4/10.

**TABLE 14.16** Focused Charting

### Charting by Exception

**Charting by exception** is based on the assumption that unless a deviation from standard or expected outcomes is observed, a patient's care is following the established plan (Roberts, 2020). Because only significant findings or exceptions to norms are documented, this method saves time and reduces the volume of paperwork. However, this approach may overlook important details that do not qualify as exceptions but are still relevant to patient care.

### Case Management Model

The **case management model** involves comprehensive documentation that coordinates and tracks patient care across different stages and settings. This model focuses on continuity of care, especially for patients with complex or long-term health needs. It encompasses a broad overview of patient care, from admission to discharge and beyond. The challenge with this model is maintaining a high level of detail over extended periods and across various healthcare settings (Registered Nursing, 2023).

## Summary

### 14.1 The Nurse's Role in Implementation

The implementation phase is crucial in the nursing process, involving the active execution of planned interventions while adapting to the patient's evolving needs. Nurses apply their clinical knowledge to perform various tasks, from administering medications to assisting with rehabilitation exercises tailored to facilitate the patient's recovery and well-being.

Continuous monitoring and assessment are key because they allow nurses to gauge the effectiveness of interventions and make necessary adjustments, ensuring care remains dynamic, responsive, and patient-centered. Nurses prioritize patient needs, allocate resources efficiently, and ensure smooth transitions between care settings, particularly during discharge. From beginning to end, the implementation phase calls on the nurse's critical-thinking and clinical judgment skills, psychomotor abilities for performing interventions safely and effectively, interpersonal communication skills for providing patient support, and cognitive skills for decision-making and flexibility.

### 14.2 Types of Interventions

The implementation phase of care highlights the complex and essential nature of nursing and involves applying various interventions tailored to each patient's specific needs. Nurses utilize different interventions to address actual, potential, and collaborative problems based on nursing diagnoses. Interventions can be direct (e.g., medication administration) or indirect (e.g., care coordination). The interventions can also be dependent (provider-ordered), independent (nurse-initiated), and interdependent (collaborative). The type of intervention is chosen based on a patient's situation and the nursing diagnosis. Prioritization of interventions is also crucial. Nurses prioritize interventions using frameworks such as the ABC framework and Maslow's hierarchy to address urgent needs efficiently, emphasizing patient safety. Effective delegation and collaboration within interdisciplinary teams are also essential, combining clinical expertise with a holistic understanding of patient needs and leveraging each member's expertise for safe, effective care—all of which facilitate a patient's recovery and promote well-being.

### 14.3 The Nurse's Role in Evaluation

During the evaluation phase, the nurse must continue to call on the skills for documentation that have helped them to record patient data at other points in time delivering care. Effective documentation in nursing is crucial for patient care, serving as a key communication tool, legal safeguard, and continuity of care facilitator. All documentation must be accurate, comprehensive, and timely to reflect the patient's condition and the care provided, as well as to support the evaluation of intervention effectiveness. It must use appropriate terminology and abbreviations to capture changes in the patient's condition, including improvements and declines, to guide clinical decisions and care adjustments.

Nursing documentation is an essential tool for risk management, as it provides a system for measuring outcomes and effectiveness. It is during the evaluation stage when the nurse may use documentation to assess "what went wrong" and look for opportunities to "do better." This may include taking steps to reduce errors in documentation or making it more readily available to different members of the interdisciplinary care team to promote continuity of care. All methods help the nurse organize and track patient care, interventions, and outcomes effectively and ensure clear, professional, and comprehensive records.

### 14.4 Evaluation Methods

QA programs systematically evaluate healthcare services to ensure they align with standards and focus on structure (e.g., facilities, staff), processes (e.g., procedures, interactions), and outcomes (e.g., recovery rates, complications). QI initiatives aim to enhance patient care and outcomes by using collaborative, data-driven strategies to identify and address inefficiencies, with a strong emphasis on meeting patient needs and preferences and utilizing data analytics for informed decision-making.

Nursing-specific patient safety and quality initiatives are integral to the evaluation phase of the nursing process. These initiatives aim to minimize risks and errors in nursing care, ultimately enhancing patient safety. They achieve this by monitoring nursing-sensitive quality indicators, such as fall rates, pressure ulcers, and hospital-acquired infections. Patient satisfaction programs, such as HCAHPS, also help gather feedback to guide improvements.

Through tracking these indicators and analyzing the collected data, healthcare organizations can pinpoint areas where nursing care can be improved and implement targeted interventions. Feedback from nurses and other healthcare professionals is also incorporated to continuously refine and improve patient safety practices. A prominent example of such an initiative is the National Database of Nursing Quality Indicators (NDNQI), which collects data on nursing-sensitive indicators from hospitals nationwide, providing benchmarks for comparison and highlighting opportunities for improvement. By integrating these initiatives into the evaluation process, healthcare organizations can foster a culture of continuous improvement, ensuring that nursing care is consistently safe, effective, and patient-centered.

### 14.5 Guidelines for Effective Documentation

Effective documentation in nursing is a critical aspect of patient care, playing a key role in communication, legal protection, and continuity of care. Nurses must be able to identify the data to be collected during each phase of the nursing process and document a wide range of data, including patient assessments, medication administration, treatment responses, and patient education. To ensure it is a useful tool in risk management, the documentation must be correct, comprehensive, and timely to ensure that it completely and accurately reflects the patient's condition and the care provided. It serves not only as a record of care but also as a tool for evaluating the effectiveness of interventions and guiding future care decisions.

When documenting data collected during the implementation phase, it's crucial to note changes in a patient's condition, which may include improvements and deteriorations. These developments are essential for guiding clinical decisions and ensuring appropriate care adjustments. Accurate documentation of changes is vital for communication within the healthcare team and provides a clear and objective record for future care planning and evaluation.

Risk management is a key area where documentation plays a vital role. Nurses document potential safety concerns and the development of new problems as part of their risk management efforts. This includes noting environmental hazards, potential allergic reactions, and the onset of new symptoms or complications. Effective documentation in risk management helps in early intervention and prevention of further complications, ensuring patient safety.

It is important to use appropriate terminology in documentation, including approved abbreviations and complete descriptions. Nurses are encouraged to focus on documenting the care provided, rather than conflicts or interpersonal issues, to maintain professionalism and ensure patient-centered care.

There are several approaches to documentation, including source-oriented and problem-oriented. Source-oriented documentation segregates information based on the healthcare professional providing it, whereas problem-oriented documentation organizes records around individual patient issues. Problem-oriented methods include SOAP (Subjective, Objective, Assessment, Plan) and PIE (Problem, Intervention, Evaluation), as well as focused charting, charting by exception, and the case management model. These methods support comprehensive and coherent patient records, allowing healthcare providers to track the progress of each problem, the interventions implemented, and their outcomes.

### Key Terms

**admission sheet** the initial record filled out when a patient is admitted to a healthcare facility

**case management model** a comprehensive form of documentation that involves coordinating and tracking patient care across different stages and settings

**charting by exception** the practice of documenting only significant findings or exceptions to norms

**clinical knowledge** a nurse's understanding of health and disease processes, treatments, and interventions

**cognitive skills** the mental processes involved in understanding patient needs, planning care, problem-solving, and decision-making

**cultural sensitivity** awareness and respect of a patient's cultural background and beliefs

**dependent intervention** an action that a nurse carries out under the orders or direction of a healthcare provider, such as a physician

**direct care** interventions that involve personal contact or interaction with patients

**Donabedian model** a framework used in healthcare quality assessment and improvement that organizes the elements necessary for evaluating healthcare quality into three main categories: structure, process, and

outcomes

**evaluation** the systematic determination of a patient’s progress toward the achievement of outcomes and goals set during the care-planning process

**flow sheet** a brief form that contains the most important information about a patient; it travels in their chart

**focused charting** the practice of documenting care and observations based on specific patient concerns or behaviors

**Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS)** a standardized survey instrument and data collection methodology for measuring patients’ perspectives on hospital care throughout the United States

**implementation** the step of the nursing process when the plan of care for a patient is put into action

**independent intervention** an action that a nurse initiates and carries out based on their own clinical judgment, without instructions from others

**indirect care** interventions that are performed away from patients but are vital to their overall care

**interdependent intervention** an action that requires the nurse to coordinate with other providers as part of a care team

**interpersonal skills** the abilities that enable effective communication and interaction with patients, their families, and other healthcare professionals

**intervention** an action intended to stop a harmful outcome or promote a healthful one

**narrative notes** documentation written in paragraph form to better “tell the story” of a patient’s health

**National Database of Nursing Quality Indicators (NDNQI)** a comprehensive repository of data relevant to nursing-sensitive quality indicators in the United States

**nursing-sensitive quality indicators** specific metrics that are influenced by nursing behaviors and that reflect the quality of nursing care

**outcome evaluation** an assessment of the results of health care on patients and populations

**PIE method** a form of problem-oriented documentation consisting of Problem, Intervention, and Evaluation data

**problem-oriented documentation** a method of recording patient care that focuses on the patient’s specific health problems rather than the source of data

**process evaluation** an assessment of how a healthcare system or provider delivers care

**psychomotor skills** the practical, hands-on abilities required to effectively implement interventions

**quality assurance (QA)** oversight to ensure that current quality standards are being met across a department or agency and that staff are receiving the education and infrastructure support to maintain that quality

**quality health care** the provision of health services that improve the chances of preferred outcomes, decrease the chances for error, and are consistent with current evidence and knowledge

**quality improvement (QI)** a framework to improve patient care and outcomes systematically

**SOAP method** a form of problem-oriented documentation consisting of Subjective, Objective, Assessment, and Plan data

**source-oriented documentation** a traditional method of recording healthcare information, in which data is organized based on the person providing it

**structure evaluation** an assessment of the characteristics of a healthcare system or provider

## Assessments

### Review Questions

1. What is the emphasis for nurses during the implementation phase of the nursing process?
  - a. carrying out the established care plan
  - b. developing a new care plan for the patient
  - c. systematically determining the effectiveness of the care plan
  - d. focusing on the patient’s emotional well-being
2. What example demonstrates ongoing assessment during the implementation phase of the nursing process?
  - a. planning a patient’s future healthcare appointments
  - b. documenting a patient’s health history during their initial visit
  - c. evaluating the effectiveness of hospital-wide policies on a patient’s care

- d. monitoring a patient's pain levels and response to medication after surgery
3. What skill is essential during the implementation phase of the nursing process?
    - a. expertise in insurance policies
    - b. proficiency in critical thinking
    - c. experience managing a care team
    - d. ability to conduct diagnostic tests
  4. What two categories of patient care are included in the implementation phase of the nursing process?
    - a. direct and indirect
    - b. actual and potential
    - c. dependent and independent
    - d. physiological and psychological
  5. What type of intervention requires a provider's order before a nurse can perform it?
    - a. collaborative
    - b. dependent
    - c. independent
    - d. interdependent
  6. A nursing intervention aimed at preventing bedsores in a bedridden patient is focusing on what type of problem?
    - a. actual
    - b. collaborative
    - c. independent
    - d. potential
  7. According to the ABC framework for prioritizing nursing interventions, what type of problem should a nurse address first?
    - a. airway
    - b. breathing
    - c. circulation
    - d. pain
  8. When delegating nursing interventions, what factor is important to consider?
    - a. time of day
    - b. age of the patient
    - c. competencies of the person receiving the delegation
    - d. educational background of the person delegating the task
  9. What is the primary purpose of the evaluation phase in the nursing process?
    - a. to diagnose the patient's condition
    - b. to determine the effectiveness of care
    - c. to introduce new nursing interventions
    - d. to plan the initial nursing interventions
  10. For what reason does the nurse need to think about continuity of care during the evaluation phase?
    - a. It is when patients are initially assessed.
    - b. It is when patients are prepped for surgery.
    - c. It is when patients learn about their condition.
    - d. It is when patients transition out of the facility.
  11. How should nurses evaluate the plan of care?

- a. by delegating tasks to appropriate staff
  - b. by quizzing the patient about their condition
  - c. by determining whether goals have been met
  - d. by ending interventions that are no longer needed
- 12.** A patient has been taking medication to alleviate symptoms, and the care team determines the patient no longer has symptoms. What conclusion should the care team draw about this intervention?
- a. Delegate it.
  - b. Terminate it.
  - c. Continue administering it.
  - d. Revise it to be more effective.
- 13.** In quality assurance programs, what do structure evaluations primarily assess?
- a. how a healthcare system or provider delivers care
  - b. the results of health care on patients and populations
  - c. the characteristics of a healthcare system or provider
  - d. whether patients are satisfied or dissatisfied with care
- 14.** What would be the most likely focus of a quality improvement initiative by a healthcare provider?
- a. reducing costs
  - b. using data to support decisions
  - c. preparing nurses to service more patients
  - d. standardizing processes for all patient populations
- 15.** What is the primary purpose of the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS)?
- a. to document patient perspectives on hospital care
  - b. to measure the financial performance of hospitals
  - c. to determine the effectiveness of quality initiatives
  - d. to evaluate the technical skills of healthcare providers
- 16.** The National Database of Nursing Quality Indicators (NDNQI) is instrumental for what process?
- a. providing a platform for nursing education and research
  - b. assisting in the regulatory compliance of healthcare facilities
  - c. facilitating the monitoring and improvement of nursing practices
  - d. guiding the financial management decisions in nursing departments
- 17.** The nurse is caring for a patient and preparing to document during the implementation phase. What essential information about the patient's care will the nurse include at this phase?
- a. only the patient's initial diagnosis
  - b. general descriptions of the patient's mood
  - c. detailed and accurate records of care provided
  - d. only the medications administered to the patient
- 18.** The nurse is doing a quality review of documentation to ensure entries are comprehensive and legally compliant. What piece of documentation would the nurse identify as fulfilling this goal?
- a. "Patient seems to be feeling better today."
  - b. "Administered medication, patient did not comment."
  - c. "Patient complained about pain but I'm not sure what to do about it."
  - d. "Patient reports a decrease in pain from 7 to 4 on the pain scale after medication."
- 19.** What is a rule for using abbreviations in nursing documentation?
- a. Use abbreviations as often as possible.

- b. Use only abbreviations that are approved.
  - c. Use only abbreviations for medical jargon.
  - d. Use abbreviations that the patient recognizes.
- 20.** The nurse is advocating for the hospital where they work to use source-oriented documentation. What benefit could they highlight?
- a. It reduces the need for nurses to document routine care.
  - b. It highlights specific problems, interventions, and outcomes.
  - c. It allows for easier identification of information by discipline.
  - d. It consolidates all patient information into a single, unified document.
- 21.** What is an example of problem-oriented documentation?
- a. a narrative note by a nurse
  - b. a record of a patient's vital signs
  - c. a flow sheet of a patient's key data
  - d. a PIE note assessing a specific intervention

### Check Your Understanding Questions

1. Explain the importance of establishing priorities during the implementation phase when caring for a patient with multiple chronic conditions.
2. Explain how indirect care differs from direct care in the implementation phase of the nursing process, and provide an example of each.
3. Compare and contrast independent and interdependent interventions. Give an example of each.
4. In the context of Maslow's hierarchy of needs, explain how a nurse would prioritize interventions for a patient experiencing severe back pain and expressing feelings of loneliness.
5. How does the evaluation phase provide a system for nurses to define, explain, and measure patient care effectively?
6. Explain the role of the evaluation phase in promoting continuity of care, particularly when a patient is transitioning from hospital to home care.
7. What methods do nurses use to evaluate a plan of care, and how do these methods contribute to patient outcomes?
8. Describe the process the nurse uses to analyze conclusions during the evaluation phase and how it affects the decision-making process.
9. Explain how process evaluations in quality assurance programs contribute to the improvement of patient care.
10. How can patient satisfaction programs such as HCAHPS lead to changes in hospital policies or practices?
11. How can nursing-sensitive quality indicators influence nursing practice and patient outcomes?
12. Identify three DOs and three DON'Ts of accurate and appropriate documentation in nursing.
13. What does it mean to "chart care, not conflict"? Why is this important?
14. Provide an example of problem-oriented documentation and explain how it differs from source-oriented documentation.

### Reflection Questions

1. Reflect on how a nurse can effectively utilize both cognitive and psychomotor skills during the implementation phase for a complex patient case, such as managing care for a patient with severe burn injuries.

2. Consider a scenario in a busy healthcare setting in which prioritizing nursing interventions and effectively delegating tasks is critical. Discuss how a nurse would prioritize interventions for multiple patients and delegate tasks, considering the scope of practice and the involvement of an interdisciplinary team.
3. Imagine you are a nurse evaluating a patient who has undergone a major surgery. Reflect on how the evaluation phase enables you to determine the patient's progress; provides a system to define, explain, and measure patient care; and promotes continuity of care. Consider the implications of your findings for future care planning and family involvement.
4. Reflect on how quality assurance programs—including structure, process, and outcome evaluations—may be incorporated into the evaluation phase of nursing practice. Consider specific examples to illustrate how these evaluations contribute to the continuous improvement of patient safety and quality of care.
5. Consider the role of quality improvement programs in guiding patient care. Give a specific example and reflect on how these programs can be effectively incorporated into the evaluation phase of nursing to ensure ongoing improvement in patient outcomes and care processes.
6. Reflect on the influence of patient satisfaction programs, such as HCAHPS, on the quality of care. Provide a specific example of how insights from these programs can be incorporated into the evaluation phase to enhance nursing practices and patient outcomes. How can patient feedback drive changes in nursing care?
7. A nurse is in a hurry. To speed up her documentation of a patient, she invents several abbreviations, assuming that other team members will be able to figure out what she means from the context. Why is this a bad practice? Explain what can go wrong if nurses use unapproved abbreviations in their documentation.
8. Describe a situation in which it is likely better to use source-oriented documentation and a situation in which it is likely better to use problem-oriented documentation. Explain why each approach is better for the situation you chose.

### What Should the Nurse Do?

Mrs. Lee, a 55-year-old female with newly diagnosed type 2 diabetes, has been admitted for the management of her condition. Her care plan includes medication management, dietary changes, and education on monitoring her blood sugar levels. Mrs. Lee is also overweight and has expressed feelings of anxiety about managing her new diagnosis.

1. What priorities should the nurse establish for Mrs. Lee's care?
2. Discuss how the nurse can use cognitive skills to manage Mrs. Lee's care, especially when educating her about type 2 diabetes and its management.
3. How should the nurse ensure continuity of care for Mrs. Lee as she transitions from hospital to home management of her newly diagnosed type 2 diabetes?

Mrs. Thompson, a 68-year-old female with a history of chronic obstructive pulmonary disease (COPD), is admitted to a postsurgical unit following hip-replacement surgery. Her care involves preventing postoperative complications and beginning early rehabilitation for her hip, as well as managing her COPD. The nursing team, led by Nurse Saad, is tasked with her comprehensive care.

4. Identify one direct and one indirect care intervention that Nurse Saad and his team should provide for Mrs. Thompson.
5. Differentiate between dependent, independent, and interdependent interventions in Mrs. Thompson's care plan. Give an example of each.
6. Discuss interventions Nurse Saad might implement for the actual, potential, and collaborative problems in Mrs. Thompson's case. Give an example of each.
7. How should Nurse Saad prioritize interventions for Mrs. Thompson, considering her COPD and recent surgery?
8. If Nurse Saad needs to delegate certain tasks in Mrs. Thompson's care, what factors should be considered, and what tasks might be appropriate to delegate?

Mr. Najarian, a 67-year-old retired teacher, recently broke his leg after a fall at home. He underwent surgery and is now in the recovery phase. He has a history of diabetes and hypertension. The nursing team has been closely monitoring his progress, managing his pain, ensuring proper wound healing, and encouraging gradual mobility. His care plan includes pain management, wound care, physical therapy, and monitoring for potential complications

related to his chronic conditions.
