If diarrhea is caused by a bacterial or parasitic infection, antibiotics or antiparasitic medications may be prescribed to treat the underlying infection. Antidiarrheal medications like loperamide (Imodium) can help reduce stool frequency and improve stool consistency. However, these should be used cautiously and avoided in certain cases, such as when diarrhea is caused by bacterial or parasitic infections. Probiotics and prebiotics, which contain beneficial bacteria, may help restore the balance of gut flora and reduce the duration and severity of diarrhea, especially if it is caused by antibiotics or certain GI conditions. Medications such as antispasmodics or antiemetics may be prescribed to alleviate symptoms such as abdominal cramping or nausea.

In healthcare settings, infection control measures are paramount to prevent the spread of infectious diarrhea, with nurses enforcing strict hand hygiene protocols and isolation precautions as necessary. If diarrhea persists or is recurrent, further evaluation may be needed to determine the underlying cause. This may involve diagnostic tests (e.g., stool cultures, imaging studies) to identify infectious agents, inflammatory conditions, or other GI disorders. In some cases, rectal tubes may be prescribed to collect watery stool. However, strict monitoring is required because of possible damage to the rectal mucosa.

## Fecal Incontinence

Also known as bowel incontinence, **fecal incontinence** refers to the inability to control bowel movements, leading to involuntary leakage or passage of feces, gas, or mucus from the rectum. It can vary in severity from occasional leakage to complete loss of bowel control. Fecal incontinence can be caused by a variety of factors, including the following:

- ongoing (chronic) constipation, causing the anus muscles and intestines to stretch and weaken, leading to diarrhea and stool leakage
- fecal impaction with a lump of hard stool that partly blocks the large intestine
- long-term laxative use
- colectomy or bowel surgery
- lack of sensation of the need to have a bowel movement
- gynecological, prostate, or rectal surgery
- injury to the anal muscles in women during childbirth
- nerve or muscle damage from injury, a tumor, or radiation
- severe diarrhea that causes leakage
- severe hemorrhoids or rectal prolapse
- stress of being in an unfamiliar environment
- emotional or mental health issues (MedlinePlus, 2022)

Fecal incontinence can significantly affect an individual's quality of life, causing embarrassment, social isolation, and psychological distress.

### Clinical Manifestations

Fecal incontinence manifests through a variety of clinical indications that disrupt normal bowel control and function. Individuals grappling with fecal incontinence often endure episodes of involuntary stool leakage, gas, or mucus discharge from the rectum, causing distress and social discomfort. Accompanying this is a pervasive sense of urgency, where the sudden and uncontrollable need to defecate leads to difficulties reaching a restroom in time, resulting in accidents. These incidents of accidental bowel movements can occur during routine activities, disrupting daily life and eroding confidence. Moreover, prolonged exposure to fecal matter can precipitate skin irritation, inflammation, and susceptibility to infections in the perianal area, exacerbating physical discomfort and complicating care. Beyond the physical toll, fecal incontinence exacts a heavy psychological toll, often fostering feelings of shame, embarrassment, anxiety, and social withdrawal.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Prioritize Hypotheses: Distinguishing Fecal Incontinence from Diarrhea

Mrs. Jenkins, a 72-year-old female, presents to the clinic with complaints of fecal incontinence. Upon assessment, the nurse identifies several cues indicating the presence of this condition. Mrs. Jenkins describes experiencing episodes of involuntary stool leakage, gas, and occasional mucus discharge from the rectum. She expresses significant distress and social discomfort because of these incidents, especially when they occur during routine activities. Additionally, Mrs. Jenkins reports a pervasive sense of urgency, often unable to reach the restroom in time, resulting in accidents.

Analyzing these cues, the nurse prioritizes a hypothesis of fecal incontinence. The presence of involuntary stool leakage, gas, and mucus discharge, along with the urgency and difficulty reaching the restroom in time, align with the clinical indications of fecal incontinence. Furthermore, Mrs. Jenkins's distress and social discomfort, coupled with the potential for skin irritation, inflammation, and susceptibility to infections in the perianal area, underscore the adverse effects of fecal incontinence on her physical well-being.

Moreover, the nurse recognizes the psychological toll of fecal incontinence on Mrs. Jenkins, noting her reported feelings of shame, embarrassment, anxiety, and social withdrawal. These emotional responses further support the hypothesis of fecal incontinence, highlighting the holistic nature of patient care required to address both the physical and psychological aspects of this condition.

### Nursing Management

Nursing management of fecal incontinence encompasses a multifaceted approach aimed at addressing both the physical and emotional aspects of the condition. Nurses play a pivotal role in providing supportive care, education, and interventions to help individuals manage fecal incontinence and optimize bowel elimination. This includes conducting thorough assessments to identify underlying causes and contributing factors, such as neurological disorders, pelvic floor dysfunction, or medication side effects.

Based on these assessments, nurses develop individualized care plans that may incorporate dietary modifications, bowel management strategies, pelvic floor exercises, and medications to improve bowel control and stool consistency. Dietary modifications may involve adjustments such as increasing fiber intake to regulate bowel movements and avoiding foods and beverages that can irritate the digestive system (e.g., alcohol, caffeine, dairy products, greasy foods, spicy foods, gluten, artificial sweeteners).

Bowel training strategies help establish a regular bowel routine, enhancing predictability and reducing the risk of accidents. A **bowel retraining** involves teaching the body to have a bowel movement at a certain time of the day. This also includes encouraging the patient to go to the bathroom when feeling the urge to do so and not ignoring it. For some people, it is helpful to schedule this consistent time in the morning when the natural urge occurs after drinking warm fluids or eating breakfast. For other people, especially those with a neurological cause, a laxative may be scheduled every three days to stimulate the urge to have a bowel movement (Medline Plus, 2022).

Pelvic floor exercises (e.g., Kegel exercises) are used to strengthen the muscles of the pelvic floor, improving muscle tone and coordination. Additionally, medications may be prescribed to address underlying causes or manage symptoms, such as antidiarrheal medications to reduce stool frequency or bulking agents to improve stool consistency. In cases where conservative measures are ineffective, advanced treatments such as biofeedback therapy, sacral nerve stimulation, or surgical interventions may be considered to address specific underlying causes or improve bowel control (Medline Plus, 2022).

Additionally, nurses offer guidance on skin care and hygiene practices to prevent skin breakdown and infection in the perianal area. Education is a cornerstone of nursing management, as nurses provide information and support to help individuals understand their condition, manage symptoms, and access appropriate resources. They also play a vital role in addressing the psychosocial effect of fecal incontinence, offering empathy, reassurance, and counseling to alleviate feelings of embarrassment, shame, and isolation.

## Summary

### 27.1 Gastrointestinal Tract Structures and Functions

The GI tract encompasses a series of organs. The mouth is where food is initially broken down through chewing and mixing with saliva. The stomach further digests food using gastric juices and muscular contractions. The small intestine is where nutrients are absorbed into the bloodstream. The large intestine is responsible for water absorption and feces formation. The anus is the external opening through which waste is expelled during defecation. The nervous system, comprising the sympathetic and parasympathetic divisions, regulates bowel function by modulating activities such as peristalsis and sphincter control. The sympathetic division, activated during stress, can inhibit bowel motility and sphincter relaxation, while the parasympathetic division promotes peristalsis and sphincter relaxation, facilitating bowel movements. The GI tract performs vital functions encompassing digestion, absorption of nutrients, and elimination of waste, ensuring optimal health and well-being through coordinated physiological processes.

### 27.2 Factors Affecting Bowel Elimination

Developmental considerations affecting bowel elimination involve understanding how factors such as aging affect muscle tone, nerve function, and mobility, which can influence bowel movements. For example, infants and older adults may have less control over bowel movements because of underdeveloped or weakened muscles. Individual daily bowel habits affect elimination patterns based on factors such as diet, fluid intake, physical activity, and stress levels. Changes in these habits can affect bowel regularity and consistency, potentially leading to constipation or diarrhea. Medications can affect bowel elimination by altering bowel motility, stool consistency, or fluid balance in the colon. For instance, opioids can slow bowel movements, while some antibiotics may cause diarrhea by disrupting the balance of gut bacteria. Understanding medication effects is crucial for managing bowel function and preventing complications.

### 27.3 Diagnostic Evaluation

Diagnostic testing for proper bowel functioning encompasses a range of procedures, including the following:

- serum laboratory value analysis to assess electrolyte imbalances
- stool tests to analyze the composition of stool
- breath tests to detect bacterial overgrowth
- genetic testing to identify hereditary conditions
- imaging studies to visualize the structure and function of the bowel and surrounding organs
- endoscopic procedures such as colonoscopy and sigmoidoscopy to visualize the bowel
- laparoscopy for a more direct examination of the abdomen and bowel

Nurses are pivotal in the diagnostic and therapeutic process for functional bowel elimination by conducting thorough nursing assessments, implementing interventions like promoting adequate hydration and fiber intake, providing patient education about procedures and their implications, administering bowel preparation to cleanse the bowel, and closely monitoring patients for complications such as sedation-related adverse effects during and after endoscopic procedures.

### 27.4 Common Conditions Affecting Bowel Elimination

Constipation disrupts bowel elimination, leading to infrequent, difficult bowel movements, abdominal discomfort, and potential complications such as fecal impaction, which can significantly affect an individual's quality of life. It is managed through lifestyle modifications (e.g., increased fiber intake, improved hydration, increased activity), along with medications (e.g., laxatives, stool softeners) aiming to promote regular bowel movements and alleviate discomfort. Diarrhea accelerates bowel transit time, resulting in frequent, loose stools, urgency, and dehydration, posing risks such as electrolyte imbalances and malnutrition. Treatment for diarrhea involves rehydration to replace lost fluids and electrolytes, dietary adjustments to include bland foods, and if necessary, medications like antidiarrheal medications to reduce stool frequency and improve consistency. Fecal incontinence impairs bowel control, causing involuntary leakage of stool, gas, or mucus, often accompanied by embarrassment, skin irritation, and psychological distress, necessitating comprehensive management strategies for improved quality of life. Treatment includes dietary modifications, pelvic floor exercises, and medications to address underlying causes or

manage symptoms, with advanced interventions such as biofeedback therapy or surgery aiming to improve bowel control and enhance quality of life.

## Key Terms

**active transport** the movement of solutes through a transmembrane protein using energy expenditure

**adhesiolysis** removal of adhesions

**anal fissure** a small tear or cut in the lining of the anus, which can cause pain, bleeding, and discomfort during bowel movements

**anus** opening at the end of the digestive tract through which feces (solid waste) are expelled from the body

**ascending colon** portion of the colon that travels upward from the cecum on the right side of the abdomen

**bile** digestive fluid produced by the liver and stored in the gallbladder

**bloating** sensation of fullness or swelling in the abdomen, often accompanied by gas and discomfort

**bowel preparation (bowel prep)** a medical procedure that involves the cleansing of the gastrointestinal tract, particularly the colon, in preparation for certain medical procedures or surgeries

**bowel retraining** teaching the body to have a bowel movement at a certain time of the day

**breath test** noninvasive diagnostic tool used to assess various aspects of bowel functioning, particularly related to carbohydrate metabolism and bacterial overgrowth in the gastrointestinal tract

**Bristol Stool Chart** a diagnostic medical tool designed to classify the form of human feces into seven categories

**capsule endoscopy** imaging study used to evaluate the small intestine for abnormalities such as bleeding, inflammation, or tumors

**cardia** uppermost part of the stomach closest to the esophagus, where food enters

**cecum** initial connection point between the small intestine and the colon

**chyme** semifluid mixture produced in the stomach during digestion, which consists of partially digested food, water, and digestive juices

**Cologuard** a noninvasive screening test for colorectal cancer

**colon** consists of several segments: ascending colon, transverse colon, descending colon, and sigmoid colon

**colonoscopy** imaging study used to examine the colon and rectum for abnormalities such as polyps, inflammation, or tumors

**colostomy** involves forming a stoma using a section of the colon (large intestine), where a portion of the intestine is brought out through the abdominal wall and connected to the skin

**consistency** texture of the stool, ranging from hard and formed to soft and loose

**constipation** a common gastrointestinal condition characterized by infrequent or difficult passage of stool; often defined as less than three bowel movements per week

**contrast** special dye used for imaging tests

**defecation** the process of eliminating solid waste, known as feces or stool, from the body through the anus

**descending colon** portion of the colon that descends along the left side of the abdomen

**diarrhea** a common gastrointestinal condition characterized by frequent, loose, and watery stools; often defined as more than three unformed stools in twenty-four hours

**digital disimpaction** a medical procedure performed to remove impacted stool from the rectum and lower colon using a gloved, lubricated finger

**duodenum** shortest segment of the small intestine; resides just below the stomach, forming a C-shaped curve

**endoscopic retrograde cholangiopancreatography (ERCP)** imaging study used to assess the bile ducts and pancreatic duct for abnormalities such as stones, strictures, or tumors

**enema** an intervention used to manage constipation, involving the introduction of a liquid solution into the rectum to stimulate bowel movements and evacuate stool

**enterocyte** specialized cell that lines the wall of the small intestine and is equipped with microvilli, tiny projections that greatly increase the surface area available for absorption

**esophagogastroduodenoscopy (EGD)** imaging study used to evaluate the esophagus, stomach, and duodenum for abnormalities such as ulcers, inflammation, or tumors

**esophagus** a muscular tube behind the trachea and in front of the spine between the pharynx and stomach; peristalsis moves the food down the esophagus, while esophageal sphincters open for food to pass through and then close to prevent regurgitation

**facilitated diffusion** relies on carrier proteins but does not require energy expenditure and moves nutrients down

their concentration gradient

**fecal immunochemical test (FIT)** detects occult blood in stool samples with improved sensitivity and specificity compared to FOBT

**fecal impaction** a large, hardened mass of stool becomes lodged in the rectum or lower colon, making it difficult or impossible to pass stool normally

**fecal incontinence (also, bowel incontinence)** the inability to control bowel movements, leading to involuntary leakage or passage of feces, gas, or mucus from the rectum

**fecal occult blood test (FOBT)** detects occult blood in stool samples, indicating gastrointestinal bleeding

**feces (also, stools or bowel movements)** solid waste products of digestion that are expelled from the body through bowel elimination

**flexible sigmoidoscopy** imaging study used to evaluate the rectum and sigmoid colon for abnormalities such as polyps, inflammation, or tumors

**fundus** rounded portion of the stomach that expands as the stomach fills with food

**gastrointestinal (GI) system** a complex network of organs within the human body responsible for digestion and absorption of nutrients as well as the elimination of waste; encompasses the mouth, pharynx, esophagus, stomach, small intestine, large intestine, anus, and accessory organs

**genetic testing** evaluates proper bowel functioning by identifying genetic mutations associated with specific gastrointestinal disorders

**hematochezia (also, rectal bleeding)** bright red blood in the stools; may suggest lower GI tract bleeding

**hemorrhoids** swollen and inflamed vein in the rectum or anus that can cause discomfort, itching, and bleeding

**hydrogen breath test** primarily used to detect bacterial overgrowth in the small intestine and assess carbohydrate malabsorption, particularly lactose intolerance

**ileostomy** involves forming a stoma using a section of the ileum (small intestine), where a portion of the intestine is brought out through the abdominal wall and connected to the skin

**ileum** the longest part of the small intestine; connects the small intestine to the large intestine

**jejunum** middle portion of the small intestine that is primarily responsible for the absorption of nutrients, including carbohydrates, proteins, fats, vitamins, and minerals

**lactulose breath test** specifically designed to diagnose small intestinal bacterial overgrowth by assessing the transit time and bacterial fermentation in the small intestine

**laparoscopy** a minimally invasive surgical procedure to assess and address various GI conditions that may adversely affect bowel functioning

**large intestine** is approximately 5 ft (1.5 m) long and consists of the cecum and colon; this vital component of the gastrointestinal tract is responsible for bowel elimination

**laxative** medication commonly used to manage constipation by promoting bowel movements

**meconium** the first bowel movement of a newborn that appears sticky and dark green to black in color

**melena** black, sticky, tarry stools that may suggest upper GI bleeding

**methane breath test** evaluates bacterial overgrowth and carbohydrate malabsorption, focusing on methane-producing bacteria

**moderate sedation (also, conscious sedation)** a medical technique used to induce a state of reduced consciousness and relaxation in patients undergoing certain medical procedures or interventions

**mouth** the orifice at the beginning of the gastrointestinal tract into which food is introduced into the gastrointestinal system; the mouth consists of the lips, tongue, hard and soft palates, gums, teeth, tongue, and salivary glands

**opioid-induced constipation (OIC)** constipation caused by opioid use

**ova and parasite examination** detects parasite eggs, larvae, or cysts in stool samples, indicating intestinal parasitic infections

**passive diffusion** occurs when nutrients move across the intestinal lining from an area of higher concentration to an area of lower concentration without the need for carrier proteins or energy

**peristalsis** rhythmic, wavelike contraction and relaxation of the intestinal muscles that serves to mix food with gastric juices and propel food, water, and digestive juices forward through the digestive tract

**pharynx** a funnel-shaped, muscular organ, the walls of which constrict to help push food to the esophagus, lift the walls of the pharynx during swallowing, and prevent air from being swallowed

**pyloric sphincter** muscular valve located at the lower end of the stomach, near its junction with the small intestine

(specifically, the duodenum); responsible for the release of chyme into the small intestine

**pylorus** lower portion of the stomach that connects to the small intestine

**rectum** final straight portion of the large intestine where feces are stored before elimination through the anus

**sigmoid colon** final S-shaped segment of the colon that leads to the rectum

**small intestine** a convoluted tube approximately 22 ft (6.7 m) long that stretches from the stomach to the large intestine

**stoma** an opening surgically created in the body to allow the passage of bodily waste from the body

**stomach** muscular organ located in the upper abdomen that plays a pivotal role in the digestive process

**stomach body** central region of the stomach where most of the digestion occurs

**stool culture** detects pathogenic bacteria, viruses, or parasites responsible for gastrointestinal infections

**stool softener** medication used to alleviate constipation by adding moisture to the stool, making it softer and easier to pass

**substrate** a substance or compound that undergoes a chemical reaction or is acted on by an enzyme to produce a specific product

**suppository** solid medication inserted into the rectum, where it dissolves to release medication locally

**transverse colon** portion of the colon that runs horizontally across the abdomen, connecting the ascending and descending segments of the large intestine

## Assessments

### Review Questions

1. What organ is responsible for the initial breakdown of food through mechanical digestion?
  - a. stomach
  - b. small intestine
  - c. mouth
  - d. large intestine
2. What type of digestion involves the action of enzymes and acids?
  - a. mechanical digestion
  - b. chemical digestion
  - c. absorptive digestion
  - d. peristaltic digestion
3. Where does absorption of nutrients primarily occur in the gastrointestinal tract?
  - a. stomach
  - b. large intestine
  - c. small intestine
  - d. colon
4. What division of the nervous system is responsible for the rest-and-digest response?
  - a. sympathetic nervous system
  - b. parasympathetic nervous system
  - c. central nervous system
  - d. enteric nervous system
5. What part of the gastrointestinal tract is responsible for releasing chyme into the small intestine?
  - a. cardia
  - b. fundus
  - c. body
  - d. pylorus
6. What segment of the small intestine is primarily responsible for absorbing nutrients?
  - a. duodenum

- b. jejunum
  - c. ileum
  - d. cecum
7. When discussing toilet training readiness signs with parents of a 20-month-old infant, the nurse emphasizes that many infants begin to demonstrate awareness of bowel sensations at what age?
- a. 6 to 8 months
  - b. 12 to 18 months
  - c. 18 to 24 months
  - d. 24 to 30 months
8. What dietary component adds bulk to stool and promotes regular bowel movements?
- a. protein
  - b. fat
  - c. fiber
  - d. sugar
9. What beverage can act as a mild stimulant to the digestive system, promoting bowel movements in some individuals?
- a. water
  - b. coffee
  - c. fruit juice
  - d. milk
10. What GI side effect is commonly associated with proton pump inhibitors?
- a. constipation
  - b. diarrhea
  - c. nausea
  - d. abdominal discomfort
11. How do tricyclic antidepressants primarily affect bowel function?
- a. increasing intestinal transit
  - b. reducing stomach acid production
  - c. increasing bowel motility
  - d. slowing intestinal transit
12. What diagnostic tests will be ordered to assess bacterial overgrowth in the small intestine and carbohydrate malabsorption?
- a. liver function tests
  - b. genetic testing
  - c. breath tests
  - d. stool culture
13. What endoscopic procedure is used to evaluate the esophagus, stomach, and duodenum for abnormalities such as ulcers, inflammation, or tumors?
- a. colonoscopy
  - b. esophagogastroduodenoscopy (EGD)
  - c. flexible sigmoidoscopy
  - d. capsule endoscopy
14. A newly graduated nurse is reviewing laboratory values with their preceptor. What statement made by the newly graduated nurse would demonstrate a correct interpretation of the laboratory values?
- a. "Patients with diarrhea will experience low sodium and high potassium."

- b. “Patients with inflammatory bowel disease will experience high albumin and platelets.”
  - c. “Patients with perforated bowels will experience a high CRP.”
  - d. “Patients with dehydration will experience a high sodium and chloride.”
- 15.** A nursing student is reviewing medications used to treat constipation with the nurse. What statement made by the nursing student would warrant further education?
- a. “Stool softeners are medications used to alleviate constipation by adding moisture to the stool, making it softer and easier to pass.”
  - b. “Enemas are another intervention used to manage constipation, involving the introduction of a liquid solution into the rectum to stimulate bowel movements and evacuate stool.”
  - c. “Laxatives are medications commonly used to manage constipation by promoting bowel movements.”
  - d. “Suppositories are liquid medications inserted into the rectum, where they dissolve and release medication locally.”
- 16.** You are caring for a patient with diarrhea. What food would you recommend the patient eat?
- a. broccoli
  - b. fried rice
  - c. applesauce
  - d. beans
- 17.** A 65-year-old patient presents to the clinic with complaints of fecal incontinence. The nurse conducts a comprehensive assessment and identifies muscle weakness in the pelvic floor as a contributing factor. What intervention should the nurse include in the plan of care to address this underlying cause?
- a. Encourage the patient to increase fluid intake to prevent dehydration.
  - b. Teach the patient pelvic floor exercises, such as Kegel exercises, to strengthen muscle tone.
  - c. Instruct the patient to avoid spicy foods and caffeine to minimize bowel irritation.
  - d. Administer antidiarrheal medications to reduce stool frequency and urgency.

### Check Your Understanding Questions

1. What is chyme?
2. What triggers the urge to have a bowel movement?
3. What effects do stress and emotional well-being have on bowel habits?
4. Describe the purposes of fecal occult blood tests, stool cultures, and ova and parasite examinations in detecting specific conditions or pathogens through stool analysis.
5. Explain the role of nurses in educating patients about the procedures involved in diagnostic and therapeutic testing for functional bowel elimination.
6. Explain how constipation, diarrhea, and fecal incontinence affect bowel elimination.
7. Explain the rationale behind dietary modifications in the management of fecal incontinence.

### Reflection Questions

1. Describe the implications of impaired peristalsis on bowel function and patient outcomes.
2. Reflect on the challenges caregivers might face when promoting healthy bowel habits in school-age children.
3. What actions should the nurse take if a patient exhibits signs of respiratory depression or hypotension after undergoing moderate sedation?
4. Consider the importance of individualized care in managing constipation. How can nurses tailor interventions to meet the specific needs and preferences of each patient?
5. Why would antidiarrheals not be recommended for someone with a suspected bacterial infection?

## What Should the Nurse Do?

1. During a routine checkup, a 35-year-old patient expresses concerns to the nurse about experiencing frequent bowel symptoms such as diarrhea and abdominal discomfort, particularly during periods of high stress at work. The patient reports feeling overwhelmed and anxious about these symptoms, which are adversely affecting their daily life and productivity. What should the nurse do to support the adult patient experiencing stress-related bowel symptoms?
2. The nurse is preparing a patient for a colonoscopy. The patient expresses anxiety about the procedure. What should the nurse do?
3. The nurse is performing a digital disimpaction when the patient begins to complain of severe abdominal pain. What should the nurse do?

## Competency-Based Assessments

1. Develop a ten-minute presentation that outlines the stages of the bowel elimination process.

Sarah, a 32-year-old parent, is concerned about her infant's bowel habits. Her daughter, Emma, is 8 months old and has been experiencing occasional constipation since she started transitioning to solid foods a few months ago, which causes Emma to become upset when she has difficulty passing stool. Sarah questions if she needs to increase Emma's fiber intake. Although Emma is not on any prescription medications, Sarah remembers the iron-fortified formula she switched Emma to recently might be contributing to the constipation.

2. Identify the developmental, individual, and medication factors presented in the scenario.
3. Outline a comprehensive plan for addressing Emma's constipation.
4. Consider potential challenges or barriers to implementing the plan.
5. Discuss the importance of monitoring Emma's progress and scheduling follow-up appointments with her pediatrician to assess the effectiveness of the interventions.

Mr. Smith, a 68-year-old patient, was admitted to the hospital with complaints of severe diarrhea for the past two days. He has a history of irritable bowel syndrome (IBS) and is currently taking medications for hypertension and diabetes. On assessment, the nurse notes that Mr. Smith appears lethargic, with dry mucous membranes and decreased skin turgor. His vital signs reveal a heart rate of 110 bpm, blood pressure of 100/60 mm Hg, respiratory rate of 22 breaths per minute, and temperature of 99.2°F (37.3°C). Laboratory results are as follows: serum sodium (Na<sup>+</sup>): 130 mEq/L (normal range: 135–145 mEq/L); serum potassium (K<sup>+</sup>): 3.2 mEq/L (normal range: 3.5–5.0 mEq/L).

6. What are the potential causes of Mr. Smith's electrolyte imbalances based on his clinical presentation and laboratory results?
7. How does diarrhea contribute to the development of electrolyte imbalances such as hyponatremia and hypokalemia?
8. Discuss the relationship between dehydration and altered vital signs, including tachycardia, hypotension, and tachypnea, in patients with gastrointestinal issues like severe diarrhea.
9. What nursing interventions would you prioritize to address Mr. Smith's dehydration and electrolyte imbalances?
10. How might Mr. Smith's underlying conditions, such as irritable bowel syndrome, hypertension, and diabetes, influence his response to treatment for dehydration and diarrhea?

Mrs. Suarez, a 70-year-old female, is admitted to the hospital with complaints of fecal incontinence. During the admission assessment, the nurse listens carefully to the patient's report of symptoms and then observes the following clinical manifestations:

- Mrs. Suarez reports experiencing frequent episodes of involuntary stool leakage, particularly during routine activities such as walking or standing up from a seated position.
- Upon inspection, the nurse notes evidence of stool staining on Mrs. Suarez's undergarments and bedding.
- Mrs. Suarez expresses embarrassment and frustration over her inability to control bowel movements, stating that it has significantly affected her quality of life and social interactions.
- During toileting assistance, the nurse observes urgency and difficulty in controlling bowel movements, with Mrs. Suarez expressing a sense of urgency and discomfort just before accidents occur.

- Physical examination reveals skin irritation and redness in the perianal area, indicating potential skin breakdown caused by prolonged exposure to fecal matter.

Based on this scenario, answer the following questions:

11. Identify the clinical manifestations of fecal incontinence observed in Mrs. Suarez.
12. Discuss potential nursing actions or interventions to address Mrs. Suarez's clinical manifestations.
13. Explore the effect of fecal incontinence on Mrs. Suarez's physical and emotional well-being and discuss strategies for providing holistic care and support.
14. Reflect on the importance of maintaining Mrs. Suarez's dignity and autonomy while providing care and support for her fecal incontinence.

## CHAPTER 28

# Sleep and Rest

**FIGURE 28.1** There are numerous health benefits for getting adequate rest and sleep. (credit: modification of “How to Fall Asleep in 2 Minutes” by Rick Morris/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

- 28.1 Concepts of Sleep and Rest
- 28.2 Factors Affecting Sleep and Rest
- 28.3 Effects of Insufficient Sleep
- 28.4 Nursing Care to Promote Sleep and Rest

**INTRODUCTION** Sleep and rest are requirements for life. Both of them can refresh and restore. Although the terms are sometimes used synonymously, they do not reflect exactly the same concepts. Rest tends to be a more temporary construct, associated with a break from stress and exertion. Relaxation is commonly correlated to rest; indeed, the phrase “rest and relaxation,” or R & R, is a frequently used colloquialism. Although sleep incorporates rest, rest does not necessarily involve sleep. Sleep involves complicated neurophysiological processes that influence growth and development of the entire body, including the brain. The sleep state reduces consciousness and related neurological activity, with accompanying decline in body functions, including cardiopulmonary responses and metabolism. During nonsleeping rest, a person reduces metabolic demands, but remains alert, with muscle tone and potential for immediate responses intact.

Significant physiologic changes occur at different stages of the sleep cycle. Such changes include fluctuations of heart and respiratory rates, temperature, brain activity, and oxygen demands. Even muscular movement varies by sleep stages, notably during the rapid eye movement (REM) stage. Effects of sleep, and of sleep deprivation, can be apparent in resultant physiological changes, behaviors, and actions. Medical conditions, including kidney disease, cardiovascular problems, and a decline in immune function, are all possible repercussions of insufficient sleep. Inadequate sleep can also result in various psychological disorders and behavioral changes.

## 28.1 Concepts of Sleep and Rest

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the physiology of sleep
- Identify the stages of sleep
- Describe the sleep patterns and needs throughout the life span

Sleep is a necessary part of life with potentially significant, and even dangerous, repercussions when individuals do not receive adequate amounts and quality. The physiological processes involved in and during sleep are not simple. To an observer, however, sleep appears to be a simple enough set of actions:

- fatigue and sleepiness
- falling asleep
- maintaining sleep
- cycling through stages of sleep
- waking rejuvenated and ready for the waking, active hours

This section explores the physiology involved in sleep, starting with the contributions of the **reticular activating system (RAS)**—a group of neurons that control sleep and wakefulness, arousal, and consciousness—and the **circadian rhythms**, or the biological rhythm associated with metabolism, temperature, sleep, and wakefulness. As nurses, it is important to understand the important role sleep plays in people's lives, including contributions to health, illness, and daily function. This section will examine the physiology and stages of sleep and then delve into sleep patterns and the changing sleep needs throughout the life span.

### Physiology of Sleep

Sleep, like respiration, is a basic physiological function, under neurological control and originating in the brain stem. There are a variety of processes that occur while sleeping, including storing and cataloguing new information, and changing short-term memories into long-term memories (Nunez & Lamoreux, 2023). The **glymphatic system** is involved in regulation of interstitial fluid movement and subsequent removal of waste from the brain and cerebrospinal fluid (CSF) and is directed by sleep and circadian cycles (Hablitz & Nedergaard, 2021; Nunez & Lamoreux, 2023). Potassium and lactic acid are two of the waste products removed by processes of the glymphatic system. A peptide implicated in development of Alzheimer disease called **beta amyloid**, and **tau**, a protein also associated with Alzheimer disease development, are other wastes eliminated by the glymphatic system (Hablitz & Nedergaard, 2021). Certain areas of the brain, such as the amygdala and hippocampus related to emotional regulation, are more active during sleep (Nunez & Lamoreux, 2023).

The body requires an adequate amount of sleep. Adequacy of sleep changes over the human life span, ranging from sixteen to eighteen hours per day for newborns, to seven to nine hours of the day for adults (see more about developmental stages and sleep later in a later section of the chapter). Achieving enough sleep for one's stage of development and age allows people to grow, function, and thrive throughout life. Cognitive actions, such as learning, problem-solving, concentration, and creativity, are performed best when the body and brain have had adequate sleep. Sleep deprivation inhibits positive adaptations by the brain to stress, resulting in less effective coping responses and negative reactions while awake. Examples of such maladaptive responses include eating disorders, and use of caffeine, alcohol, and other substances. Proper organ function relies on adequate sleep as do healthy immune systems, use of insulin, effective cognition, and cardiac function.

Sleep involves coordination of the properties of homeostasis and circadian rhythm. A person tends to associate feelings of fatigue and drowsiness with a need for sleep, which is the homeostatic mechanisms at work. The circadian rhythm includes the body's natural responses to light and dark, which normally involve being awake and alert during hours of light, and feeling tired, sleepy, and subsequently sleeping, during periods of darkness. Melatonin is a modulator involved in circadian rhythm changes, with increasing levels during darkness, and decreasing levels during hours of light.

During hours of sleep, consciousness remains active, but is generally reduced, with a change in responsiveness. When a person is awake, they are acutely aware of external stimuli; while asleep, consciousness is predominantly responsive to internal rather than external stimuli (Brinkman et al., 2023). As a person experiences sleepiness, if

there is a safe environment for sleep, the hypothalamus initiates actions to inhibit areas of the brain involved in arousal. As the person reaches the sleep state, the regions of the brain stem, thalamus, and cortex operationally disengage (Brinkman et al., 2023). An **electroencephalogram (EEG)**, a linear tracing of the electricity of brain waves, is able to identify the different periods or stages of sleep. In brief, the first period is **non-rapid eye movement (NREM)** sleep, and is comprised of three stages of sleep itself (Figure 28.2). The EEG waveforms change during the different stages. As one falls asleep (stage I sleep), a fast **alpha wave** is typical while awake and resting, but is followed by a **theta wave**, which is also fast, with variable frequencies (Patel et al., 2024). In stage II, two characteristic EEG changes are apparent: a short, intermittent burst of neurological activity called **sleep spindle** and **K-complex**, each of which lasts about one second and is associated with the **delta wave**, which is slower but have more amplitude. In stage III of NREM sleep, the EEG displays slow delta waves; this stage is also referred to as **slow-wave sleep (SWS)** (Patel et al., 2024).

**FIGURE 28.2** During different stages of sleep, brain waves change, as seen on an EEG. (modification of work from Psychology 2e. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The other sleep stage is **rapid eye movement (REM)** sleep, which is associated with fast movements of both eyes. REM is generated by activation of “REM-on neurons” that stimulate responses from both the parasympathetic and sympathetic nervous systems (Brinkman et al., 2023). This increased brain activity is apparent on the EEG, as the waveform during REM sleep appears much like that of someone who is awake (Patel et al., 2024).

### Reticular Activating System

Located in the anterior of the brain stem, the reticular activating system (RAS) is integral in some of the most basic functions, including consciousness, sensory perceptions and responses, ability to focus, and the sleep-wake cycle. Specifically, the RAS adjusts fast and slow sleep rhythms, which assist with coordination of wakefulness and sleep (Arguinchona & Tadi, 2023). Additionally, the RAS moderates muscle tone during different stages of sleep, most particularly contributing to the lack of muscle tone apparent during REM sleep, which prevents movement of the extremities during dreams.

The RAS is also involved in responses to pain and some mental health and neurological disorders, such as schizophrenia, Parkinson disease, post-traumatic stress disorder (PTSD), and **narcolepsy**, a sleep disorder involving sleep and wakefulness with abnormal episodes of daytime sleep (see [Central Disorders of Hypersomnolence](#)).

### LINK TO LEARNING

Watch this [RAS video \(https://openstax.org/r/77RAS\)](https://openstax.org/r/77RAS) for more information about the RAS.

### Circadian Rhythms

Wakefulness, metabolism, temperature, and the timing of sleepiness and subsequent sleep, are part of circadian rhythms. Such rhythms likely originated historically from humans as hunters and gatherers (Casiraghi et al., 2021).

These early peoples, by necessity, would use the improved visibility during daylight hours for most hunting, searching for other food sources, and other activities. Their own safety was also of paramount importance, and therefore it was also valuable to be able to see potential dangers.

The control of circadian rhythms initiate within the hypothalamus, where there are centers for sleep and wakefulness. These are set to respond to light and darkness through messages from the retinas. The results include feeling sleepy, physiologically welcoming the onset of sleep two or three hours after dark, and naturally awakening shortly before, or at sunrise (Figure 28.3).

**FIGURE 28.3** The circadian rhythm includes the influences of light and dark on organ systems during related periods of day and night. (modification of “The master circadian clock in the human brain” by Ian B Hickie, Sharon L Naismith, Rébecca Robillard, Elizabeth M Scott, and Daniel F Hermens/Wikimedia Commons, CC BY 3.0)

Chemical contributions to sleep are regulated by the circadian rhythm and include the nighttime secretion of melatonin, which assists in promoting sleep by opening the “sleep gate” (Viganò et al., 2023), promoting NREM sleep and improving the continuity of REM sleep. The release of prolactin, adrenocorticotrophic hormone (ACTH), and norepinephrine are also under circadian influence (Patel et al., 2024). The neurotransmitter adenosine is associated

with a person's feeling the need for sleep (Bryan, 2023). Additionally, adenosine is thought to promote deep slow-wave sleep and its restorative properties (Bryan, 2023). This chemical is metabolized during sleep, so low levels are apparent in the morning. Cortisol is another chemical involved in circadian rhythm, as its early-morning release prepares the body to awaken.

## REAL RN STORIES

---

### Shift Work and Circadian Rhythm

**Nurse:** Peggy, RN

**Clinical setting:** ICU

**Years in practice:** 10

**Facility location:** Suburban community hospital in Colorado

I worked steady night shift for ten years. It's kind of odd: I tend to naturally be more of a morning person, but I never had trouble staying awake at work, probably because it was always so busy! I also had no problem sleeping during the day when I worked nights, although I never figured out how to sleep well on my days off. I tried all different options, and finally just decided to go to sleep whatever felt right each day and not to try to create a particular habit. So most times, I would sleep about four hours, then get up and do a few things, take a nap about 2:00 p.m. for an hour or so. When I woke up, I'd run errands or do stuff around the house, fix supper, and go to bed at about 9:00 p.m. (Sometimes when I was very tired, I'd sleep through the day, and I'd still go to bed about 9:00 p.m.) Even now, I still wake up between 1:00 and 3:00 a.m. for two or three hours. In the ICU, that time was usually pretty busy, even if our patients were stable. That's when we'd do their baths, change central line dressings and other "housekeeping" tasks. Being busy during that time kept me awake, and brought me to the time for lab draws, x-ray coming for morning images, and prepping for shift change. Now though, some years later, I suppose ten years of shiftwork has had an impact on my circadian rhythm.

---

### Stages of Sleep

Sleep occurs in a series of four stages, briefly introduced earlier, which accord with associated EEG waves. These sleep stages happen throughout the sleep session (typically overnight) in a cyclical pattern, with a person spending about 75 percent of sleep time in NREM stages I through III, and 25 percent in stage IV REM sleep (Suni, 2023). Each cycle encompasses approximately 90 to 110 minutes, and it is normal to experience four or five cycles during a night's sleep.

#### Stage I

Stage I (N1) is the first stage of sleep onset; this stage normally happens quickly—on average taking no more than seven minutes of body and brain relaxation to fall asleep (Patel et al., 2024; Suni, 2023). Only about five percent of total sleep time is spent in stage I (Patel et al., 2024). As the individual relaxes, physiological activities, including those in the brain, become slower. This is often noted by a reduced heart rate, slow and regular respirations, and slow, rolling eye movements (Lockett, 2023). There may be occasional muscular movements seen, because skeletal muscle tone remains present during this phase (Suni, 2023). It is during this stage that EEG waves change from the beta waves associated with being awake to alpha waves of a relaxed but awake state, to theta waves of light sleep (Patel et al., 2024). If not disturbed during stage I, a person usually proceeds promptly to stage II and may not return to this stage for any significant amount of time. It is easy to awaken someone from stage I sleep.

#### Stage II

Stage II (N2) sleep involves more changes, as sleep becomes deeper, with heart rate, respiratory rate and temperature all continuing to decrease. Eye movement that slowed during stage I stops and people may grind teeth, with brief episodes of brain activity that offer resistance to waking (Suni, 2023). Such bursts of activity within the brain are presumed to be involved in the solidification of memories (Patel et al., 2024). It is during this cycle that delta waves begin, with sleep spindles and K-complexes, on the EEG. The first stage II cycle lasts between ten and twenty-five minutes, and each following cycle becomes longer, until a total of about 45 percent of sleep time is spent in this stage (Patel et al., 2024; Suni, 2023).

### Stage III

Brain waves slow considerably during stage III (N3), so this stage is referred to as slow-wave sleep (SWS) (Patel et al., 2024; Suni, 2023). While brain waves slow, metabolic, immune, and restorative actions occur. These include production of growth hormones, regulation of immune function, and repair of muscle tissue (Patel et al., 2024; Lockett, 2023; Suni, 2023). In addition, the depth of sleep during stage III is implicated as contributing to creativity, memory, and higher-level thinking (Suni, 2023). Stage III involves further decrease of temperature, heart and respiratory rates, and relaxation to the point of loss of skeletal muscle tone. This stage of sleep is when the deepest sleep occurs, and it is hard to be awakened, even by loud noise. If awakened during this stage, it is typical for the person to experience **sleep inertia**, or slowed processing of thoughts (Patel et al., 2024). Urinating while asleep (**enuresis**) and sleepwalking (**somnambulism**) happen during stage III sleep (Patel et al., 2024). Individuals can dream in this phase, with dreams typically being realistic in nature. Stage III predominantly occurs within the first half of a night's sleep, with these early cycles lasting twenty to forty minutes each and getting shorter throughout the night as more REM sleep begins (Suni, 2023). Approximately 25 percent of sleep is spent in stage III.

### Stage IV Rapid Eye Movement (REM) Sleep

REM sleep is considered stage IV of the sleep cycle. REM sleep, as the name indicates, is characterized by rapid movements of the eyes. Additionally, during this stage, metabolism increases, as noted by increases and changes in respiratory patterns and cardiac rhythms (Nunez & Lamoreux, 2023). Brain activity also increases during REM. Memory storage, integration of learned concepts, and creativity are associated with REM sleep (Nunez & Lamoreux, 2023; Suni, 2023). A lack of REM sleep can lead to psychophysiological symptoms and diagnoses related to sleep deprivation in general, which will be explored later in the chapter. Because REM sleep is associated with actions such as memory consolidation, particularly those memories related to skill acquisition, and problem-solving (Peters, 2023), a lack of REM sleep can have negative impacts on processing thoughts and emotions, and in making connections. These effects can manifest in a variety of ways, including depression, anxiety, a lack of clarity in thinking, or decreased higher-level cognition (Peters, 2023).

People lose skeletal muscle tone (except the diaphragm and muscles of the eyes), eliminating movement during REM sleep (Brinkman et al., 2023; Lockett, 2023; Patel et al., 2024). Dreams are common and tend to be very clear, emotional, and unbelievable. Nightmares also may occur during this phase, as well as sexual stimulation in the form of penile erections and clitoral dilation (Patel et al., 2024).

### LINK TO LEARNING

This video shows the [rapid movement of the eyes \(https://openstax.org/r/77RapidEyeMvmt\)](https://openstax.org/r/77RapidEyeMvmt) and a summary of typical events associated with REM sleep.

REM sleep increases during the second half of the night, as stage III sleep decreases, increasing from a ten-minute first cycle, to a final REM stage of sixty minutes (Suni, 2023). Approximately 25 percent of sleep is spent in REM, and it is common to awaken in the morning in the midst of REM sleep ([Table 28.1](#)).

Sleep Stage	Type of Sleep	Length of Stage (minutes)	Sleep Time (percent)
Stage I/N1	NREM	1–7	5
Stage II/N2	NREM	10–25	45
Stage III/N3	NREM	20–40	25
Stage IV/REM	REM	10–60	25

**TABLE 28.1** Sleep Stages (Source: Patel et al., 2024)

## LINK TO LEARNING

For a [summary of what is happening during a night's sleep \(https://openstax.org/r/77SleepEvents\)](https://openstax.org/r/77SleepEvents) watch this video. You will need to scroll down about halfway.

## Sleep Patterns and Needs

A period of sleep is typically overnight, and sleep occurs in the stages described in cyclical fashion. Such sleep cycles repeat until natural awakening, which frequently correlates with morning light, or until wakened by an alarm or other interruption. In many societies, this **monophasic sleep pattern** is most common, with one major block of time allocated for sleep.

In some regions of the world, a **biphasic sleep pattern** may be the norm, with two sleep sessions per day, including a sleep period of several hours overnight, and another, shorter sleep in the later morning or afternoon. Another is the **polyphasic sleep pattern**, which is normal for infants and young children, who sleep several times in a twenty-four-hour period. Until a neonate's sleep pattern normalizes to days and nights, even the overnight sleep cycles are not particularly long. Sleep patterns continue to change throughout the life span, with developmental influences influencing amounts and times of sleep from infancy through older adulthood.

### Sleep Cycle

A full sleep cycle is comprised of three NREM stages and one REM stage. For most adults, the first cycle encompasses approximately 70 to 100 minutes, and subsequent cycles involve 90 to 100 minutes (Brinkman et al., 2023; Suni, 2023). Adults typically experience four to six cycles of sleep nightly, or during the major session of sleep. The most restorative sleep occurs during the N3 stage, and most of this sleep stage occurs in the first few hours of sleep, with REM increasing in the latter cycles of sleep.

## PATIENT CONVERSATIONS

### What's Going on While I Sleep?

**Scenario:** A patient is being interviewed prior to seeing the primary care physician for problems sleeping. The patient has dark circles under the eyes and is yawning frequently.

**Nurse:** Mr. Richardson, I'm Christy, and I understand you're having trouble sleeping. Can you tell me more about this?

**Patient:** Of course. Gosh, it's been about a month now. It seems every night it takes longer for me to fall asleep. Then, I wake up at the lightest noises. But then, it's almost funny—my wife says sometimes I'm so hard to wake up!

**Nurse:** I'm sorry this is happening—it can be so frustrating to not sleep well. Let me tell you a little about what happens when you're asleep.

**Patient:** How much can happen? I'm asleep, after all!

**Nurse:** That's just it, Mr. Richardson. You'd be surprised how much happens while you're asleep. So, sleep includes four stages, and they work in a pretty predictable cycle. Normally, it only takes a few minutes to fall asleep—no more than seven to ten minutes.

**Patient:** It's taking me a half hour most nights now.

**Nurse:** We'll talk about some possible reasons for that shortly, and maybe I can help with some ideas. So, that first stage is N1 sleep, and the next is N2, and during this time your body slows things down. Your eyes stop moving, your body cools down, your heart and breathing slow down. Your brain is working on things that happened during the day, and starts to build memories. This is when you're waking up easily, though, which can be very bothersome.

**Patient:** Very! And then I have to fall asleep again.

**Nurse:** The other thing happening at that time, before you woke up, is your body was getting ready for N3, the next stage, when you sleep really soundly. But it has to start over to get you there, because first you have to fall asleep. N3 is when your wife struggles to wake you up.

**Patient:** She says I sleep like a rock!

**Nurse:** During N3 sleep, you're sleeping very deeply, and your body slows down even more, but your mind is still busy removing toxins and fixing things.

**Patient:** That's fascinating. Who knew so much was going on?

**Nurse:** Your brain is a busy place while you're sleeping. And in the next stage, your body gets busy again. REM stands for "rapid eye movement." When you're in REM sleep, as you can imagine from the name, your eyes are moving quickly, and your brain is busy again, like it is during the day. You breathe faster again, and your heart speeds back up. And this is when your dreams often include actions that don't make sense, like flying or breathing underwater.

**Patient:** Sometimes when I wake up, those are the wild dreams I wake up from!

**Nurse:** It's quite possible. The dreams you might have during N3, you often don't remember, and you rarely wake up during them, and you sleep in N3 a lot in the first part of the night. Then you go into REM more for the rest of the night. And, it's easier to wake up in REM, and since it occurs more as you get close to waking up, that's often the stage you're sleeping in when you wake up.

**Patient:** I had no idea so much was going on overnight, especially in my mind!

**Scenario follow-up:** The nurse proceeds with further inquiry as to the patient's sleep history, and offers sleep hygiene ideas that may help with falling asleep. Christy also explains she will see the patient after the physician visit to provide further education and assistance.

Sleep patterns are also referred to as **sleep architecture**. A sleep study, or **polysomnography**, involves results of assorted physiologic monitors, including EEG, electrocardiogram (ECG), electrooculogram (EOG), electromyogram (EMG), and oxygen saturation (SaO<sub>2</sub>). The individual's sleep architecture is displayed as a graph, called a **hypnogram** (Figure 28.4).

**FIGURE 28.4** A hypnogram is a diagram of the stages of sleep as they occur during a period of sleep. This hypnogram illustrates how an individual moves through the currently recognized stages of sleep. (modification of work from *Psychology 2e*. attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The first sleep cycle of the night, if undisturbed, includes all three NREM stages, including a repeat of N2, followed by REM, with continued cycles through the stages in this manner: N1—N2—N3—N2—REM (Cherry, 2023). Unless awakened, N1 is not repeated. Healthy transitions between the stages of sleep happen more often if an individual has

good **sleep hygiene**, or healthy sleep habits. Factors affecting sleep hygiene include

- maintaining regular sleep and wake times,
- providing an environment conducive to sleep (e.g., dark, quiet, cool room),
- allowing enough time for adequate sleep,
- reducing substance use (e.g., alcohol, caffeine, and nicotine), and
- addressing sleep-related disorders (e.g., sleep apnea, restless leg syndrome (Suni, 2023)).

### Developmental Patterns

During growth and development phases, sleep patterns change (Table 28.2). This includes quality of sleep, time preference, sleep stages, and sleep patterns, with resulting adjustments to sleep architecture. With advancing age, from infancy to older adults, the need for sleep tends to lessen to some extent, from the majority of a twenty-four-hour period to about eight hours.

Gender also has some general differences, with men in stage I sleep and waking more times overnight than women. Women tend to take longer entering sleep, and spend longer in SWS. Pregnancy and the postpartum period bring their own challenges, with more sleepiness during the day and struggles to find comfortable positions in advanced stages of pregnancy.

Infancy (0–12 months)	Neonate	<ul style="list-style-type: none"> <li>• Circadian rhythms not developed</li> <li>• Irregular sleep patterns, especially in first weeks</li> <li>• Sleep sixteen to eighteen hours/day in divided (2.5- to 4-hour) episodes</li> <li>• Three sleep types:               <ul style="list-style-type: none"> <li>◦ active sleep—similar to NREM</li> <li>◦ quiet sleep—similar to REM</li> <li>◦ indeterminate sleep</li> </ul> </li> <li>• Onset of sleep through quiet sleep/REM</li> <li>• Only one to two sleep cycles per episode</li> </ul>
	Infant	<ul style="list-style-type: none"> <li>• By approximately 2–3 months:               <ul style="list-style-type: none"> <li>◦ circadian rhythms develop</li> <li>◦ duration of sleep at night increases</li> </ul> </li> <li>• At approximately 3 months:               <ul style="list-style-type: none"> <li>◦ melatonin and cortisol release starts</li> <li>◦ onset of sleep through NREM</li> </ul> </li> <li>• At approximately 6 months:               <ul style="list-style-type: none"> <li>◦ sleep duration approximately six hours per episode; fourteen to fifteen hours per day</li> </ul> </li> <li>• At approximately 12 months:               <ul style="list-style-type: none"> <li>◦ sleep twelve to fifteen hours per day with only two stages during daytime</li> </ul> </li> </ul>
Childhood (1–9 years)	Toddler (1–3 years)	<ul style="list-style-type: none"> <li>• At approximately 2–5 years:               <ul style="list-style-type: none"> <li>◦ sleep need decreases by approximately two hours, from thirteen to eleven hours</li> </ul> </li> </ul>
	Child (3–9 years)	<ul style="list-style-type: none"> <li>• At approximately 6 years:               <ul style="list-style-type: none"> <li>◦ development of sleep phase preferences and tendencies: “night owl” or “early bird”</li> <li>◦ begin shorter REM with more time in N3</li> </ul> </li> </ul>

**TABLE 28.2** Developmental Stages and Sleep Patterns (Sources: Johnson, 2024; Nunez & Lamoreux, 2023; Patel et al., 2024.)

Adolescence	10–18 years	<ul style="list-style-type: none"> <li>• Require nine to ten hours of sleep</li> <li>• Hormone changes lead to less N3/SWS and more N2</li> <li>• Increased sleepiness during day</li> <li>• Typical preference for staying up later and sleeping later in morning</li> </ul>
Adulthood (18+)	Young/middle age adult (18–65)	<ul style="list-style-type: none"> <li>• Require seven to nine hours of sleep</li> <li>• Earlier sleep time (bedtime)</li> <li>• Less consolidated sleep (more frequent awakenings)</li> </ul>
	Older adult (65+)	<ul style="list-style-type: none"> <li>• Require seven to eight hours of sleep</li> <li>• Pattern changes to waken approximately 1.5 hours earlier (than young adult) and bedtime approximately one hour earlier than when in 20s and 30s</li> </ul>

## 28.2 Factors Affecting Sleep and Rest

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze physiological considerations that affect sleep and rest
- Understand lifestyles and habits that affect sleep and rest
- Recognize common sleep disorders

The quantity and quality of sleep varies according to different factors. Physiological considerations include developmental patterns and changes as well as the impacts on sleep that can be attributed to illness or medications. Medications, whether to prevent illness and maintain health, or to treat a particular disorder or disease, are often accompanied by side effects and can affect sleep. Culture and lifestyle choices or habits also influence sleep quality and quantity. Stress can be a major contributor to changes in sleep hygiene, amount and quality of sleep, illness, and use of substances to assist with coping.

Sleep disorders also affect sleep quality and quantity. Aside from insomnia, disorders that affect breathing and those involving excessive movements lead to a lack of sleep. Additionally, this section will consider issues that result in more sleep than normal.

### Physiological Considerations Affecting Sleep

There are various physiological considerations when it comes to sleep. This section explores influences on sleep, including developmental sources, illness, medications, and culture.

#### Development Stage

Sleep patterns change at different times in a life span. Neonates for example, fall directly into REM sleep, and sleep in rather short episodes for up to eighteen hours a day ([Figure 28.5](#)) (Johnson, 2024). As growth and developmental stages continue through childhood, adolescence, and adulthood, more outside influences such as the demands of school, hormonal changes and growth spurts, and employment expectations affect sleep. Quality may be influenced by stress, worry, or poor health; quantity may be affected by the addition of a baby to the family, personal or family obligations, or the need to get up early or stay up late for work.

**FIGURE 28.5** A baby falls directly into REM sleep, and may sleep up to eighteen hours a day. (credit: “Safe Infant Sleep for SIDS Awareness Month” by NIH Image Gallery/Flickr, Public Domain)

Another developmental consideration is pregnancy, during which physical changes may include gastrointestinal discomfort (e.g., heartburn or reflux), causing wakefulness and the need for position changes. Fetal growth can lead to more frequent urination, difficulty finding a comfortable sleep position, and shortness of breath for the childbearing person.

Some of these developmental effects on sleep, such as hormonal changes with adolescence, excessive fatigue during a growth spurt, or poor sleep while pregnant are temporary. Other effects may become longstanding, as natural aging processes affect sleep over time, or when poor sleep perpetuates further sleep problems and chronic issues develop (Nunez and Lamoreux, 2023).

### Illness

Chronic illness or episodes of acute illness are frequent contributors to disruptions of normal sleep patterns. They can also create new sleep patterns as an adaptive mechanism (Table 28.3). Some of these circumstances increase sleep, such as when the immune system is combatting an infection or recovering from a surgery or trauma. Other circumstances involve less sleep, or poor-quality sleep, which does not achieve the rejuvenation and restful state normally associated with sleep. If a person is unable to spend adequate time in stage III’s SWS, and/or does not reach REM, the sleep is not as restorative.

Disorder	More Sleep	Less Sleep	Notes
Bipolar disorder	X	X	Changes in sleep pattern often occurs prior to cycling of manic or depressive episode (especially mania). Depression is associated with an increase or decrease of sleep; mania is associated with decreased sleep.
Chronic obstructive pulmonary disease (COPD)		X	Especially in advanced stages, COPD affects sleep position; it may cause air hunger and frequent awakenings.

**TABLE 28.3** Disorders and Sleep Patterns

Disorder	More Sleep	Less Sleep	Notes
Depression	X	X	Depression is commonly accompanied by sleep disorder, with either more or less sleep.
Diabetes mellitus (DM)		X	Episodes of poor control (hyperglycemia) are characterized by polyuria, polydipsia, and polyphagia, which can all disrupt sleep patterns.
Heart failure (HF)		X	Similar to COPD, in advanced stages, HF affects sleep position, and it may cause air hunger and frequent awakenings. Treatment may cause frequent urination.
Infection	X	X	Infection and related symptoms (e.g., fever, pain, mental status change) may increase or decrease sleep. Sleep may be disrupted and of poor quality.
Narcolepsy	X		Narcolepsy is associated with unexpected and sudden sleep episodes during the day. Sleep quality is not necessarily restful or restorative.
Pain		X	Pain often causes sleep disruptions and an inability to sleep deeply. Treatment may cause drowsiness, but sleep quality may still be hindered.
Restless leg syndrome (RLS)		X	RLS tends to hinder falling asleep, but can also waken a person from sleep.
Sleep apnea		X	Episodes of apnea cause frequent awakenings, and inhibit achieving deep levels of sleep (N3 or REM); restorative rest is reduced.

**TABLE 28.3 Disorders and Sleep Patterns**

### Medications

There are some medications designed to assist with sleep and others designed to maintain alertness and stay awake. Medications for sleep work with the central nervous system (CNS) in some capacity, to improve entry to sleep, to help maintain sleep, or both. There are some over-the-counter (OTC) natural remedies available as well, and for some people they work as well as medications approved by the Federal Drug Administration (FDA). Nurses should engage patients in a discussion about use of such easily available choices, as combination of natural supplements or OTC medications with other sleep aids, or other medications of any sort, should be approved by the healthcare prescriber (physician, nurse practitioner, or physician's assistant). An introduction to some of the sleep-related medications follows.

Examples of natural sleep aids include melatonin, valerian, and kava kava. Although easily available, they have many of the same potential side and adverse effects as OTC and prescription sleep medications. An example of a commonly used OTC is diphenhydramine (e.g., Benadryl), which is a first-generation antihistamine, but is used for its sedating side effect. It is generally considered safe for patients over 12 years old, and tends to work well as a sleep aid, particularly for inducing sleep. If enough time for sleep is not provided, some people find themselves drowsy when they need to wake and start the day. Major CNS side effects are not common. Some of the common side or adverse effects of diphenhydramine include the following:

- Drug hangover: This includes difficulty waking the morning after taking the medication; may include slower reactions and residual sleepiness.
- Respiratory depression: This is typically dose-related, with higher doses, or if combined with certain other drugs (e.g., opioids), potentially affecting the respiratory center.
- REM rebound: This may manifest as nightmares or other brain activities associated with REM sleep.

## LIFE-STAGE CONTEXT

### Babies, Children, and Diphenhydramine

The risk for CNS effects with diphenhydramine is particularly apparent in infants and young children, as well as older adults. Hallucinations, seizures, and death are possible, especially with excessive dosing. It is not advised to use diphenhydramine as a sleep aid for children, and although it commonly causes drowsiness in adults, it may paradoxically cause excitation in children. It is not recommended to use diphenhydramine for children under 2 years old for any reason, and only on the advice of a healthcare prescriber for children between 2 and 5 years old for use to treat allergic reactions (Drugs.com, 2022).

Benzodiazepines, also known as **anxiolytic** drugs, are drugs commonly prescribed to reduce anxiety; some are prescribed as sleep aids. Insomnia is sometimes associated with anxiety, which can make the choice of this class of drug ideal in certain circumstances. Because of the possibility for more significant side effects, especially if they have been used for a long period and are suddenly discontinued, most benzodiazepines (e.g., diazepam, lorazepam, midazolam) are not used as often as in years past for treatment of insomnia. When they are prescribed, they tend to be for a limited duration. An exception, though still not recommended for long-term use, is temazepam, which is perhaps the benzodiazepine most used as a sleep aid and marketed with an associated brand name, Restoril.

Benzodiazepines have the potential to affect the CNS more than some other drugs, and may result in effects such as tolerance (taking a higher dose in order to achieve the anticipated effect) and dependence (caused by chronic use and development of an addiction to the drug; a withdrawal syndrome results from discontinuation).

There are several nonbenzodiazepines that have become commonly used as sleep aids over the past few years. These fall into the class of sedative-hypnotics. Following is a list of these drugs, with their brand names:

- eszopiclone (Lunesta)
- ramelteon (Rozerem)
- suvorexant (Belsomra)
- zaleplon (Sonata)
- zolpidem (Ambien, or Ambien CR [controlled-release])

Although these are more specifically designed for sleep (induction, maintenance, or both), they do have CNS effects and are therefore associated with a variety of side effects. Specific effects depend on the **mechanism of action (MoA)**; for example, ramelteon initiates results similar to those of melatonin; the MoA of eszopiclone and zaleplon involves gamma-aminobutyric acid (GABA).

Whether a medication is being used for its primary effect or a desired side effect, nurses should be aware of the properties, including the MoA. This medication knowledge allows nurses to review individual patients' use of medications; anticipate drug-to-drug interactions and side or adverse effects; and assess whether or not the desired effects are achieved. See [Table 28.7](#) located later in the chapter.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Patient-Centered Care

Disclaimer: Always follow the agency's policies regarding medication safety and administration.

**Definition:** The nurse recognizes the patient and/or designee as in control of their own care and specific needs.

**Knowledge:** The nurse understands that patient safety can be enhanced by actively involving the patient and significant other in administration of a nonbenzodiazepine sleep aid.

**Skill:** Involve the patient and significant other in active participation of safety and self-care management. The nurse will educate the patient and significant other about the prescribed nonbenzodiazepine, zolpidem. This will include the following information:

- mechanism of action
- amount of time before bedtime it should be taken
- potential side/adverse effects, including the following (Drugs.com, 2024a, PDR, 2024):
  - dizziness
  - hypersomnia
  - hallucinations
  - amnesia
  - gastrointestinal disturbances (nausea, vomiting, diarrhea)
  - parasomnias (sleepwalking, sleep driving, sleep shopping)
  - hypersensitivity reactions (anaphylaxis)
  - cognitive or behavioral changes
- what to do if concerning side/adverse effects occur

**Attitude:** The nurse values the active relationship with the patient and significant other in the care plan by assisting with education and evaluating understanding prior to starting medication regimen.

---

Treatment for difficulty sleeping, including sleep aids, is often adequate to improve patients' sleep and resolve problems with feeling sleepy while awake or falling asleep during the day. There are circumstances, however, when **hypersomnolence** (excessive feelings of fatigue and sleepiness, or episodes of sleep during normal times to be awake) is severe enough that medications are indicated to promote wakefulness. Medications range from caffeine to prescription drugs. Caffeine is available in tea and coffee beverages, energy drinks, and chocolate (Peters, 2023). There are also specific caffeine preparations available. There are several prescription medications that also promote wakefulness. Stimulants assist the brain's ability to focus and be attentive (Peters, 2023). Examples of prescription stimulants include the following (Drugs.com, 2024b; Peters, 2023):

- methylphenidate (Ritalin, Concerta)
- amphetamine and dextroamphetamine (Adderall)
- armodafinil (Nuvigil)
- modafinil (Provigil)

Central hypersomnolence disorders, such as narcolepsy, are discussed later in the section and frequently require prescription therapy. Drug treatment tends to start with stimulants. Some patients may not respond well to first-line treatment so may be prescribed selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), or tricyclic antidepressants (TCAs). See [Table 28.8](#) later in the chapter.

### Lifestyle, Habit, and Cultural Considerations

Habits, lifestyle, and culture influence sleep. Whether one participates in regular physical activity or lives a sedentary life can impact the quality and quantity of sleep. Caffeine and nicotine habits have potential to diminish the ability to sleep or to sleep well. Alcohol, although a depressant, can also lead to poor sleep. Additionally, life's stressful circumstances, and the body's response, are common contributors to issues with sleep. The importance of sleep, according to Lockett (2023), is as critical in health and wellness as the roles of exercise and nutrition.

Electronics have become a ubiquitous part of most lives. For many, electronic connectivity has become such a central part of life, they are viewing their screens right before bed, and perhaps responding to message alerts when they would previously have been entering deep sleep cycles. The additional light exposure of electronics also impacts sleep onset; it potentially also impacts quality, particularly by its reduction of melatonin production (AlShareef, 2022; Casiraghi et al., 2021).

Children and adolescents are frequently the first to come to mind as the primary users of electronics, through social media and other points of access. Indeed, some of the recent studies have focused on this population. In children ages 6 to 12, a delayed bedtime was noted due to the use of electronics (Lund et al., 2021). Additionally, these children identified experiencing poor quality sleep. In a slightly older group of students, ages 13 to 15, there was an association between difficulty falling asleep and time spent using electronics, as well as poor sleep with the use of social media (Lund et al., 2021).

An Iranian study of 290 participants with an age median of 17 years, smart electronic device use was at least 7.5

hours per day (Pirdehghan et al., 2021). Boys were associated with more use than girls in this group, and more than 60 percent of participants indicated having their cell phones in the bedroom while sleeping. Participants identified poor sleep related to their use of phones (Pirdehghan et al., 2021). Also linked to frequent use of electronic media were an increase in upper back and neck pain, body mass index (BMI), and vision disturbances associated with strained eyes, as well as noted decrease in function during the day and problems with relationships between parents and children (Pirdehghan et al., 2021).

University students between the ages of 17 and 29 years old were identified with high use of social media (97 percent of 300 participants) (Kolhar et al., 2021). Results included spending significant time using social media for chatting and shopping, with only one percent of time spent on academics. Impacts identified included delayed bedtimes, reduced social interactions, and distraction from academics (Kolhar et al., 2021). Additionally, a decrease in physical activity was noted, and an increase in risk for mental health concerns such as anxiety and depression (Kolhar, 2021).

A large sample (10,106) of adults were surveyed regarding electronics use and sleep quality, with consideration for daytime hypersomnia (AlShareef, 2022). More than 95 percent of participants slept with smart phone(s) in the bedroom, and more than 80 percent used the phones regularly during the night. Advances in technology and improvements in living standards are associated with expectations of around-the-clock availability, which was exacerbated by changes involving increased electronic/internet use during COVID-19 (AlShareef, 2022). Such frequent use was identified as contributing to poor quality of sleep and excessive sleepiness during the day (AlShareef, 2022).

## LIFE-STAGE CONTEXT

---

### Addicted to Social Media

Many adolescents and young adults identify themselves as addicted to social media. Of 300 women studying at a Saudi Arabian university, 57 percent considered themselves addicted to social media (Kolhar et al., 2021). Inquiries as to use of electronics and social media by nurses can contribute valuable information to other members of the multidisciplinary healthcare team and assist with individualized care planning.

---

### Physical Activity

Physical activity supports sleep and prevents insomnia. Exercise tends to have general health benefits and promote psychophysiological homeostasis. Physical activity contributes to a body's normal functioning by maintaining flexibility, improving oxygenation and perfusion, and fostering other metabolic actions and reactions. The revitalizing effects of sleep involve toxin clearance from the body and the restorative capabilities that are especially associated with SWS (Shafiq et al., 2024). Additionally, physical activities lead to physical fatigue and therefore a desire and need for the recuperation and rejuvenation that occurs during sleep.

Although an appropriate amount of physical activity is usually associated with positive results, excessive activity may lead to strained muscles or injuries that may cause pain, which can disrupt sleep patterns. Recommended exercise includes 150 minutes weekly. Many people incorporate that into three fifty-minute sessions, but for sleep promotion it may be better to work out five times weekly for thirty minutes each session (Nunez, 2020). Timing of activity can be important, as too much physical activity close to bedtime can actually inhibit falling asleep or interfere with quality sleep. It is typically recommended to avoid exercise within approximately five hours of anticipated sleep, but some recent evidence indicates only one hour from bedtime is enough of a buffer for moderate physical activity (Nunez, 2020).

### Caffeine, Nicotine, and Alcohol Intake

Stimulants, such as caffeine and nicotine, are common contributors to insomnia. Although there are some people who drink coffee or other caffeinated beverages with or after the evening meal, many avoid them as a way to promote good quality sleep. In addition to the potential for caffeine to directly inhibit sleep through stimulation, its diuretic effects may cause frequent urination, which can also prevent sleep. For those who partake of just a cup of post-dinner coffee, recent research indicates only a minimal impact on insomnia (Krans, 2019; Spadola et al., 2019).

Nicotine has been implicated as having more of a negative impact on sleep than caffeine (Krans, 2019; Spadola et al., 2019). No matter the form (e.g., cigarettes, smokeless tobacco, or vapes), nicotine can impede sleep by minimizing the feelings of sleepiness and readiness for bedtime. Patients should avoid nicotine within two hours of planned sleep. Nicotine is also associated with waking earlier in the morning. The early awakening is a result of the addictive nature of nicotine and the effect on the brain as it withdraws from the chemical overnight (Krans, 2019).

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Prioritize Hypotheses: Coffee and Cigarettes

A nurse has been talking with a patient about their inability to fall asleep promptly at bedtime. The patient is interested in behavior modification that will improve the nightly routine. During their discussion, the patient has provided the following cues about caffeine and nicotine: the patient consumes four cups of coffee every morning. Throughout the day, and up to bedtime, the patient smokes cigarettes. The patient has been a pack-per-day smoker for fifteen years. The nurse is aware that both caffeine and nicotine are stimulants and can contribute to the delay in falling asleep. Considering the time of day for use of each substance, the nurse suggests nicotine is the primary habit of concern.

Another chemical associated with insomnia is alcohol. Although alcohol is typically identified as a depressant, there is a stimulant effect involved with its metabolism (Krans, 2019; Spadola et al., 2019). This is why drinking an alcoholic beverage may assist someone in falling asleep, but within a relatively short time, the person is likely to awaken from the stimulant effects of alcohol metabolism (Krans, 2019). It can be difficult to fall asleep again. Recommendations are to limit alcohol to one or two drinks around the evening meal, then to avoid alcohol for three or four hours prior to bedtime (Krans, 2019; Spadola et al. 2019).

### LINK TO LEARNING

This video discusses [the effects of nicotine, alcohol, caffeine, and stress \(https://openstax.org/r/77SleepProbs\)](https://openstax.org/r/77SleepProbs) on sleep.

#### Life Stressors

The stress response involves activation of the sympathetic nervous system and hormones associated with the fight-or-flight response (see [Stress, Adaptation, and Homeostasis](#) for more information). Hormones such as cortisol, epinephrine, and norepinephrine cause physical responses of stimulation. These physical responses may include tachycardia, tachypnea, hypertension, an increase in release of glucose, and even anxiety. When stressors affect patients' lives, it can be difficult to slow down the mind as well as the physical reactions. This can make falling asleep difficult, and even for those who are able to fall asleep, they may wake prematurely and find it hard to return to sleep. Control of stress, and learning techniques for appropriately coping with stressful situations, can help with insomnia caused by such life events.

#### Culture

Cultural influences and practices may impact the quality and quantity of sleep. Culture may influence how people think about sleep throughout the life span. For instance, some cultures frown upon naps in adulthood. Yet other cultures embrace naps throughout life's stages and even build such afternoon breaks into the workday. Some cultures are more or less likely to include and encourage health and wellness activities, such as exercise, immunizations, and preventive visits to healthcare providers. Such preventive measures tend to contribute to health promotion and disease prevention. This can contribute to improved health or to peace of mind. Those whose cultural mores and practices encourage participation in such actions may be more likely to experience adequate, restorative sleep.

Dietary choices are also frequently culturally based, not only as to specific foods and drinks, but also in terms of timing and withholding. For instance, some cultures and religions include periods of fasting or a single daily meal later in the evening. Others may discourage drinking alcohol. By way of example, fasting may affect sleep quality or quantity because an individual may be hungry, have gastrointestinal discomfort, or altered bladder or bowel

patterns.

Grief, also influenced by culture, can affect sleep. Cultural norms and practices often dictate the availability and amount of support a grieving person has from family and community. Sadness can be overwhelming, and may affect sleep patterns; depression can lead to a lack or excess of sleep.

## Common Sleep Disorders

Some common sleep disorders include an inability to sleep or stay asleep (insomnia), or abnormal behaviors while asleep (**parasomnia**). Additionally, there are breathing and movement disorders that can affect both quality and quantity of sleep. There are also disorders of the central nervous system that can result in hypersomnolence.

### Insomnia

Insomnia is an inability to fall asleep, to stay asleep, or to achieve good quality sleep. Lack of sleep results in feeling fatigued and sleepy, often throughout the day, and can hinder the ability to complete activities and obligations. Insomnia may also be a consequence of a physical or psychological disorder or condition. Insomnia often affects concentration, moods, and energy levels (Roddick & Cherney, 2024). Sleep disruptions are also associated with some cognitive disorders, including Alzheimer disease. Keep in mind that sleep is necessary to maintain clear thinking, to prompt reactions, and to process complex thoughts and circumstances.

Insomnia can be acute or chronic. Acute, or short-term, insomnia is temporary and may occur in response to a stressful situation, or a change to a person's sleep schedule, such as a later night than usual or having to get up earlier than expected. Jet lag is commonly associated with acute insomnia because it changes normal sleep cycles and patterns. Chronic insomnia, on the other hand, lasts longer than three months and/or occurs more than three nights per week. The risk for developing certain disorders, such as hypertension, coronary artery disease, diabetes mellitus, cancer, depression, and anxiety, is higher for those who experience chronic insomnia.

## LINK TO LEARNING

Watch this video regarding [insomnia \(https://openstax.org/r/77Insomnia\)](https://openstax.org/r/77Insomnia) that includes a description, possible causes, and treatment.

Parasomnias are abnormal behaviors while a person is asleep (Table 28.4). These manifest in dreams, movements, and vocalizations that occur as a person is falling asleep, while asleep, or as they wake up (Schwab, 2022). With many of the parasomnia behaviors, the person does not remember the activities. Associated dreams may be recalled immediately upon waking, but most are not remembered long term. There is an almost cyclical relationship between insomnia and parasomnias, as lack of sleep can contribute to the occurrence of parasomnias, and parasomnias may result in a lack of sleep.

Parasomnia	Activity/Behavior
Confusional arousal	<ul style="list-style-type: none"> <li>• Confused/disoriented to space and time</li> <li>• Appear awake, eyes may be open, may sit upright, may speak or cry</li> </ul>
Enuresis	<ul style="list-style-type: none"> <li>• Occurs in adults or children at least 5 years old</li> <li>• At least twice weekly, for at least three months</li> </ul>
Head banging	<ul style="list-style-type: none"> <li>• Bangs head into mattress, pillow, wall, or floor</li> <li>• Occurs while falling asleep or during REM</li> <li>• More common in children than adults</li> </ul>

**TABLE 28.4** Parasomnias and Associated Activities or Behaviors (Sources: Cleveland Clinic, 2021; Schwab, 2022.)

Parasomnia	Activity/Behavior
Jaw clenching/ teeth grinding	<ul style="list-style-type: none"> <li>Grinding teeth or clenching jaw muscles while asleep</li> </ul>
Nightmares	<ul style="list-style-type: none"> <li>Scary dreams and sudden awakening</li> <li>Often happen with stress, excessive fatigue, alcohol consumption, or fever</li> <li>May contribute to insomnia</li> </ul>
Night terrors	<ul style="list-style-type: none"> <li>Sudden, terrified awakening: tachycardia, tachypnea, dilated pupils, diaphoresis</li> <li>May scream or cry</li> <li>Typically happen during SWS or partial arousal</li> <li>More common in children than adults</li> </ul>
Recurrent isolated sleep paralysis	<ul style="list-style-type: none"> <li>Possible extension of REM into another sleep stage</li> <li>Inability to move extremities or body while asleep</li> <li>Happens while falling asleep (stage I) or awakening (any sleep stage, including normal waking from REM and restoration of skeletal muscle movement)</li> <li>Can be halted by being touched or spoken to</li> </ul>
REM sleep disorder	<ul style="list-style-type: none"> <li>Speaking profanity, with aggressive movements during dreaming</li> <li>Common in older adults; often occurs with degenerative brain disorder (e.g., Parkinson disease, Lewy body dementia, multiple system atrophy, stroke)</li> <li>Dreams may be recalled</li> </ul>
Sexsomnia	<ul style="list-style-type: none"> <li>Enact sexual behavior(s) while asleep: vocalizations, masturbation, intercourse, sexual assault, fondling bedmate</li> </ul>
Sleep talking	<ul style="list-style-type: none"> <li>Talking while asleep</li> <li>May be a sound or a conversation</li> <li>More common in children than adults</li> </ul>
Somnambulism	<ul style="list-style-type: none"> <li>Arise from bed and walk around</li> <li>Eyes open</li> <li>May be combined with sleep talking</li> <li>May include driving, urinating in an abnormal location, arranging a space or furniture</li> <li>Unaware of actions and surroundings; can be dangerous</li> <li>More common in children than adults</li> </ul>

## LINK TO LEARNING

This video describes different [parasomnias \(https://openstax.org/r/77Parasomnias\)](https://openstax.org/r/77Parasomnias) and their symptoms, causes, diagnosis, and treatment.

### Sleep-Related Breathing Disorders

Breathing disorders associated with sleep include obstructive, central, and mixed sleep apneas; sleep-related

hypoventilation; and sleep-related hypoxemia. Obstructive sleep apnea (OSA) is common and involves relaxation of the muscles of the posterior pharynx (back of the throat) (Figure 28.6). If these muscles relax excessively, they do not support structures within the mouth and throat, including the soft palate, tongue, and sides of the throat, resulting in the airway being blocked or narrowed (Mayo Clinic, 1998–2024; Newsom, 2023a).

**FIGURE 28.6** Airflow through the normal airway is free and unobstructed through the nasal and oral airways; with OSA (shown here), the flow of air is impeded by structures within the mouth and throat, such as the tongue, soft palate, and sides of the throat. (credit: “Obstruction ventilation apnée sommeil” by Habib M'henni /Wikipedia, Public Domain)

The impaired breathing causes an accumulation of carbon dioxide ( $\text{CO}_2$ ), which, upon reaching a certain level, causes the brain to waken the individual, open the airway, and take a deep breath. Depending on the level of  $\text{CO}_2$  and oxygen ( $\text{O}_2$ ), it may take a few deep breaths to normalize the blood gases. Many people have no recollection of the frequent awakenings, as they return to sleep quickly. Nonetheless, if their sleep is disrupted several times each hour, it fragments their sleep, and they may be very drowsy during the day, have mood swings, and find it difficult to concentrate on tasks and thoughts.

Central sleep apnea (CSA) is less common than OSA. It involves a lack of communication between the brain stem and the muscles involved in breathing (Mayo Clinic, 1998–2024; Newsom, 2023a). The airway remains open, but the impaired messaging causes frequent apneic episodes throughout a sleep cycle. Patients with CSA tend to experience the same fragmented sleep as those with OSA, but they also may notice nighttime discomfort in the chest, headaches in the morning, and insomnia (Mayo Clinic, 1998–2024; Newsom, 2023a). Mixed sleep apnea, as the title indicates, is simply a combination of obstructive and central sleep apnea. Therefore, both disorders occur in the same person throughout sleep.

## REAL RN STORIES

### Central Sleep Apnea

**Nurse:** Ellen, BSN

**Clinical Setting:** ICU

**Years in practice:** 6

**Facility location:** Community hospital in the metropolitan Denver area

I was taking care of a young man named Walter, in his early 20s. He had had a benign brain tumor removed and had been in the ICU for about a month, because he was not recovering well neurologically. I had taken care of him for several nights during that month, and I guess I had come to know him pretty well. Because he was minimally responsive, nurses had to use various other cues for many aspects of his assessment. He would open his eyes, sometimes spontaneously, and he could move all extremities, but not to command at that point. Neuro assessments can change, often for the worst, so fast; I was always a bit on edge about his neuro status. One night, as I was catching up on charting, I heard Walter begin snoring loudly, followed by a respiratory pause. I jumped up and started for his room! As I ran, I heard him gasp for a deep breath. By the time I got to his room, he was snoring again. “What’s wrong?” one of my colleagues asked from the nurses’ station, startled by my fast departure. “Walter doesn’t SNORE!!!” I yelled, flipping on the light so I could do a more complete neuro assessment. He continued to have significant pauses in his breathing, and there were other changes that made me think pressure was rising in his

skull, causing central sleep apnea. I called Dr. Monroe, the neurosurgeon, to let him know. He was there within a half hour, putting in a bolt. When the drill punctured through the skull and dura, CSF spurted across the room, but as the pressure was normalized, Walter's neuro status returned to his baseline. No more snoring.

---

There are several other breathing disorders associated with sleep as well. Sleep-related hypoventilation means shallow and unusually slow respirations while asleep. Such inadequate breathing allows for the patient to develop hypercapnia, or elevated blood CO<sub>2</sub>. Sleep-related hypoxemia (low level of O<sub>2</sub> in the blood) is typically not a primary disorder but the result of another condition, usually respiratory, such as chronic obstructive pulmonary disease (COPD).

---

### Sleep-Related Movement Disorders

Although some of the parasomnias discussed earlier do involve repetitive motions while asleep, such as jaw clenching, teeth grinding, and head banging, this section focuses on three sleep-related movement disorders: restless legs syndrome (RLS), periodic limb movement disorder (PLMD), and sleep-related leg cramps.

RLS, as the name indicates, involves leg movements that tend to begin in the evening and become acute when a person lies down to sleep. The sensation of the need to move the legs can become uncontrollable, and may even be painful, with the person moving not only the legs, but frequently repositioning in an attempt to calm the urge for movement. For some, arms and neck may become involved in the restless feelings (Newsom, 2023b).

Nutrition and medications may contribute to episodes of RLS. Alcohol, nicotine, and caffeine are sometimes involved in RLS symptoms, and deficiencies in iron, zinc, vitamin D, and magnesium may also be apparent in those who experience RLS (National Institute of Neurological Disorders and Stroke [NINDS], 2023; Pacheco, 2024). Antihistamine use may cause RLS symptoms and there is a genetic component for some patients; for many it is idiopathic. Some conditions that may lead to RLS include neuropathy, pregnancy, renal disease/failure and hemodialysis (NINDS, 2023).

RLS is not curable, but there are symptomatic treatments, which may include lifestyle adjustments and medications. If particular foods or drinks are identified as contributing to the symptoms, reducing or eliminating these is helpful (NINDS, 2023). Sleep hygiene and improved sleep patterns can prove helpful, as can regular moderate exercise; massage of the legs may also reduce symptoms (NINDS, 2023; Pacheco, 2024). Depending on the patient, medication therapy for RLS may include iron, dopamine agonists (e.g., pramipexole, rotigotine, ropinirole), opioids, and benzodiazepines (NINDS, 2023).

PLMD is associated with movements of the arms, legs, or feet while asleep. PLMD occurs with RLS for more than 80 percent of those who experience it (Newsom, 2023b; NINDS, 2023). Movements are involuntary and are typically repetitive; twitching is common, though patients may also kick. These episodes of movement can be very short term (five seconds) or may last more than a minute, and they may occur more than fifteen times hourly, which leads to awakening and a very fragmented sleep (Newsom, 2023b). Unlike with RLS, people experiencing PLMD do not notice pain, nor do they feel the deliberate need to move their extremities. As with RLS, nutritional imbalances and medications may contribute to episodes of PLMD, and some of the same treatments for RLS may help patients; no medications are recommended specifically for PLMD (Newsom, 2023b).

Cramps and muscle spasms can be quite painful; for some people, they occur while asleep and are therefore identified as sleep-related leg cramps (Newsom, 2023b). Such cramping can last from seconds to minutes, and they can wake a person up or prohibit falling asleep. Sleep-related leg cramps are associated with tired muscles and certain diagnoses, such as electrolyte abnormalities, dehydration, and nerve problems (Newsom, 2023b; Sumner, 2024). Application of heat and massage of cramping muscles may relieve the cramps, and medication therapy is typically focused on identifying and treating underlying conditions (Newsom, 2023b; Sumner, 2024).

### Central Disorders of Hypersomnolence

Hypersomnolence is characterized by an inability to stay awake during waking hours. The sleepiness related to hypersomnolence is out of proportion to an individual's need for sleep. In other words, getting what should be enough sleep overnight does not change the daytime hypersomnolence (Cleveland Clinic, 2024). Hypersomnolence disorders often negatively affect work and relationships, and patients are at risk for accidents, such as falling or motor vehicle accidents (MVA). Central nervous system hypersomnias include narcolepsy, Kleine-Levin syndrome, and idiopathic hypersomnia (Cleveland Clinic, 2024; Moawad, 2024). These are considered primary hypersomnia, as the hypersomnia is not caused by something else; these are quite rare. Levels of neurotransmitters (e.g., orexin, histamine, dopamine, serotonin, and GABA) may be implicated in narcolepsy (Cleveland Clinic, 2024). Low orexin levels have been noted with type 1 narcolepsy (Cleveland Clinic, 2024). Individuals with type 1 narcolepsy are liable to experience **cataplexy** (muscle weakness) after exposure to an emotional situation involving stress, fear, excitement, and even laughter. Type 2 narcolepsy involves the same sort of sudden episodes of sleep but without cataplexy or low orexin levels (Cleveland Clinic, 2024). Treatment for narcolepsy includes stimulant drugs, SNRIs and SSRIs, and TCAs.

Kleine-Levin syndrome (KLS) involves occurrences of hypersomnia, behavioral or cognitive disorders, hypersexuality, and compulsive eating (Shah & Gupta, 2023). The cause of KLS has not been identified, though possible contributors include

- abnormal levels of neurotransmitters (e.g., dopamine, serotonin),
- infection,
- mental health disorder(s),
- toxins, and
- trauma (Shah & Gupta, 2023).

Treatment for KLS is multifaceted and may include psychiatric and pharmaceutical approaches (Shah & Gupta, 2023). As with treatment of narcolepsy, stimulants are used to directly address the hypersomnia, but they do not improve the cognitive and behavioral aspects of the syndrome (Shah & Gupta, 2023). Although there has not been one particular drug or class of drugs identified as particularly effective in treating the behavioral and mental health aspects of KLS, drug classes used include anticonvulsants, antidepressants, and mood stabilizers (Shah & Gupta, 2023).

*Idiopathy* indicates there is not a particular cause identified for a disorder.

Idiopathic hypersomnia therefore involves daytime sleepiness, in spite of adequate sleep, without a specific cause. Identification may take time and involve trial and error. Various treatment options may similarly be tried over time, in an effort to find the right drug or drug combination for individual patients.

Secondary hypersomnia occurs as a result of something else, such as a disease process or use of substance(s). Hypersomnolence disorders are not common and typically affect women more than men ([Table 28.5](#)) (Cleveland Clinic, 2024). Some of the medical conditions associated with secondary hypersomnia include

- depression
- multiple sclerosis (MS),
- neurological damage or trauma, and
- sleep apnea (Stubblefield, 2023).

Treatment of secondary hypersomnia may involve at least temporary treatment with medications such as stimulants used to treat narcolepsy. Treating the source of the problem, however, is more definitive, so the primary cause of the daytime drowsiness (medical diagnosis, drugs, or alcohol) becomes the focus of treatment.

Type of Hypersomnia	Subtype/ Cause of Hypersomnia	Notes
Primary	Narcolepsy type 1	<ul style="list-style-type: none"> <li>• Sudden episode of falling asleep with muscle weakness (cataplexy)</li> <li>• Initiated by emotions</li> <li>• Low orexin (neurotransmitter) level</li> <li>• May be accompanied by sleep paralysis and hallucinations</li> <li>• Common onset between 10 and 25 years old</li> </ul>
	Narcolepsy type 2	<ul style="list-style-type: none"> <li>• Sudden episodes of sleepiness and sleeping</li> <li>• Normal orexin level</li> <li>• Common onset in adolescence</li> </ul>
	Kleine-Levin syndrome	<ul style="list-style-type: none"> <li>• Recurrent hypersomnia associated with behavioral or psychiatric problems</li> <li>• Hypersomnia, obsessive overeating, hypersexuality</li> <li>• Each occurrence lasts up to ten days (may last months and recur through the year)</li> <li>• Level of alertness is normal between episodes</li> <li>• Young men are primarily affected</li> <li>• Episodes decrease over time (reduced episodes and resolution over approximately eight to ten years)</li> </ul>
	Idiopathic hypersomnia	<ul style="list-style-type: none"> <li>• Unknown reason for extreme somnolence</li> <li>• Not improved by ample sleep</li> </ul>
Secondary	Hypersomnia from a medical condition	<ul style="list-style-type: none"> <li>• Diagnoses associated with hypersomnolence include bipolar disorder, depression, encephalitis, epilepsy, multiple sclerosis, multiple systems atrophy, obesity, OSA, and Parkinson disease</li> </ul>
	Hypersomnia from drugs or alcohol	<ul style="list-style-type: none"> <li>• Sedatives—benzodiazepines, barbiturates, melatonin</li> <li>• Antihypertensives</li> <li>• Antiepileptics</li> <li>• Anti-Parkinson's drugs</li> <li>• Muscle relaxants</li> <li>• Antipsychotics</li> <li>• Opiates</li> <li>• Cannabis</li> <li>• Alcohol</li> <li>• Note: Withdrawal from use of some drugs can also cause hypersomnia.</li> </ul>
	Insufficient sleep syndrome	<ul style="list-style-type: none"> <li>• Not achieving seven to nine hours of sleep</li> <li>• Not following good sleep habits</li> </ul>

**TABLE 28.5** Types and Examples of Hypersomnia (Source: Cleveland Clinic, 2024.)

## PATIENT CONVERSATIONS

### Narcolepsy in a Learning Environment

**Scenario:** A nursing student failed a medical-surgical nursing exam. When the student met with the faculty nurse to review the exam and plan for improvement, the following conversation took place:

**Nurse:** I'm concerned about your exam result, Nicole.

**Student:** So am I. I studied.

**Nurse:** Well, that's a good start. Do you have test anxiety?

**Student:** Not that I've noticed before. Well, maybe some, but it's never been a big deal.

**Nurse:** Do you have any ideas?

**Student:** Not really.

**Nurse:** I've noticed you sleeping during classes. Not just a little bit, but several times. You're missing a lot of content.

**Student** [looking down, blushing]: I'm so sorry. I don't know what's happening. I think this stuff is interesting, but I can't stay awake sometimes.

**Nurse:** Has this happened before? In other classes? At other times or places?

**Student:** Yes. More over the past year or year-and-a-half. I can fall asleep about anywhere. I fall asleep in all my classes.

**Nurse:** Do you feel more tired, or does it just happen?

**Student:** Sometimes I do, but sometimes, like in class, it just comes on me suddenly. I can't hold it back, like I used to be able to. I just get weak, and then I'm asleep. Sometimes I can still sort of hear you talking in class. But I guess it's not like normal. I don't remember things like when I'm really awake.

**Scenario follow-up:** The faculty and student reviewed the exam results, and discussed techniques for improved studying. The concern remained though, that if the student continued to fall asleep in class, exam scores would not improve.

**Nurse:** I wonder if you have a sleep disorder. Has your doctor ever mentioned such a thing? Maybe narcolepsy?

**Student:** No. Nothing like that.

**Nurse:** I'm not a nurse practitioner, but that just comes to mind. I think it would be worth getting checked out, because I worry about your success in all your classes. And if it's not narcolepsy, at least there might be something—maybe a medication—you can take to normalize your sleeping so you're not so drowsy during the day.

**Student:** I'll make an appointment right away.

**Nurse:** Excellent. Let me know if there's anything I can help with.

**Scenario follow-up:** The student notified faculty about a narcolepsy type 1 diagnosis later in the semester.

## 28.3 Effects of Insufficient Sleep

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine the effects of insufficient sleep in children
- Recognize the effects of insufficient sleep in adults
- Analyze behavioral effects of insufficient sleep

Sleep has so many functions throughout the life span. In early development, much neurological growth and

development occurs during sleep. At any stage, recuperative, healing, and rejuvenating events happen primarily while a person sleeps. Sleep is also necessary simply for feeling adequately energized and ready for the expectations and activities of a normal day.

Insufficient sleep caused by either a total lack of sleep or a lack of quality sleep can affect people in many ways. For children, sleep insufficiency may influence growth and development, and, for both children and adults, sleep inadequacy can have behavioral, psychological, and physiological implications.

### Insufficient Sleep in Children

Problems sleeping affect 25 to 50 percent of young children, and approximately 40 percent of adolescents (Pacheco, 2023). Results of insufficient sleep may be apparent in growth and development, mental health, behavior, and performance issues. It also places these children at higher risk for obesity and related health concerns.

#### Growth and Development

Insufficient sleep can affect a child's normal growth and development. Inadequate sleep has direct effects on cognitive operations, alertness, the ability to focus and pay attention, the acquisition of vocabulary, and memory (Liu et al., 2024; Pacheco, 2023). Growth hormone has a relationship to circadian rhythms, with typical release during sleep. Not enough sleep during infancy can result in secretion of insufficient amounts of growth hormone, therefore potentially impacting normal growth at such a critical time (Pacheco, 2023). Chronic lack of growth hormone results in reduced growth, impaired focus and alertness, and inability to regulate moods or positively adapt and develop resiliency. For toddlers, napping is needed to consolidate memories and to develop motor skills and high-level attention.

The impact of insufficient sleep on adolescents is seen physically through development of risk factors for, or diagnosis of, cardiovascular, metabolic, and inflammatory disorders. Hypertension, cardiovascular disease, and diabetes mellitus (especially type 2) are becoming more commonplace in adolescence and even childhood, and insufficient sleep is one major factor (Liu et al., 2024; Pacheco, 2023). Behavioral, mental health, and performance issues in this age group are also associated with sleep insufficiency.

### LINK TO LEARNING

Watch this video about [typical development \(https://openstax.org/r/77LackOfSleep\)](https://openstax.org/r/77LackOfSleep) and consider what effects are likely without adequate sleep.

#### Behavioral and Mental Health Concerns

Insufficient sleep can impact the behavior and mental health of children in many ways. It has the potential to influence the ability to

- pay attention,
- focus,
- plan,
- tolerate frustrating circumstances,
- regulate moods,
- adapt,
- develop resilience, and
- learn (Liu et al., 2024; Pacheco, 2023).

Children and adolescents who have no history of mental health concerns may experience such issues as depression or anxiety when sleep deprived; those who have an existing mental health diagnosis are at greater risk for such challenges to worsen (Columbia Psychiatry, 2022).

## PATIENT CONVERSATIONS

---

### An Angry, Irritable First Grader

**Scenario:** A young mother has brought her 6-year-old child to the pediatrician's office because the child is becoming increasingly difficult to control.

**Nurse:** Good morning, Ms. Solange, I'm Susan, Dr. Jackson's nurse. And this must be Lorene? Hi, Lorene.

**Patient:** Hi, Susan.

**Nurse:** Lorene, I'm going to ask your mom some questions, okay? If you have something to add, you can. Is that okay?

**Patient:** Sure.

**Nurse:** Ms. Solange, tell me more about what's going on with Lorene.

**Patient's mother:** She started first grade in August. She loved school. She would even help me in the mornings. Then, about a month ago, she brought home a note from the principal. She'd been in a scuffle at school.

**Patient:** She slapped me first, Mom.

**Patient's mother:** I know, Lorene. But I have to tell the nurse what happened.

**Nurse:** Any other events?

**Patient's mother:** Yes. She's been bringing home notes from the teacher that she's not reading up to grade level, and her spelling is getting worse, not better.

**Nurse:** How is her behavior at home?

**Patient's mother:** She's been grumpier. Sometimes she acts . . .

**Patient:** I'm not grumpy!

**Patient's mother:** I'm sorry, honey, but sometimes you seem unhappy and get a little angry about things. Don't you?

**Nurse:** It's okay, Lorene, sometimes we all get a little grumpy. Do you feel like you're getting enough sleep at night?

**Scenario follow-up:** Lorene and her mother were a little startled by the question, but it opened a flood of emotions.

**Patient:** Mom, you know about Emeline, at school?

**Patient's mother:** Yes. She's the one who slapped you, and you slapped back, right?

**Patient:** Yeah. That's her. Well, she didn't stop after that day.

**Nurse:** Is this girl still bothering you at school, Lorene?

**Patient:** Yes. She hasn't hit me again, but she's so mean.

**Patient's mother:** Oh Lorene, baby. You didn't tell me.

**Scenario follow-up:** Susan and the Solanges discuss that Ms. Solange will contact the teacher and principal and determine what can be done to resolve the situation. Lorene is seen by the pediatrician who confirms stress-related insomnia.

**Nurse:** Now, as for Lorene's being grumpy at home and not doing well at school, it's complicated but likely because she's not sleeping well and has significant stress going on at school. The stress has affected her sleep, which affects her ability to handle Emeline and whatever else was difficult. Then she'd worry at home, and not sleep even more. Did I miss anything, Lorene?

**Patient:** I think you got it. Am I in trouble?

**Patient's mother:** No, you're not. I'm sorry it went on so long, Lorene. But now we know some things to do.

**Nurse:** So, you've got some work to do with the school, and I'll give you some ways to improve Lorene's ability to reduce stress and improve sleep. In one week, let me know how it goes with the school and how Lorene is doing.

## LINK TO LEARNING

Behavioral and mental health consequences of [insufficient sleep \(https://openstax.org/r/77InsuffSleep\)](https://openstax.org/r/77InsuffSleep) are described in this video. Some of the recommendations for improving sleep quantity and quality may be helpful for nursing care and patient education.

### Performance Deficits

Neurophysiological development requires sleep to provide the circumstances that foster certain healing and restorative actions that cannot be accomplished while awake (Nunez & Lamoreux, 2023). Without these revitalizing benefits, performance may suffer. Possible effects on performance include

- lack of alertness,
- inability to concentrate and complete tasks,
- impaired cognitive and reasoning abilities,
- poor memory,
- slowed reaction times,
- poor development of motor skills, and
- lack of academic achievement (Liu et al., 2024; Nunez & Lamoreux, 2023).

### Risk for Obesity

Obesity is an issue in pediatric populations as well in the adult population. Insufficient sleep is associated with development of some of the physiologic (e.g., metabolic) and psychologic (e.g., depression) factors involved in the occurrence of obesity in children (Pacheco, 2023). Studies have noted an inverse relationship between sleep duration and occurrence of overweight and/or obesity (Morrissey et al., 2020). Research indicates that lack of sleep leads to alterations in hormone regulation, which results in an energy imbalance, a subsequent reduction of activity level, and increased intake of calories. Many sleep-related factors affect children's weight, including quality of sleep (as measured by polysomnography), quantity of sleep, where in the twenty-four-hour day sleep occurs, and whether it is easy for a child to fall asleep and stay asleep.

Obesity tends to be accompanied by metabolic disorders, including insulin resistance and cardiovascular-related concerns such as **hyperlipidemia** (elevated blood lipids) and **dyslipidemia** (abnormal blood lipids), hypertension, and coronary artery disease. Anxiety and depression can also contribute to obesity. Additionally, such mental health concerns perpetuate the cycle of insomnia, and all the associated consequences.

### Insufficient Sleep in Adults

Some of the same factors that affect children's sleep are involved in insufficient sleep occurring in adulthood. Chronic sleep insufficiency negatively affects mental and physical health and wellness. Cognitive and behavioral outcomes include decreased reasoning skills; risky, impulsive actions; and poor mood and judgment.

Depression, anxiety, mood disorders, and attention deficit hyperactivity disorder (ADHD) are examples of psychological disorders commonly impacted by lack of sleep (Sun, 2024). Physiological issues that may have a connection to sleep deprivation include cardiovascular, respiratory, gastrointestinal, and metabolic disorders.

### Psychological and Cognitive Concerns

Sleep insufficiency is associated with anxiety, depression, concentration, memory, and mood (Sun, 2024). This relationship sometimes occurs in a bidirectional manner, whereby lack of sleep can be both a contributor to, and the effect of, a mental disorder (Columbia Psychiatry, 2022; Sun, 2024). Even patients who have no history of a mental health disorder might experience issues after episodes of insomnia, especially if the sleep problems become chronic. Psychological distress and insomnia can then become a self-perpetuating problem. Treating the sleep disorder sometimes improves the mental health problem (Sun, 2024).

### **Anxiety**

Anxiety can be a cause of sleep insufficiency or an occurrence secondary to lack of sleep (Columbia Psychiatry, 2022; Pacheco, 2023; Roddick & Cherney, 2024). Anxiety can be mild or any level of severity up to and including a panic attack. Furthermore, the influence on sleep may be mild, and merely cause a slightly lengthened time to fall asleep. Or it may involve enough worry to cause fear and result in hyperarousal, with not only slower time to achieve sleep, but fragmented sleep and an inability to reach the REM stage because of frequent awakenings and difficulty returning to sleep.

Acute episodes of insomnia in people who have no longstanding history of an anxiety disorder will likely result only in mild anxiety. Chronic anxiety is likely to be more severe when coupled with chronic insufficient sleep (Pacheco, 2023; Suni, 2024). PTSD, involving a combination of hyperarousal and recurrent episodes based on trauma, can worsen sleep issues with nightmares and sudden traumatic awakenings (Suni, 2024). Likewise, insomnia can worsen the consequences of PTSD.

### **Depression**

Another psychological concern frequently associated with insufficient sleep is depression. Similar to anxiety, depression may lead to insufficient sleep, or the loss of sleep may result in depression (Suni, 2024). Depression may occur as a result of an event, such as the death of a family member or friend. In such an acute case, the situational depression and linked problem sleeping is relatively short-lived and tends to resolve without interventions. Chronic depression and related insomnia may necessitate a variety of treatments.

Patients may also turn to substance use as a way of self-medicating depression and feeling better temporarily. This, unfortunately, may result in increasing the negative cycle of poor sleep worsening depression and depression worsening sleep (Pacheco, 2023). Additionally, suicidal risk may increase as a consequence of inadequate sleep, even when the patient has no history of depression (Suni, 2024).

### **Concentration and Memory**

While sleeping, the brain is able to recover from the day's demands, including those involved in learning, concentration, and memory consolidation (Pacheco, 2023; Suni, 2023). Insufficient sleep, especially a lack of SWS and REM sleep, negatively impacts these functions and impedes development of healthy adaptations to stress (Suni, 2024). Hypersomnolence may also be implicated in poor memory, confusion, or an inability to concentrate (Cherry, 2023). Other psychological disorders such as ADHD; **seasonal affective disorder (SAD)**, which is depression occurring relative to lack of light; and symptoms of bipolar disorder and schizophrenia can all be adversely affected by insufficient sleep. Manifestations tend to involve worsening of symptoms, including those involved with concentration and the ability to recall information.

### **Severe Mood Swings**

Mood swings may be a result of, or worsened by, insufficient sleep. Without proper rest, patients may feel easily frustrated, tense, and irritable (Cherry, 2023; Suni, 2024). Adequate, restorative sleep fosters positive coping and resilience; sleep deprivation reduces normal brain function and can increase tension, reactivity, and aggression (Cherry, 2023). Such mood changes contribute to negative results in home, school, and/or work environments. Treating the insufficient sleep is likely to improve the mood swings and often begins by discussing sleep hygiene and habits with the patient. Further workup by the healthcare provider may include polysomnography and medication therapy.

### **Hallucinations**

Ineffective sleep can cause neuronal stimulation and excitability in the region of the brain involved in movement. This can result in intensified processing of information and hallucinations with chronic lack of sleep (HealthMatch, 2022). In fact, chronic lack of sleep is associated with a fourfold increase in the potential to experience hallucinations; those experiencing only mild insomnia are at two to three times the risk of such distorted perceptions than someone with adequate sleep (HealthMatch, 2022).

Hallucinations may manifest as simple or complex and may involve changes in an object's color, an object's size, or distance and depth perception (HealthMatch, 2022). Persons experiencing hallucinations may be unable to recognize common items and sounds. Those who have a diagnosis involving altered perception of reality, such as schizophrenia, may experience hallucinations at baseline, with worsening symptoms if sleep deprived.

## Physiological Concerns

Insufficient sleep also affects the body's physiological responses or maintenance of homeostasis. Various neurohormonal responses occur during sleep cycles, including healing and restoring actions as well as the secretion of hormones that sustain normal physiological functions. Sustaining the normal function of the human body involves complex, coordinated activities between the brain and the different organ systems. Sleep is necessary for these systems to perform their necessary tasks and sustain a homeostatic state.

### Gastrointestinal

The gastrointestinal system is affected by quantity and quality of sleep, in a bidirectional fashion. Therefore, insufficient or poor sleep can contribute to gastrointestinal disorders, and gastrointestinal problems can result in ineffective sleep (Orr et al. 2020; Vernia et al., 2021). Gastrointestinal distress often leads to fragmented sleep. Subsequently, the shortened sleep duration contributes to actual and perceived gastrointestinal symptoms, such as reflux, pain, and bloating. Some of the gastrointestinal disorders commonly exacerbated by lack of sleep include

- gastroesophageal reflux disease (GERD),
- irritable bowel syndrome (IBS),
- irritable bowel disease (IBD),
- colon cancer, and
- nonalcoholic fatty liver disease (NAFLD).

There is a pathophysiological relationship observed between OSA and NAFLD. The intermittent hypoxia associated with OSA also contributes to other metabolic disorders, including hyperlipidemia and cellular resistance to insulin (Orr et al., 2020). Secretion of some hormones, growth hormone (GH), prolactin, melatonin, serotonin, and testosterone, can be affected by nutrient intake and circadian rhythms (Vernia et al., 2021).

Nutrition is also potentially contributory to gastrointestinal health or illness. Vernia et al. (2021) noted the psychophysiological relationship of healthy diet and lifestyle and good sleep. Dietary habits such as the following can disrupt sleep:

- eating fast
- irregular or skipped meals
- overeating
- poor-quality food selections
- caffeine
- alcohol

### Cardiovascular

The cardiovascular system is particularly sensitive to insufficient sleep. Implications can be seen in inflammatory responses and the development of atherosclerosis, hypertension, hyperlipidemia, hyperglycemia/diabetes mellitus (DM), obesity, and subsequent myocardial infarction (MI) and stroke (Cleveland Clinic, 2020; Suni, 2023). More specifically, lack of sleep can result in excess calcium deposited in the coronary arteries. This, along with hyperlipidemia and inflammation, contribute to plaque formation. Plaque increases the risk for MI and stroke. Chronic hypertension causes stress on the heart and can contribute to MI and heart failure (HF). The kidneys and brain are also prone to damage secondary to poor perfusion (Suni, 2023).

The interplay between insufficient sleep and these cardiovascular problems can themselves contribute to poor sleep. Depending on the stage of HF, symptoms may include fluid retention and subsequent difficulty breathing. Patients often worry about their physical status and the potential for the condition to worsen. These actual and potential symptoms can negatively impact the quality and quantity of sleep.

Seven to eight hours of quality sleep is recognized as an optimal amount for adults, with lack of sleep contributing to negative cardiac effects. While in NREM sleep, especially stage III, the parasympathetic nervous system counters the effects of stress: heart rate and blood pressure reduce, and respirations become slower and shallower. Without sufficient time spent in stage III NREM sleep to foster relaxation and rejuvenation, pathological changes may appear (Cleveland Clinic, 2020; Suni, 2023).

### Metabolic

Metabolism is influenced by sleep and insufficient sleep in a few ways. The intermittent hypoxia involved in obstructive sleep apnea (OSA) is related to such metabolic disorders as insulin resistance and hyperlipidemia (Orr et al., 2020). Diet is also influenced by sleep, as lower levels of the hormones ghrelin and leptin result in not feeling full and food cravings for choices high in fats and carbohydrates.

Related lipid abnormalities, especially the combination of high triglycerides and low high-density lipoprotein (HDL), insulin resistance, hyperglycemia, hypertension, and weight gain, are commonly associated with metabolic syndrome and DM (Chasens et al., 2021). Those who sleep less than five hours, or more than nine hours per day, are at elevated risk for development of metabolic syndrome.

### Immunity

Sleep fosters normal immune function, and insufficient sleep is related to both adaptive and innate immune function alterations (Garbarino et al., 2021). Sleep supports the body's immunological memory. Immune cells are among those produced primarily during sleep (Heid, 2023). Adequate sleep is necessary for maintenance of normal immune function, homeostasis, the ability to fight microbial invasions, and/or to mount a normal and effective inflammatory response. Patients who do not receive the sleep they need are more susceptible to infections, autoimmune reactions, and exaggerated inflammatory responses resulting in infections and chronic inflammatory responses. These may include pathological changes in the cardiovascular and metabolic systems, autoimmune and neurodegenerative diseases, and cancers, especially colorectal, prostate, and breast cancers (Garbarino et al., 2021). Autoimmune disorders, such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA), are also more common in those who experience chronic sleep loss. Due to chronic illness, the normal immune response becomes unregulated and intensified, causing a more drastic inflammatory response and continuation of chronicity (Garbarino et al. 2021).

## Behavioral Effects of Insufficient Sleep

Decision-making can become impaired by lack of sleep, resulting in behavior changes, including impulsive actions. Misuse of substances and risky, dangerous driving are two potentially damaging behaviors that can be associated with inadequate sleep. Additionally, hypersomnia can negatively affect all different types of behaviors.

### Increased Risk for Substance Misuse

Insufficient sleep can have various psychological results, which can then impact behavior because inadequate sleep can have deleterious effects on clear thinking, coping, and decision-making. Many people self-medicate with substances, such as alcohol, OTC medications, marijuana, and other illicit drugs in order to stay awake, fall asleep, and cope with feelings of anxiety, mood changes, frustration, and insecurity. Some look for ways to feel happier, and some search for methods to calm down, even when such relief is temporary and may even result in worsening long-term effects.

Substance use often backfires when it comes to improving sleep. Alcohol is an example: while it may contribute to falling asleep, it is not typically a good quality sleep and, as the alcohol is metabolized, it often results in waking up with symptoms of feeling overheated and dehydrated. Using substances as a coping mechanism also contributes to the chronicity of ineffective sleep patterns and continues the negative cycle, which can be very hard to break.

### Motor Vehicle Accidents

According to the National Sleep Foundation (NSF, 2022), driving while drowsy equals driving while impaired. The NSF (2022) estimates that approximately 21 percent of motor vehicle accidents (MVAs) resulting in death are attributable to drowsy driving; about 13 percent of drowsy driving MVAs result in hospitalizations. These statistics are significant and frightening, and the morbidity, mortality, and healthcare costs are enormous. The NSF goes on to describe drowsy driving as worthy of being classified as the fourth "D" regarding driving:

- drunk
- drugged
- distracted
- drowsy

Driving while drowsy is preventable but requires the necessary recognition and respect of its influence on safe

driving. The NSF (2022) describes three to five hours of sleep within the previous twenty-four hours as likely to cause impaired driving for most people.

## LINK TO LEARNING

The NSF's [Breaking Report \(https://openstax.org/r/77DrowsyDriving\)](https://openstax.org/r/77DrowsyDriving) shares information regarding drowsy driving, including the graphs about frequency, perceptions about risk, hours of sleep needed for safety, and driving ability confidence.

## 28.4 Nursing Care to Promote Sleep and Rest

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify nursing assessment skills for sleep disturbances
- Describe education to encourage good sleep hygiene practices
- Understand medication administration for sleep and rest

Nurses play an important role in caring for patients with sleep disturbances. Through the data collection (assessment) phase, patient education to improve sleep, and medication administration and education, nurses are involved directly in engaging with patients. Nurses can gather vital information about a patient's personal and family history, advise about keeping a sleep log, and provide information about sleep studies for those who are prescribed such diagnostic testing. The role of the nurse often includes educating patients about issues they are experiencing and ideally helping identify methods to improve problems.

### Assessment for Sleep Disturbances

Nursing care begins with the assessment—gathering necessary and helpful information upon which to build care planning—and continues with prioritizing patient problems, identifying ways to approach them, implementing the identified actions, and evaluating the outcome(s). In the case of sleep disturbances, data collection begins with a detailed family and personal history focused on particular factors that may influence rest and sleep.

Patients who have been experiencing insufficient sleep are often asked to keep a sleep log, and the nurse is able to analyze this diary of events, providing important information to the prescriber. Some patients are prescribed a sleep study, and nurses can educate the patient prior to such a study and assist with poststudy follow-up with the patient and family, if indicated.

Nursing assessment should also include inquiry as to any changes the patient has noticed—psychologically or physiologically—that could be a result of the lack of sleep. The patient may have made the connection or may not have considered sleep as the root of the changes. The nurse may be the first to recognize the link, particularly if already familiar with disorders that are often related to sleep disturbances.

### Collect a Detailed History

Family and patient history, including diagnoses, surgeries, and medications, is a starting point for assessment. The nurse should perform a focused assessment, exploring sleep patterns, hours of sleep, and whether the patient or significant other reports loud snoring, or apneic periods followed by episodes of gasping as the body works to recover from the apnea-related hypoxia. Note that for those who work nights, times for sleep may need to be adjusted or follow-up questions added about time at work versus time off. [Table 28.6](#) offers some guiding questions and can be modified to fit the practice needs of individual nurses.

Questions	Answers
On an average night, how many hours do you sleep?	Recommended: Infants (4–12 months) 12 to 16 hours/day (including naps) Children (1–2 years) 11 to 14 hours/day (including naps) Children (3–5 years) 10 to 13 hours/day (including naps) Children (6–12 years) 9 to 12 hours/day Teens (13–18 years) 8 to 10 hours/day Adults (18 years or older) 7 to 8 hours/day
How do you rate your overall sleep quality over the past month?	Excellent Very good Fairly good Good Poor
Do you go to bed and wake up at about the same time every day, even on days off?	Yes No
While you're doing things during the day, how likely is it for you to fall asleep or to struggle to stay awake?	Very likely Likely Not likely Unlikely
How often do you have trouble going to sleep or staying asleep?	Never Rarely Occasionally Often
During the past two weeks, how many times was loud snoring reported by your sleep partner?	Never Any number

**TABLE 28.6** Sleep-Related Focused Interview Questions

### Analyze the Patient's Sleep Log

It is helpful to have patients keep track of their sleep by using a **sleep log** (Figure 28.7). This may also be referred to as a sleep diary or journal. There is often more information desired by the healthcare team than just hours slept. Examples of questions to consider including in a sleep diary in order to provide comprehensive data include the following:

- What medication(s) do you take? What time do you take it/each?
- Do you exercise? How often? What time?
- How long did it take to fall asleep?
- How well did you sleep?
- How many disruptions during sleep time? How long did the disruptions last?
- How many daytime naps? How long were the naps?
- Did you drink caffeine or alcohol? How much? What time?
- Did you use tobacco or other drug substances? At what time?

Such a log quantifies the amount of sleep normally achieved, as well as the frequency of sleep disturbances, severity, and the impact on the patient's activities during normally active times. It can also help patients to consider their sleep patterns and learn more about their sleep hygiene practices, distractions, and interruptions. Upon completion of a sleep log for the requested period of time, the nurse can analyze the data for specific details and trends.

Day	Hours Slept																							
	9	10	11	12	1	2	3	4	5	6	7	8	9	10	11	12	1	2	3	4	5	6	7	8

THUR																								
FRI																								
SAT																								

**FIGURE 28.7** A straightforward sleep log is shown here, with the patient logging the numbers of hours of sleep by highlighting the appropriate times each day. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## LINK TO LEARNING

The National Institute of Health's National Heart, Lung, and Blood Institute offers a [template for a much more comprehensive sleep log \(https://openstax.org/r/77SleepLog\)](https://openstax.org/r/77SleepLog) that incorporates most of the desired details listed. Add any items not included but important for particular patients.

### Sleep Study

Polysomnography simultaneously records physiologic monitoring, including EEG for recording brain waves, ECG for the electrical cardiac cycle, EOG for recording eye movements, EMG for recording muscle movements, and SaO<sub>2</sub> (Figure 28.8). Monitoring leads for this recording are placed at locations on the scalp, face, eyelids, chest, and limbs, and a pulse oximeter is placed on a finger. Results display on a hypnogram and contribute to diagnosis of insomnia, sleep apnea, narcolepsy, somnambulism, and RLS.

**FIGURE 28.8** A patient demonstrates the setup for a sleep study: leads, wires, belts, and devices are in place for the polysomnogram. (modification of "All Hooked Up" by Tony Alter/Flickr, CC BY 2.0)

Depending on the complexity of the information desired, the sleep study may be done in a sleep center or with a portable system at home. Typically, the data are collected throughout a normal sleep session or at least over several hours. A sleep specialist, often a pulmonologist, reviews the results. The polysomnography carried out at the sleep

center is considered the gold standard. Advantages for the home test include fewer wires, leads, and devices, as well as sleeping in one's own bed; it is also more cost effective unless it ultimately leads to a follow-up inpatient sleep study.

## Education to Encourage Good Sleep Hygiene Practices

Sleep disorders can range from simple to complex and can be acute or chronic. Treatment can be straightforward or may require a multipronged approach. For some people, creating or supporting good sleep hygiene is sufficient. Others may need extensive diagnostics and some combination of medications, therapy, and lifestyle modifications in order to establish efficient sleep patterns. Several practices contribute to good sleep hygiene, often relieving insomnia and other sleep-related issues. Certain beverages, such as herbal teas or warm milk, may foster sleep, with the caveat that drinking near bedtime may cause early arousals in order to void (Cherry, 2023; Cleveland Clinic, 2024). Routines, such as a warm bath, toothbrushing, and selection of sleep clothing, often support the sleep schedule, as the mind and body associate the habits and feelings with bedtime, rest, and sleep.

### Maintain a Consistent Schedule for Sleep

Sleep schedule consistency can be important for sleep promotion. When activity and sleep schedules vary, it is more difficult for the body to maneuver between the two cycles and promptly establish restful sleep. Some people tend to stay up and get up later on days off, but this is actually counterproductive. It is better to set and maintain a consistent sleep schedule—the same bedtime and wake-up time every day, or at least approximately (Cherry, 2023; Cleveland Clinic, 2024). Sleep routines are personal, and different times and techniques may work for different people. It may take some time, and trial and error, to identify the “right way” for an individual to best prepare for sleep.

Establishing consistent lifestyle choices that promote sleep can also be helpful. This includes eliminating food and beverages (e.g., caffeine, alcohol) that cause wakefulness, or minimizing them to some hours prior to bedtime (Cherry, 2023; Cleveland Clinic, 2024). Creating a regular exercise routine is also helpful, as it produces a physical tiredness contributing to the overall desire and need for sleep. Other health benefits of exercise may add indirectly to sleep promotion and quality.

### Incorporate a Relaxation Routine

Recall that sleep is closely associated with cycles of light and dark and circadian rhythms. Within these natural patterns, the release of chemicals assists with sleep (e.g., melatonin) and waking (e.g., cortisol). Working with these natural tendencies by limiting light at bedtime can help promote sleep. This can be especially helpful for those who work night shifts; investing in room-darkening blinds can provide a daytime environment of darkness and subsequent sleep promotion.

## LIFE-STAGE CONTEXT

### Let There Be Light!

Age-related changes to the brain can limit circadian rhythm function and disrupt an older adult's response to light and dark, thereby potentially causing problems with the sleep-wake cycles. Also, melatonin production tends to decrease with age. Nurses should ask patients about their sleep environments, whether they receive adequate exposure to natural light during the day, and if they reduce their light exposure before bedtime and overnight. Nurses can recommend patients turn television and lights off an hour before bed, use room-darkening blinds overnight, and, shortly after rising, open curtains and blinds or go outside to expose themselves to natural light at the time melatonin production normally begins (Casiraghi et al., 2021; Viganò et al., 2023).

Incorporating a relaxation routine can prove helpful for many patients. This may include one or a combination of

activities or techniques, including mellow sounds or music, reading, meditation, yoga, and intentional breathing (Nunez, 2020). Watching TV and using computers, cell phones, or tablets tends to stimulate rather than relax, and may even cause stress. The light from such devices is also counterproductive toward sleep. Again, the choice of method, and the amount of time needed, will be based on what works for a particular person, and it may change periodically over time.

## LINK TO LEARNING

---

Although using an electronic device is not advised as part of a sleep routine, there are [several applications and videos \(https://openstax.org/r/77GetToSleep\)](https://openstax.org/r/77GetToSleep) available. The video portion can be disregarded and the device placed with no light visible, with only the audio playing as part of a bedtime routine.

---

### Sustain a Temperature-Controlled Environment

Comfort during sleep is important, and temperature is one of those comforts. A cool room tends to be more conducive to falling and staying asleep. Maintaining a comfortable temperature for sleep may involve adjusting the thermostat or number of blankets, using a fan, or opening a window. Avoid temperature fluctuations in the bedroom.

### Avoid Electronics Prior to Sleep

Electronics tend to be stimulating and, depending on the device and what is being done, may be stress-inducing or aggravating as well. The light from electronic devices such as cell phones, tablets, and computers can be distracting and can also make it more difficult to fall asleep. Even TV can make it more difficult to fall asleep. Allow some time before bedtime to be electronics-free, to enhance the transition from wakefulness to sleep (Nunez, 2020; Suni, 2024). Although notifications on some electronic devices can be silenced, for some people that may not be possible based on employment or family obligations and expectations. When possible, turning off devices is best, but putting them away from the sleeping area may be a viable alternative. Nurses teaching patients and families about sleep schedules and relaxation routines can guide their audience to a healthful and helpful transition time from stimulation and activity to quiet and rest.

### Medication Administration for Sleep

Safe medication administration is a critical goal for nurses. Nurses need to know the different types of drugs used to promote sleep and their classifications, which are typically based on their MoA, or how a particular drug works. Other necessary information includes the reason the patient has been prescribed the drug, dosages for different uses, routes for administration, potential positive and negative side effects, possible adverse effects, and potential drug-to-drug, and/or drug-to-herbal interactions.

Medications to promote falling asleep and/or staying asleep are available over-the-counter (OTC) and by prescription. Patients may also take herbal remedies to help sleep as well. The common OTC choice for sleep are antihistamines, because drowsiness is a side effect of first-generation antihistamines. Other drugs are categorized as sedatives and/or hypnotics.

## REAL RN STORIES

---

### Mixed Methods

**Nurse:** Margaret, RN

**Clinical setting:** ICU

**Years in practice:** 1

**Facility location:** ICU in suburban area near Denver

I was taking care of one of my first postoperative patients who had open-heart surgery. He was having a fair bit of pain and hadn't been able to sleep, so after I bathed him, I thought about how to make him comfortable enough to rest. He certainly should have been tired enough to sleep. The surgeon's orders included the following:

- Morphine sulfate 4 mg every 6 hours intramuscular injection (IM) for pain. May be given intravenously (IV) in

divided doses.

- Hydroxyzine 50 mg IM PRN for sleep.

After four hours caring for the patient, I had given him a few of the IV divided doses of morphine and felt confident administration of the two drugs at the same time would not adversely affect the patient's respiratory status. I wanted to administer the two drugs in one syringe. I called pharmacy to review the order and dosages. Pharmacy verified the two drugs could be combined in the same syringe, but while the morphine could be given by IM or IV route, the hydroxyzine was limited to the IM route. All the more reason for using just one syringe, as this way the patient would only need one IM injection. The meds were given, and with his pain under control, the patient slept for a couple of solid hours, even sleeping through me going in and out of the room making sure all was well.

### Safe Medication Administration

Medication administration is a major part of nursing care, and its accurate implementation is a critical component of patient safety (MacDowell et al., 2021). Like any medications, those prescribed to help with rest and sleep are prone to adverse drug events (ADEs) at different steps in the administration process. As part of the larger medical system, nurses must be vigilant in avoiding interruptions while giving medications, using safety measures such as barcode scanning of patients and drugs, and having a high level of knowledge of the drugs being administered (MacDowell et al., 2021).

Safe dosage incorporates the original five rights: right patient, medication, dose, time, and route. A nurse's understanding that medications prescribed for sleep-related issues work in various ways with the CNS, with the potential for interactions with certain other drugs (e.g., opioid pain medications), is critical to maintain safe patient care. [Table 28.7](#) provides examples of drugs, a brief description of how they work, typical dosage for sleep, common side effects, and concerning potential adverse effects. Check a reliable, current nursing drug resource for new updates. Also, be aware of the individuality of patient responses, and do not underestimate the importance of assessment and evaluation in nursing care.

Drug Class	Example Drug	MoA	Adult Dose & Route	Side Effects	Adverse Effects
Benzodiazepines	Lorazepam (Ativan)	Enhances GABA	2–4 mg PO at bedtime	<ul style="list-style-type: none"> <li>• Drowsiness</li> <li>• Respiratory depression</li> <li>• Nausea/vomiting/diarrhea</li> </ul>	<ul style="list-style-type: none"> <li>• Severe sedation, respiratory depression possible if combined with other drugs with CNS depressant actions (e.g., opioids, other sedatives, muscle relaxants)</li> <li>• ECG changes; cardiac arrest potential</li> <li>• Paradoxical effects are possible</li> </ul>
	Temazepam (Restoril)		15–30 mg PO at bedtime		
	Triazolam (Halcion)		0.125–0.25 mg PO at bedtime		

**TABLE 28.7** Drugs to Promote Sleep (Sources: Drugs.com, 2024; PDR, 2024; Memorial Sloan Kettering Cancer Center, 2024.)

Drug Class	Example Drug	MoA	Adult Dose & Route	Side Effects	Adverse Effects
Nonbenzodiazepines	Eszopiclone (Lunesta)	Interacts with GABA receptors	1–3 mg PO at bedtime (start with small dose)	<ul style="list-style-type: none"> <li>• Hallucinations</li> <li>• Headache</li> <li>• Rash</li> <li>• Dry mouth</li> <li>• Taste changes</li> </ul>	<ul style="list-style-type: none"> <li>• Parasomnias</li> <li>• Cognitive/behavioral changes</li> <li>• Chest pain</li> <li>• Peripheral edema</li> </ul>
	Ramelteon (Rozerem)	Melatonin agonist	8 mg PO at bedtime	<ul style="list-style-type: none"> <li>• Dizziness</li> <li>• Headache</li> <li>• Nausea/vomiting/diarrhea</li> </ul>	<ul style="list-style-type: none"> <li>• Parasomnias</li> <li>• Suicidal thoughts/behaviors</li> <li>• Angioedema</li> <li>• Insomnia</li> </ul>
	Suvorexant (Belsomra)	Orexin A & B antagonist	10–20 mg PO at bedtime	<ul style="list-style-type: none"> <li>• Dose-related CNS depression</li> <li>• Hypersomnia</li> <li>• Hallucinations</li> </ul>	<ul style="list-style-type: none"> <li>• Parasomnias</li> <li>• Increasing depression</li> <li>• Suicidal ideation</li> </ul>
	Zaleplon (Sonata)	Binds to GABA receptors	10 mg PO at bedtime; 5 mg if > 65 or of a lighter weight	<ul style="list-style-type: none"> <li>• Dizziness</li> <li>• Impaired movement</li> <li>• Vision changes</li> </ul>	<ul style="list-style-type: none"> <li>• Nightmares</li> <li>• Peripheral edema</li> <li>• Epistaxis</li> <li>• Colitis</li> <li>• Dyspepsia</li> <li>• Vertigo</li> </ul>
	Zolpidem (Ambien)	Binds to GABA receptors	Women: 5 mg PO, SL, or spray at bedtime (may increase to 10 mg if lower dose not effective) Men: 5–10 mg PO, SL, or spray at bedtime	<ul style="list-style-type: none"> <li>• Hypersomnia</li> <li>• Dizziness</li> <li>• Hallucinations</li> <li>• Amnesia</li> <li>• Nausea/vomiting/diarrhea</li> </ul>	<ul style="list-style-type: none"> <li>• Parasomnias</li> <li>• Cognitive/behavioral changes</li> <li>• Hypersensitivity (anaphylaxis)</li> </ul> <p><i>Note: Parasomnias with these drugs may include complex sleep behaviors such as sleep walking, driving, or shopping.</i></p>

**TABLE 28.7** Drugs to Promote Sleep (Sources: Drugs.com, 2024; PDR, 2024; Memorial Sloane Kettering Cancer Center, 2024.)

Drug Class	Example Drug	MoA	Adult Dose & Route	Side Effects	Adverse Effects
Antihistamines	Diphenhydramine (Benadryl) <i>Note: Diphenhydramine is packaged alone or combined with OTC analgesics (acetaminophen, ibuprofen).</i>	Histamine antagonist at H1 receptors	1 mg/kg PO 20–30 minutes before bedtime; not to exceed 50 mg	<ul style="list-style-type: none"> <li>• Dizziness</li> <li>• Headache</li> <li>• Anorexia</li> <li>• Dry mouth</li> </ul>	<ul style="list-style-type: none"> <li>• Hypotension</li> <li>• Palpitations</li> <li>• Chest tightness</li> <li>• Dysuria, urinary frequency or retention</li> <li>• Paradoxical effects</li> <li>• Delirium</li> </ul> <p><i>Note: Adverse effects are more likely in older adults. Not recommended for sleep in those over 60.</i></p>
	Hydroxyzine (Atarax, Vistaril) <i>Note: Hydroxyzine for insomnia is an off-label use.</i>	Subcortical CNS depression; competes with H1 receptor sites	50–100 mg PO 30–60 minutes before bedtime 50 mg IM 30–60 minutes before bedtime	<ul style="list-style-type: none"> <li>• Dizziness</li> <li>• Headache</li> <li>• Dry mouth</li> <li>• Increased appetite</li> <li>• Nausea/diarrhea</li> </ul>	<ul style="list-style-type: none"> <li>• Seizures</li> <li>• Depression</li> <li>• Hypotension</li> </ul>
Herbal	Kava kava	Alters emotions at limbic system; anxiolytic, sedation effects.	<i>Herbals are not FDA approved and dosages are not definitively determined</i>	<ul style="list-style-type: none"> <li>• Headache</li> <li>• Weight loss</li> <li>• Vision changes</li> <li>• Pupillary dilation</li> </ul>	<ul style="list-style-type: none"> <li>• Sensory disturbances</li> <li>• Hepatotoxicity</li> <li>• Extrapyramidal symptoms</li> <li>• Possible increased suicidal risk</li> <li>• Decreased platelets</li> <li>• Muscle weakness</li> </ul>

**TABLE 28.7** Drugs to Promote Sleep (Sources: Drugs.com, 2024; PDR, 2024; Memorial Sloan Kettering Cancer Center, 2024.)

Drug Class	Example Drug	MoA	Adult Dose & Route	Side Effects	Adverse Effects
	Melatonin	Synthesized from tryptophan and serotonin to help induce sleep		<ul style="list-style-type: none"> <li>• Dizziness</li> <li>• Headache</li> <li>• Nausea</li> </ul>	<ul style="list-style-type: none"> <li>• Hives</li> <li>• Angioedema</li> </ul>
	Valerian	May increase GABA		<ul style="list-style-type: none"> <li>• Headache</li> <li>• Dry mouth</li> </ul>	

**TABLE 28.7** Drugs to Promote Sleep (Sources: Drugs.com, 2024; PDR, 2024; Memorial Sloan Kettering Cancer Center, 2024.)

Examples of stimulant drugs used for treatment of hypersomnolence are shown in [Table 28.8](#) with a brief description of how they work, typical dosage for sleep, common side effects, and concerning potential adverse effects.

Drug Class	Example Drug	MoA	Adult Dose & Route	Side Effects	Adverse Effects
Stimulants	Caffeine	Stimulates the CNS	Do not exceed 400 mg/day	<ul style="list-style-type: none"> <li>• Agitation</li> <li>• Headache</li> <li>• Upset stomach</li> </ul>	<ul style="list-style-type: none"> <li>• Seizures, coma</li> <li>• Difficulty breathing</li> <li>• Muscle twitching</li> <li>• Decreased urine output</li> </ul>
	Methylphenidate (Ritalin, Concerta)		20-30 mg PO in 2-3 divided doses, 30-45 minutes before meals.	<ul style="list-style-type: none"> <li>• Anorexia</li> <li>• Stomach upset or pain</li> <li>• Vomiting</li> </ul>	<ul style="list-style-type: none"> <li>• Agitation</li> <li>• Confusion</li> <li>• Fever</li> <li>• Tachycardia</li> <li>• Chest pain</li> <li>• Hives</li> </ul>

**TABLE 28.8** Drugs to Treat Hypersomnolence (Source: Drugs.com, 2024.)

Drug Class	Example Drug	MoA	Adult Dose & Route	Side Effects	Adverse Effects
	Amphetamine (Evekeo)		5–60 mg/day PO in divided doses (Start with lowest effective dose & adjust for individual.)	<ul style="list-style-type: none"> <li>• Dry mouth</li> <li>• Anorexia</li> <li>• Stomach upset</li> </ul>	<ul style="list-style-type: none"> <li>• Agitation</li> <li>• Anxiety</li> <li>• Bladder pain/cloudy or bloody urine/ urinary frequency changes</li> <li>• Mood changes</li> <li>• Feeling of detachment/ unreality</li> <li>• Emotional lability</li> </ul>
	Amphetamine/ dextroamphetamine (Adderall)		10 mg/day PO in divided doses (May be increased weekly by 10 mg until desired effect is reached.)	<ul style="list-style-type: none"> <li>• Dry mouth</li> <li>• Weakness</li> <li>• Stomach pain</li> </ul>	<ul style="list-style-type: none"> <li>• Anxiety</li> <li>• Bladder pain/cloudy or bloody urine/ urinary frequency changes</li> <li>• Tachycardia</li> <li>• Palpitations</li> </ul>

**TABLE 28.8** Drugs to Treat Hypersomnolence (Source: Drugs.com, 2024.)

Drug Class	Example Drug	MoA	Adult Dose & Route	Side Effects	Adverse Effects
	Armodafinil (Nuvigil)		150–250 mg/day PO in a.m.	<ul style="list-style-type: none"> <li>• Anorexia</li> <li>• Stomach upset</li> <li>• Cough</li> <li>• Thirst</li> <li>• Sweating</li> <li>• Feelings of sadness/illness</li> </ul>	<ul style="list-style-type: none"> <li>• Vision changes</li> <li>• Chest pain</li> <li>• Dyspnea</li> <li>• Feeling unsteady/fainting</li> <li>• Confusion</li> <li>• Mood changes</li> <li>• Uncontrolled face or mouth movements</li> </ul>
	Modafinil (Provigil)		200 mg/day PO in a.m.	<ul style="list-style-type: none"> <li>• Headache</li> <li>• Nausea</li> <li>• Nervousness</li> <li>• Anorexia</li> </ul>	

**TABLE 28.8** Drugs to Treat Hypersomnolence (Source: Drugs.com, 2024.)

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety: Combining Compatible Drugs

Disclaimer: Always follow the agency's specific policy and procedure for medication administration.

**Definition:** Reduces risk for harm to patients.

**Knowledge:** The nurse will use strategies to support safe medication administration through multiple means.

**Skill:** Use strategies, such as interdisciplinary collaboration, to maintain current best practice, accuracy, and safety. The nurse will:

- Not rely entirely on memory in preparation for medication administration (e.g., dose, route, time to onset).
- Consult with interdisciplinary partners' written or electronic resources to review current practice regarding medication compatibility and administration.

**Attitudes:** Understand the limits of human memory and abilities.

### Education on Risks

The effects of medications to induce or foster sleep can have significant effects on the central nervous system. Therefore, nurses need to perform frequent assessments and reassessments relative to effectiveness and results. Nurses can be key players in providing education for patients as they consider or begin a new drug. As indicated, CNS effects can be as serious as seizures, hallucinations, and parasomnias. Cardiovascular and respiratory problems also may accompany some of the drugs, and renal function may be affected. Nurses should anticipate laboratory tests for organ function. Allergic reactions, such as angioedema and anaphylaxis, can be life-threatening, and patients should be educated about these potential reactions, including signs and symptoms of their presentation. For more on patient education, see [Chapter 17 Patient and Family Education](#).

## PATIENT CONVERSATIONS

---

### Benadryl for Sleep

**Scenario:** A patient, Reginald Washington, age 78, has been having trouble sleeping and calls and asks the nurse, Melissa, about using Benadryl, since there is some in the medicine cabinet at home. The nurse is concerned about this medication for Mr. Washington because it has a high risk of causing undesired effects in those over 60.

**Nurse:** Mr. Washington, I guess you've been having some trouble sleeping?

**Patient:** Yes, Melissa. I haven't slept well for a few weeks now. It makes me feel fuzzy during the day to be so tired.

**Nurse:** Feeling that way is pretty common if you're not sleeping well. You asked about using Benadryl.

**Patient:** Yes, my wife used it about a year ago, and it really helped her. So I thought I'd check because I'm on a blood pressure medicine.

**Nurse:** I'm very glad you asked about it. I'm not so concerned about the blood pressure medicine, but diphenhydramine, which is the drug you know as Benadryl, is not recommended for people over 60 years old.

**Patient:** Oh, really? I guess my wife shouldn't have taken it.

**Nurse:** True. I guess she didn't have problems.

**Patient:** No, she was fine. And she slept well.

**Nurse:** Some people, even over 60, have no issues. But it is on a list of risky medications for older adults because it can make the side effects worse, leading to adverse outcomes. Some people experience delirium or become more confused. I think we should check with your doctor to see what is recommended for you.

**Patient:** Oh, okay.

**Nurse:** I'll check and call you back to let you know what is safer to help you sleep.

**Patient:** That sounds like a good idea.

---

## Summary

### 28.1 Concepts of Sleep and Rest

Like breathing, sleep seems simple and automatic, but the physiological processes involved in sleep involve coordination of multiple body systems and complicated neurological and physical responses. Originating in the brain stem, and involving other regions of the neurological system, sleep is influenced by factors such as circadian rhythms. Although a person is unaware of much of what happens during sleep, there are four stages that occur in cycles throughout the hours of sleep.

For those whose sleep is uninterrupted, they experience stage I sleep just once as they fall asleep. They then continue through multiple cycles in a predictable fashion every 90 to 110 minutes, until awakening. Throughout the human life span, there are changes in sleep patterns and how they progress through sleep cycles. There are also developmental alterations regarding the amount of sleep necessary at different life stages, with neonates experiencing a slightly different sleep before circadian rhythms are established, and spending most of a twenty-four-hour day sleeping. Sleeping needs of adults tend to be only seven to nine hours. The amounts of sleep within the different stages also change throughout the life span, as the neurological system develops and various other factors influence growth and development.

### 28.2 Factors Affecting Sleep and Rest

Many things can affect the quality and quantity of sleep and rest. This section covered physiological considerations affecting sleep and rest, including growth and development, illness, and medications. Lifestyle, habits, and culture also affect sleep. Sedentary lifestyles tend to lead to poor quality and quantity of sleep. Activity and exertion contribute to physical fatigue, which helps the body ready itself, and have a need for, rest and sleep. Choices, such as caffeine, nicotine, and alcohol use, which easily become habitual, have negative effects on sleep, with nicotine having some of the most significant effects. Stress, and its associated physiological responses, tends to cause problems falling asleep or staying asleep. The section also explored several sleep disorders, including insomnia, parasomnias, and breathing and movement disorders.

### 28.3 Effects of Insufficient Sleep

Insufficient sleep has the potential to cause several psychophysiological effects. For neonates and children, neurological changes can be significant because sleep affects growth and development. Lack of sleep is also a frequent contributor to behavioral and certain mental health concerns. Performance deficits may be apparent at school or in family interactions through the inability to pay attention or remember certain things, in development of intelligence, and in academic accomplishments. Physiologically, sleep increases the pediatric risk for obesity and other related metabolic disorders.

Many of the same issues affecting children who do not achieve adequate sleep affect adults. Poor coping and various mental health diagnoses, including anxiety, mood lability, impaired focus, and memory, can be related to inadequate sleep. Physiologically, results of insufficient sleep show up in gastrointestinal, cardiovascular, metabolic, and immune symptoms and disorders. Lack of sleep and related disorders tend to have bidirectional relationships, making it difficult in some situations to identify whether the insufficient sleep caused the diagnosis or the diagnosis contributed to the poor sleep.

### 28.4 Nursing Care to Promote Sleep and Rest

Nursing assessment plays an important role in assisting patients with sleep disturbances. Gathering key information through health history, sleep logs, and effects of insufficient sleep on the patient's well-being is necessary for the multidisciplinary team to plan and implement next steps. One of the first strategies for patients who experience poor sleep is to explore their sleep hygiene practices. Nurses can help by providing education as to how to improve sleep hygiene through various means. Medications are sometimes helpful for patients to fall asleep and/or stay asleep. Safety is critical. Again, education is vital, so nurses should help patients to understand risks of these medications and their interactions with any other drugs.

## Key Terms

**alpha wave** a fast wave as seen on an EEG, associated with the first part of falling asleep

- anxiolytic** a type of drug that reduces anxiety
- beta amyloid** a peptide implicated in development of Alzheimer disease
- biphasic sleep pattern** a sleep pattern with two sleep sessions per day
- cataplexy** muscle weakness
- circadian rhythm** the biological rhythm associated with metabolism, temperature, sleep, and wakefulness
- delta wave** EEG brain wave that is slower with higher amplitude
- dyslipidemia** abnormal blood lipids
- electroencephalogram (EEG)** a linear tracing of the electricity of brain waves
- enuresis** urination during sleep
- glymphatic system** a body system involved in the regulation of interstitial fluid movement and subsequent removal of waste from the brain and CSF
- hyperlipidemia** elevated blood lipids
- hypersomnolence** excessive feelings of fatigue and sleepiness, or episodes of sleep during normal times to be awake
- hypnogram** a graph representing a person's sleep architecture
- K-complex** EEG delta wave lasting approximately one second each
- mechanism of action (MoA)** how a particular drug works
- monophasic sleep pattern** a sleep pattern involving one major block of time allocated for sleep
- narcolepsy** a sleep disorder involving episodes of daytime sleep
- non-rapid eye movement (NREM)** the three stages of sleep not characterized by eye movement
- parasomnia** an abnormal behavior while a person is asleep
- polyphasic sleep pattern** a sleep pattern including several sleep sessions in a twenty-four-hour period
- polysomnography** a sleep study incorporating different physiologic monitors
- rapid eye movement (REM)** the sleep stage characterized by the speed of eye movements and vivid, unbelievable dreams
- reticular activating system (RAS)** a crucial neural network in the brainstem responsible for regulating arousal, attention, and consciousness
- seasonal affective disorder (SAD)** a form of depression related to lack of light
- sleep architecture** an individual's sleep patterns
- sleep hygiene** sleep habits
- sleep inertia** slowed thought processing related to lack of sleep
- sleep log** a written collection of sleep-related information, including hours slept daily
- sleep spindle** a short, intermittent burst of neurological activity, seen on an EEG
- slow-wave sleep (SWS)** a sleep stage typified by the slower delta waves seen on an EEG
- somnambulism** sleepwalking
- tau** a protein associated with the development of Alzheimer disease
- theta wave** an EEG wave that is fast and has variable frequencies

## Assessments

### Review Questions

1. A patient describes frequent dreams in which he is able to fly. The nurse recognizes such fanciful dreams as happening during what sleep stage?
  - a. stage I
  - b. stage II
  - c. stage III
  - d. REM
2. What hormone is associated with opening the “sleep gate”?
  - a. cortisol
  - b. epinephrine
  - c. melatonin
  - d. oxytocin

3. An adult typically spends the majority of a night's sleep in what sleep stage?
  - a. stage I
  - b. stage II
  - c. stage III
  - d. REM
  
4. The reticular activating system (RAS) controls what aspect of sleep?
  - a. length of time in REM
  - b. fast and slow waves
  - c. different sleep stages
  - d. developmental changes
  
5. A person who splits their sleep into a major overnight period for six hours and a three-hour nap is implementing what sleep pattern?
  - a. monophasic
  - b. biphasic
  - c. triphasic
  - d. polyphasic
  
6. A patient tells the nurse nightmares began after starting to take diphenhydramine to sleep. The nurse explains what side effect as the likely cause of the nightmares?
  - a. drug hangover
  - b. REM rebound
  - c. tolerance
  - d. dependence
  
7. A nurse is reviewing lifestyle recommendations to promote sleep with a patient who has been experiencing insomnia. What recommendation about timing moderate exercise will the nurse include?
  - a. "Exercise just before bedtime is good, because exercise is always beneficial."
  - b. "Drink three eight-ounce glasses of water and exercise an hour before bedtime."
  - c. "Avoid exercise within five hours of bedtime, so you're tired but not stimulated."
  - d. "You should only exercise in the morning if you want to sleep well at night."
  
8. A parent describes a child having episodes of screaming at night. When the parent arrives at the bedside, the child is sitting up, eyes are dilated, and the child's heart is racing. The nurse will prepare to teach the parent and child about what sleep disorder?
  - a. nightmares
  - b. sleep paralysis
  - c. somnambulism
  - d. night terrors
  
9. Neonates fall asleep into what stage of sleep?
  - a. stage I
  - b. stage II
  - c. stage III
  - d. REM
  
10. A patient who experiences several episodes of falling asleep during the day is experiencing what sleep problem?
  - a. insomnia
  - b. sleep apnea
  - c. hypersomnia
  - d. sleep paralysis

11. An 11-year-old patient is seen by the pediatrician for chronic insomnia and slowed growth. What other clinical presentation does the nurse anticipate may be related to the child's poor sleep?
  - a. a very peaceful affect
  - b. a short ability to concentrate
  - c. an ease with problem-solving
  - d. advanced reading skills
  
12. An 8-year-old child who has not slept more than five hours per night for a year has gained twenty pounds during that time. What finding does the nurse conclude is also sleep-related?
  - a. hypotension
  - b. a four-inch growth spurt
  - c. dyslipidemia
  - d. low total cholesterol
  
13. What hormone is least likely to impair gastrointestinal homeostasis?
  - a. ghrelin
  - b. melatonin
  - c. leptin
  - d. calcitonin
  
14. A nurse is reviewing a patient's recent examination and laboratory results. What combination does the nurse determine to be associated with metabolic syndrome?
  - a. hyperglycemia, low HDL, elevated triglycerides
  - b. obesity at the hips, high HDL, low triglycerides
  - c. hypoglycemia, low HDL, high triglycerides
  - d. abdominal obesity, high HDL, hyperglycemia
  
15. The NSF recognizes how many hours of sleep in the previous twenty-four hours as likely impairing a person's driving ability?
  - a. two hours
  - b. three hours
  - c. six hours
  - d. eight hours
  
16. A nursing instructor corrects a student for suggesting what as a component of good sleep hygiene?
  - a. Listen to peaceful forest sounds at bedtime.
  - b. Read from an electronic tablet before bed.
  - c. Follow a planned time for bed and rising.
  - d. Use the same bedtime steps every night.
  
17. A patient asks which electrical monitoring will record the classic rapid eye movements of REM sleep; the nurse should provide what reply?
  - a. electrocardiogram (ECG)
  - b. electromyogram (EMG)
  - c. electrooculogram (EOG)
  - d. electroencephalogram (EEG)
  
18. OTC drugs prescribed as sleep aids work by what mechanism of action?
  - a. improve the action of GABA
  - b. antagonists to orexin A&B
  - c. melatonin agonist effects
  - d. inhibit action of histamine 1

19. The nurse explains to a patient that there is a major concern for combining opioid pain medication with benzodiazepines for what reason?
  - a. increasing respiratory depression
  - b. developing somnambulism
  - c. worsening anorexia
  - d. potential for nightmares
  
20. A patient asks the nurse about advantages for doing a home sleep study instead of staying at the sleep lab. What answer should the nurse include?
  - a. The sleep center staff will wake you frequently.
  - b. You will probably feel able to move more freely.
  - c. You will be limited in sleeping positions.
  - d. The home monitor is more accurate than at the lab.

### Check Your Understanding Questions

1. Describe why a patient who is awakened numerous times in the first few hours of sleep does not feel rested the following day?
2. A patient has been diagnosed as having narcolepsy type I. Describe at least three characteristics of this central sleep disorder.
3. Sleep insufficiency can result in various physiologic disorders. Name two body systems that may be adversely affected by lack of sleep, and provide an example for each.
4. Explain the value of including the patient's medications and time of administration on a sleep log.

### Reflection Questions

1. Consider your own sleep patterns: if you frequently awaken from a dream, is it realistic or fantastic? Which sleep stage is indicated by these types of dreams?
2. Reflect upon times you have felt stressed. Explain at least two physiologic symptoms you experienced, and whether your sleep was impacted.
3. Consider the relationship between healthy eating habits and sleep, and whether any of these are common among students of university age. Explain why you know (from experience) or suspect your conclusions.
4. Review your bedtime routine and describe whether your sleep hygiene practices support or hinder quality sleep.

### What Should the Nurse Do?

1. A first-grader's parents visit the pediatrician's office to discuss daily sleepiness interfering with school, including difficulty concentrating, irritability, and dozing off during class. The nurse asks about sleeping habits, and the parents describe it is difficult to get the child to sleep before 11:00 p.m.; they don't understand what is happening. What should the nurse do?
2. A patient describes having difficulty falling asleep, and waking several times each night. The patient's electronic health record indicates the patient smokes a pack of cigarettes daily and has for ten years. To help the patient improve sleep habits, what should the nurse do?
  - a. Insist the patient should quit smoking immediately.
  - b. Advise the patient to avoid smoking within two hours of bedtime.
  - c. Suggest the patient reduce cigarette smoking to a half-pack per day.
  - d. Recommend the patient drink warm milk an hour before bedtime.

An adult patient describes problems with distorted depth perception and difficulty seeing distances. Less than a week ago, the patient's optometry examination was normal.

3. What hypothesis might the nurse have as to what is happening to this patient?

4. What should the nurse do?
5. A patient with a history of hepatitis is planning to begin taking kava kava to improve sleep. What should the nurse do?

### Competency-Based Assessments

1. Circadian rhythms support the natural changes that help a person fall asleep, and stay asleep. Do some research and describe how light and darkness may have contributed to early human history and sleep patterns.
2. Write a paragraph (up to fifty words) describing symptoms of obstructive sleep apnea (OSA).
3. Read this information about [drowsy driving \(https://openstax.org/r/77TeenDrowsyDrv\)](https://openstax.org/r/77TeenDrowsyDrv) and teens. Create a one-page flyer with key information for an audience of high school students.
4. Select one of the nonbenzodiazepine medications for sleep, and describe the possible adverse effects of the drug in layman’s terms so a patient with minimal medical knowledge will understand.
5. You are interviewing a 55-year-old male patient who was recently diagnosed as having obstructive sleep apnea. He says he does not sleep well at all and is very sleepy during the day, which worries him. Use the [Epworth Sleepiness Scale \(ESS\) Questionnaire \(https://openstax.org/r/77Epworth\)](https://openstax.org/r/77Epworth) with the following information from your patient:
  - “I fall asleep while reading or watching TV almost as soon as I sit down. But if I lie down to nap, sometimes I have trouble dozing off. The exception is right after lunch—boy I can fall asleep at my desk after lunch!”
  - “I’m worried I might lose my job, because the other day I fell asleep in a meeting at work. I have to get up and walk around at work often or I’ll doze off in the middle of a conversation.”
  - “If I’m driving, I don’t get sleepy in the car, but if someone else is driving, I’m asleep in minutes!”

What is your patient’s total score?

## CHAPTER 29

# Sensory Alterations

**FIGURE 29.1** Impaired sensory perception can have negative effects on one's health. (credit: "Eye see you" by Airman First Class Antoinette Lyons/U.S. Air Force, Public Domain)

### CHAPTER OUTLINE

- 29.1 Sensory Functioning
- 29.2 Impaired Sensory Function
- 29.3 Factors Affecting Sensory Function

**INTRODUCTION** Imagine a world without the ability to hear the laughter of loved ones, the soothing melodies of music, or the gentle whispers of nature. Without the gift of sight, the vibrant colors of a sunset, the intricate details of a loved one's face, and the breathtaking beauty of a starry sky would remain hidden from view. Deprived of the sense of smell, the ability to savor the aroma of freshly brewed coffee, the fragrance of blooming flowers, and the comforting scent of home-cooked meals would be lost. Similarly, a world without taste would deprive the joy of savoring delicious flavors, indulging in culinary delights, and experiencing the richness of diverse cuisines. Last, without the sense of touch, one would miss out on the warmth of a comforting hug, the sensation of soft silk against one's skin, and the joy of holding hands with a loved one. Each sensory modality contributes to our perception of the world and enriches our lives in profound ways, emphasizing their immense importance in our daily existence, as well as highlighting the significant impact of impairment on individuals' sensory experiences and overall quality of life.

## 29.1 Sensory Functioning

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize the function of sensory perception in the body
- Recall the function of the reticular activating system
- Identify the different states of arousal of the brain

Understanding the function of sensory perception in the body is fundamental to comprehending how individuals perceive and engage with their surrounding environment. While navigating through diverse environments, individuals' sensory systems consistently receive and process information, enabling them to effectively interpret and respond to stimuli. Additionally, the **reticular activating system (RAS)** serves as a neural network in the brain stem responsible for regulating arousal, attention, and the consciousness network of neurons located in the brain stem that extends from the medulla oblongata to the midbrain. By identifying the different states of arousal of the brain, insight is gained into the complex mechanisms underlying cognitive processes and behavioral responses. Within this section, the intricacies of sensory perception and the role of the RAS in modulating arousal are explored, providing a comprehensive understanding of these essential aspects of human physiology. Through exploration of these topics, the aim is to enhance knowledge of sensory function and its implications for overall health and well-being.

## Sensory Perception

The process by which organisms gather information from the environment through the senses (such as sight, hearing, touch, taste, and smell) and interpret and make sense of that information is called **sensory perception**. It involves the reception, transmission, and interpretation of sensory stimuli, allowing individuals to understand and interact with their surroundings. It encompasses the complex processes through which sensory information is detected, processed, and interpreted by the nervous system to create meaningful perceptions of the environment. Each sensory modality, including hearing, vision, smell, taste, and touch, plays a unique role in providing individuals with valuable information about their surroundings, guiding behaviors, and shaping experiences. Through sensory perception, individuals are able to detect and respond to stimuli ranging from light and sound to temperature, pressure, and chemical cues, allowing for adaptive interactions with the external world. Moreover, sensory perception plays a vital role in guiding behaviors, shaping experiences, and facilitating adaptive responses to environmental changes.

### Senses

The physiological mechanisms by which organisms perceive and respond to stimuli from their environment are referred to as **senses**. Each sense occupies a distinct role, contributing to a comprehensive understanding of our environment. Vision allows one to perceive the world in terms of shapes, colors, and spatial relationships, providing essential information for navigation and object recognition. Hearing enables individuals to detect and interpret sound waves, facilitating communication and alerting to potential dangers in one's surroundings. Smell and taste add richness to the sensory experience, influencing dietary choices, emotional responses, and memories. The sense of touch provides critical information about texture, pressure, and temperature, guiding interactions with objects and the physical environment. Collectively, these senses construct a sensory network that influences our perceptions, emotions, and engagements with the surrounding environment.

#### Auditory

The sense of hearing is primarily facilitated by **auditory sensory perception**, the process by which the auditory system receives, transmits, and interprets sound stimuli from the environment. It initiates with the reception of sound waves by the outer ear, composed of the pinna and the ear canal, which collectively funnel sound waves toward the tympanic membrane (eardrum). On contact, the eardrum vibrates, converting sound energy into mechanical vibrations transmitted through the ossicles (bones) in the middle ear—the malleus, incus, and stapes. These ossicles amplify and relay vibrations to the cochlea, a fluid-filled structure in the inner ear. Within the cochlea, the fluid motion stimulates hair cells, specialized sensory receptors, initiating cochlear transduction. Hair cells convert mechanical energy into electrical signals, which travel along the auditory nerve to the brain stem and ascend to the auditory cortex in the temporal lobes for processing. In the brain, these electrical signals are interpreted, allowing the perception and understanding of sound, including recognizing pitch, volume, and the spatial location of sounds (National Institute on Deafness and Other Communication Disorders, 2022).

#### Visual

The interpretation of light stimuli and the formation of visual perceptions are enabled by **visual sensory perception**, the process by which the visual system detects, interprets, and makes sense of visual stimuli. It begins with the eyes, where light enters through the cornea and passes through the pupil, which regulates the amount of light entering the eye. The lens then focuses the light onto the retina, a light-sensitive layer at the back of the eye. The

retina contains photoreceptor cells known as rods and cones, which convert light energy into electrical signals. Rods are responsible for low-light vision and peripheral vision, while cones detect color and fine detail in brighter conditions. These electrical signals travel along the optic nerve to the brain's visual processing centers, including the primary visual cortex located in the occipital lobes (Dana Foundation, 2023). Here, the brain processes the signals, interpreting them to form visual perceptions such as shapes, colors, and motion (STAR Institute, n.d.). Additionally, the brain integrates visual information with input from other sensory modalities to construct a cohesive representation of the external world. Visual perception plays a crucial role in tasks ranging from recognizing faces and objects to navigating the environment and interpreting complex visual stimuli.

### **Olfactory**

The ability to detect and interpret smells using the olfactory system is called **olfactory sensory perception**. The process begins with the olfactory epithelium, a specialized tissue located in the upper part of the nasal cavity. This epithelium contains millions of olfactory receptor cells, each equipped with odorant receptors that can detect various odor molecules. When airborne odorants enter the nasal cavity during inhalation, they dissolve in the mucus lining the olfactory epithelium and bind to specific odorant receptors on the olfactory receptor cells. This binding triggers a series of biochemical signals, leading to the generation of electrical impulses that are transmitted along the olfactory nerve fibers to the olfactory bulb, a structure at the base of the brain (Sharma et al., 2019). Within the olfactory bulb, these electrical signals are processed and relayed to higher brain regions, including the olfactory cortex, where they are further analyzed and interpreted (STAR Institute, n.d.). The brain integrates olfactory information with input from other sensory modalities, memories, and emotions to create a rich and complex olfactory experience. Olfactory perception enables individuals to detect and identify a wide range of odors, including those associated with food, danger, social cues, and emotional responses (STAR Institute, n.d.). Additionally, the sense of smell plays a significant role in taste perception, as it contributes to the flavor of foods by detecting volatile compounds released during eating.

### **Gustatory**

The ability to detect and interpret tastes using the gustatory system is called **gustatory sensory perception**. The process of gustation begins with taste receptor cells located within specialized structures called taste buds, which are primarily found on the tongue, soft palate, and throat. These taste buds contain various types of taste receptor cells that can detect five primary tastes: sweet, sour, salty, bitter, and umami (savory) (Vincis & Fontanini, 2019). When food or drink enters the mouth, molecules from the substances dissolve in saliva and come into contact with the taste receptor cells within the taste buds. This triggers a cascade of biochemical signals that result in the generation of electrical impulses, which are transmitted along the gustatory nerve fibers to the brain stem and then to higher brain regions, including the gustatory cortex. In the brain, these electrical signals are processed and integrated with input from other sensory modalities, such as olfaction (sense of smell), texture, temperature, and even visual cues, to create the perception of flavor. Gustatory perception enables individuals to distinguish between different tastes, assess the palatability and quality of foods, and make dietary choices based on preferences and nutritional needs. Additionally, the sense of taste plays a crucial role in the regulation of appetite and digestion as well as in the enjoyment and social aspects of eating.

### **Tactile**

The ability to detect and interpret touch sensations is called **tactile sensory perception**. The skin, the body's largest organ, contains various types of sensory receptors that detect mechanical stimuli such as pressure, vibration, temperature, and pain. These receptors are distributed throughout the skin's surface, providing comprehensive coverage and sensitivity to tactile stimuli across the body. When an object or surface comes into contact with the skin, mechanical forces are applied, leading to deformation of the skin and activation of the sensory receptors. These receptors generate electrical signals in response to the mechanical stimuli, which are transmitted via sensory nerves to the spinal cord and then relayed to the brain. In the brain, these electrical signals are processed and integrated in various regions of the somatosensory cortex, enabling the perception and interpretation of tactile sensations such as texture, pressure, temperature, and pain (Jenkins & Lumpkin, 2017). Tactile perception plays a crucial role in numerous aspects of daily life, including object recognition, manual dexterity, spatial awareness, and social interactions. It allows individuals to navigate their environment, manipulate objects, and communicate through gestures and touch. Furthermore, tactile sensory perception contributes to emotional experiences, such as comfort, pleasure, and pain, and serves as a fundamental aspect of human connection and communication.

## LINK TO LEARNING

Watch this video to further review the anatomy and physiology of [the five senses \(https://openstax.org/r/77fivesenses\)](https://openstax.org/r/77fivesenses) of the body.

### Orientation of Senses

Complementing the five primary senses, **kinesthetic sense**, also known as a **proprioceptive sense**, and **visceral sense**, also known as an **interoceptive sense**, provide vital feedback about the body's internal state and movements, further enriching the sensory experience. Kinesthetic senses provide feedback about one's body movement, position, and tension, allowing for coordinated motion and balance. Meanwhile, visceral senses offer insight into internal bodily functions, guiding one's responses to physiological needs and states such as hunger, thirst, and discomfort. Collectively, these sensory orientations contribute to a comprehensive understanding of oneself and one's engagement with the world, influencing behaviors, emotions, and overall well-being.

### Kinesthetic Senses

The kinesthetic senses play a crucial role in body awareness and movement control. These senses provide feedback about the position, movement, and tension of muscles and joints, allowing individuals to coordinate their movements and maintain balance and posture. Specialized sensory receptors located in muscles, tendons, and joints, known as **proprioceptors**, detect changes in muscle length, tension, and joint position, providing continuous feedback to the brain about the body's position in space (STAR Institute, n.d.). This proprioceptive feedback is essential for activities requiring precise coordination and motor control, such as walking, running, reaching, and grasping objects. Additionally, proprioception contributes to the sense of body ownership and self-awareness, enabling individuals to distinguish between their own body and external objects. Dysfunction or impairment of kinesthetic senses can lead to difficulties with movement, coordination, balance, and motor skills, affecting activities of daily living and increasing the risk of injury.

### Visceral Senses

The visceral senses are responsible for detecting and monitoring internal body sensations such as hunger, thirst, pain, and visceral organ function. These senses provide feedback about the physiological state of the body, helping regulate essential bodily functions and maintain homeostasis. Specialized sensory receptors located in organs such as the stomach, intestines, and heart detect changes in temperature, pressure, and chemical composition, signaling the brain to initiate appropriate responses (Engelen et al., 2023). Visceral sensations play a vital role in guiding behaviors related to survival and well-being, such as eating, drinking, and responding to pain or discomfort. Additionally, visceral sensory input is integrated with emotional and cognitive processes, influencing mood, motivation, and decision-making. Dysfunction of visceral senses can lead to disturbances in appetite regulation, gastrointestinal disorders, and altered perception of bodily sensations, impacting overall health and quality of life.

### Reticular Activating System

The reticular activating system (RAS) serves as a crucial neural network in the brain stem responsible for regulating arousal, attention, and consciousness. It plays a crucial role in regulating wakefulness, arousal, and consciousness. The RAS acts as a filter for sensory information, determining which stimuli are relayed to higher brain centers for further processing. Dysfunction of the RAS can lead to disruptions in arousal states, manifesting as conditions such as **coma** (an extreme form of unconsciousness, where individuals are in a profound state of unresponsiveness and lack awareness of their surroundings, typically resulting from severe neurological injury or dysfunction), attention deficit disorders, and sleep disturbances (Arguinchona & Tadi, 2023). The proper functioning of the RAS is essential for maintaining wakefulness, arousal, and consciousness.

### Adaptation

The process by which sensory systems adjust to ongoing stimuli, optimizing processing efficiency is referred to as **adaptation**. The RAS plays a role in adaptation by modulating the sensitivity of sensory pathways to different stimuli. Through adaptation, sensory receptors become less responsive to constant stimuli over time, reducing their sensitivity and preventing sensory overload. For example, when exposed to a continuous background noise, the RAS may dampen the responsiveness of auditory neurons, allowing individuals to focus on more relevant auditory cues

while filtering out irrelevant noise. This adaptive process ensures sensory systems remain responsive to new or significant changes in the environment, helps to maintain optimal arousal levels, and prevents sensory overload.

Nursing assessment related to adaptation involves observing how patients respond to sensory input over time, noting any changes in responsiveness or sensory thresholds. Nurses meticulously observe patients' reactions to various sensory inputs, including visual, auditory, tactile, gustatory, and olfactory stimuli, noting any signs of sensory overload or aversion (Table 29.1). They also engage in communication with patients and caregivers to gather subjective information about changes in sensory perception and preferences.

Sensory Input	Examples of Nursing Assessment
Auditory	<ul style="list-style-type: none"> <li>• Observe patient response to various levels of environmental noise.</li> <li>• Assess hearing acuity and tolerance to loud sounds.</li> <li>• Note any complaints of difficulty concentrating in noisy environments.</li> </ul>
Gustatory	<ul style="list-style-type: none"> <li>• Observe patient reactions to different tastes and textures of food and fluids.</li> <li>• Assess appetite and enjoyment of meals.</li> <li>• Note any complaints of taste alterations or preferences.</li> </ul>
Olfactory	<ul style="list-style-type: none"> <li>• Evaluate patient ability to detect and identify various scents and odors.</li> <li>• Monitor for changes in sense of smell and sensitivity to different odors.</li> <li>• Note any reports of olfactory fatigue or decreased smell perception.</li> </ul>
Tactile	<ul style="list-style-type: none"> <li>• Assess skin sensitivity and response to touch using different stimuli (e.g., light touch, pressure).</li> <li>• Evaluate for signs of desensitization or hypersensitivity in specific areas.</li> <li>• Monitor for changes in pain perception or discomfort over time.</li> </ul>
Visual	<ul style="list-style-type: none"> <li>• Monitor pupil response to light stimuli over time.</li> <li>• Assess visual acuity regularly to detect changes.</li> <li>• Evaluate for signs of eye fatigue or strain during prolonged visual tasks.</li> </ul>

**TABLE 29.1** Examples of Adaptation

Nurses may implement environmental modifications to reduce sensory overload or aversion, such as providing a calm and quiet space for patients sensitive to noise or adjusting lighting to accommodate visual preferences. Additionally, nurses educate patients and caregivers about relaxation techniques and sensory coping strategies to promote adaptive responses to stimuli. Interventions may also include sensory stimulation activities tailored to individual preferences and capabilities, such as soothing music therapy or gentle tactile stimulation.

### Sensoristasis

The maintenance of a balance between under- and overstimulation, optimizing arousal levels for sensory perception and cognitive function is referred to as **sensoristasis**. The reticular activating system (RAS) is involved in sensoristasis by continuously monitoring sensory input and adjusting arousal levels to match the demands of the environment. Maintaining sensoristasis involves achieving an optimal level of arousal that allows for alertness and responsiveness without overwhelming the nervous system. For instance, in situations requiring heightened vigilance, such as during a challenging task or in response to a potential threat, the RAS increases arousal to enhance sensory perception and cognitive performance. Conversely, during periods of low sensory input, such as during relaxation or sleep, the RAS decreases arousal to conserve energy and promote restorative processes. By modulating arousal levels, sensoristasis ensures that individuals can effectively process sensory information, sustain attention, and regulate emotions, contributing to overall well-being and adaptive functioning.

Assessment of sensoristasis within the framework of the RAS entails a meticulous evaluation of patients' ability to maintain a balance between sensory stimulation and arousal levels. Nurses closely monitor patients for signs of under- or overstimulation, observing their responsiveness to environmental stimuli and any fluctuations in arousal states. Through direct observation and communication, nurses gather information about patients' sensory preferences, aversions, and coping strategies for managing sensory input. Additionally, nurses assess patients' overall level of alertness, vigilance, and responsiveness to stimuli, using standardized tools to evaluate consciousness and attention. By considering contextual factors such as the patient's medical history and environmental conditions, nurses develop a comprehensive understanding of patients' sensoristasis and its impact on adaptive functioning within the RAS. This holistic assessment guides the development of individualized care plans aimed at promoting optimal sensory experiences and maintaining an appropriate balance between stimulation and arousal for each patient.

Nursing interventions aimed toward addressing sensoristasis focus on maintaining an optimal balance between sensory stimulation and arousal levels. Nurses may implement strategies to promote sensory engagement and arousal when patients are understimulated, such as providing stimulating activities or sensory experiences tailored to individual preferences. Conversely, nurses may employ techniques to reduce sensory input and promote relaxation when patients are overstimulated, such as creating a calming environment or offering **sensory modulation** (the brain's ability to regulate and respond appropriately to sensory stimuli from the environment) techniques like deep breathing exercises or guided imagery. Education about self-regulation techniques and coping strategies is also essential to empower patients in managing their arousal levels effectively.

### Awareness

The conscious perception and understanding of oneself, one's surroundings, and the experiences that arise from sensory input and cognitive processes is known as **awareness**. It involves being attuned to sensory stimuli, thoughts, emotions, and bodily sensations, as well as the ability to reflect on and integrate this information into a coherent sense of self and reality. Awareness is influenced by various factors, including attention, memory, and cognitive processes, as well as emotional and social factors, and plays a central role in guiding behavior, decision-making, and personal growth.

The reticular activating system (RAS) plays a central role in generating and maintaining awareness by regulating the overall level of cortical activity in the brain. It integrates sensory input from various modalities and internal physiological processes, contributing to the formation of conscious experiences. Additionally, disruptions to the RAS can lead to alterations in awareness, such as drowsiness, confusion, or coma. By modulating arousal levels and directing attention, the RAS helps ensure that individuals remain aware of themselves and their surroundings, facilitating adaptive responses to environmental changes.

Assessment of awareness within the context of the RAS involves a nuanced evaluation of patients' conscious perception and understanding of themselves and their surroundings. Nurses observe patients for signs of altered consciousness or awareness, such as confusion, disorientation, or fluctuations in attention. They also engage in communication with patients and caregivers to gather subjective information about patients' perceptions, thoughts, emotions, and experiences. Additionally, nurses assess patients' ability to integrate sensory input with cognitive processes, memory, and emotional responses, using standardized tools to evaluate cognitive function and orientation. By considering the interaction between sensory processing, cognitive function, and emotional regulation, nurses develop a holistic understanding of patients' awareness within the RAS. This comprehensive assessment informs the development of tailored interventions aimed at promoting optimal cognitive functioning, enhancing self-awareness, and facilitating adaptive responses to the environment.

Additionally, nurses assess patients' overall level of arousal, attention, and consciousness, utilizing standardized tools like the Glasgow Coma Scale to evaluate responsiveness and consciousness. The **Glasgow Coma Scale (GCS)** is a neurological assessment tool used to evaluate a patient's level of consciousness and neurological function ([Table 29.2](#)) (Cleveland Clinic, 2023; Jain & Iverson, 2023). It assesses three components: eye opening, verbal response, and motor response, assigning a score ranging from three to fifteen. A higher score indicates a higher level of consciousness, with fifteen being the highest possible score indicating full consciousness (Cleveland Clinic, 2023; Jain & Iverson, 2023). The GCS helps healthcare providers to objectively quantify and monitor changes in a patient's level of consciousness over time, aiding in treatment decisions and prognostication. In addition to the standard GCS components, the Glasgow Coma Scale–Pupil (GCS-P) includes assessment of pupil reactivity,

providing valuable information about neurological status and potential signs of brain injury or dysfunction (Cleveland Clinic, 2023). By integrating findings from sensory assessments with broader neurological evaluations, nurses develop a comprehensive understanding of patients' adaptability within the context of the reticular activating system (RAS), laying the groundwork for tailored care plans and interventions aimed at optimizing sensory experiences and enhancing patient well-being.

Component Tested	Response	Score
Eye response	No eye opening	1
	Eye opening to pain	2
	Eye opening to sound	3
	Eyes open spontaneously	4
Verbal response	No verbal response	1
	Incomprehensible sounds	2
	Inappropriate words	3
	Confused	4
	Oriented	5
Motor response	No motor response	1
	Abnormal extension to pain	2
	Abnormal flexion to pain	3
	Withdrawal from pain	4
	Localizing pain	5
	Obeys commands	6
Interpretation	<ul style="list-style-type: none"> <li>• A score of thirteen to fifteen indicates mild impairment or normal consciousness.</li> <li>• A score of nine to twelve indicates moderate impairment or decreased level of consciousness.</li> <li>• A score of eight or lower indicates severe impairment or coma.</li> </ul>	

**TABLE 29.2** Glasgow Coma Scale

## LINK TO LEARNING

Learn more about the [Glasgow Coma Scale \(https://openstax.org/r/77glcomascal\)](https://openstax.org/r/77glcomascal) at this website, including how to conduct the assessment for pediatric patients.

Nurses may implement cognitive stimulation activities to enhance patients' attention, memory, and cognitive function, such as puzzles, memory games, or reminiscence therapy. Additionally, nurses provide sensory stimulation and environmental cues to facilitate patients' orientation and promote engagement with their surroundings. Education about the importance of sensory input and cognitive engagement in maintaining awareness is essential for patients and caregivers. Furthermore, nurses collaborate with interdisciplinary teams to address underlying factors contributing to alterations in awareness, such as medication management or addressing physiological needs. For example, if a patient exhibits confusion or disorientation due to medication side effects, nurses work with pharmacists and providers to adjust medication dosages or explore alternative treatments. Additionally, if a patient's altered awareness is linked to unmet physiological needs, such as pain or dehydration, nurses collaborate with nutritionists, physical therapists, and other healthcare professionals to develop comprehensive care plans that address these needs effectively. Through holistic interventions, nurses support patients in maintaining optimal awareness levels, facilitating meaningful interactions with their environment, and promoting overall cognitive well-being. For instance, nurses may implement sensory stimulation techniques, such as providing calming music or

engaging in therapeutic touch, to promote alertness and engagement in patients with altered consciousness.

## States of Arousal

The **states of arousal** refer to various levels of physiological and psychological alertness and responsiveness exhibited by an individual. The brain exhibits various states of arousal, ranging from wakefulness to deep sleep. During wakefulness, the brain is in a state of high arousal, characterized by alertness, responsiveness to external stimuli, and cognitive engagement. As individuals transition into drowsiness and light sleep, arousal levels decrease, leading to reduced awareness and relaxation. In deeper stages of sleep, such as non-rapid eye movement (NREM) and rapid eye movement (REM) sleep, arousal levels fluctuate, with REM sleep associated with heightened brain activity resembling wakefulness despite reduced muscle tone (Cherry, 2023). These different states of arousal are regulated by complex interactions between neurotransmitter systems, neurochemicals, and neural circuits in the brain stem, thalamus, and cortex, facilitating transitions between wakefulness and sleep and supporting essential functions such as memory consolidation and emotional regulation (Patel et al., 2024).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### Ensuring Safety During States of Arousal

Understanding and effectively managing alterations in states of arousal are essential for providing safe and patient-centered care. Arousal states play a critical role in determining patients' responsiveness to their environment and their ability to participate in their care.

- **Quality improvement:**
  - Nurses identify and address factors contributing to alterations in states of arousal, such as monitoring protocols for assessing consciousness levels and response to interventions.
  - Nurses implement evidence-based practices to optimize patient outcomes related to arousal states, including protocols for managing sedation levels in critical care settings.
- **Patient-centered care:**
  - Nurses recognize the individualized nature of responses to alterations in states of arousal, considering factors such as age, comorbidities, and cultural preferences.
  - Nurses involve patients and families in discussions and decision-making regarding interventions and goals of care related to changes in consciousness levels.
- **Safety:**
  - Nurses implement strategies to ensure patient safety during transitions between different states of arousal, such as protocols for preventing falls and injuries in patients with altered consciousness.
  - Nurses utilize appropriate assessment tools and technology to monitor patients' responses to interventions and identify potential complications promptly.
- **Teamwork and collaboration:**
  - Nurses communicate effectively with interprofessional team members to coordinate care for patients with alterations in states of arousal, including nurses, physicians, respiratory therapists, and pharmacists.
  - Nurses collaborate with other disciplines to develop comprehensive care plans tailored to individual patient needs and goals.
- **Evidence-based practice (EBP):**
  - Nurses incorporate current evidence and best practices into the assessment, management, and evaluation of alterations in states of arousal, including guidelines for diagnosing and managing conditions such as coma, delirium, and sleep disorders.
  - Nurses participate in ongoing education and professional development activities to stay updated on emerging research and advances in the field of consciousness and arousal states.
- **Informatics:**
  - Nurses utilize electronic health records and clinical decision support tools to document assessments, interventions, and patient responses related to alterations in states of arousal.
  - Nurses access and interpret relevant data, such as vital signs, laboratory results, and medication records, to inform clinical decision-making and evaluate patient outcomes.

By incorporating the principles of the QSEN competency framework into the management of alterations in states of arousal, nurses can contribute to enhancing the quality and safety of care delivery for all patients.

### Conscious States

The range of mental experiences and subjective awareness that individuals perceive as part of their waking life are known as **conscious states**. Consciousness involves being awake, aware, and responsive to oneself and the environment, as well as experiencing thoughts, emotions, and sensations (Bauer et al., 2023). It includes various dimensions such as self-awareness, introspection, and the ability to reflect on one's own mental states and experiences. Conscious states are mediated by widespread neural networks distributed across the brain, with key regions such as the prefrontal cortex, parietal cortex, and thalamus implicated in generating and sustaining conscious awareness (Bauer et al., 2023).

Nursing assessments primarily involve evaluating the patient's level of consciousness (including being **alert**, having **altered consciousness**, being **lethargic**, and experiencing **obtundation**), cognition, and physiological status to ensure timely detection of changes and facilitate appropriate interventions (Table 29.3). Assessment also includes a comprehensive neurological assessment to monitor mental status and cognitive abilities as well as vital sign assessments to evaluate physiological stability. Nurses also observe behavior, mood, and interactions with the environment to assess emotional well-being and psychosocial needs, alongside pain assessment to ensure patient comfort.

Level of Consciousness	Definition	Description
Alert	A state of heightened wakefulness, attentiveness, and responsiveness in which an individual is fully awake, aware of their surroundings, and capable of actively engaging with stimuli and tasks.	The patient opens their eyes spontaneously, looks at you when spoken to in a normal voice, responds appropriately to stimuli, and movements are purposeful.
Altered consciousness	Any deviation from the normal waking state of consciousness, characterized by changes in perception, cognition, or awareness.	Examples include drowsiness, confusion, disorientation, or difficulty maintaining attention and focus. Individuals may have impaired cognitive function or altered perception.
Lethargic	A state of drowsiness, sluggishness, and reduced energy levels in which an individual appears excessively tired or fatigued.	The patient appears drowsy but opens their eyes to loud verbal stimuli and looks at you, responds to questions, and then falls back asleep.
Obtundation	A state of decreased alertness and responsiveness in which an individual opens their eyes in response to tactile stimuli or other external cues but responds slowly and may appear confused or disoriented.	The patient opens their eyes with tactile stimuli and looks at you but responds to you slowly and may be confused.

**TABLE 29.3** Levels of Consciousness

In conscious states, nursing interventions focus on maintaining and promoting patient comfort, safety, and well-being. Nurses prioritize frequent monitoring of vital signs and neurological status to detect changes in consciousness promptly. Additionally, they ensure a supportive and therapeutic environment conducive to promoting alertness and engagement. Nursing care may include facilitating communication with the patient, addressing their needs and preferences, and providing emotional support to alleviate anxiety or distress. Furthermore, nurses collaborate with interdisciplinary teams to implement appropriate pain management strategies

and optimize the patient's overall comfort and satisfaction.

### Unconscious States

The mental processes and activities that occur without conscious awareness or voluntary control are known as **unconscious states**. These states may include automatic bodily functions, such as heartbeat and respiration, as well as unconscious cognitive processes, such as implicit memory and automatic responses to environmental stimuli. Examples of levels of unconscious states (including **asleep**, **stupor**, coma, and **vegetative state**, also known as **unresponsive wakefulness syndrome**) can be found in [Table 29.4](#). While unconscious states lack conscious awareness, they still play a crucial role in regulating physiological functions, maintaining homeostasis, and supporting adaptive behaviors. Unconscious processes are mediated by subcortical brain structures, such as the basal ganglia and brain stem, as well as by distributed neural networks involved in automatic and reflexive responses (Bauer et al., 2023).

Unconscious State	Definition	Description
Asleep	A natural state of rest characterized by reduced consciousness, diminished responsiveness to external stimuli, and altered brain activity during sleep.	The individual is lying down with eyes closed and exhibits minimal or no response to external stimuli such as noise or touch. Breathing is regular, and muscle tone is relaxed. Movements may occur, but they are typically involuntary and spontaneous.
Stupor	A state of reduced consciousness marked by extreme lethargy, diminished responsiveness, and a significant decrease in alertness and awareness.	The individual is typically lying down or sitting and may appear drowsy or unresponsive. They may respond briefly to strong stimuli such as shaking or loud noises but quickly return to a state of reduced awareness. Movements are sluggish and may be purposeless.
Coma	A profound state of unconsciousness characterized by a complete loss of consciousness, absence of wakefulness, and lack of response to external stimuli.	The individual is unresponsive to all forms of stimulation, including pain, light, and sound. They do not open their eyes, exhibit purposeful movements, or communicate in any way. Breathing may be irregular, and vital signs may require medical monitoring.
Vegetative state (also known as unresponsive wakefulness syndrome)	A condition marked by wakefulness without awareness, in which the individual appears awake but lacks meaningful responsiveness.	The individual may open their eyes spontaneously or in response to external stimuli but does not demonstrate purposeful behavior or communication. Sleep-wake cycles are present, but there is no evidence of awareness or interaction with the environment.

**TABLE 29.4** Unconscious States

Nursing assessments are geared toward monitoring vital signs, neurological status, and respiratory function to detect changes in condition and prevent complications. This involves neurological assessments, including assessment of pupillary response, reflexes, and motor responses (with frequency tailored to the patient's acuity), to evaluate the depth of unconsciousness and assess for signs of neurological deterioration. Also essential is continuous monitoring of respiratory rate, depth, and effort to detect respiratory compromise or failure promptly. Nurses also assess skin integrity and hydration status to prevent skin breakdown and promote tissue perfusion, utilizing monitoring technologies and collaborating with the healthcare team to guide treatment decisions.

In unconscious states, nursing interventions are geared toward preventing complications, ensuring patient safety, and providing comprehensive care to support neurological function and recovery. Nurses maintain a vigilant watch over the patient's vital signs, airway, and neurological status, implementing interventions to prevent aspiration, pressure injuries, and other complications associated with decreased consciousness. They carefully position and support the patient to optimize respiratory function and prevent respiratory compromise. Additionally, nurses implement measures to protect the patient from injury, such as padding bedrails and maintaining a clutter-free environment. Collaboration with the healthcare team and utilization of monitoring technologies, such as continuous electroencephalography (EEG) monitoring, assist in assessing brain function and guiding treatment decisions. Effective communication with family and caregivers ensures they are informed and involved in decision-making regarding care and treatment options.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Recognize Cues: Maintaining Physiological Functioning in an Unconscious State

Scenario: Mr. Thompson, a 70-year-old patient with a history of severe traumatic brain injury following a car accident, is admitted to the intensive care unit (ICU) in a medically induced coma. He underwent emergency neurosurgery to address intracranial bleeding and swelling, and his medical team decided to induce a coma to reduce cerebral metabolic demands and protect his brain from further injury. Mr. Thompson is unresponsive to stimuli, with closed eyes and absence of purposeful movements. He is intubated and mechanically ventilated to support his breathing, and he is receiving intravenous medications to maintain sedation and control intracranial pressure.

Understanding cues that indicate physiological functioning in an unconscious state is crucial. In this scenario, stable vital signs, such as heart rate, blood pressure, and oxygen saturation levels, would suggest the body's cardiovascular and respiratory systems were functioning adequately. Regular monitoring of intracranial pressure would help to ensure effective management of cerebral edema, while continuous assessment of arterial blood gases and neurological stability would confirm proper respiratory and neurological function, even in the absence of consciousness. These cues would collectively provide valuable insights into the patient's overall physiological status, guiding nursing care and interventions.

## 29.2 Impaired Sensory Function

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify sensory overload and the effects on the body
- Detect sensory deprivation and the effects on the body
- Recognize alterations in sensory perception

Impaired sensory functioning refers to disruptions or deficiencies in the ability to perceive, process, or respond to sensory stimuli effectively. This can manifest in various ways, including sensory overload, deprivation, or alterations in sensory perception. Understanding impaired sensory functioning is crucial for nurses, as it significantly impacts an individual's overall well-being and quality of life. Sensory impairments can affect various aspects of daily functioning, from communication and social interaction to mobility and safety. Furthermore, they can contribute to increased vulnerability to accidents, falls, and other adverse health outcomes. By recognizing and addressing impaired sensory functioning, nurses can play a vital role in promoting optimal sensory health, enhancing patient safety, and improving the overall quality of care.

### Sensory Overload

When an individual is exposed to an excessive amount of sensory stimuli that overwhelms their ability to process and integrate information effectively, **sensory overload** occurs. This overwhelming sensory input can lead to difficulties in concentrating, maintaining attention, and regulating emotions (Watson, 2021). Common examples of sensory overload in an inpatient hospital environment include being in crowded or noisy environments, being exposed to bright lights or strong odors, and prolonged use of electronic devices. When sensory overload occurs, the body's stress response may be activated, leading to symptoms such as irritability, agitation, anxiety, and fatigue

(Watson, 2021).

### Symptoms of Sensory Overload

Sensory overload manifests in various ways, often presenting as overwhelming stimuli that disrupt an individual's ability to process sensory information effectively. This overload can lead to a range of symptoms, including irritability and agitation, as individuals struggle to cope with the excessive input bombarding their senses. Feelings of anxiety and restlessness may ensue, accompanied by a noticeable difficulty in concentrating on tasks due to the overwhelming sensory distractions. Physical discomfort, such as headaches and muscle tension, may also arise as the body responds to the stress induced by the excessive stimuli (Watson, 2021). Moreover, individuals experiencing sensory overload may exhibit sensory-seeking behaviors or become hypersensitive to certain stimuli, further complicating their ability to manage the influx of sensory information. In response, they may withdraw from or avoid situations that trigger sensory overload, impacting their engagement in daily activities and social interactions. Recognizing these symptoms is crucial for providing appropriate support and implementing strategies to mitigate the effects of sensory overload on individuals' well-being and functioning.

### Causes of Sensory Overload

Sensory overload can stem from a multitude of factors, ranging from environmental stimuli to internal sensory processing challenges. Environmental triggers, such as loud noises, bright lights, crowded spaces, and strong odors, can overwhelm the sensory system and contribute to sensory overload. In addition to external factors, internal stimuli can also contribute to sensory overload. This includes sensations like pain, discomfort from medical tubes (such as IVs, urinary catheters, or nasogastric tubes), and feelings of stress and anxiety related to the illness itself. Additionally, changes in routine or exposure to unfamiliar situations may exacerbate sensory sensitivity, leading to heightened responses to stimuli (Watson, 2021).

In healthcare settings, sensory overload may emerge from diverse origins, leading to an overwhelming influx of stimuli that inundate individuals' sensory systems. One primary cause is the proliferation of medical equipment and technology, such as monitors, alarms, and machinery, which generate continuous noise and visual cues. In ICUs and emergency departments, where monitoring is intensive and patient conditions can change rapidly, the density of alarms and equipment is particularly high, amplifying the risk of sensory overload. Moreover, crowded, and bustling environments, frequent interruptions, and multiple simultaneous tasks further exacerbate sensory overload, especially for patients with heightened sensitivity or cognitive impairments. Additionally, environmental factors like bright lighting, strong odors, and lack of privacy can contribute to sensory overload, particularly in long-term care facilities or psychiatric units where patients may already be at-risk due to underlying health conditions. Identifying the specific triggers and underlying factors contributing to sensory overload is essential for implementing targeted interventions and creating supportive environments tailored to individuals' sensory needs.

## LINK TO LEARNING

Alarm fatigue, a phenomenon prevalent in healthcare settings, occurs when healthcare workers become desensitized to the multitude of alarms generated by medical devices, such as monitors and infusion pumps. This desensitization can lead to delayed response times or even ignoring alarms altogether, potentially resulting in missed critical events and patient harm. Furthermore, the constant sounding of alarms contributes to increased stress and burnout among healthcare workers, exacerbating already challenging work environments. Recognizing the severity of alarm fatigue, healthcare organizations have prioritized addressing this issue as part of their patient safety initiatives, aligning with goals set forth by accrediting bodies like The Joint Commission. Take a look at [The Joint Commission's National Patient Safety Goals \(https://openstax.org/r/77JCNPSG\)](https://openstax.org/r/77JCNPSG) to learn about the recommendations for reducing alarm fatigue.

Nursing interventions for sensory overload aim to minimize sensory input and create a calming and supportive environment for the patient. This may involve adjusting the physical environment to reduce sensory stimuli, such as dimming lights, reducing noise levels, providing earplugs or headphones, and removing clutter or distracting objects. Nurses may also employ techniques to promote relaxation and sensory modulation, such as deep breathing exercises, progressive muscle relaxation, guided imagery, or sensory-focused activities like listening to soothing music or engaging in tactile stimulation with textured objects. Additionally, providing clear communication and

reassurance to the patient, offering opportunities for breaks or quiet time, and implementing individualized coping strategies based on the patient's preferences and sensory needs are essential components of nursing interventions for sensory overload. Collaborating with interdisciplinary team members, including occupational therapists, psychologists, and environmental specialists, can further enhance the effectiveness of interventions and support the patient in managing sensory overload effectively.

## REAL RN STORIES

---

### Causes of Sensory Overload in an Intensive Care Unit

**Nurse:** Liam, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 2

**Facility location:** Mobile, Alabama

During my time working in the ICU, I encountered a patient who experienced sensory overload due to the constant alarms and beeping monitors surrounding their bed. The patient, already in a delicate condition after a significant surgery, grew more agitated and distressed as the persistent sounds continued day and night. Despite efforts to adjust the alarm settings and minimize unnecessary alerts, the sheer volume and frequency of alarms in the ICU environment were overwhelming for the patient. The patient developed ICU delirium, which is an acute state of confusion and disorientation commonly observed in critically ill patients who are hospitalized in the ICU.

Recognizing the detrimental impact of sensory overload on the patient's well-being and recovery, our interdisciplinary team collaborated to address the issue. We implemented strategies to mitigate sensory stimuli, such as using earplugs and providing noise-canceling headphones to block out excessive noise. Additionally, we prioritized regular communication with the patient and their family members to reassure them and address any concerns or anxieties related to the alarms.

To further support the patient's comfort and promote a healing environment, we advocated for changes in ICU protocols and alarm management practices. This included conducting regular audits of alarm settings, educating staff members on the importance of alarm fatigue and sensory overload, and implementing protocols for alarm customization based on individual patient needs.

Over time, with concerted efforts from the healthcare team and adjustments to the care environment, we observed improvements in the patient's overall well-being and ability to cope with the ICU environment until the patient could be transferred to a lower level of care. By addressing sensory overload associated with ICU alarms and prioritizing patient-centered care, we were able to create a more supportive and healing environment for our patients.

---

### Conditions Associated with Sensory Overload

Certain medical conditions are associated with heightened sensory sensitivity and an increased risk of experiencing sensory overload. Autism spectrum disorder (ASD) is one such condition characterized by difficulties in social interaction, communication, and repetitive behaviors. Individuals with ASD often exhibit sensory sensitivities, such as hypersensitivity to loud noises, bright lights, or certain textures, which can lead to sensory overload in overwhelming environments. Similarly, attention deficit hyperactivity disorder (ADHD) may involve sensory processing difficulties, contributing to distractibility and difficulties filtering out irrelevant stimuli. Sensory processing disorder (SPD) is another condition with which individuals have challenges regulating and responding to sensory input, leading to sensory overload in response to everyday stimuli. Additionally, stress, fatigue, anxiety disorders, post-traumatic stress disorder (PTSD), and certain medical conditions like migraine headaches or fibromyalgia can exacerbate sensory sensitivity and increase susceptibility to sensory overload (Watson, 2021). Understanding these conditions and their impact on sensory processing is crucial for nurses to provide appropriate support and accommodations to individuals experiencing sensory overload.

### Sensory Deprivation

The absence or reduction of normal sensory inputs, leading to a state of decreased stimulation and sensory isolation, is **sensory deprivation**. Prolonged sensory deprivation can have profound effects on the body, affecting

both physical and mental health. Without adequate sensory stimulation, neural pathways may become underutilized or dysregulated, leading to alterations in brain function and perceptual processing. This can manifest as changes in cognition, mood, and behavior as well as disruptions in sleep patterns and circadian rhythms. Physiologically, sensory deprivation may also impact sensory organs and systems, potentially leading to sensory hypersensitivity or diminished sensory acuity over time (Khan & Khan, 2022; Rauschecker, 2018; Sahoo et al., 2022).

### Symptoms of Sensory Deprivation

Symptoms of sensory deprivation can manifest across various domains, affecting both physical sensations and psychological well-being. Physically, individuals may experience a heightened awareness of bodily sensations, such as tingling or numbness, as well as changes in proprioception or spatial orientation. Sensory deprivation can also lead to alterations in sensory perception, including visual or auditory hallucinations, distortions in the perception of time, delirium (a state of acute confusion and disorientation), and hypersensitivity to sensory stimuli on reintroduction (Rauschecker, 2018; Sahoo et al., 2022).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Ensuring Patient Safety Amid Sensory Deprivation

Quality and Safety Education for Nurses (QSEN) competencies provide a framework for nurses to deliver high-quality care that prioritizes patient safety and satisfaction. This feature box explores how QSEN competencies can guide nursing practice in addressing sensory deprivation, a critical aspect of patient care that requires vigilant assessment, intervention, and collaboration.

- Quality improvement:
  - Nurses identify and address symptoms of sensory deprivation through ongoing assessment and evaluation protocols.
  - Nurses implement evidence-based interventions to mitigate the effects of sensory deprivation and improve patient outcomes.
- Patient-centered care:
  - Nurses recognize the individualized nature of responses to sensory deprivation, considering factors such as age, cultural background, and previous experiences.
  - Nurses involve patients in decision-making regarding their care plans and interventions to address sensory deprivation symptoms.
- Safety:
  - Nurses implement strategies to ensure patient safety amid sensory deprivation, including fall prevention measures and environmental modifications.
  - Nurses utilize appropriate screening tools and assessment protocols to identify patients at risk of sensory deprivation and implement preventive measures.
  - Nurses recognize potential behavioral and psychosocial changes associated with sensory deprivation, such as anxiety, depression, and suicidal ideation, and provide comprehensive support and interventions to address these concerns.
- Teamwork and collaboration:
  - Nurses communicate effectively with interdisciplinary team members to coordinate care for patients experiencing sensory deprivation.
  - Nurses collaborate with other healthcare professionals to develop comprehensive care plans tailored to address the specific needs of patients with sensory deprivation.
- Evidence-based practice (EBP):
  - Nurses incorporate current evidence and best practices into the assessment, management, and evaluation of sensory deprivation symptoms.
  - Nurses participate in ongoing education and professional development activities to stay updated on emerging research and interventions related to sensory deprivation.
- Informatics:
  - Nurses utilize electronic health records and clinical decision support tools to document assessments, interventions, and patient responses related to sensory deprivation.

- Nurses access and interpret relevant data, such as screening results and patient history, to inform clinical decision-making and evaluate the effectiveness of interventions.

---

Psychologically, sensory deprivation can induce feelings of boredom, restlessness, or agitation, as individuals lack external stimuli to engage their attention and occupy their minds. This may lead to difficulties concentrating, maintaining focus, or sustaining interest in activities. Emotional responses to sensory deprivation can range from irritability and anxiety to feelings of isolation, loneliness, or depression. In some cases, prolonged sensory deprivation can trigger existential thoughts or existential crisis as individuals grapple with the absence of sensory input and its implications for their perception of self and reality (Rauschecker, 2018; Sahoo et al., 2022).

Symptoms of sensory deprivation can vary depending on the duration and severity of the deprivation as well as individual factors such as age and preexisting health conditions. The duration and severity of the deprivation play a significant role, with longer periods of deprivation often leading to more pronounced symptoms. In acute cases, individuals may initially experience heightened sensitivity to stimuli, followed by a decline in sensory perception as adaptation sets in. However, prolonged, or chronic sensory deprivation, can result in more severe symptoms, including hallucinations, cognitive disturbances, and emotional distress (Rauschecker, 2018; Sahoo et al., 2022). Age also influences the manifestation of symptoms, as younger individuals, particularly children, may display different responses compared to older adults. Similarly, preexisting health conditions or sensory impairments can exacerbate or modify symptoms of sensory deprivation. For example, individuals with conditions affecting sensory processing or neurological functioning may be more susceptible to experiencing hallucinations or cognitive distortions during periods of sensory deprivation.

### Causes of Sensory Deprivation

Causes of sensory deprivation can vary widely and may include physical, environmental, or psychological factors. Physical causes can include conditions that limit sensory input, such as blindness, deafness, or immobilization due to injury or illness. Environmental factors such as isolation, confinement, or exposure to monotonous or sterile surroundings can also contribute to sensory deprivation. Additionally, medical interventions or conditions that limit sensory input, such as prolonged bed rest, immobilization, or the use of sensory-depriving equipment like blindfolds or earplugs, can induce sensory deprivation. Neurological conditions or injuries affecting sensory processing pathways in the brain may also lead to deprivation by disrupting the transmission or interpretation of sensory signals. Additionally, psychological factors such as trauma, stress, neglect, or social withdrawal may lead to self-imposed sensory deprivation as individuals avoid or restrict exposure to external stimuli (Rauschecker, 2018; Sahoo et al., 2022). In healthcare settings, sensory deprivation may occur inadvertently as a result of sedation, anesthesia, or prolonged bed rest, highlighting the importance of proactive measures to prevent and address sensory deprivation in patient care.

### Conditions Associated with Sensory Deprivation

Sensory deprivation can be associated with various conditions, both acute and chronic, affecting individuals across the life span. In acute medical settings, such as ICUs or postanesthesia recovery units (PACUs), patients may experience sensory deprivation due to the use of sedative medications, mechanical ventilation, or prolonged periods of immobility (Khan & Khan, 2022). Chronic conditions that limit mobility or sensory input, such as paralysis, coma, or neurodegenerative disorders like Alzheimer disease, can also lead to sensory deprivation over time. Additionally, individuals in solitary confinement or confined spaces may experience sensory deprivation as a result of prolonged isolation and restricted sensory stimulation.

Prolonged sensory deprivation has been linked to cognitive deficits, including impaired memory, attention, and executive function. It can also exacerbate symptoms of mental health disorders such as depression, anxiety, and PTSD (Khan & Khan, 2022). In addition, sensory deprivation may increase the risk of accidents or injuries due to impaired perception and awareness of environmental hazards. Sensory deprivation has been associated with prolonged hospital stays, increased healthcare costs, and decreased patient satisfaction, highlighting the need for interventions to mitigate its effects and promote sensory stimulation and engagement for optimal patient outcomes (Drahota et al., 2012).

### Alterations in Sensory Perception

Alterations in sensory perception refer to changes in how individuals perceive and interpret sensory stimuli from

their environment. Alterations in sensory perception encompass a range of changes in how individuals interpret and respond to sensory stimuli. These alterations can occur due to various factors, including neurological conditions, trauma, aging, or environmental influences. Common alterations include heightened sensitivity (hypersensitivity), diminished perception (hyposensitivity), or distortions in sensory experiences. For example, individuals may experience increased sensitivity to light, sound, or touch, leading to discomfort or pain, while others may have difficulty perceiving or distinguishing sensory stimuli, affecting their ability to navigate their surroundings effectively. These alterations can significantly impact daily functioning, social interactions, and emotional well-being, highlighting the importance of tailored interventions to support individuals experiencing such changes in sensory perception (Khan & Khan, 2022).

## LIFE-STAGE CONTEXT

---

### Alterations in Senses with Aging

Aging is accompanied by physiological changes that can impact sensory perception. Understanding age-related alterations in senses is crucial for providing holistic and person-centered care to older adults.

- Vision:
  - decreased visual acuity and contrast sensitivity due to changes in the lens and retina
  - increased risk of age-related eye conditions such as cataracts, glaucoma, and macular degeneration
  - strategies to promote optimal sensory health: encouraging regular eye exams as well as providing adequate lighting, and assistive devices such as magnifiers or large-print materials
- Hearing:
  - gradual decline in hearing acuity, particularly in high-frequency sounds
  - increased susceptibility to age-related hearing loss (presbycusis) and conditions such as tinnitus
  - strategies to promote optimal sensory health: encouraging regular hearing screenings and use of hearing aids or assistive listening devices to improve communication and social engagement
- Taste and smell:
  - diminished taste and smell sensitivity due to changes in taste buds and olfactory receptors
  - decreased ability to detect and differentiate flavors, leading to decreased appetite and enjoyment of food
  - strategies to promote optimal sensory health: promoting sensory stimulation through flavorful and aromatic foods as well as maintaining oral hygiene to support taste sensation
- Touch:
  - reduced sensitivity to touch and pressure due to changes in skin thickness, nerve endings, and blood flow
  - increased risk of skin injuries such as pressure ulcers and burns
  - strategies to promote optimal sensory health: implementing strategies to maintain skin integrity through regular skin assessments, moisturizing, and protective measures

As individuals age, changes in sensory function can impact their quality of life and independence. By recognizing and addressing age-related alterations in senses, nurses can develop tailored interventions to support optimal sensory health and well-being in older adults. Through proactive assessment, education, and interdisciplinary collaboration, healthcare teams can empower older adults to maintain sensory function and enhance their overall quality of life as they age.

---

### Sensory Deficits

A **sensory deficit** refers to an impairment or loss in one or more sensory modalities, such as vision, hearing, touch, taste, or smell. These deficits can arise from congenital conditions, injuries, diseases, or aging processes, resulting in diminished sensory perception and decreased ability to detect or discriminate sensory stimuli. Individuals with sensory deficits may face difficulties in communication, mobility, safety, and social engagement, requiring adaptive strategies and accommodations to navigate their environment effectively. Addressing sensory deficits often involves multidisciplinary approaches, including medical management, rehabilitative therapies, and assistive devices, aimed at optimizing sensory function and enhancing quality of life.

Nursing assessment for sensory deficits involves a comprehensive evaluation of the patient's sensory function, including sight, hearing, touch, taste, and smell. This assessment typically includes direct observation of the

patient's responses to sensory stimuli, such as their ability to follow commands, react to visual or auditory cues, and perceive tactile sensations. Nurses may also utilize screening tools or standardized assessments to quantify the extent of sensory deficits and identify specific areas of impairment. Additionally, it is essential for nurses to consider the patient's medical history, current medications, and any environmental factors that may impact sensory function. Through thorough assessment, nurses can gain insights into the nature and severity of sensory deficits, enabling them to develop individualized care plans to address the patient's needs effectively.

Nursing interventions for sensory deficits aim to compensate for impaired sensory function and promote the patient's safety, comfort, and quality of life. These interventions may include modifying the environment to reduce sensory distractions or hazards, such as minimizing noise or ensuring adequate lighting for visually impaired patients. Nurses may also provide assistive devices or technologies to enhance sensory perception, such as hearing aids or magnifying glasses. Education and training on adaptive strategies and techniques can empower patients to maximize their remaining sensory abilities and navigate daily activities more independently. Additionally, nurses collaborate with interdisciplinary teams to address underlying conditions contributing to sensory deficits, such as managing chronic diseases or coordinating rehabilitative therapies. By implementing holistic interventions, nurses play a vital role in supporting patients with sensory deficits and optimizing their overall well-being.

### Sensory Processing Disorder

A neurological condition that affects how individuals process and respond to sensory information from the environment is known as **sensory processing disorder (SPD)**. In SPD, the brain has difficulty organizing and interpreting sensory input, leading to atypical responses or behaviors. Individuals with SPD may experience hypersensitivity (over-responsiveness) or hyposensitivity (under-responsiveness) to sensory stimuli such as touch, sound, taste, smell, or movement. This can result in challenges with sensory modulation, **sensory discrimination** (the brain's ability to interpret and distinguish between different sensory stimuli), or **sensory integration** (the brain's ability to organize and make sense of information received through the senses), impacting various aspects of daily life, including behavior, attention, social interaction, and emotional regulation. Sensory processing difficulties can occur independently or in association with other developmental or neurological conditions, such as ASD, ADHD, or anxiety disorders. Treatment for SPD often involves sensory integration therapy, environmental modifications, and sensory-based interventions tailored to address individual sensory processing patterns and enhance functional outcomes. Early identification and intervention are crucial for supporting individuals with SPD and optimizing their participation and engagement in daily activities (Jones, 2024).

Nursing assessment for individuals with SPD involves comprehensive evaluation of sensory processing patterns, including sensory modulation, discrimination, and integration abilities. Assessment may include gathering information from caregivers or family members regarding the individual's sensory responses and behaviors across different environments and activities. Observation of the individual's reactions to various sensory stimuli, such as touch, sound, movement, and visual input, can provide valuable insights into their sensory processing difficulties. Additionally, standardized assessment tools, such as the sensory profile or sensory processing measure, may be utilized to quantify sensory processing patterns and identify specific areas of challenge or strength.

### LINK TO LEARNING

A [sensory profile \(https://openstax.org/r/77sensprofile\)](https://openstax.org/r/77sensprofile) refers to an assessment tool used to evaluate an individual's sensory processing patterns, preferences, and sensitivities across various sensory modalities, such as touch, taste, smell, sight, sound, and movement. It helps identify how an individual responds to sensory input and how these responses may impact their daily functioning, behavior, and participation in activities.

Nursing interventions for sensory processing disorder (SPD) focus on creating a sensory-friendly environment that promotes comfort, regulation, and participation in daily activities. This may involve implementing sensory-based strategies to address specific sensory needs, such as providing sensory input through tactile, proprioceptive, or vestibular activities to promote self-regulation. Environmental modifications, such as reducing sensory triggers or providing sensory accommodations, can also help minimize sensory overload and support the individual's sensory well-being. Collaborating with interdisciplinary teams and educating caregivers about sensory processing difficulties are essential components of nursing interventions to optimize outcomes for individuals with SPD.

## REAL RN STORIES

### Assessing a Patient with Sensory Processing Disorder

**Nurse:** Pauleena, BSN

**Clinical setting:** Pediatric outpatient clinic

**Years in practice:** 4

**Facility location:** Savannah, Georgia

As a pediatric nurse, every child I meet holds a unique story, and Jake's journey with SPD was one I won't forget. When Jake and his parents walked into my office, I could sense their concern. Jake, a lively 5-year-old, seemed a bit apprehensive, his eyes darting around the room. His parents described his struggles with sensory overload—loud noises made him cover his ears, and certain textures sent him into a frenzy. I knew this was going to be more than just a routine assessment. It was about understanding Jake's world and helping him navigate it better.

As I started the assessment, I brought out an array of toys and tools, each designed to uncover a piece of Jake's sensory puzzle. Watching him interact with them was fascinating. Sometimes he would recoil from a touch, other times he'd dive right in, craving more sensation. One activity stands out vividly in my memory. I set up a mini obstacle course with different textures on the floor—soft rugs, bumpy mats, smooth tiles. Watching Jake cautiously navigate through, I saw determination in his eyes as he conquered each texture, one step at a time. Throughout the assessment, I tried to create a space where Jake felt safe and understood. When he got overwhelmed, I was there to offer a comforting hand or a reassuring smile. Building that trust was key to unlocking his world of sensory experiences.

After the assessment, I sat down with Jake's parents, armed with insights and strategies to help Jake thrive. We talked about creating a sensory-friendly home environment, incorporating calming activities into his routine, and being mindful of his triggers. Seeing Jake's progress over time was incredibly rewarding. With the right support and understanding, he started to navigate his world with more confidence and ease. And knowing I played a part in that journey fills my heart with joy. Jake's story taught me the power of patience, empathy, and personalized care. It's a reminder that behind every diagnosis is a unique individual with their own story waiting to be heard and understood.

## 29.3 Factors Affecting Sensory Function

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe physiological factors affecting sensory perception
- Explain psychosocial factors affecting sensory perception
- Identify medications affecting sensory perception
- Discuss disorders affecting sensory perception

Understanding the physiological factors that influence sensory perception is essential for nurses to assess, interpret, and respond to individuals' sensory experiences accurately. Physiological mechanisms contribute to the detection, transmission, and processing of sensory information throughout the body. From the neurological pathways transmitting signals to the sensory organs receiving them, each physiological component plays a pivotal role in shaping one's perception of the world. Additionally, psychosocial factors, including psychological states, cultural backgrounds, and past experiences, contribute to how individuals interpret sensory stimuli. Furthermore, medications can alter sensory experiences, either enhancing or dampening one's perception of stimuli, while disorders such as neuropathy or SPDs add another layer of complexity to sensory perception. Understanding these factors equips nurses to provide tailored interventions that honor the diversity of human sensory experiences.

### Physiological Factors

Sensory perception, the process by which organisms interpret and respond to sensory stimuli from their environment, is influenced by a multitude of physiological factors. These factors encompass various aspects of sensory function, including the structure and function of sensory organs, neural pathways, and sensory processing mechanisms. From genetics to age-related changes and current health states, physiological factors play a pivotal

role in shaping how individuals perceive and interpret sensory information.

### Developmental Considerations

Developmental considerations play a crucial role in shaping sensory perception, as sensory abilities evolve and mature over the course of an individual's life span. In the early stages of life, such as infancy and childhood, sensory systems undergo rapid maturation, enabling infants to progressively interpret and respond to sensory stimuli from their environment. As neural pathways mature and connections strengthen, infants become more adept at processing various sensory inputs, including sound, touch, taste, smell, and visual cues. However, sensory thresholds in children may differ from those in adults, with younger individuals often exhibiting higher thresholds and less refined sensory processing abilities. During childhood and adolescence, the process of sensory integration becomes increasingly significant, as the brain learns to organize and interpret sensory information from multiple sources to create a coherent perceptual experience. Developmental factors, such as brain maturation and **neural plasticity** (the brain's ability to reorganize and adapt its structure and function in response to changes), play pivotal roles in shaping sensory integration processes, which influence individuals' interactions with their surroundings.

Furthermore, sensory preferences and processing patterns may vary among children and adolescents, influenced by developmental stages, personality traits, and past experiences. While some children may demonstrate preferences for certain sensory stimuli, others may experience challenges related to atypical sensory processing, which can contribute to the development of SPDs such as ASD or ADHD.

Nurses play a crucial role in assessing and addressing how developmental factors impact sensory perception. One key nursing intervention involves conducting thorough developmental assessments to identify age-related changes in sensory function and potential sensory deficits. For example, in pediatric nursing, nurses assess sensory development milestones and screen for any delays or abnormalities in sensory processing, ensuring early detection and intervention. Additionally, in geriatric nursing, nurses evaluate age-related sensory changes, such as diminished vision or hearing, and implement interventions to support sensory functioning and maintain quality of life.

### LINK TO LEARNING

The STAR Institute for Sensory Processing is an organization dedicated to understanding and addressing SPDs. They offer several [checklists \(https://openstax.org/r/77ckltsensory\)](https://openstax.org/r/77ckltsensory) designed to identify potential symptoms and behaviors associated with sensory processing disorder (SPD) across different age groups. These checklists are often used as screening tools to identify potential sensory processing difficulties based on developmental stages.

Nursing interventions may include providing sensory stimulation activities, such as tactile or auditory stimulation, to enhance sensory experiences and promote cognitive functioning in older adults. For example, nurses can offer textured objects like sensory balls or soft brushes for exploration, or play calming music or nature sounds to create a soothing auditory environment. Furthermore, nurses educate patients and caregivers about age-related sensory changes and strategies to optimize sensory perception and compensate for sensory deficits. This may involve recommending assistive devices, such as hearing aids or magnifiers, and teaching techniques for adapting the environment to enhance sensory stimulation and reduce sensory overload.

### Age Considerations

Age considerations significantly influence sensory perception, encompassing a spectrum of physiological changes that occur as individuals progress through different stages of life. As individuals age, alterations in sensory organs, neural pathways, and sensory processing mechanisms can lead to shifts in sensory acuity and perception ([Table 29.5](#)).

Decline in Sensory Function	Rationale
Changes in tactile sensation	<ul style="list-style-type: none"> <li>• Degenerative processes: Age-related changes in skin thickness, nerve density, and blood flow affect tactile sensation.</li> <li>• Cumulative exposure to environmental factors: Chronic exposure to physical stressors and environmental toxins can impair tactile perception.</li> <li>• Natural aging of sensory structures: Alterations in the structure and function of cutaneous receptors and peripheral nerves occur with age, leading to diminished tactile sensation (Correia et al., 2016).</li> </ul>
Diminished taste and smell sensitivity	<ul style="list-style-type: none"> <li>• Degenerative processes: Aging affects the number and function of taste buds and olfactory receptors, diminishing taste and smell sensitivity.</li> <li>• Cumulative exposure to environmental factors: Factors such as smoking, medication use, and chronic health conditions can contribute to taste and smell impairment over time.</li> <li>• Natural aging of sensory structures: Changes in the density and distribution of taste buds and olfactory receptor cells occur with age, reducing sensitivity to taste and smell stimuli.</li> </ul>
Hearing loss	<ul style="list-style-type: none"> <li>• Degenerative processes: Age-related changes in the inner ear, including loss of hair cells and stiffening of the cochlear membrane, lead to hearing loss.</li> <li>• Cumulative exposure to environmental factors: Exposure to loud noises over time can damage the delicate structures of the inner ear, resulting in sensorineural hearing loss.</li> <li>• Natural aging of sensory structures: Gradual deterioration of auditory structures, such as the cochlea and auditory nerve, occurs with age, leading to hearing impairment.</li> </ul>
Reduced visual acuity	<ul style="list-style-type: none"> <li>• Degenerative processes: Age-related changes in the eye's structure, such as lens opacity (cataracts) and retinal degeneration, impair visual acuity.</li> <li>• Cumulative exposure to environmental factors: Prolonged exposure to ultraviolet radiation and environmental pollutants can contribute to vision deterioration over time.</li> <li>• Natural aging of sensory structures: Changes in the density and elasticity of ocular tissues occur with age, affecting visual acuity.</li> </ul>

**TABLE 29.5** Common Sensory Declines in Older Adults

Consequently, age-related changes in sensory perception can have profound implications for individuals' daily functioning, social interactions, and overall quality of life. Understanding the physiological factors underlying age-related changes in sensory perception is essential for developing targeted interventions and strategies to support older adults in maintaining optimal sensory function and enhancing their overall well-being.

Nurses should conduct thorough assessments to identify age-related changes in sensory function and potential sensory deficits. For instance, in older adult nursing, nurses evaluate age-related sensory changes, such as diminished vision or hearing, and implement interventions to support sensory functioning and maintain quality of life. Nursing interventions may include providing sensory stimulation activities, such as tactile or auditory stimulation, to enhance sensory experiences and promote cognitive functioning in older adults.

Furthermore, nurses educate patients and caregivers about age-related sensory changes and strategies to optimize sensory perception and compensate for sensory deficits. This may involve recommending assistive devices, such as

hearing aids or magnifiers, and teaching techniques for adapting the environment to enhance sensory stimulation and reduce sensory overload.

### Current Health State

The current health state of an individual can shape sensory perception, encompassing a wide range of physiological factors that can influence sensory function. Health conditions, both chronic and acute, can impact sensory organs, neural pathways, and sensory processing mechanisms, thereby affecting an individual's ability to perceive and interpret sensory stimuli accurately. For instance, neurological disorders like Parkinson disease or stroke can disrupt the transmission of sensory information within the brain, leading to sensory deficits or distortions. Similarly, sensory impairments such as vision or hearing loss can profoundly affect sensory perception by limiting the ability to receive or process sensory input. Additionally, systemic health issues such as diabetes or cardiovascular disease may indirectly impact sensory function through vascular changes or metabolic imbalances.

Nurses evaluate and manage the impact of different health conditions on sensory function and perception. One key nursing intervention involves conducting thorough assessments to identify any changes or deficits in sensory perception related to the patient's current health state. For example, nurses may assess sensory function in patients with neurological conditions, such as stroke or multiple sclerosis, to detect alterations in sensation, proprioception, or tactile perception. Additionally, nurses monitor patients with acute or chronic illnesses for signs of sensory impairment, such as altered pain perception or sensory hypersensitivity, and implement interventions to alleviate discomfort and promote recovery.

Nursing interventions may include providing sensory stimulation techniques, such as therapeutic touch (hands-on healing) or aromatherapy (scent-based therapy), to enhance sensory experiences and reduce stress or anxiety associated with the patient's health condition. Furthermore, nurses educate patients and caregivers about the potential effects of their health status on sensory perception and teach strategies to optimize sensory function and manage sensory-related symptoms.

## PATIENT CONVERSATIONS

---

### Educating Patients about the Influence of Current Health Status Impacts Sensory Perception

**Nurse:** Good morning, Mrs. Johnson. Today, I would like to discuss how your recent diagnosis of diabetes may impact your sensory perception and share some strategies to help manage any related symptoms.

**Patient:** Good morning, nurse. I appreciate you taking the time to explain this to me. How exactly does diabetes affect my sensory perception?

**Nurse:** Well, Mrs. Johnson, diabetes can lead to a condition called diabetic neuropathy, where prolonged high blood sugar levels damage the nerves throughout your body. This can result in altered sensations, such as numbness or tingling in your hands and feet, making it challenging to feel things as you normally would.

**Patient:** That makes sense. I have noticed some tingling sensations in my feet recently. What can I do about it?

**Nurse:** There are several strategies we can explore to help manage these symptoms. First, it is essential to keep your blood sugar levels under control through proper diet, medication, and regular exercise. Additionally, we can discuss ways to protect your feet from injury, such as wearing comfortable shoes and checking them daily for any signs of damage.

**Patient:** Thank you for the advice. Are there any specific exercises or treatments that can help improve my sensory function?

**Nurse:** Yes, Mrs. Johnson. We can incorporate exercises like balance training and gentle stretching into your routine to help improve nerve function and reduce discomfort. Also, certain medications or topical treatments may be prescribed by your doctor to alleviate any pain or tingling sensations you may be experiencing.

**Patient:** That's reassuring to know. I'll make sure to follow your recommendations and stay proactive about managing my diabetes.

**Nurse:** That's great to hear, Mrs. Johnson. Remember, we're here to support you every step of the way on your journey to better health. If you have any further questions or concerns, please don't hesitate to reach out to me or the healthcare team.

---

### Genetics

Genetics influence various aspects of sensory function and processing. Genetic factors contribute to the development and structure of sensory organs, neural pathways, and sensory processing mechanisms, ultimately determining an individual's sensory abilities and preferences. For example, genetic variations can impact the sensitivity of sensory receptors, such as taste buds or photoreceptors in the eyes, affecting an individual's perception of taste or color. Additionally, genetic factors can influence the transmission of neural signals within the brain, modulating how sensory information is processed and interpreted. Certain genetic mutations or polymorphisms may predispose individuals to sensory disorders or conditions, such as congenital deafness or color blindness, altering their sensory experiences. Moreover, genetic predispositions may contribute to individual differences in sensory perception, including thresholds for sensory stimuli and preferences for certain sensory experiences.

Nurses conduct thorough assessments to identify any genetic predispositions or hereditary conditions that may affect sensory perception. For example, nurses may assess family medical history to identify genetic disorders or conditions associated with sensory impairment, such as congenital deafness or retinal degeneration. Additionally, nurses collaborate with genetic counselors and other healthcare providers to perform genetic testing and counseling for patients at risk of inherited sensory disorders. Nursing interventions may include providing education and support to patients and their families about the genetic basis of sensory conditions, offering resources for genetic testing and counseling, and facilitating access to specialized care and interventions to manage genetic-related sensory issues.

### Psychosocial Factors

Psychosocial factors play a fundamental role in shaping sensory perception, encompassing a wide array of psychological and social elements that influence how individuals interpret and respond to sensory stimuli. These factors include mental health, personality traits, behaviors, cultural norms, and societal expectations, all of which contribute to the complexity of sensory experiences. By recognizing the impact of mental health on sensory experiences, healthcare providers can develop targeted interventions to support individuals in managing sensory symptoms and improving overall well-being.

### Mental Health

Mental health significantly influences sensory perception, as psychological factors can profoundly impact how individuals perceive and interpret sensory stimuli. Conditions such as anxiety, depression, or PTSD can alter sensory processing and perception, leading to heightened sensitivity, distorted perceptions, or reduced sensory awareness. For example, individuals experiencing anxiety may exhibit heightened arousal and vigilance toward sensory stimuli, leading to increased sensitivity to sounds or tactile sensations. Conversely, individuals with depression may experience reduced sensory pleasure and decreased interest in sensory experiences, known as **anhedonia**. Additionally, trauma or adverse childhood experiences can shape sensory processing patterns and contribute to sensory hypersensitivity or dissociation (Khan & Khan, 2022).

Nurses conduct comprehensive assessments to identify any mental health issues that may affect sensory perception. For example, nurses may assess patients with depression or anxiety for alterations in sensory processing, such as heightened sensitivity to stimuli or decreased perception of sensory input. Additionally, nurses monitor patients with psychiatric disorders for signs of sensory disturbances, such as hallucinations or sensory distortions, and implement interventions to manage these symptoms effectively. Nursing interventions may include providing sensory stimulation activities, such as relaxation techniques or guided imagery, to promote sensory integration and reduce distress associated with mental health conditions. Furthermore, nurses collaborate with mental health professionals to develop holistic care plans that address both mental health and sensory needs, ensuring comprehensive support for patients.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Mental Health and Sensory Perception

Mental health plays a crucial role in shaping sensory perception, influencing how individuals interpret and respond to sensory stimuli. Here's how Quality and Safety Education for Nurses (QSEN) competencies guide nursing practice in addressing mental health impacts on sensory perception:

- Quality improvement:
  - Nurses conduct thorough assessments of sensory perception in individuals with mental health conditions, identifying alterations or deficits in sensory processing.
  - Based on assessment findings, nurses implement evidence-based interventions to address sensory perception challenges and enhance quality of life for individuals with mental health disorders.
- Patient-centered care:
  - Nurses recognize the individualized nature of sensory experiences in mental health, considering factors such as diagnosis, symptom severity, and personal preferences when developing care plans.
  - Nurses involve individuals with mental health conditions in decision-making regarding sensory interventions, promoting autonomy and empowerment in sensory perception management.
- Safety:
  - Nurses implement safety measures to minimize the risk of falls related to sensory perception deficits, such as ensuring clear pathways and using appropriate assistive devices.
  - Nurses make environmental adjustments to promote sensory safety, reducing sensory overload and creating calming spaces for individuals with mental health disorders.
- Teamwork and collaboration:
  - Nurses collaborate with mental health professionals to coordinate sensory assessment and intervention strategies, ensuring holistic care for individuals with mental health conditions.
  - Nurses connect individuals with mental health disorders to community resources and support services that address sensory perception challenges and promote well-being.
- Evidence-based practice (EBP):
  - Nurses integrate current evidence into the assessment and management of sensory perception in mental health, staying informed about emerging research and interventions.
  - Nurses evaluate the effectiveness of sensory perception interventions in individuals with mental health conditions, adjusting care plans as needed to optimize outcomes.
- Informatics:
  - Nurses utilize electronic health records to document sensory perception assessments, interventions, and outcomes in individuals with mental health disorders, ensuring comprehensive and accurate recordkeeping.
  - Nurses analyze sensory perception data to identify trends and patterns in individuals with mental health conditions, informing evidence-based practice and quality improvement initiatives.

By integrating QSEN competencies into nursing practice, nurses can address the complex relationship between mental health and sensory perception, promoting safety, well-being, and quality of life for individuals with mental health disorders.

---

### Personality and Behaviors

Personality traits and behaviors play a significant role in shaping sensory perception, influencing how individuals process and respond to sensory stimuli. Personality traits such as **extraversion** (personality trait characterized by sociability, outgoingness, and a preference for social interactions), neuroticism (personality trait characterized by emotional instability, negative affectivity, and a tendency to experience distress, anxiety, and mood swings), or **sensation seeking** (tendency to seek out novel, varied, and intense experiences) can impact sensory sensitivity, preferences, and thresholds. For example, individuals high in sensation seeking may actively seek out novel or intense sensory experiences, whereas those high in neuroticism may be more sensitive to sensory stimuli and prone to heightened emotional reactions. Additionally, individual behaviors, habits, and coping strategies can influence sensory perception. Engaging in mindfulness practices, relaxation techniques, or exposure therapy can modulate

sensory processing and enhance sensory awareness. Conversely, maladaptive behaviors such as avoidance or sensory overload can exacerbate sensory difficulties and impair sensory functioning.

Nurses should conduct thorough assessments to identify personality characteristics and behaviors that may affect sensory processing, as appropriate. For example, nurses may assess patients with high levels of anxiety or stress for alterations in sensory perception, such as heightened sensitivity or reduced attention to sensory stimuli. Additionally, nurses monitor patients with specific personality traits, such as sensation-seeking behaviors, for potential risks associated with sensory experiences, such as engaging in risky behaviors or seeking intense sensory stimulation.

Nursing interventions may include providing education and support to patients to help them understand how their personality and behaviors influence sensory perception and offering coping strategies to manage sensory-related challenges effectively. Furthermore, nurses collaborate with multidisciplinary teams, including psychologists or counselors, to develop individualized care plans that address both personality traits and sensory needs, ensuring comprehensive support for patients.

### Cultural Considerations

Cultural considerations exert a profound influence on sensory perception, shaping individuals' experiences and interpretations of sensory stimuli within their social and cultural contexts. Cultural norms, values, beliefs, and practices influence how individuals perceive, prioritize, and respond to sensory information. For example, cultural differences in food preferences and culinary traditions can influence taste perception, with certain cultures valuing spicy or aromatic flavors more than others. Similarly, cultural norms regarding touch, personal space, and physical contact can impact tactile sensitivity and comfort levels during social interactions. Moreover, cultural beliefs about illness, healing, and the body-mind connection can influence individuals' perceptions of pain and discomfort. The diversity of cultural perspectives on sensory processing and perception highlights the significance of taking sociocultural factors into account when comprehending and managing challenges related to the senses. By acknowledging the cultural diversity of sensory experiences, healthcare providers can develop culturally sensitive interventions and strategies to support individuals in navigating their sensory worlds effectively within their cultural contexts.

Nurses play a pivotal role in assessing and addressing how cultural beliefs, values, and practices can impact sensory function and perception. One key nursing intervention involves conducting culturally sensitive assessments to identify how cultural factors may influence sensory processing. For example, nurses may explore cultural norms regarding touch, pain expression, or sensory preferences to understand how patients perceive and experience sensory stimuli differently based on their cultural background. Additionally, nurses collaborate with patients and their families to respect and accommodate cultural preferences related to sensory experiences, such as incorporating traditional healing practices or adjusting environmental stimuli to align with cultural beliefs.

Nursing interventions may include providing education and support to patients to help them navigate cultural differences in sensory perception and promoting culturally relevant coping strategies to manage sensory-related challenges effectively. Furthermore, nurses advocate for culturally inclusive care practices within healthcare settings, ensuring that all patients receive equitable access to sensory support and interventions.

## PATIENT CONVERSATIONS

### Culture-Centered Care: Enhancing Patient Experience through Sensory Considerations

**Nurse:** Good afternoon, Mr. Patel. How are you feeling today?

**Patient:** Hello, nurse. I'm feeling a bit disoriented, to be honest. Everything seems so different here compared to back home.

**Nurse:** I understand. It can be quite an adjustment being in a new environment, especially when it comes to your senses. Could you tell me more about what you're experiencing?

**Patient:** Well, for starters, the lighting in this room is much brighter than what I'm used to. In my culture, we tend to prefer softer, dimmer lighting, which helps create a more calming atmosphere.

**Nurse:** I see. We can certainly adjust the lighting in your room to better suit your comfort level. Would you prefer a softer, dimmer setting?

**Patient:** Yes, that would be great, thank you. Also, the food here tastes very different from what I'm accustomed to. In my culture, we use a lot of spices and herbs in our cooking, which gives our meals a rich and flavorful taste.

**Nurse:** Your cultural culinary preferences are important to consider. We can speak with the kitchen staff to see if they can incorporate more spices and herbs into your meals to better align with your taste preferences.

**Patient:** Thank you, nurse. I really appreciate your understanding. Oh, and one more thing, the noise levels in the hospital are much higher than I'm used to. In my culture, we value quiet environments that promote relaxation and concentration.

**Nurse:** I completely understand. We can explore options to make your environment more conducive to relaxation and concentration, such as providing earplugs or finding a quieter area for you.

**Patient:** That would be wonderful, thank you. I feel much better knowing that you're taking my cultural considerations into account.

**Nurse:** It's my pleasure, Mr. Patel. Your cultural background and comfort are important aspects of your care. If there's anything else you need or if you have any other concerns, please don't hesitate to let me know.

## Medications Affecting Sensory Perception

Whether by suppressing or alerting the central nervous system (CNS), medications can modulate neural activity and neurotransmitter function, leading to changes in sensory awareness, sensitivity, and processing. Certain medications have the potential to induce taste alterations (e.g., amoxicillin, Paxlovid, chemotherapy, selective serotonin reuptake inhibitors, haloperidol) or exert **ototoxic** effects (medications that have the potential to cause damage to the structures of the inner ear or the auditory nerve) (e.g., furosemide, chemotherapy), further complicating their impact on sensory perception. Taste alterations may manifest as a metallic or bitter taste, diminishing the enjoyment of food and potentially affecting nutritional intake (Schiffman, 2018). Ototoxic medications can harm the delicate structures of the inner ear, leading to hearing loss or balance disturbances (Cone et al., n.d.). Understanding the effects of medications on sensory perception is essential for nurses to anticipate and manage potential sensory-related symptoms or side effects in patients.

### Medications that Suppress the Central Nervous System

Medications that suppress the CNS can significantly impact sensory perception by altering neural activity and neurotransmitter function within the brain (Table 29.6). These medications, which include benzodiazepines, opioids, and certain antipsychotics, work by depressing CNS activity, leading to sedation, relaxation, and pain relief. However, one of the common side effects of CNS depressants is a reduction in sensory awareness and perception. For example, benzodiazepines, commonly used to treat anxiety and insomnia, can cause drowsiness and cognitive impairment, which may dull sensory experiences. Similarly, opioids, prescribed for pain management, can induce feelings of euphoria and drowsiness, potentially blunting sensory responses to external stimuli. Certain antipsychotic medications, used to treat psychiatric disorders such as schizophrenia, may also have sedative effects that impact sensory perception (Melinosky, 2023).

Medication Name	Effect on Central Nervous System	Examples
Benzodiazepines	Sedation	alprazolam (Xanax) diazepam (Valium)
Opioids	Respiratory depression	morphine hydrochloride (morphine) oxycodone hydrochloride (oxycodone)

**TABLE 29.6** Medications that Suppress the Central Nervous System

Medication Name	Effect on Central Nervous System	Examples
Antidepressants	Sedation	sertraline (Zoloft) fluoxetine hydrochloride (Prozac)
Antipsychotics	Sedation	haloperidol (Haldol) olanzapine (Zyprexa)
Anticonvulsants	Sedation	valproate sodium (Depakote) gabapentin (Neurontin)
Muscle relaxants	Muscle relaxation	cyclobenzaprine (Flexeril) baclofen
Antihistamines	Sedation and drowsiness	diphenhydramine (Benadryl) cetirizine hydrochloride (Zyrtec)

**TABLE 29.6** Medications that Suppress the Central Nervous System

Nurses should assess and monitor patients for potential adverse effects associated with CNS depressants, implement interventions to mitigate these effects, and promote patient safety and comfort. One essential nursing intervention involves conducting a thorough assessment of the patient's medical history, including any preexisting conditions or medications that may interact with CNS depressants. This assessment helps nurses identify patients who may be at higher risk for adverse reactions, such as older adults or those with respiratory conditions.

## LIFE-STAGE CONTEXT

### Age-Related Considerations: Medications that Suppress the Central Nervous System and Sensory Perception

As individuals age, they may be more susceptible to the effects of medications that suppress the CNS, leading to alterations in sensory perception. Here are some age-related considerations regarding the use of CNS-suppressing medications:

- **Increased sensitivity:** Older adults often experience heightened sensitivity to CNS-suppressing medications due to age-related changes in metabolism, liver function, and drug clearance. This increased sensitivity can amplify the sedative effects of these medications, affecting sensory awareness and perception.
- **Risk of falls:** Medications that suppress the CNS, such as benzodiazepines, opioids, and certain antipsychotics, can impair balance, coordination, and reaction times, increasing the risk of falls and injuries, particularly among older adults. Changes in sensory perception may further exacerbate these risks, as individuals may have difficulty detecting environmental hazards or maintaining stability.
- **Cognitive impairment:** Some CNS-suppressing medications have been associated with cognitive impairment, including confusion, memory loss, and disorientation, especially in older adults with preexisting cognitive conditions such as dementia or Alzheimer disease. These cognitive effects can impact sensory processing and contribute to sensory disturbances or distortions.
- **Medication interactions:** Older adults often take multiple medications simultaneously, increasing the risk of drug interactions and adverse effects on sensory perception. Some CNS-suppressing medications may interact with other drugs, such as antihypertensives or antidepressants, leading to additive CNS depression and sensory impairment.
- **Monitoring and adjustment:** Healthcare providers should carefully monitor older adults receiving CNS-suppressing medications for signs of sensory impairment, cognitive decline, or adverse reactions. Regular medication reviews and dose adjustments may be necessary to minimize sensory-related symptoms and optimize therapeutic outcomes while reducing the risk of adverse events.

By considering these age-related factors and implementing appropriate monitoring and management strategies, healthcare providers can ensure the safe and effective use of CNS-suppressing medications in older adults while minimizing the impact on sensory perception and overall well-being.

Monitoring patients closely for signs of CNS depression is another critical nursing responsibility. Nurses should regularly assess vital signs, level of consciousness, respiratory rate, and other indicators of CNS function to promptly detect any changes or abnormalities. Patients receiving CNS depressants may exhibit symptoms such as drowsiness, confusion, respiratory depression, or hypotension, which require prompt intervention. In addition to monitoring, nurses can implement various interventions to prevent or manage adverse effects associated with CNS depressants. These interventions may include positioning the patient to optimize ventilation, providing supplemental oxygen if necessary, encouraging deep breathing exercises to prevent respiratory complications, and promoting mobility to prevent complications such as venous thromboembolism.

Furthermore, patient education plays a crucial role in preventing adverse reactions to CNS depressants. Nurses should educate patients and their families about the potential side effects of these medications, signs of overdose or toxicity, and strategies to promote safety and well-being while taking CNS depressants. This may involve providing information on medication adherence, avoiding alcohol and other CNS depressants, and seeking medical assistance if experiencing concerning symptoms.

#### Medications that Alert the Central Nervous System

Medications that stimulate or alert the CNS can have profound effects on sensory perception by enhancing neural activity and neurotransmitter function within the brain (Table 29.7). These medications, such as stimulants like amphetamines and caffeine, work by increasing the release of neurotransmitters such as dopamine and norepinephrine, which play key roles in arousal, attention, and alertness. As a result, individuals taking CNS stimulants may experience heightened sensory awareness, increased focus, and enhanced perception of sensory stimuli. For example, caffeine, commonly found in coffee and energy drinks, can improve alertness and concentration, leading to sharper sensory perception and quicker reaction times. Similarly, medications used to treat ADHD, such as methylphenidate and dextroamphetamine, can improve attention and focus, potentially enhancing sensory processing abilities. However, excessive CNS stimulation can also lead to side effects such as anxiety, agitation, and sensory overload, highlighting the need for careful monitoring and dosage management when using medications that alert the CNS (Pope, 2023).

Medication Class	Effect on Central Nervous System	Example
Amphetamines	Increased alertness	dextroamphetamine sulfate- dextroamphetamine saccharate- amphetamine aspartate- amphetamine sulfate (Adderall); dextroamphetamine (Dexedrine)
Analeptics	Enhanced alertness	modafinil (Provigil)
Methylxanthines	Heightened awareness	caffeine
Nicotinic agonists	Increased arousal	nicotine
Piperidine derivatives	Increased focus	methylphenidate hydrochloride (Ritalin; Concerta)

**TABLE 29.7** Medications that Alert the Central Nervous System

Nurses play a key role in assessing patients' suitability for CNS stimulant medications, monitoring their response to treatment, and implementing interventions to minimize adverse effects while maximizing benefits. One essential nursing intervention involves conducting a thorough assessment of the patient's medical history, including any preexisting conditions or medications that may interact with CNS stimulants. This assessment helps nurses identify

patients who may benefit from CNS stimulant therapy while also identifying those at higher risk for adverse reactions, such as individuals with cardiovascular disease or a history of substance abuse.

Additionally, nurses play a crucial role in monitoring patients for signs of CNS stimulation, such as increased heart rate, blood pressure, or agitation. Regular assessments of vital signs and behavior help nurses identify any adverse reactions promptly, allowing for timely intervention. If patients experience side effects or complications related to CNS stimulation, nurses can implement various interventions to address these issues. This may include providing reassurance, offering supportive care, adjusting medication dosages or schedules, or collaborating with other healthcare providers to explore alternative treatment options.

## REAL RN STORIES

---

### Medications Stimulating the Central Nervous System and Impact on Sensory Perception

**Nurse:** Morton, BSN

**Clinical setting:** Pulmonary unit

**Years in practice:** 6

**Facility location:** Norfolk, Virginia

I remember caring for a patient, Mrs. Ramirez, who was admitted to the hospital for acute respiratory distress. Mrs. Ramirez was prescribed a combination of bronchodilators and corticosteroids to manage her respiratory symptoms and improve her breathing. These medications, while essential for treating her condition, had notable effects on her sensory perception. Throughout my shifts, I observed Mrs. Ramirez's response to the medications closely. Initially, she exhibited signs of heightened alertness and agitation, which are common side effects of medications that stimulate the CNS. Mrs. Ramirez reported feeling jittery and restless, and she struggled to relax or sleep comfortably.

Recognizing the impact of these medications on Mrs. Ramirez's sensory perception, I collaborated with the healthcare team to implement strategies to mitigate their effects. We adjusted the timing of medication administration to minimize disruptions to Mrs. Ramirez's sleep-wake cycle and incorporated relaxation techniques, such as deep breathing exercises and guided imagery, to promote a sense of calm and comfort. Over time, Mrs. Ramirez's sensory perception began to stabilize, and she reported feeling more at ease and less agitated. By closely monitoring her response to the medications and tailoring our interventions accordingly, we were able to optimize her sensory experience and support her overall well-being during her hospitalization.

My experience with Mrs. Ramirez reaffirmed the importance of individualized medication management and its impact on sensory perception. Through proactive assessment and targeted interventions, healthcare providers can ensure that patients receive effective treatment while minimizing the adverse effects on their sensory function.

---

Furthermore, patient education is essential in ensuring safe and effective medication use. Nurses should educate patients and their families about the purpose of CNS stimulant medications, potential side effects, and strategies to minimize risks. This may involve discussing medication adherence, lifestyle modifications, and the importance of regular follow-up appointments to monitor treatment effectiveness and safety.

### Disorders that Alter Sensory Perception

Disorders that alter sensory perception encompass a diverse range of conditions that affect the processing and interpretation of sensory stimuli. These disorders can impact various sensory modalities, including touch, taste, smell, hearing, and vision, leading to disturbances in sensory experiences. Whether due to neurological, developmental, psychological, or environmental factors, these disorders pose significant challenges for individuals in navigating their surroundings and engaging with their environment. Understanding the nature and effects of these disorders is essential for nurses to provide comprehensive care and support to affected individuals. Through tailored interventions and support strategies, individuals with sensory perception disorders can better manage their symptoms and enhance their overall quality of life.

#### Sensory Modulation Disorder

The condition **sensory modulation disorder (SMD)** is characterized by atypical responses to sensory stimuli,

resulting in difficulties regulating and processing sensory information. Individuals with SMD may experience sensory overresponsivity, where they are hypersensitive to certain stimuli, such as loud noises or bright lights, leading to intense emotional or behavioral reactions. Conversely, others may exhibit sensory underresponsivity, where they have a reduced awareness or responsiveness to sensory input, often appearing disengaged or withdrawn. Additionally, individuals with SMD may demonstrate sensory-seeking behaviors, actively seeking out sensory stimulation to regulate their arousal levels. These sensory modulation challenges can significantly impact daily functioning, affecting an individual's ability to participate in various activities and engage with their environment. Treatment for SMD typically involves sensory integration therapy, which aims to help individuals regulate their sensory responses and develop coping strategies to manage sensory challenges effectively (Brain Therapy, 2023; STAR Institute, n.d.).

Nursing interventions for SMD focus on helping individuals regulate their sensory responses and develop coping strategies to manage sensory challenges effectively. One essential intervention involves conducting thorough assessments to identify the specific sensory modulation difficulties experienced by the individual. Nurses collaborate with occupational therapists and other healthcare professionals to develop individualized sensory integration therapy plans tailored to the individual's needs and preferences. These therapy plans may include sensory-based activities and exercises aimed at desensitizing hypersensitive responses, increasing sensory awareness in individuals with underresponsivity and providing sensory input to meet the needs of individuals with sensory-seeking behaviors. Additionally, nurses educate individuals and their families about SMD, helping them understand the condition and its impact on daily functioning. Nurses provide guidance on environmental modifications to create sensory-friendly spaces and teach relaxation techniques and self-regulation strategies to help individuals cope with sensory challenges in various settings.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Form a Hypothesis: Sensory Modulation Disorder

Scenario: Sam, a pediatric nurse, is caring for a 6-year-old patient, Alex, who has been diagnosed with SMD. Alex presents with symptoms of hypersensitivity to auditory stimuli, often becoming overwhelmed and distressed in noisy environments such as the hospital playroom.

- **Identify cues:** While observing Alex during playroom activities, Sam notices that he covers his ears and becomes visibly distressed whenever other children engage in loud play or when medical equipment emits beeping sounds. Alex's heightened sensitivity to auditory stimuli is evident in his behavioral response to noise, suggesting a potential sensory modulation issue.
- **Analyze cues:** Reflecting on Alex's behavior, Sam considers the context of his reactions and compares them to expected responses for his age and developmental stage. He notes that Alex's sensitivity to auditory stimuli significantly impacts his ability to participate in age-appropriate activities and social interactions, highlighting the potential impact on his daily functioning.
- **Forming a hypothesis:** Based on his assessment of Alex's behavior and symptoms, Sam forms a hypothesis that he may be experiencing sensory modulation difficulties, specifically hypersensitivity to auditory stimuli. He considers how this sensory issue may contribute to Alex's challenges in navigating his environment and interacting with others, prompting him to explore interventions to support his sensory needs.

This clinical judgment measurement model provides a structured approach for nurses like Sam to assess and address sensory modulation issues such as sensory modulation disorder (SMD) in pediatric patients. By identifying relevant cues, analyzing their significance, and forming hypotheses based on observed behaviors, nurses can develop tailored interventions to promote optimal sensory functioning and improve patient outcomes.

### Sensory-Based Motor Disorder

A **sensory-based motor disorder (SBMD)** is a condition characterized by challenges in coordinating motor movements due to underlying sensory processing difficulties. Individuals with SBMD may experience disruptions in their ability to plan, execute, and control movements, resulting in motor coordination deficits. These deficits can

manifest in various ways, such as difficulties with balance, posture, fine motor skills, and gross motor coordination. Individuals with SBMD may struggle with tasks requiring precise movements, such as writing or tying shoelaces, and may appear clumsy or uncoordinated in their movements. Additionally, sensory processing challenges, such as hypersensitivity or hyposensitivity to tactile, proprioceptive, or vestibular input, can further exacerbate motor coordination difficulties (STAR Institute, n.d.).

Nurses play a crucial role in collaborating with interdisciplinary teams to develop individualized care plans tailored to the specific needs of each patient. One key intervention involves conducting comprehensive assessments to identify motor coordination deficits and sensory processing difficulties. Nurses work closely with occupational therapists and physical therapists to implement therapeutic interventions aimed at improving motor skills and sensory integration. These interventions may include sensory integration therapy sessions, which involve engaging in activities that provide sensory input to support motor coordination development. Nurses also educate individuals and their families about SBMD, helping them understand the condition and its impact on daily functioning. They provide guidance on techniques and strategies to promote motor skill development, such as practicing balance exercises or using adaptive equipment to support activities of daily living. Additionally, nurses advocate for environmental modifications to create sensory-friendly spaces that accommodate the individual's sensory needs and promote safety and independence.

### Sensory Discrimination Disorder

The condition **sensory discrimination disorder (SDD)** is characterized by difficulties in accurately interpreting and distinguishing between sensory stimuli. Individuals with SDD may struggle to perceive and differentiate sensory input, leading to challenges in recognizing and interpreting sensory information. This can affect various sensory modalities, including tactile, auditory, visual, and olfactory sensations. For example, individuals with SDD may have difficulty distinguishing between textures or temperatures when touching objects, identifying speech sounds in noisy environments, recognizing facial expressions or visual patterns, or discriminating between different smells or tastes. These difficulties in sensory discrimination can impact daily functioning and may interfere with activities such as communication, social interactions, and learning (STAR Institute, n.d.).

Nurses play a vital role in supporting individuals to improve their ability to interpret and differentiate sensory stimuli accurately. Nursing interventions typically begin with a comprehensive assessment to identify specific challenges related to sensory discrimination. Nurses work collaboratively with occupational therapists and other healthcare professionals to develop personalized care plans tailored to the individual's needs. Interventions may involve sensory integration therapy sessions, which aim to enhance sensory processing abilities and refine sensory discrimination skills. Additionally, nurses provide education to individuals and their families about SDD, helping them understand the condition and its impact on daily life. Nurses offer guidance on strategies and techniques to improve sensory discrimination, such as sensory-focused activities and environmental modifications.

## Summary

### 29.1 Sensory Functioning

Sensory perception is the process through which individuals gather information from the environment via senses like sight, hearing, touch, taste, and smell, interpreting it to understand and interact with surroundings. Each sensory modality, including vision, hearing, smell, taste, and touch, plays a unique role in providing valuable information about the environment. Auditory perception involves the reception of sound waves by the ear, which are transmitted and interpreted by the nervous system, allowing for the perception and understanding of sound. Visual perception entails the interpretation of light stimuli by the visual system, forming perceptions such as shapes and colors, while olfactory and gustatory perception involve the detection and interpretation of smells and tastes, respectively. Additionally, tactile perception enables the detection and interpretation of touch sensations, guiding interactions with objects and the physical environment. Complementing the primary senses, kinesthetic senses provide feedback about body movement and position, while visceral senses monitor internal bodily sensations, collectively enriching the sensory experience and influencing behaviors and well-being.

The reticular activating system (RAS) plays a crucial role in regulating wakefulness and maintaining consciousness by filtering sensory stimuli and modulating arousal levels in the brain. Identifying the different states of arousal of the brain involves recognizing variations in consciousness, ranging from alertness and wakefulness to drowsiness, sleep, and coma, each influenced by complex interactions within the brain's neural networks. Adaptation allows the sensory systems to adjust to constant stimuli, ensuring efficient processing of relevant information. Sensoristasis refers to the optimal arousal level for sensory perception and cognitive function, maintaining a balance between under- and overstimulation. Awareness encompasses conscious experiences, including sensory perceptions, thoughts, and emotions, while conscious and unconscious states represent different levels of awareness and responsiveness to external stimuli.

### 29.2 Impaired Sensory Function

Sensory overload occurs when individuals are exposed to an overwhelming amount of sensory stimuli, leading to difficulties in processing and integrating information effectively. This can lead to symptoms such as irritability, agitation, anxiety, and fatigue, activating the body's stress response. Conversely, sensory deprivation refers to the absence or reduction of normal sensory inputs, resulting in decreased stimulation and potential cognitive deficits, altered perception of time, and emotional distress. Recognizing alterations in sensory perception involves identifying changes in how individuals interpret and respond to sensory stimuli, which can manifest as sensory deficits and sensory processing disorder (SPD). These alterations can significantly impact daily functioning, social interactions, and emotional well-being, necessitating tailored interventions to support individuals experiencing such changes.

### 29.3 Factors Affecting Sensory Function

Physiological factors affecting sensory perception encompass various elements such as developmental stage, age, current health status, and genetics, all of which can influence how individuals perceive and interpret sensory stimuli. Psychosocial factors affecting sensory perception include mental health conditions, personality traits, behaviors, and cultural considerations, which can significantly impact an individual's sensory experiences and responses. Medications affecting sensory perception range from those that suppress the CNS to those that stimulate it, altering sensory processing and perception. Disorders affecting sensory perception, such as sensory modulation disorder (SMD), sensory-based motor disorder (SBMD), and SDD, disrupt the normal processing of sensory information, leading to challenges in interpreting and responding to sensory stimuli.

## Key Terms

**adaptation** the process by which sensory systems adjust to ongoing stimuli, optimizing processing efficiency

**alert** a state of heightened wakefulness, attentiveness, and responsiveness in which an individual is fully awake, aware of their surroundings, and capable of actively engaging with stimuli and tasks

**altered consciousness** any deviation from the normal waking state of consciousness, characterized by changes in perception, cognition, or awareness

**anhedonia** reduced sensory pleasure and decreased interest in sensory experiences

**asleep** a natural state of rest characterized by reduced consciousness, diminished responsiveness to external

stimuli, and altered brain activity during sleep

**auditory sensory perception** the process by which the auditory system receives, transmits, and interprets sound stimuli from the environment

**awareness** conscious perception and understanding of oneself, one's surroundings, and the experiences that arise from sensory input and cognitive processes

**coma** a profound state of unconsciousness characterized by a complete loss of consciousness, absence of wakefulness, and lack of response to external stimuli

**conscious states** range of mental experiences and subjective awareness that individuals perceive as part of their waking life

**extraversion** personality trait characterized by sociability, outgoingness, and a preference for social interactions

**Glasgow Coma Scale (GCS)** a neurological assessment tool used to evaluate a patient's level of consciousness and neurological function

**gustatory sensory perception** the ability to detect and interpret tastes using the gustatory system

**kinesthetic sense (also, proprioceptive sense)** the sense of body awareness and movement control

**lethargic** a state of drowsiness, sluggishness, and reduced energy levels in which an individual appears excessively tired or fatigued

**neural plasticity** the brain's ability to reorganize and adapt its structure and function in response to changes

**obtundation** a state of decreased alertness and responsiveness in which an individual opens their eyes in response to tactile stimuli or other external cues but responds slowly and may appear confused or disoriented

**olfactory sensory perception** the ability to detect and interpret smells using the olfactory system

**ototoxic** medications that have the potential to cause damage to the structures of the inner ear or the auditory nerve

**proprioceptors** specialized sensory receptors located in muscles, tendons, and joints that detect changes in muscle length, tension, and joint position, providing continuous feedback to the brain about the body's position in space

**reticular activating system (RAS)** a crucial neural network in the brainstem responsible for regulating arousal, attention, and consciousness

**sensation seeking** tendency to seek out novel, varied, and intense experiences

**senses** physiological mechanisms by which organisms perceive and respond to stimuli from their environment

**sensoristasis** balance between under- and overstimulation, optimizing arousal levels for sensory perception and cognitive function

**sensory deficit** impairment or loss in one or more sensory modalities, such as vision, hearing, touch, taste, or smell

**sensory deprivation** refers to the absence or reduction of normal sensory inputs, leading to a state of decreased stimulation and sensory isolation

**sensory discrimination** the brain's ability to interpret and distinguish between different sensory stimuli

**sensory discrimination disorder (SDD)** a condition characterized by difficulties in accurately interpreting and distinguishing between sensory stimuli

**sensory integration** the brain's ability to organize and make sense of information received through the senses

**sensory modulation** the brain's ability to regulate and respond appropriately to sensory stimuli from the environment

**sensory modulation disorder (SMD)** a condition characterized by atypical responses to sensory stimuli, resulting in difficulties regulating and processing sensory information

**sensory overload** occurs when an individual is exposed to an excessive amount of sensory stimuli that overwhelms their ability to process and integrate information effectively

**sensory perception** process by which organisms gather information from the environment through the senses (such as sight, hearing, touch, taste, and smell) and interpret and make sense of that information

**sensory processing disorder (SPD)** a neurological condition that affects how individuals process and respond to sensory information from the environment

**sensory-based motor disorder (SBMD)** a condition characterized by challenges in coordinating motor movements due to underlying sensory processing difficulties

**states of arousal** levels of physiological and psychological alertness and responsiveness exhibited by an individual

**stupor** a state of reduced consciousness marked by extreme lethargy, diminished responsiveness, and a significant decrease in alertness and awareness

**tactile sensory perception** the ability to detect and interpret touch sensations

**unconscious states** mental processes and activities that occur without conscious awareness or voluntary control

**vegetative state (also, unresponsive wakefulness syndrome)** a condition marked by wakefulness without awareness, in which the individual appears awake but lacks meaningful responsiveness

**visceral sense (also, interoceptive sense)** responsible for detecting and monitoring internal body sensations such as hunger, thirst, pain, and visceral organ function

**visual sensory perception** the process by which the visual system detects, interprets, and makes sense of visual stimuli

## Assessments

### Review Questions

1. The nursing student is reviewing sensory perception with the preceptor. What statement made by the nursing student would indicate an accurate understanding of sensory perception?
  - a. “Senses refer to the psychological mechanisms by which individuals perceive and respond to stimuli from their environment.”
  - b. “Kinesthetic senses are important because they play a crucial role in body awareness and movement control.”
  - c. “Senses typically become more refined and detect more subtle changes as individuals age.”
  - d. “Olfactory sensory perception is important because it enables individuals to distinguish between different tastes.”
  
2. What sense is primarily responsible for indicating hunger?
  - a. visceral
  - b. kinesthetic
  - c. gustatory
  - d. olfactory
  
3. What is adaptation in the context of sensory processing?
  - a. the process of maintaining arousal levels
  - b. the conscious perception of oneself and surroundings
  - c. the modulation of attentional resources
  - d. the adjustment of sensory systems to ongoing stimuli
  
4. What does sensoristasis involve maintaining a balance between?
  - a. conscious and unconscious states
  - b. sensory input and motor output
  - c. under- and overstimulation
  - d. sympathetic and parasympathetic activation
  
5. In conscious states, what brain regions are implicated in generating and sustaining conscious awareness?
  - a. hippocampus and amygdala
  - b. basal ganglia and cerebellum
  - c. prefrontal cortex and thalamus
  - d. occipital lobe and brain stem
  
6. What condition is associated with an increased risk of sensory overload?
  - a. hypothyroidism
  - b. ASD
  - c. type 2 diabetes
  - d. hypertension
  
7. What condition is associated with sensory deprivation?

- a. ADHD
  - b. ASD
  - c. Alzheimer disease
  - d. PTSD
- 8.** What is SPD?
- a. loss of sensory function in one or more modalities
  - b. enhanced sensitivity to sensory stimuli
  - c. absence of sensory stimuli
  - d. a neurological condition affecting sensory processing
- 9.** A patient with ASD is admitted to the emergency department and displays signs of sensory overload. What nursing intervention would be most beneficial for this patient?
- a. dimming the lights in the room to reduce visual stimuli
  - b. engaging the patient in a group activity with other patients
  - c. administering a sedative medication to calm the patient
  - d. providing the patient with a strong-smelling lotion for relaxation
- 10.** A patient in a hospital complains of feeling overwhelmed by the constant beeping of monitors and medical equipment. What intervention by the nurse would be most appropriate to address the patient's sensory overload?
- a. providing a bright reading light to improve visibility
  - b. placing the patient in a room with large windows for natural light
  - c. offering noise-canceling headphones or earplugs to block out excessive noise
  - d. providing scented candles to create a calming atmosphere
- 11.** What sensory perception change is commonly associated with aging?
- a. improved vision acuity
  - b. enhanced taste sensitivity
  - c. diminished tactile sensation
  - d. increased auditory processing speed
- 12.** Medications that suppress the CNS may lead to what sensory perception change?
- a. increased sensory acuity
  - b. drowsiness and sedation
  - c. enhanced cognitive function
  - d. improved motor coordination
- 13.** How is sensory modulation disorder described in terms of sensory perception?
- a. difficulties in accurately interpreting sensory stimuli
  - b. hypersensitivity to certain stimuli
  - c. reduced awareness or responsiveness to sensory input
  - d. challenges in coordinating motor movements
- 14.** What is a common manifestation of SBMD?
- a. hypersensitivity to tactile stimuli
  - b. difficulties with balance and posture
  - c. challenges in accurately interpreting speech sounds
  - d. reduced awareness of environmental stimuli
- 15.** What characterizes SDD?
- a. hypersensitivity to olfactory stimuli
  - b. difficulties in motor coordination

- c. reduced responsiveness to auditory input
- d. challenges in accurately distinguishing between sensory stimuli

### Check Your Understanding Questions

1. Name the five senses and describe how each of the senses affects sensory perception.
2. How does the sense of taste contribute to the perception of flavor?
3. Define sensory deprivation and its impact on individuals' well-being.
4. Explain the difference between sensory deprivation and sensory deficit, providing examples of each.
5. How do mental health conditions such as anxiety and depression influence sensory perception?
6. What are some potential complications of sensory overload in patients taking medications that alert the CNS?

### Reflection Questions

1. A patient experiences confusion following a head injury. What assessments should the nurse prioritize to evaluate the function of the RAS?
2. Reflect on the importance of maintaining patient safety during transitions between different states of arousal. How can effective communication and teamwork contribute to this goal?
3. An older adult reports changes in taste perception. What interventions should the nurse implement?
4. Reflect on the impact of environmental factors, such as noise and lighting, on patients' sensory experiences. How can nurses advocate for changes to create more sensory-friendly environments?
5. How do nurses ensure cultural sensitivity when assessing patients' sensory perception?

### What Should the Nurse Do?

1. What should the nurse prioritize when caring for a patient experiencing alterations in states of arousal?
2. How should the nurse advocate for changes in the healthcare environment to accommodate patients with altered sensory perception, such as those with ASD?
3. A patient with sensation-seeking behaviors seeks intense sensory experiences. How can the nurse ensure the patient's safety while addressing their sensory needs?
4. A patient reports experiencing dizziness and blurred vision after taking a newly prescribed medication that suppresses the CNS. What should the nurse do first?

### Competency-Based Assessments

1. Outline the key components of nursing interventions for unconscious states.
2. Determine and interpret the GCS score for the following scenarios:
  - a. Scenario 1: Joel, a 45-year-old construction worker, was brought into the emergency department after falling from a height at a construction site. On arrival, Joel is unconscious and unresponsive. He has a laceration on his forehead and is bleeding profusely.
  - b. Scenario 2: Maggie, a 20-year-old college student, was involved in a motor vehicle accident. Emergency medical services bring her to the hospital with complaints of severe headache and confusion. On examination, Maggie is conscious but disoriented. Her eyes open spontaneously, and she obeys commands. She is unable to provide coherent answers to questions about the accident and appears drowsy.

Scenario: Shanda, a 25-year-old patient with a history of ADHD, is admitted to the inpatient unit following a severe asthma exacerbation. She is receiving IV steroid therapy and supplemental oxygen due to respiratory distress. Despite her exhaustion from a sleepless night and the discomfort of her asthma symptoms, Shanda finds it challenging to rest in her hospital room. She is restless, tossing and turning in her bed, unable to find a comfortable

position. Shanda becomes increasingly irritable, snapping at nurses and expressing frustration with the constant beeping of IV pumps and monitors. Her attention is easily distracted, and she struggles to focus on conversations or instructions from healthcare providers.

3. Is Shanda experiencing sensory overload, sensory deprivation, sensory deficit, or SPD? Please explain your rationale.
4. Define the impaired sensory functioning identified in Question 1.
5. Identify at least three symptoms associated with the impaired sensory functioning identified in Question 1.
6. Identify critical nursing assessments the nurse should perform.
7. Identify possible nursing interventions the nurse could implement.
8. Outline the potential consequences of prolonged sensory deprivation on patient outcomes.
9. Complete the table, identifying the primary characteristics and manifestations of the disorders affecting sensory perception.

Disorder	Primary Characteristics	Manifestations
Sensory-based motor disorder (SBMD)		
Sensory discrimination disorder (SDD)		
Sensory modulation disorder (SMD)

## CHAPTER 30

# Pain Assessment

**FIGURE 30.1** Pain is considered the fifth vital sign and an important aspect of a comprehensive assessment. When patients endure from impaired comfort and pain, nurses can provide compassionate patient-centered care. (credit: “RE:Union – A story of cancer in the family” by “mescon”/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

- 30.1 The Pain Process
- 30.2 Responses to Pain
- 30.3 Factors Affecting Pain
- 30.4 Pain Assessment
- 30.5 Pain Management

**INTRODUCTION** According to the International Association for the Study of Pain (2021b), pain is defined as “an unpleasant sensory and emotional experience associated with, or resembling that associated with, actual or potential tissue damage.” Pain can be acute or chronic, mild or severe, and expressed in many different ways. Pain is triggered by a perceived danger or stress and tells the body to withdraw from threatening stimuli. Most pain resolves after the painful stimulus is removed and the body has healed, but sometimes pain persists despite removal of the stimulus and apparent healing of the body.

Pain is a subjective experience and can be influenced by biological, psychological, and social factors. Pain affects people in every aspect of health care, requiring nurses to be able to assess, manage, and treat it. Pain is subjective, meaning the patient defines the pain (ANA Center for Ethics and Human Rights, 2018). Patients can express pain through verbal and nonverbal behaviors. Some patients may rate their pain on a pain scale while other patients can only exhibit nonverbal cues such as grimacing, crying, and vital sign changes.

Because the experience of pain has so many variables, pain assessment and management must be comprehensive to be effective. Nurses must perform frequent comprehensive pain assessments to determine what pain

interventions would be most effective for each patient. Pain management plans must be individualized and involve the patient and healthcare team. Pain is one of the most common reasons for patients seeking care, and treating pain must be a top priority for healthcare providers in all settings.

## 30.1 The Pain Process

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the physiologic process of pain
- Analyze the gate control theory of pain
- Identify the classifications of pain

In order to assess and manage pain effectively, nurses must first understand the physiologic process of pain. Painful stimuli travel through the central nervous system via the pain pathway to the brain where the brain processes and initiates a response. The body's response to pain is dependent on the classification of pain and any factors affecting pain.

Pain can be classified by duration, location, and cause. Pain can be acute, chronic, localized, referred, or idiopathic. Nurses must know how to classify pain to effectively treat the pain. Pain can also be affected by biological, psychological, and social factors. The patient's age, attitude, emotions, or culture can affect how they perceive pain and how they want the pain to be treated. All these factors play a role in how nurses approach pain management for each patient.

### The Physiologic Process of Pain

Pain can be processed physiologically and emotionally through the body. Pain motivates the individual to withdraw from dangerous stimuli, to protect a damaged body part while it heals, and to avoid similar experiences in the future. Pain can resolve after the stimulus is removed and the body has healed, but sometimes pain persists. Pain can also occur in the absence of a stimulus, damage, or disease.

Sensory receptors in the peripheral nervous system called nociceptors play an important role in the pain process. A **nociceptor** is designed to respond to potentially damaging stimuli by sending nerve signals to the spinal cord and brain. The process by which painful stimuli are detected by nociceptors and begin to send the pain signals from the peripheral nervous system to the brain is called **nociception** (Chen et al., 2023). After nociception occurs, the body processes the pain through four major steps: transduction, transmission, perception, and modification ([Figure 30.2](#)).

**FIGURE 30.2** Nociception is the process by which the body sends painful stimuli from the peripheral nervous system to the brain, where it is processed and a response is formed. (credit: modification of “Blausen 0822 SpinalCord.png” by “BruceBlaus”/Wikimedia Commons, CC BY 3.0)

### Transduction of Pain

The starting point of the body passing painful stimuli to the brain is called **transduction of pain**. It occurs when activated nociceptors in the peripheral nervous system send a pain signal to the central nervous system, starting in the dorsal root of the spinal cord (Yam et al., 2018). Activation of nociceptors can occur internally or externally, such as from a cut from a knife, an infection, or a sprained ankle (Answine, 2018).

There are several types and functions of nociceptors:

- Thermal nociceptors are activated by heat or cold, such as a hot pan.
- Mechanical nociceptors are activated by excess pressure or mechanical deformation, such as a finger getting caught in a car door. They also respond to incisions that break the skin surface.
- Chemical nociceptors are activated by a wide variety of spices commonly used in cooking. For example, capsaicin is a compound in chili peppers that causes a burning sensation of the mucous membranes.

Transduction of pain is the first step of the pain process. Once the spinal cord receives the pain signal, the next step is transmitting the pain signal from the spinal cord to the brain.

### Transmission of Pain

The spinal cord, brain stem, and cerebral cortex are all involved in the transmission of pain (Yam et al., 2018). After the nociceptive signal is activated, **transmission of pain** sends the pain signal through the central nervous system.

The pain signal is sent from the spinal cord to the nucleus of the brain stem, which initiates the brain's perception of pain (Chen et al., 2023). The pain signal is categorized as a thermal, mechanical, or chemical nociceptor. The brain then localizes the pain and creates an appropriate physical or emotional response (Answine, 2018).

### Perception of Pain

After the brain stem receives the pain signal, it is sent to the cerebral cortex where the brain perceives the severity of the pain. When the brain receives the nociceptive signal, it perceives the message as pain to activate the body's defense to the perceived threat (Yam et al., 2018). The perception of pain occurs when the brain becomes aware of the pain through the cerebral cortex and determines an appropriate response to protect the body (Answine, 2018). For example, when a person stubs their toe, the brain perceives the painful stimuli and signals the body to take action. The person may grab their foot or cry out to express their pain. Individuals may perceive pain differently and perception can be altered due to many different factors. Past experiences, external factors, other health issues, and environmental differences are just a few things that can affect the perception of pain.

### Modification of Pain

There are many factors that can affect the perception of pain; and there may be situations where the brain may modify pain signals in order to protect the body. The **modification of pain** occurs when the brain changes the intensity of the pain signal based on the situation that originated the pain signal (Answine, 2018). For example, a person may get injured from a dog bite, but the brain chooses to ignore the pain signal so the person can run away from the dog.

A chemical called a **neurotransmitter** carries messages between neurons to communicate throughout the body. Many neurotransmitters, such as norepinephrine and serotonin, can be involved in modifying the pain signals the brain receives (Answine, 2018). Nonpainful signals, such as electrical nerve stimulation, touch, or pressure can help counteract the severity of the pain signals. This is part of the gate control theory of pain.

### The Gate Control Theory of Pain

The gate control theory of pain was developed by Ronald Melzack and Patrick Wall in 1965. Their research helped explain how sensory and psychological aspects affect how patients perceive pain (Campbell et al., 2020). The gate control theory states that the central nervous system can use neurological “gates” to determine when pain is felt. These “gates” determine which pain signals are allowed through to the brain and acts as a survival mechanism for the body (Cleveland Clinic, 2022). When the “gates” are open, the pain signal can travel to the brain and be perceived as pain. When the “gates” are closed, the pain signal is blocked from traveling to the brain. If the body perceives pain in two different locations at the same time, one “gate” may close to prioritize a response for the other cause of pain. Individuals can also use methods such as massage and acupuncture to help the body close these “gates” to decrease painful stimuli.

### LINK TO LEARNING

Watch this video to better understand the [gate control theory \(https://openstax.org/r/77gatecntrl\)](https://openstax.org/r/77gatecntrl) of pain.

The gate control theory states that different pain signals can be transmitted to the brain faster than others can. Signals such as touch or sensation can be received by the brain faster than signals that send pain or temperature to the brain (Cleveland Clinic, 2022). Stimulating signals such as pressure can help decrease the pain signals to the brain. This explains why clutching an injured extremity can help decrease the pain sensation.

The gate control theory acknowledges that there are many factors that can affect pain (Trachsel et al., 2023). Factors such as mental health disorders, mindset, stress, or lifestyle choices have been shown to affect how the brain perceives pain. These factors can prevent the “gates” from closing, which can increase the pain intensity and frequency.

### Factors Affecting the Theory of Pain

Biological, psychological, and social factors can all affect how a patient perceives pain ([Table 30.1](#)). Nurses must

consider these factors while assessing and providing holistic nursing care for patients experiencing pain.

Biological Factors	Psychological Factors	Social Factors
<ul style="list-style-type: none"> <li>• Age</li> <li>• Brain function</li> <li>• Cognitive function</li> <li>• Genetic sensitivity</li> <li>• Hormones</li> <li>• Illness</li> <li>• Inflammation</li> <li>• Injury, past or present</li> <li>• Medical diagnosis</li> <li>• Nociception</li> <li>• Obesity</li> <li>• Source of pain</li> </ul>	<ul style="list-style-type: none"> <li>• Anxiety</li> <li>• Attitudes</li> <li>• Beliefs</li> <li>• Coping mechanisms</li> <li>• Developmental stage</li> <li>• Emotional status</li> <li>• Expectations</li> <li>• Fatigue</li> <li>• Fear</li> <li>• Meaning of pain</li> <li>• Memory</li> <li>• Mood/affect</li> <li>• Sleep</li> <li>• Stress</li> <li>• Trauma</li> </ul>	<ul style="list-style-type: none"> <li>• Culture</li> <li>• Education</li> <li>• Environment</li> <li>• Ethnicity</li> <li>• Social support</li> <li>• Socioeconomic status</li> <li>• Spirituality</li> <li>• Values</li> </ul>

**TABLE 30.1** Biological, Psychological, and Social Factors Affecting Pain

Age is a significant biological factor in the perception of pain. Newborns and infants can feel pain but are unable to verbalize it. School-aged children and adolescents may try to be “brave” and rationalize the pain. Older adults are at increased risk for undertreatment of pain because they are less likely to report it and pain can present atypically with confusion and agitation. Older adults and patients with diabetes/neuropathy may also feel pain differently due to decreased sensations.

Psychological factors also play a considerable role in pain perception. A patient’s expectations of pain can often increase or decrease the severity. If a patient believes they will have a lot of pain, their perception can increase. In contrast, if a patient believes an intervention will be effective, their pain may decrease (Heshmat, 2023). For example, a patient who believes physical therapy will decrease their pain may have better pain outcomes than a patient who believes physical therapy will not have any effect on their pain. The interpretation of pain can also have an impact on pain perception. How pain affects a patient’s quality of life can change their perception of pain. For example, a patient who is having pain from chronic arthritis may perceive their pain differently than a patient who is having pain from delivering a baby (Heshmat, 2023).

It is important for nurses to understand how social factors can affect a patient’s perception of pain. Factors such as culture and socioeconomic status can influence how a patient perceives and articulates their pain (Heshmat, 2023). Certain cultures may be more expressive in their pain than others, and patients may hide their pain in fear of judgment of their socioeconomic status. For example, people from Asian cultures are more stoic and less vocal, while people from Middle Eastern cultures may be more vocal about their pain.

The complex interactions between factors affecting pain and individual perception can create a wide range of reactions to pain (Trachsel et al., 2023). Pain management must be multimodal and different for each patient to effectively treat pain.

### Emotional State

Pain is always defined as a sensory and emotional experience. The patient’s emotional state and pain go hand in hand, especially in patients with chronic pain. Research has shown that patients with chronic pain have higher rates of negative emotions such as anxiety, depression, and frustration (Gilam et al., 2020). Both negative and positive emotions can shape a patient’s perception of pain. Research has also shown that patients with negative emotions such as anxiety tend to have a lower pain threshold (Heshmat, 2023), but positive emotions can decrease pain severity. This is why patients who practice relaxing activities such as listening to music can have reduced pain (Kober et al., 2020).

### Social and Cultural Environment

Social and cultural environments can play a large role in the perception of pain. Factors such as a patient's home environment and social support can affect pain perception. Patients who have supportive social circles have been shown to have improved pain outcomes. Social isolation can contribute to poor pain outcomes, especially in chronic pain and older adult patients (Chadwick et al., 2022).

Other patient populations who can be affected by social factors include

- patients with a history of addictive disease;
- patients who are nonverbal, cognitively impaired, or unconscious;
- patients who endure pain without complaining due to cultural or religious beliefs;
- patients who are non-English speaking, where communication is a barrier; and
- patients who are uninsured or underinsured, where cost of medications is a barrier.

Nurses need to be aware of the impact of social environment and culture on pain management. Providing culturally competent care is essential to effective pain management for all patients.

## CULTURAL CONTEXT

---

### Cultural Competence in Pain Management

Cultural competence is essential in effective pain management. Patients who are non-English speaking are at higher risk for experiencing undertreated pain due to communication barriers. Interpreters can be helpful in ensuring patients are able to effectively express their pain and communicate their needs. Cost and availability are two cited barriers to having interpreters readily available in healthcare settings (Yelton & Jildeh, 2023). However, any intervention to ensure cultural competence in healthcare settings should be explored regardless of barriers. Cultural practices and beliefs play a big role in how a patient perceives pain and their expectations of pain management. Lack of understanding of cultural differences can damage the provider-patient relationship and create barriers to effective pain management. For example, some Asian cultures may not express their pain and appear reserved despite being in severe pain. Religion can also play a role in perception of pain. Some religions may believe that pain is a test of faith or part of the path God has planned for them. If nurses are not aware of these cultural differences, the patient could experience ineffective pain management (Givler et al., 2023). The different cultures and personal experiences of nurses can affect how pain is perceived in patients. Nurses should be aware of how their personal beliefs and experiences can impact how they care for patients who are different from them.

---

### Classification of Pain

Classifying pain can help effectively evaluate and treat pain. Pain can be classified based on the severity, duration, or location. The World Health Organization (WHO) developed the analgesic ladder ([Figure 30.3](#)) in 1986 to help select analgesics for patients with cancer pain, but it can be broadened for managing pain appropriately for all patients. The ladder classified pain into three categories: mild, moderate, and severe. The WHO defines pain severity based on the type of medication needed to treat the pain. For example, mild pain may require only nonopioid analgesics while severe pain requires opioid medications such as morphine or fentanyl (Anekar et al., 2023).

**FIGURE 30.3** The WHO pain ladder classifies pain into three categories. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Pain can also be classified based on the duration or location of pain. Using tools such as pain location charts can help patients pinpoint the location of their pain, which may give healthcare providers a better idea of the cause of pain. The duration of pain can also help determine the potential cause and effective pain management strategies. For example, acute abdominal pain may indicate appendicitis whereas chronic back pain could indicate a past injury.

### Duration

The duration of pain can determine the treatment method. Acute, chronic, or breakthrough pain are all defined based on the duration of time the pain persists. Acute pain is defined as Pain that is short in duration and caused by an acute event. For example, **acute pain** can be caused by an acute event such as a car accident or sports injury. Chronic pain is defined as pain that lasts longer than six months. Patients with chronic illnesses often experience **chronic pain** that can vary in severity. For example, patients with chronic pancreatitis often experience chronic abdominal pain that is caused by the inflammation of the pancreas. Acute pain that exists along with chronic pain is called breakthrough pain. Breakthrough pain persists even when interventions are present to treat chronic pain (Robertson, 2022). Patients receiving pain medication for chronic abdominal pain caused by pancreatitis may also experience breakthrough pain. If patients are receiving pain interventions but are still having severe pain, they may need to be hospitalized for further management to treat the breakthrough pain.

### Acute Pain

Acute pain is a short-lived response that alerts the brain to an acute event caused by injury, trauma, surgery, or illness (Dowell et al., 2022). Acute pain can last a few seconds or a few months and is usually resolved when the acute event is treated (International Association for the Study of Pain [IASP], 2021a). Symptoms of acute pain can include numbness, tingling, sharp, throbbing, and stabbing pain (IASP, 2021a). Acute pain may cause appetite changes, sleep disturbances, diaphoresis, changes in vital signs, and behaviors such as distraction, guarding, protectiveness, and restlessness. Examples of acute pain include postoperative pain; burns; acute musculoskeletal pain from conditions such as strains, sprains, and fractures; pain associated with labor and delivery; and pain from traumatic injury.

Because acute pain can vary in severity, the type of treatment may vary based on individual patient needs (Robertson, 2022). Treatment for acute pain may include rest, ice or heat, physical therapy, nonopioid medications, or exercise (IASP, 2021a). The first step in treating acute pain is identifying the cause and ensuring that patients receive treatment before the pain becomes severe. Acute pain is often resolved when the cause is treated, so identifying the cause is an important first step in treating acute pain.

### Chronic Pain

Chronic pain is ongoing and persistent for longer than six months and is not always confined to a specific area of the body. Chronic pain often affects an individual's psychological, social, and behavioral responses that can influence

daily functioning. Causes of chronic pain can include chronic disease, injury, inflammation, or an unknown cause (Dowell et al., 2022). Chronic medical problems, such as osteoarthritis, spinal conditions, fibromyalgia, and peripheral neuropathy, are common causes of chronic pain. Chronic pain can continue even after the original injury or illness that caused it has healed or resolved.

It is estimated that one in five adults in the United States experiences chronic pain (Dowell et al., 2022). People who have chronic pain often have physical effects that are stressful on the body. These effects include tense muscles, limited mobility, lack of energy, and appetite changes. Emotional effects of chronic pain include depression, anger, anxiety, and fear of reinjury. These effects can limit a person's ability to return to their regular work or leisure activities. Multiple factors can lead to chronic pain becoming more centralized, which can result in a decreased pain threshold. This can cause patients to experience an increased severity of pain and to need complex pain management (Dydyk & Grandhe, 2023).

## LINK TO LEARNING

Chronic pain affects so many individuals in the United States and throughout the world. Observing a [patient interview with someone who experiences chronic pain \(https://openstax.org/r/77chrpainintv\)](https://openstax.org/r/77chrpainintv) can be useful for nurses to understand how chronic pain affects everyday life and the many different ways to manage chronic pain.

### Location

Pain can be defined based on location. Sometimes it is easy for patients to identify the location of their pain and sometimes it may be difficult. Pain perceived at a location other than the site of the painful stimulus is called **referred pain**. The abdomen, extremities, and head are common areas to experience pain. Pain location charts can be helpful for patients to describe their pain ([Figure 30.4](#)).

**FIGURE 30.4** Pain location charts can be helpful for patients to identify where their pain is felt on their body. Locating the pain can help healthcare providers in developing effective treatment plans. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Identifying the location of a patient's pain can better help healthcare providers effectively assess and manage pain. Pain location charts show areas of the body, and the patient can point to a specific area where they are feeling their

pain. Areas of pain such as knee pain can result from different causes based on location (Askinazi, 2023). For example, pain above the knee can be caused by inflammation while pain at the kneecap can be caused by a stress fracture. Location may be hard to determine for certain types of pain, but it can be helpful in the pain assessment and treatment plans.

### Cutaneous Pain

Pain that is perceived from the skin is called **cutaneous pain**. Cutaneous pain is often acute pain that is resolved after the underlying injury or condition is treated. However, sometimes cutaneous pain can become chronic. Cutaneous nociceptors respond to heat, cold, and mechanical and chemical stimuli. Causes of cutaneous pain can include diabetes, autoimmune diseases, and other painful skin conditions (Gudin et al., 2022).

Patients who have diabetes often experience skin infections that can become painful. Other skin conditions such as shingles and dry skin can cause cutaneous pain. Shingles is caused by the virus that causes chickenpox and creates a vesicular rash that is painful and itchy. Autoimmune diseases such as lupus can cause inflammation, rash, and lesions that can cause cutaneous pain (Stucky & Mikesell, 2022). Many patients who experience cutaneous pain can also experience pain elsewhere in their body at the same time. Cutaneous pain can often be easy to identify due to outward signs of the cause of pain, such as cuts, burns, swelling, rashes, and bruising.

### Visceral Pain

Visceral structures are internal organs such as the stomach, kidneys, spleen, and appendix. Visceral structures are highly sensitive to stretch, ischemia, and inflammation. When these internal organs are injured or damaged it creates **visceral pain** (Ford, 2019). Visceral pain is diffuse, difficult to locate, and often referred to as a distant, usually superficial, structure. It may be accompanied by nausea and vomiting and vital signs changes. Visceral pain may be described as sickening, deep, squeezing, aching, pressure, and dull. Visceral pain can be caused by gallstones, appendicitis, or irritable bowel syndrome (Santos-Longhurst, 2018).

Visceral pain can be difficult to locate due to the pain being internal, and patients often struggle to pinpoint an exact location. Unlike cutaneous pain, visceral pain does not typically show any outward signs of the cause of pain, which can make it difficult to locate.

### Somatic Pain

Pain initiated by stimulation of nociceptors in ligaments, tendons, bones, blood vessels, fascia, and muscles is called **somatic pain**; it is a dull, aching, poorly localized pain. Somatic pain can be aching, deep, or superficial. For example, a ligament tear will cause deep somatic pain whereas a burn will cause superficial somatic pain. Somatic pain can be caused by broken bones, muscle stress, connective tissue diseases, joint pain, cuts, or burns (Santos-Longhurst, 2018). Somatic pain may show outward signs of the cause of pain such as a broken bone, cuts, burns, swelling, or bruising. Deep somatic pain may show no outward signs of the cause of pain, so further diagnostic testing may be needed to identify the location.

### Referred Pain

Pain can radiate from one area to another. For example, back pain caused by a herniated disk can cause pain to radiate down an individual's leg. Referred pain is different from radiating pain because it is perceived at a location other than the site of the painful stimulus. For example, pain from retained gas in the colon can cause pain to be perceived in the shoulder. Referred pain can happen because all nerves are connected and sometimes the brain sends a pain signal to a different area from where the pain started (Watson, 2019).

Referred pain can be felt anywhere, which is why it can be difficult to diagnose. Common areas of referred pain are shoulders, neck, back, and jaw (Watson, 2019). For example, lower back pain can indicate that there is something wrong with the kidneys, and jaw pain could be an early sign of a heart attack. It is important that nurses are aware of these signs to help identify and treat serious conditions such as a heart attack.

## REAL RN STORIES

### Signs of a Heart Attack: Referred Pain

**Nurse:** Amy, BSN

**Clinical setting:** Emergency department

**Years in practice:** 2

**Facility location:** Teaching hospital in downtown Chicago, Illinois

Being in a big urban hospital, we see a wide range of patient populations, especially in the emergency department (ED). I enjoy working in the ED because you never know who will walk in the door and you must be ready for anything. I have seen a lot in my five years in the ED, but one patient story has always stuck with me.

I had been working in the ED for about a year, and it was my first night working as the triage nurse. As the triage nurse, my job was to quickly assess the patients when they first walk in and determine the level of care they would need. A younger woman walked into the ED with no signs of distress. She reported that she was having a “weird pain” in her armpit. She rated her pain a 3 out of 10 and described it as sharp and persistent. She said her pain had begun about an hour ago. I asked her a series of standard triage questions to assess if she was having any other symptoms or pain elsewhere in her body. She reported no other symptoms and had a calm demeanor while speaking to me. She had no health history and appeared to be in good health. I initially assumed she may have injured her arm and an x-ray might show what was causing the pain. I determined her symptoms were not urgent and asked her to wait for the next available bed.

About thirty minutes later, the woman came back up to me and appeared pale, diaphoretic, and was complaining of the continued pain in her armpit and nausea. I immediately escalated her status and called my charge nurse. My charge nurse took one look at her and immediately brought her back to an exam room and asked the physician for an EKG and labs. My charge nurse seemed a little nervous, so I quietly asked her what was going on. She responded “I think this patient is having a heart attack. We need to get the provider right away.” I was shocked. This patient’s only symptom on arrival was mild pain, so how was she now having a heart attack? I then began to worry that I had missed something during triage.

My charge nurse helped stabilize the patient and transport her to the cardiac unit for further evaluation. After we had safely transported the patient, I told her what happened in triage and that I was terrified I had missed something. She explained to me that early signs of a heart attack could be referred pain to the arms, shoulders, or jaw. She said most of the time the pain is accompanied by other symptoms, but it is possible that the referred pain could be the only sign of a heart attack. She explained that as a new nurse, I may not have been aware of referred pain as a heart attack symptom and that I triaged the patient according to my knowledge. We worked together to help me understand how to identify potential referred pain for the future. A few years later, I had a similar patient come into the ED while I was the triage nurse. I was able to identify a potential heart attack early due to referred pain and stabilize my patient just as my charge nurse had done for me.

---

## Etiology

The **etiology of pain** describes the specific cause of pain. Pain can result from various health conditions such as genetics, trauma, degenerative diseases, cancer, surgical procedures, infection, mechanical cause, or an unknown cause (Arumugam et al., 2019). Nociceptive, neuropathic, and idiopathic pain are all types of pain resulting from a specific cause. These causes can include heat, cold, chemicals, or neurological damage. The cause of pain can also be unknown.

### Nociceptive Pain

Pain caused by stimulation of pain receptors by a mechanical or chemical cause such as heat or cold is called **nociceptive pain** (Ford, 2019). Because nociceptors are found everywhere in the peripheral nervous systems, nociceptive pain originates in the peripheral nervous system (Dydyk & Grandhe, 2023). The severity of nociceptive pain is directly related to the degree of injury. For example, stubbing a toe may cause mild pain while burns from a house fire may cause severe pain.

Nociceptive pain can be acute, chronic, somatic, or visceral depending on the duration and location of the pain. Nociceptive pain is usually acute, but sometimes the nociceptors may remain more sensitive to pain after the cause of pain has been resolved (Jacques, 2023). For example, a past head injury may have chronic pain due to frequent headaches even after the injury is treated.

Treatment of nociceptive pain is dependent on the duration and location of the pain. Acute nociceptive pain may

only need mild pain interventions, such as an ice pack for a stubbed toe. Chronic or more severe nociceptive pain may require a combination of pharmacological and alternative pain management (Jacques, 2023).

### Neuropathic Pain

Pain caused by neurological damage or dysfunction is called **neuropathic pain**. Neuropathic pain can be peripheral and centralized, and it is estimated that 10 percent of adults in the United States experience neuropathic pain (Dydyk & Grandhe, 2023). Neuropathic pain results in stimulation from something that is not considered painful, but due to the neurological damage, the body perceives the stimuli as painful (Yam et al., 2018). Neuropathic pain can result from conditions such as diabetes, neurological disorders, cancer, trauma, or toxins.

Neuropathic pain can be described as burning, numbness, tingling, shooting, or stabbing and can occur in response to nonpainful stimuli such as temperature changes. Diabetes is one of the most common causes of neuropathic pain. Patients who have diabetes can develop numbness and tingling in their lower extremities due to decreased circulation. This can lead to pain, decreased sensation, and injury to the lower extremities. Central nervous systems disorders such as multiple sclerosis and Parkinson disease can cause neuropathic pain. Patients receiving cancer treatment such as radiation or chemotherapy may also experience neuropathic pain due to their treatments (Santos-Longhurst, 2018).

Neuropathic pain is generally undertreated because it typically does not respond to traditional analgesics. Medications such as tricyclic antidepressants and gabapentin are typically used to manage this type of pain. These medications work on blocking the sensation to the affected nerves. Many patients are not aware that their chronic condition could lead to neuropathic pain. Nurses should provide education for patients with these conditions to ensure that their pain is managed effectively.

## PATIENT CONVERSATIONS

---

### Assessing Neuropathic Pain in Patients Who Have Diabetes

**Scenario:** The nurse is caring for an established patient with diabetes who was admitted for hyperglycemia. The nurse is providing discharge education about the patient's diabetes home management and the patient is asking about pain management.

**Patient:** I often have numbness and tingling in my feet, and it really bothers me. Why is that happening?

**Nurse:** Are you having any pain right now?

**Patient:** No, not right now. But the pain comes and goes a lot when I am at home.

**Nurse:** That kind of pain is common in patients with diabetes. Diabetes can cause decreased circulation in your legs, which can lead to the numbness and tingling.

**Patient:** No one has told me that before.

**Nurse:** Have you ever spoken to your doctor about this pain?

**Patient:** No, I haven't seen my doctor in a long time. I probably should make an appointment with them.

**Nurse:** Many typical pain medications will not be effective for this type of pain, but there are some medications that are very effective. Let me help you set up an appointment with your doctor and we can work on getting you the right treatment plan for your pain.

**Patient:** Thank you very much. I had been taking Motrin but that was not helping. I am glad to hear there is something that may help my pain.

---

### Idiopathic Pain

Sometimes patients can have pain without a known cause. This is called **idiopathic pain**, a chronic pain that is from an unknown origin. Idiopathic pain from an injury or medical condition may also persist long after the cause is healed. Medical conditions in which idiopathic pain may be present include fibromyalgia, multiple sclerosis, headaches, joint disorders, peripheral neuropathy, and irritable bowel syndrome (Jacques, 2021). Patients may

often experience idiopathic facial pain in the jaw, ears, or cheeks. Patients may feel dull, aching, throbbing, or tingling sensations in their face without any identified cause of pain (Cleveland Clinic, 2021).

Idiopathic pain can be difficult to diagnose. The symptoms of idiopathic pain can often be similar to those of other conditions. Healthcare providers tend to rule out other medication conditions before idiopathic pain is diagnosed. Because the underlying cause is not known, idiopathic pain can also be difficult to treat. A combination of medications and alternative therapies such as acupuncture, biofeedback, and meditation can help reduce pain (Cleveland Clinic, 2021).

## 30.2 Responses to Pain

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the physiologic response to pain
- Identify behavioral response to pain
- Identify affective response to pain

Patients can have many different responses to pain. The body perceives pain as a sign of danger and will immediately initiate responses to help the person stay safe. The sympathetic and parasympathetic nervous systems play a big role in physiologic responses to pain. Many patients may experience sympathetic body changes to a perceived threat of pain. Behavioral and emotional responses can also be observed in patients experiencing pain. Vocalization, facial expressions, movement, and negative emotions can all be responses to pain.

Patients may experience a wide variety of behaviors when in pain. Patients may lash out or become quiet and withdrawn when in pain. Patients in acute pain are more likely to vocalize their pain and exhibit facial expressions of pain. Patients experiencing chronic pain may struggle with anxiety and depression from the continued feeling of pain. Patients may even experience an extreme fear of pain and avoid any situation that may cause pain.

### Physiologic Response

Pain warns a person of danger to prevent damage to the body (Arcuri, 2022). The **physiologic response** to pain is the body's involuntary responses to a painful stimulus such as inflammation or changes in heart rate and blood pressure. Physiologic responses can include sympathetic nervous system reactions and behavioral reactions such as facial expressions, emotions, vocalizations, and movement. Many of the observed nonverbal cues from patients are physiologic responses to pain.

### CLINICAL SAFETY AND PROCEDURES (QSEN)

---

**QSEN Competency: Patient-Centered Care: Recognizing Physiologic Pain Response**

**Definition:** Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs.

**Knowledge:** Demonstrate comprehensive understanding of the concepts of pain and suffering, including physiologic models of pain and comfort.

**Skill:** Assess presence and extent of pain and suffering. The nurse will:

- Focus on the duration, location, and etiology of the patient's pain.
- Ask the patient how long the pain has lasted to determine if the pain is acute, chronic, or breakthrough pain.
- Ask the patient to identify the location of the pain.
- Ask the patient to describe how the pain feels and what causes or makes the pain worse to try to determine the cause of pain.

**Attitude:** Appreciate the role of the nurse in relief of all types and sources of pain or suffering.

---

### Sympathetic Nervous System

The autonomic nervous system contains the sympathetic and parasympathetic nervous systems and regulates the involuntary physiologic responses of the body (Figure 30.5). The role of the sympathetic nervous system is to

respond to perceived stressful or dangerous situations. The main response from the sympathetic nervous system is the **fight-or-flight response**, which triggers the body to either run away from or fight a perceived threat. For example, the body may perceive an encounter with a wild animal as a threat. The sympathetic nervous system will activate and tell the person to run away from the animal to safety. The fight-or-flight response may not be activated in perceived less stressful situations, but the body may still illicit a sympathetic response (Yeater et al., 2021). For example, a patient may be experiencing postsurgical pain even with pain medication. The sympathetic nervous system may respond to the pain by elevating the heart rate and blood pressure.

The sympathetic pain response involves many automatic bodily functions such as:

- enlarging pupils to improve vision;
- slowing digestion to allow the body to use energy in other places; and
- increasing heart rate and blood pressure to improve circulation (Cleveland Clinic, 2022b).

Nurses may notice these nonverbal signs of pain in a patient even before the patient states they are in pain. Noticing sympathetic pain responses is especially important in patients who cannot communicate their pain. Patients who are unconscious, confused, nonverbal, young, or cognitively impaired may not be able to adequately express their pain.

### Parasympathetic Nervous System

The parasympathetic nervous system opposes the sympathetic nervous system and regulates the automatic bodily functions in times of rest and relaxation. Once the perceived stress or threat is gone, the parasympathetic nervous system takes over and returns the body to its normal functioning (Cleveland Clinic, 2022a).

The parasympathetic response includes:

- constricting pupils to limit light;
- producing saliva and mucus to assist in digestion and breathing;
- lowering heart rate and blood pressure to reduce workload;
- directing energy toward digestion to help break down food;
- directing the pancreas to create insulin to regulate blood sugar; and
- relaxing muscles to assist with urination and defecation (Cleveland Clinic, 2022a).

These responses indicate to the nurse that the patient is experiencing adequate pain relief. In the same way that the nurse observes sympathetic responses to detect a patient's pain, the nurse may observe parasympathetic responses to determine if pain interventions are effective ([Figure 30.5](#)).

**FIGURE 30.5** The parasympathetic and sympathetic divisions of the autonomic nervous system have opposite effects on various systems. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Vital signs can be an indicator of pain, and nurses can use vital sign measurements along with the patient's response to determine if pain interventions are effective. Measuring vital signs as an indicator of pain can be especially useful for patients who cannot verbalize their pain. Pain can cause an increase in blood pressure, heart rate, and respiratory rate. Abnormal vital signs can occur without pain, so it is important that nurses perform other methods of assessment for pain as well. Nurses can also measure vital signs to determine if they have normalized after pain interventions. For example, if a patient has elevated blood pressure and is exhibiting signs of pain, the nurse can assess their blood pressure after pain medication has been given to ensure that it has normalized. This can help indicate that the pain interventions are effective.

### Behavioral Response

Behavior plays a big role in pain response. Nurses can easily observe behavioral responses to pain and can measure the severity of pain based on a patient's behavior. Noticing behavioral pain responses is especially important in patients who cannot communicate their pain.

Behavioral pain responses may include:

- facial expressions,
- vocalization,
- movement,
- emotions, and
- interactions with others.

Behavioral pain responses are often big reactions that others easily notice. For example, when a professional athlete gets injured during a game, everyone in the crowd understands the athlete is in pain due to their behavior. The

athlete may fall to the ground, grab the area of their injury, and yell out in pain (Figure 30.6).

**FIGURE 30.6** Athletes are prone to injuries and can be seen publicly displaying behavioral responses to pain. (credit: “Injury” by Olympus Digital Camera/Flickr, Public Domain)

### Vocalization

Patients will sometimes use sounds, noises, and words to express pain. This is called **vocalization**; and it most often occurs in acute pain of varying severity. Vocalization of pain includes crying, screaming, moaning, gasping, or grunting (Helmer et al., 2020). Patients can vocalize their pain by using pain rating scales. Asking patients to rate their pain on a numeric scale can be an effective way to assess patients for pain. Patients can also vocalize pain descriptors such as severity, duration, location, and type of pain.

The use of vocalization to express pain is used often in younger children (Helmer et al., 2020). Younger children have limited communication when trying to express pain. The most common way for infants to express discomfort is by crying. Older children may be capable of stating their pain using appropriate pain scales, such as the Wong-Baker FACES Pain Rating Scale, but may still use crying or yelling to express pain (Venable, 2018).

## LIFE-STAGE CONTEXT

### Behavioral Pain Response in Infants

Assessing pain in pediatric patients can be difficult, especially in infants. Nurses must be aware of behavioral responses to pain when caring for infants. Infants primarily express their needs through crying, but not all crying equates to pain. The FLACC (Face, Legs, Activity, Cry, Consolability) scale can be used to assess an infant’s pain. The FLACC scale is recommended to be used in younger patients as it measures appropriate behavioral responses in young children. The FLACC scale scores patients’ pain based on five criteria: facial expressions, body posture, activity, crying, and the ability to console (Trottier et al., 2022). The total score is 0 to 12, with each category receiving 0 to 2 points based on patient response. Nurses can try comfort measures such as swaddling, feeding, and rocking to ease the infant’s crying. If no comfort measures work, the crying may be due to pain (Helmer et al., 2020).

### Facial Expression

Facial expressions not only demonstrate emotions such as happiness, fear, or sadness, they can also demonstrate pain. Frowning, closing eyes, clenching teeth, opening the mouth, biting lips, grimacing, furrowing eyebrows, and scowling can all be used to express pain (Figure 30.7) (Cho & Hong, 2020).

**FIGURE 30.7** Facial expressions such as grimacing, frowning eyebrows, and closing eyes are a common way for patients to express pain. (credit: “The pain is brutal for these Marines 150306-M-IN448-056.jpg” by Sgt. Matthew Callahan/Wikimedia Commons, Public Domain)

Some research shows that social context can change the way a person expresses pain (Kappesser, 2019). For example, a young child may cry and use facial expressions to demonstrate pain around their parents. However, they immediately stop crying and try to smile when their older sibling comes into the room because they want to appear more mature. Another example is a person feeling comfortable enough to show facial expressions of pain in the presence of their partner rather than in front of a colleague or stranger (Kappesser, 2019). Patients may not feel comfortable showing facial expressions when in pain. They may try to hide their facial expressions in the presence of healthcare providers. It is important that nurses always help patients feel comfortable expressing their pain.

### Body Movement

Patients may demonstrate pain through movement such as guarding, touching the location of the pain, withdrawing from touch, or tremors (Cho & Hong, 2020). Nurses may notice muscle tension and resistance to examination of the painful location.

Children often show pain through withdrawal of touch. While they may seek the comfort of their parents, they will often resist someone touching or manipulating the painful area due to fear of touch causing more pain. This can be difficult for nurses to assess the location of pain. Severe pain may require pharmacological interventions prior to assessment of the location of pain. Nurses must be mindful of the location of pain when doing a physical assessment. Visual assessment, diagnostic imaging, and descriptors of pain from the patient can help provide a comprehensive pain assessment without touching the painful area.

### Social Interaction

The way that patients interact with others can change when they are in pain. Patients in chronic pain may withdraw

from social interactions and become isolated. This can make the pain worse and contribute to deteriorating physical health in patients (Bannon et al., 2021). When patients are in pain and around others, they may appear quiet, reserved, and uninterested (Oommen & Shetty, 2020). Nurses can educate patients that these social interactions are a normal response to pain and help them verbalize to their loved ones that these negative emotions are responses to pain. It is important that patients are able to verbalize their pain in social situations, so they do not become socially isolated and withdrawn. Research has shown that supportive social environments can help patients cope with pain (Bannon et al., 2021).

## Affective Response

The **affective response** to pain refers to the emotional interpretation of pain, such as how uncomfortable the pain is. The affective response can help determine how much pain is felt (Cleveland Clinic, 2022a). Negative emotions such as fear and anxiety can be connected to pain. Because pain is a subjective experience, patients may have different emotional responses to pain. For example, an athlete with a knee injury may feel fear along with pain because they are worried the pain means a season-ending injury. Another patient feeling pain from a broken leg may feel anxiety along with the pain because they will not be able to work while recovering from their injury.

Interventions such as cognitive behavioral therapy, guided imagery, and meditation can help patients adjust their affective response to pain because they promote relaxation and decreased stress (Talbot et al., 2019). These interventions can help decrease negative emotions such as fear and anxiety while also decreasing the perception of pain.

## Negative Emotion

Pain is an unpleasant sensation and associated with negative emotions. Negative emotions can include anger, frustration, fear, anxiety, depression, guilt, and sadness. Negative emotions can make it difficult to complete daily activities and can lead to social withdrawal. Everyone can feel negative emotions and they are not always connected to pain. However, it is important for patients to understand that pain can bring on negative emotions, especially anxiety and depression. If patients are not able to cope with negative emotions in healthy ways, it can lead to unhealthy consequences (Scott, 2022).

Accepting emotions and finding healthy coping mechanisms is essential to reducing pain and preventing negative consequences. Healthy coping mechanisms for negative emotions can include acceptance and understanding of the emotions, exercise, meditation, and lifestyle changes (Scott, 2022).

## Anxiety

Anxiety often goes hand in hand with pain and is more commonly seen in patients with chronic pain. Pain can affect patients' daily lives and can have a big impact on their physical, mental, and social health. Many patients who experience anxiety with pain may also experience depression. Research shows that 65 percent of patients seeking help for depression also report pain symptoms (Harvard Health Publishing, 2021).

Anxiety and depression can make it harder to treat pain. Patients experiencing anxiety and depression may be less motivated to find ways to treat their pain and may be unable to focus on pain management strategies. Cognitive behavioral therapy, mindfulness, and medications can help treat anxiety, depression, and pain in patients. These therapies can be multimodal in that they can treat the negative emotions and the pain at the same time.

## Fear

The perception of pain can be influenced by fear (Oommen & Shetty, 2020). Some patients may even have a phobia of pain. When that phobia of pain is extreme, it's called **algophobia**. Patients may experience anxiety and fear at the thought of pain. Algophobia can make patients more sensitive to pain and they may perceive normal activities as a potential cause of pain (Cleveland Clinic, 2021).

Fear of pain can cause patients to catastrophize pain. The act of **catastrophizing** is the picturing the worst possible outcome for a situation (Cleveland Clinic, 2021). Patients may be intensely focused on avoiding pain and can see the potential of pain in any situation. Patients may become anxious and withdrawn as they try to avoid situations that could cause pain. If patients are experiencing pain, they may avoid situations that they think can make their pain worse. Cognitive behavioral therapy and mindfulness can help patients deal with their fear of pain. Exposure to

potential painful situations can also help patients rationalize their fear of pain and continue living their daily lives.

## 30.3 Factors Affecting Pain

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe psychosocial factors affecting pain
- Identify physiological factors affecting pain
- Recognize psychological factors affecting pain

Psychosocial, physiological, and psychological factors can all affect pain. An important part of a pain assessment is recognizing the factors that could be influencing pain (Dydyk & Grandhe, 2023). Factors such as poor social support, past experiences, and age can make an impact on the patient's perception of pain.

These factors can negatively or positively impact a patient's perception and expectations of pain. A patient who has had negative past experiences with chronic pain and pain management may believe that their pain can never get better. A patient who has a good support system and believes that improving their lifestyle can heal their chronic pain may find their pain improving over time. It is important that patients are aware of the different factors that can affect pain and how different choices, lifestyle, and mindset can affect their perception and overall outcome of pain.

### Psychosocial Factors Affecting Pain

A psychosocial factor is a social factor that relates to a person's perception of pain. Social factors can include mood, trauma, interpersonal relationships, environment, and education. Research shows that past experience and interpersonal relationships can have a large impact on the perception of pain. Patients who have pain due to past trauma may have a different perception of pain than someone who has never experienced pain. The impact of others can also affect patients' pain. For example, a patient may be more likely to report pain in the presence of a supportive environment than a patient who is alone.

#### Mood

Research shows that there is a connection between mood and pain. Mood disorders such as anxiety, depression, and bipolar disorder can impact the perception of pain. Emotions such as fear, frustration, and anger can also impact pain. If negative emotions persist during chronic pain, patients may be at an increased risk of suicide (Antioch et al., 2020). Chronic debilitating pain combined with a history of depression can give patients a feeling that there is no sense of pain relief.

Positive emotions can in turn help patients deal with their pain. Patients who are optimistic and have a positive lifestyle may view pain as a minor inconvenience rather than a life-altering change. Practicing interventions such as cognitive behavioral therapy, mindfulness, and relaxation techniques can help patients keep a positive mood while dealing with pain.

#### Distress

Negative attitudes in combination with pain can often lead to distress. Distress is experiencing extreme physical or mental suffering such as pain, anxiety, or sadness. Often patients find that their pain is beyond their ability to cope, which can cause distress when dealing with pain (Craig & MacKenzie, 2021). Distress when dealing with pain can lead to decreased quality of life, depression, anxiety, and catastrophizing (Fancourt & Steptoe, 2018). Patients may be so preoccupied with their pain that they begin to catastrophize and neglect other areas of their lives. For example, a patient with severe chronic pain may begin to think that there is no hope for pain relief and withdraw from their daily life. They may stop going into work, reduce physical and social activity, and turn to substance use as a coping mechanism. These poor lifestyle choices can lead to a decreased quality of life and more health complications.

#### Trauma

Pain and trauma are often interconnected. Many times, a patient's pain may be directly caused by trauma and therefore be a constant reminder of the traumatic experience (Jackson, 2021). Physical trauma such as car accidents or abuse can cause chronic pain. Patients may have chronic pain due to their injuries sustained in the traumatic experience or experience chronic pain due to **post-traumatic stress disorder (PTSD)**. Post-traumatic stress disorder (PTSD) is a psychiatric disorder where a person experiences lingering effects triggered by a past

traumatic event. These lingering effects can include chronic pain and can lead to anxiety and catastrophizing.

Research shows that childhood trauma can be linked to chronic pain later in life (Jackson, 2021). Childhood trauma may include physical, emotional, or sexual abuse, neglect, or parental separation. Children often do not know how to deal with traumatic experiences and may not receive support afterward, so they can have lingering effects of the trauma for many years. Research shows that treating the trauma can provide pain relief. Different types of therapy and mental health resources can help the patient deal with the trauma and any residual effects.

### Interpersonal Factors

It is important for nurses to understand how social factors can affect a patient's perception of pain. Supportive environments may allow patients to be more open in voicing their pain. For example, a patient may be more open in discussing their pain in the presence of a loved one than when alone in a healthcare setting (Gilam et al., 2020). Factors such as culture and socioeconomic status can influence how a patient perceives and articulates their pain (Heshmat, 2023). Certain cultures may be more expressive in their pain than others, and patients may hide their pain in fear of judgement of their socioeconomic status.

The complex interactions between factors affecting pain and individual perception can create a wide range of reactions to pain (Trachsel et al., 2023). Perceived social rejection, lack of social support, and relationship struggles can impact a patient's perception of pain. A patient without adequate social support may view their pain as more unmanageable than a patient with a strong support system does.

### Physiological Factors Affecting Pain

Physical factors that are related to a person's perception of pain are called physiological factors. Physiological factors can include age, developmental level, sex, ethnicity, and lifestyle choices. Research shows that physiological factors such as hunger, stress, substance use, and sedentary lifestyle can put a person at an increased risk for pain (Dydyk & Grandhe, 2023). Substance use may be used to try to relieve pain. Alcohol is often used by patients to self-medicate, but the pain-relieving properties are short-lived. Healthy lifestyle choices such as exercise, healthy foods, and sunlight can be used to decrease pain and prevent further health complications (Mills et al., 2019).

#### Developmental Level

The developmental level of the patient can impact how they perceive and express pain, especially in children. It is important to note that developmental level does not always correspond with the patient's age. For example, a patient with Down syndrome could be 18 years old but have the developmental level of a school-aged child due to the cognitive effects of Down syndrome. Patients with childhood traumatic brain injuries could remain at a lower developmental level as they age.

Infants cannot verbalize pain and express all distress through crying. The nurse must use other behavioral cues and rule out other causes to determine if the crying is related to pain. Toddlers and preschoolers often have difficulty describing, identifying, and locating pain. Instead, pain may be demonstrated behaviorally with crying, anger, physical resistance, or withdrawal. School-aged children and adolescents are more responsive to explanations of pain.

Adults are able to verbally express pain and can understand most pain rating scales. However, adults who are developmentally delayed may express pain similar to how a child does. Pain in older adults can present atypically with confusion and agitation. Patients who are confused may have trouble perceiving and adequately expressing their pain. Pain is often underreported in patients of different developmental levels, so nurses must be aware that people of different developmental levels will express pain in very different ways.

#### Age

Just as children relate differently to pain based on their developmental levels, older adults can be at greater risk of chronic pain due to age-related health concerns. Older adult patients have a higher risk of illness or injury, which can lead to chronic pain (Mills et al., 2019). Older adult patients have a higher rate of chronic pain due to these age-related changes. Older adults are also less likely to express pain. Many patients have the attitude that pain is "just what happens with old age." Dementia and confusion can also make expressing pain more difficult (Mills et al., 2019). Patients who experience chronic conditions such as Alzheimer disease may not be able to recognize that they are in pain or adequately communicate how they are feeling. Many older adult patients experience social

isolation, which can further discourage them from seeking pain management.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Analyze Cues: Linking Physiological Factors to Pain

The nurse is performing an initial assessment on an older adult patient admitted for a urinary tract infection. The nurse observes that the patient is confused and does not know they are in the hospital. The patient is visibly distressed and states they are scared because they do not know where they are or where their spouse is. The nurse observes that the patient arrived at the hospital in a wheelchair and notes chronic back pain in their health history. The nurse notes that the patient has chronic pain medication listed on their home medication list. When the nurse asks the patient if they are in pain, the patient states “no” and continues to express distress that they are not at home with their spouse. However, the nurse notes that the patient continues to rub their back and struggles to move from the wheelchair to the bed. The nurse understands that confusion due to age in older adult patients can impact the patient’s perception of pain. The nurse notes that the patient’s vocalization of pain does not match the physical signs of pain and may be due to the patient’s confusion. The nurse understands that further evaluation is needed to assess the patient’s pain and factors that may impact their pain management.

### Culture/Ethnicity

Culture and ethnicity can play a role in the perception and management of pain. Various cultures can express pain differently. For example, Asian cultures are typically more reserved when discussing pain while other cultures may be more vocal and expressive in their pain (Givler et al., 2023). Research has shown that chronic pain is more prevalent in developing countries (Mills et al., 2019). Cultures with fewer resources and less access to health care have higher risk of pain being underassessed and undertreated.

Research has shown that socioeconomic background may affect pain more than culture and ethnicity. Underrepresented communities often have limited access to health care and can be at higher risk of chronic pain, substance misuse, and opioid addiction (Dydyk & Grandhe, 2023). Patients may not have the education or financial stability to seek out care when dealing with chronic pain. Patients from an underrepresented community may have limited access to health insurance, financial stability, job security, and other factors that complicate their perception of pain and the ability to manage it. Patients experiencing chronic pain may be concerned about the cost of treatment or job security and may avoid seeking care for chronic pain (Mills et al., 2019).

### Sex Assigned at Birth

Pain can be perceived differently between males and females. When discussing the impact of biological sex on pain, it is important to differentiate between biological sex and gender. Biological sex refers to the assignment of male, female, or Intersex at birth based on different genitalia and chromosomes. Gender refers to the characteristics of male or female based on social and cultural norms. A person may be assigned a biological sex that does not align with their gender. For example, a person may have sex characteristics of a male, but identify socially and culturally as a female. Both biological sex and gender can play a role in pain.

Research has shown that males are less likely to express pain and seek treatment for pain than females (Mills et al., 2019). People assigned female at birth may also experience pain that males do not, such as menstrual pain and labor pain.

Females experiencing pain are often more likely to be undertreated than males (Casale et al., 2021). The understanding of pain related to specific female health conditions has historically been misunderstood. Many researchers are advocating for development of pain medication specifically designed for females (Casale et al., 2021). Research shows that females are affected by pain more severely and more frequently than males (Casale et al., 2021). Recent research shows that there are significant differences in the physiologic mechanisms of pain related to sex. Females perceive pain differently than males do and hormones can affect pain signals (Osborne & Davis, 2022). Recent research has been more inclusive of females, but there is still more needed. Because of the lack of inclusion of females in studying the effects of pain, many feel misunderstood when seeking pain management from healthcare providers. It is important for nurses to understand how sex and gender can impact patients’ perception of pain and that more research is needed to determine the extent of its effect.

## Psychological Factors Affecting Pain

A patient's expectations of pain can often increase or decrease the severity. If a patient believes they will have a lot of pain, their perception can increase. In contrast, if a patient believes an intervention will be effective, their pain may decrease (Heshmat, 2023). The interpretation of pain can also have an impact on pain perception. How pain affects a patient's quality of life can change their perception of pain. For example, a patient who is having pain from an elective surgery may perceive their pain differently than a patient who is having chronic pain from cancer treatment does.

### PATIENT CONVERSATIONS

---

#### What If Your Patient Believes Nothing Will Work to Treat Their Pain?

**Scenario:** The nurse is caring for a patient who is experiencing chronic pain from cancer treatment. The patient is exhibiting signs of withdrawal and depression and looks worried when the nurse walks into the room.

**Nurse:** Hi, my name is Emily, and I am going to be your nurse today. Do you mind verifying your name and birthday for me?

**Patient:** Sure, Alice Wilde 12/13/1960.

**Nurse:** Nice to meet you, Alice. Are you experiencing any pain right now?

**Patient:** Yes, I am always in pain. I don't think it's ever going to go away.

**Nurse:** What would you rate your pain on a scale of zero to ten, with zero being no pain and ten being the worst pain?

**Patient:** A seven. It's always a seven. You all ask me the same questions every day. My pain is in my abdomen, and it feels dull and achy. I never get any relief from it even though they have me on all these medications that make me so sleepy.

**Nurse:** I am sorry to hear that. Have you tried anything besides the medications for your pain?

**Patient:** Why bother? I know it won't get any better. I have pain because I have cancer. Everyone I know who has had cancer was in so much pain all the time, so I know it will be that way for me.

**Nurse:** Sometimes having a positive mindset can make a big difference in your pain. I know that can be hard to do, but maybe we could try a few techniques to see if it will help?

**Patient:** I guess, although I really do not think anything will help my pain. The doctors tell me I'm on the maximum dose of medications and nothing is helping.

**Nurse:** I understand it can be frustrating that the interventions are not helping your pain. Why don't we try looking at your pain a different way?

**Patient:** What do you mean?

**Nurse:** Sometimes, you experience pain when you expect it. So, if you think your pain will always be a seven, then that is what it will feel like. If you can change your mindset to a more positive outlook for your pain, you may find your pain decreasing.

**Patient:** I have never thought about it that way. I am willing to give that a try.

---

#### Experience

Past experience of pain can impact how a patient perceives pain in the present or future. Pain can be a learned behavior (Cosio, 2020). Children who see their parents in chronic pain may assume that all adults experience pain. Children learn to express pain by watching others. For example, a child who stubs their toe may yell a profanity and grab their toe because they saw their father do the same thing. Patients also learn what pain interventions are effective, even if they can have negative consequences. For example, a patient may realize that lying on the couch relieves their back pain. However, prolonged inactivity can lead to chronic pain and more adverse effects (Cosio,

2020).

### Expectation

The perception of pain can be shaped by expectations. If a patient believes they will have a lot of pain, their perception can increase. Patients may catastrophize and assume the worst possible outcome for their pain. This can cause the patient to feel worse pain and add negative emotions, such as fear and anxiety, to their pain (Heshmat, 2023).

Patients can also improve their pain with appropriate expectations. If the patient expects an intervention to work, they may experience decreased pain (Heshmat, 2023). This is called a placebo effect. A **placebo effect** is when a certain treatment proves to be an effective pain reliever due to the patient believing it will be effective (Cosio, 2020). Nurses can educate patients on the importance of appropriate expectations when managing their pain to improve patient outcomes.

### Interpretation

Patients all have different interpretations of pain. Because pain is a subjective experience, it is important for nurses to accept the pain for whatever the patient says it is. Some patients may interpret pain as debilitating whereas another patient may interpret the same pain as mild (Heshmat, 2023). A patient may interpret ankle pain as “dull and achy” whereas another patient may interpret ankle pain as “sharp and stabbing.” Situational awareness can also impact a patient’s interpretation of pain. For example, a patient who is having their first child may interpret pain as a joyful sign of new life and welcome the pain. Another patient who is in hospice care for chronic pain may interpret pain as a sign that death is imminent. It is important for nurses to remember that all patient interpretations of pain are correct and to be mindful of how a patient interprets their pain when providing pain interventions.

### Avoidance

Some patients may choose to deal with pain by avoiding it. Patients may refuse to discuss their pain or may not disclose pain at all. Patients who are unable to cope with their pain may be more likely to ignore it (Cosio, 2020). It is natural for a person to run away from pain so patients should be aware that this is an understandable reaction to pain (Fournier, 2020). However, patients need to understand that avoiding pain does not make it better or go away. Sometimes avoiding pain can make it worse. Pain can also be a sign of further health complications and ignoring it can lead to negative outcomes. For example, a patient experiencing chronic migraines may ignore the pain because they do not want to seem like a burden on their family. However, the pain could be a sign of a more serious issue such as a brain tumor. Ignoring the pain could lead to the patient delaying diagnosis and treatment of a more serious issue.

## 30.4 Pain Assessment

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe how to collect subjective data for a pain assessment
- Identify how to collect objective data for a pain assessment
- Recognize how to document a pain assessment

Pain is a subjective experience, which means it cannot always be observed externally. Because patients do not always outwardly display signs of pain, the pain assessment must be multidimensional (Wideman et al., 2019). Both subjective and objective data need to be included in a comprehensive pain assessment to get a complete picture of the patient’s pain.

Using a variety of assessment tools allows the patient to express the quality, type, and intensity of the pain. The nurse may use a pain rating scale and different types of questions to collect subjective data. Objective data can be collected by performing a physical assessment, measuring vital signs, and observing patient behaviors such as posture and facial expressions.

A comprehensive pain assessment is the key to adequately treating pain and is a crucial nursing skill. Without comprehensive baseline data, it can be difficult to provide effective pain management for patients.

## Collecting Subjective Data

Because pain is a subjective experience, most of the collected data will be subjective (Wideman et al., 2019). Information obtained from the patient and/or family members and offers important cues from their perspective is called subjective data. A comprehensive pain assessment includes questions that assess the quality, region, severity, potential cause, timing, and aggravating and relieving factors of the patient's pain. Asking the patient open-ended questions allows them to elaborate on their pain and helps the nurse fully understand the patient's concerns.

The PQRSTU mnemonic is often used to remember these subjective assessment questions:

- Provocation/Palliation: What makes your pain feel worse or better?
- Quality: What does the pain feel like?
- Region: Where exactly do you feel the pain? Does it radiate?
- Severity: How would you rate your pain on scale of 0 to 10?
- Timing/Treatment: When did the pain start? How long does the pain last? Have you taken anything to relieve the pain?
- Understanding: What do you think is causing the pain?

These pain assessment questions help the nurse establish a baseline assessment of the patient's pain.

## PATIENT CONVERSATIONS

### A Comprehensive Pain Assessment Using the PQRSTU Questions

**Scenario:** The nurse is caring for a patient who has come into the emergency department. The nurse begins asking the patient questions about their pain including follow-up questions using PQRSTU assessment.

**Nurse:** Hi, my name is Sulee, and I am going to be your nurse today. What brings you in today?

**Patient:** My lower back is killing me. I am in so much pain.

**Nurse:** I am sorry to hear that. I am going to ask a few more questions about your pain so we can get an idea of what is causing it and how we can help alleviate your pain. What makes your pain worse?

**Patient:** Sometimes it gets worse if I am sitting for a long time.

**Nurse:** Do you have to sit for a long period of time often?

**Patient:** Yes, I sit at a desk all day at work. My back always hurts when I get home.

**Nurse:** What does the pain feel like?

**Patient:** It starts feeling sore and aching, but by the end of the day it feels like a knife is stabbing me in the back.

**Nurse:** Where do you feel the pain in your back?

**Patient:** In my lower back.

**Nurse:** Does the pain radiate to somewhere else in your back or in your body?

**Patient:** No, the pain is just across my lower back.

**Nurse:** How would you rate your pain on a scale of zero to ten with zero being no pain and ten being the worst pain?

**Patient:** Probably a seven.

**Nurse:** Would you rate your pain differently after sitting for a long period of time?

**Patient:** Yes, it's a nine when I get home from work.

**Nurse:** Is the pain constant or does it come and go?

**Patient:** The aching is constant, but the stabbing feeling comes and goes.

**Nurse:** Have you taken any medication to relieve the pain?

**Patient:** I take ibuprofen daily and sometimes I try to lie down after work.

**Nurse:** Does the ibuprofen and lying down relieve the pain?

**Patient:** Sometimes it makes it better, but the pain never goes away.

**Nurse:** What do you think is causing the pain?

**Patient:** I was in a car accident last year and my back has hurt me ever since.

**Nurse:** Thank you for sharing that information. I am going to do a few other assessments so I can better understand your pain and how we can help you.

---

Collecting subjective data allows the nurse to begin to understand the type and location of the patient's pain. In addition to the PQRSTU mnemonic, there are many different pain rating scales the nurse can use depending on the patient's cognitive and developmental level.

### Numeric Rating Scale

Asking a patient to use a numeric rating scale to rate the severity of their pain from 0 to 10, with "0" being no pain and "10" being the worst pain imaginable, is a common way to assess patients for pain. Most patients find the numeric rating scale easy to use and healthcare providers find the results easy to interpret (Zambon, 2020). However, the numeric rating scale may not be appropriate for all patients. Factors such as age, native language, literacy level, and cognitive ability may prohibit patients from understanding the numeric rating scale (Zambon, 2020). Some patients may be too young or cognitively delayed, or even sedated to understand how the numbers relate to the severity of pain. Patients from various cultures and native languages may not understand the numbers on the scale and may prefer a more visual pain rating scale. The nurse must ensure the patient can understand the numeric rating scale before using it. If the patient does not understand, a different assessment tool must be used.

When using a numeric rating scale, the nurse should always accept the patient's pain for what they say it is (Wideman et al., 2019). For example, one patient with a sprained ankle may rate their pain as a 4 out of 10, while another patient with a sprained ankle may rate their pain as an 8 out of 10. Both patients are right as their interpretation of pain is subjective (Dydyk & Grandhe, 2023).

The numeric rating scale provides the nurse with the severity of a patient's pain but does not provide any other information (Wideman et al., 2019). Additional questions must be asked to obtain a thorough pain assessment and to assess the patient's comfort-function goal. The comfort-function goal is an individualized patient goal identifying their acceptable pain tolerance while maintaining their daily functions. This goal provides the basis for the patient's individualized pain treatment plan and is used to evaluate the effectiveness of interventions. Each patient's comfort-function goal will be different. For example, one patient may have a comfort-function goal of 4 out of 10 pain severity while another patient may have a goal of 0 out of 10 pain severity.

The numeric rating scale is the most common pain rating scale used in nursing due to its simplicity and ease of understanding. However, it is important for nurses to know other pain rating options to best suit individual patient needs.

### Wong-Baker FACES Pain Rating Scale

The **Wong-Baker FACES Pain Rating Scale** is a visual tool used to evaluate pain severity. The scale uses drawings of different faces exhibiting increasing levels of pain and was created in 1983 by two pediatric healthcare workers, Donna Wong and Connie Baker, to help children express their pain. Today, the scale can be used for anyone age three and older to visually represent their pain level (Wong-Baker FACES Foundation, 2023).

## LINK TO LEARNING

The [Wong-Baker FACES Pain Rating Scale \(https://openstax.org/r/77WongBaker\)](https://openstax.org/r/77WongBaker) can be used for a variety of patients including children, patients of diverse cultures and native languages, and patients who are nonverbal due to

its simplistic illustrations.

To use this scale, use the following evidence-based instructions. Explain to the patient that each face represents a person who has no pain (hurt), some pain, or a lot of pain. “Face 0 doesn’t hurt at all. Face 2 hurts just a little. Face 4 hurts a little more. Face 6 hurts even more. Face 8 hurts a whole lot. Face 10 hurts as much as you can imagine, although you don’t have to be crying to have this worst pain.” Ask the patient to choose the face that best represents the pain they are feeling.

Even though this pain rating scale was intended for children, research shows that many adult patients may prefer a visual scale. Patients with different native languages or patients who are cognitively delayed may have an easier time understanding a visual scale compared to a numeric rating scale.

### McCaffrey Initial Pain Assessment Tool

The **McCaffrey Initial Pain Assessment Tool** is another assessment tool that helps patients express their pain. The McCaffrey Initial Pain Assessment Tool uses visual aids and questions including elements of the PQRSTU mnemonic to provide a comprehensive pain assessment. The McCaffrey tool provides a more comprehensive picture of a patient’s pain than the numeric rating scale or the Wong-Baker FACES scale.

The McCaffrey pain assessment tool includes questions pertaining to the severity, causes, contributing factors, and effects of pain. Images of the human body are included to help patients identify the exact location of their pain. There are detailed questions to help patients express the effects of pain such as accompanying emotions or symptoms, decreased quality of life, decreased physical activity, and poor sleep.

### Collecting Objective Data

Collecting objective data is the second half of a comprehensive pain assessment. Objective data include things that the nurse can measure, such as vital signs and patient behavior. Objective data can help the nurse understand the patient’s pain rating and corroborate the subjective assessment data (Xu & Huang, 2020).

An objective pain assessment includes measuring vital signs, physical assessment, and observing for nonverbal indicators of pain, such as grimacing or moaning. It is especially important to observe for nonverbal indicators of pain in patients unable to self-report their pain, such as infants, children, patients who have a cognitive disorder, patients at end of life, patients who are non-English speaking, or patients who tend to be stoic due to cultural beliefs.

Nurses should be aware that pain can be exhibited through physical symptoms and patient behaviors. A pain assessment should be performed by the nurse prior to any patient interventions to determine if physical assessment findings are related to pain or something else. For example, a patient appears hunched over and guarding their stomach with reports of nausea and lack of appetite. The nurse should recognize that these symptoms could be physical signs of pain and perform a comprehensive pain assessment as the initial intervention.

Collecting objective data allows the nurse to corroborate the subjective assessment of a patient’s pain. An objective pain assessment is especially important if the patient is unable to answer questions about their pain.

## UNFOLDING CASE STUDY

### Unfolding Case Study #4: Part 8

Refer back to [Chapter 19 Oxygenation and Perfusion](#), [Chapter 22 Activity](#), [Chapter 24 Skin Integrity](#), and [Chapter 26 Urinary Elimination](#) for Unfolding Case Study Parts 1 to 7 to review the patient data. Mrs. Jenson, a 72-year-old female, presents to the emergency room with worsening shortness of breath, fatigue, and swelling in her lower extremities over the last week. She reports increasing difficulty performing activities of daily living due to weakness and increased dyspnea. She has been admitted to the telemetry unit.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, heart failure (class III), osteoarthritis</p> <p><b>Family history:</b> No significant family history reported.</p> <p><b>Social history:</b> Widowed ten years ago, currently living in an assisted care facility. No children.</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Lisinopril 20 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Metoprolol 50 mg PO once daily</li> <li>• Aspirin 81 mg PO once daily</li> <li>• Furosemide 40 mg PO once daily</li> <li>• Losartan 25 mg PO once daily</li> <li>• Ibuprofen 400 mg PO Q6 hours PRN mild arthritic pain</li> </ul>
Flow Chart	<p><b>1730: Assessment</b></p> <p>Blood pressure: 132/80 mm Hg</p> <p>Heart rate: 94 beats/minute</p> <p>Respiratory rate: 18 breaths/min</p> <p>Temperature: 98.9°F (37.2°C)</p> <p>Oxygen saturation: 94 percent on room air</p> <p>Pain: 7/10 (back pain)</p>
<ol style="list-style-type: none"> <li>1. Recognize cues: What cues are the priority for the nurse to recognize?</li> <li>2. Analyze cues: What subjective and objective information would the nurse want to obtain about the recognized cues?</li> <li>3. Prioritize hypotheses: What do you think might be some contributing factors to the patient's back pain?</li> </ol>	

### Physical Assessment

A physical assessment is crucial to develop a pain treatment plan. Assessment of the location of the patient's pain can give the nurse context to the potential cause of pain. The nurse should inspect the site of pain for any abnormalities such as swelling, lacerations, or discoloration. Areas of pain can be identified by palpating for any tenderness, swelling, or change in temperature. The nurse should note if the patient is guarding any body part as this could indicate the location of pain. Symptoms such as diaphoresis, nausea, vomiting, or lack of appetite can often be the result of pain. For example, a patient reports moderate pain on their upper back. Upon examining the patient's back, the nurse finds bruising and tenderness upon palpation on the patient's right shoulder. The physical assessment helps the nurse pinpoint a specific location of pain, which can help guide pain management.

Decreased daily activity can be another result of pain, especially if the patient is experiencing chronic unmanaged pain. Assessing the effect pain has on a patient's ability to bathe, dress, prepare food, eat, walk, and complete other daily activities is a new standard of care that assists the interdisciplinary team in tailoring treatment goals and interventions that are customized to the patient's situation. For example, for some patients, chronic pain affects their ability to be employed, so effective pain management is vital so they can return to work. For other patients receiving palliative care, the ability to sit up and eat a meal with loved ones without pain is an important goal.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Recognize Cues: Identifying Physical Pain Assessment Data

The nurse is performing an initial assessment on a school-aged patient who has arrived to the hospital after being hit with a baseball. The nurse observes that the patient is guarding their right leg and is grimacing while sitting in the bed. The nurse inspects the patient's right leg and identifies discoloration and swelling. The nurse observes the right leg is positioned at an odd angle and the patient cries out upon palpation. The patient is

unable to move their leg and states “It hurts even more when I try to move.” The nurse recognizes that the odd angle and decreased mobility of the patient’s leg is most concerning. The nurse recognizes that further evaluation is needed to determine appropriate interventions for the patient’s pain.

### Observe Expression and Posture

Nonverbal pain cues are an important part of an objective pain assessment. Expression and posture can indicate that a patient is in pain. Facial expressions such as grimacing, moaning, clenched teeth, or crying are ways for patients to express pain. Abnormal posture such as hunching over, contracting, rigidity, limited movement, or abnormal gait could also indicate that the patient is in pain ([Figure 30.8](#)).

**FIGURE 30.8** A patient can exhibit physical signs of pain such as poor posture and guarding. (credit: “day 045” by Holly Lay/Flickr, CC BY 2.0)

Abnormal posture does not always indicate pain. A patient may have a stooped posture due to certain conditions, such as scoliosis or arthritis, and report no pain. The nurse should ask the patient if the abnormal posture is normal for them and always initiate a pain assessment.

Patients often exhibit abnormal posture and abnormal facial expressions together when experiencing pain. For example, a patient may exhibit a hunched posture but appear calm and relaxed and report no pain. Another patient may exhibit a hunched posture accompanied by moaning and crying. This could indicate that this is not a normal posture for the patient and may be related to pain.

When assessing patients with abnormal posture or facial expressions, the nurse should recognize that they could be potential nonverbal pain cues. Sometimes patients are in too much pain to speak or may be unable to verbally communicate. Nonverbal indicators of pain such as abnormal posture and facial expressions can be helpful to the nurse when collecting objective pain assessment data.

### Inspect Skin, Muscles, and Joints

Performing an assessment of the skin, muscles, and joints can help the nurse identify specific areas of pain. Changes in skin, decreased range of motion, and an abnormal gait can all be indicative of pain. Through subjective data collection, the nurse can identify the general location of the patient’s pain. Then the nurse can assess the skin,

muscles, and joints in that area to provide more data to the pain assessment.

The nurse should inspect the skin for any abnormalities such as swelling, lacerations, skin breakdown, drainage, and discoloration. Areas of pain can be identified by palpating for any tenderness, swelling, or change in temperature.

Abnormal gait, decreased range of motion, and decreased muscle strength can all be signs of pain. Just like when assessing posture and facial expressions, it is important for the nurse to remember that abnormalities in the skin, muscles, and joints do not always indicate pain. The nurse should pay particular attention to what the patient is reporting about current symptoms, as well as history of any issues. Information should be compared to expectations for the patient's age group or that patient's baseline. For example, an older patient may have chronic limited range of motion in the knee due to osteoarthritis, whereas a child may have new, limited range of motion due to a knee sprain that occurred during a sports activity.

Changes in skin, muscles, and joints are not always present with pain. However, these assessments can help the nurse identify a specific location of pain or potential aggravating factors.

### Measure Vital Signs

Abnormal vital signs can be another nonverbal indicator of pain, especially when patients cannot show behavioral signs of pain (Ford, 2019). For example, a patient who is sedated and intubated cannot answer questions about their pain or exhibit any behaviors indicating pain. The nurse can measure vital signs along with other physical symptoms to assess pain.

Pain can cause hypertension, tachycardia, or tachypnea. Respiratory distress such as loud breathing, nasal flaring, or the use of accessory muscles can also indicate pain. Just like other nonverbal pain indicators, abnormal vital signs can also be present in the absence of pain. The nurse must use other assessment tools in addition to measuring vital signs to determine if the vital signs are related to pain (Ford, 2019).

In 1995, the American Pain Society introduced the concept of pain as the fifth vital sign to encourage providers to assess pain more frequently and prioritize pain assessments in patient care (Scher et al., 2017). There is ongoing debate as to whether treating pain as the fifth vital sign has contributed to the ongoing opioid crisis in America. Some providers believe that putting an intense focus on pain management can lead to the overprescribing of opioids, but other providers believe that pain management should be the priority in patient care. Current research shows that pain is an ongoing patient concern, and that consistent, multidimensional pain assessments are most effective in managing pain (Scher et al., 2017).

Nurses must always make pain a top priority of patient care. Nurses must include multiple assessment tools, such as measuring vital signs, in their pain assessments and individualize their assessments to meet each patient's needs.

### Assess Behavioral Cues

Behavioral cues can be important indicators of pain if the patient is unable to answer subjective assessment questions. The nurse may notice a flat affect in a patient in pain. Affect refers to the outward display of one's emotional state. For example, a patient with a "flat affect" refers to very few facial expressions being displayed to indicate emotion ([Figure 30.9](#)).

**FIGURE 30.9** Patients with flat affects are often associated with depression or anger, but they can also be behavioral cues of pain. (credit: “young office man suffering from backache” by centro güel/Flickr, CC BY 2.0)

The nurse must recognize that not every patient in pain will have the same behavioral cues. For example, one patient in pain may appear quiet and withdrawn while another patient may appear very angry and aggressive. A patient’s behavioral cues may not always match their subjective pain assessment. This is often the case with patients in chronic pain. For example, a patient who has cancer may rate their pain an 8 out of 10 while calmly eating lunch with their family. It is important for the nurse to remember that pain is whatever the patient says it is and that behavioral cues are only one aspect of the comprehensive pain assessment.

### Documenting Pain Assessment

Documentation of the pain assessment, interventions, and reevaluation are key to effective, individualized pain management. Pain assessments should occur at regular intervals and a reassessment of pain should occur after any interventions (The Joint Commission, 2020).

When documenting subjective data, it should be in quotation marks and start with wording such as, “The patient reports...” or “The patient’s wife states ...”. The nurse should document any subjective data stated by the patient including their pain score, what pain rating scale was used, and any follow-up information. The nurse should also document any behaviors, facial expressions, or physical attributes that could be related to pain. For example, the nurse would document “Patient states pain is a 7 out of 10 using the numeric rating scale. Patient is crying and grimacing. Patient states pain is in their right shoulder and has been ongoing for two days. Patient states heat relieves the pain for short periods of time. Patient’s right shoulder does not appear to have any skin breakdown or discoloration. Patient has decreased range of motion in their right shoulder when compared to the left shoulder.”

The nurse should also document the patient’s comfort-function goal and any communication with other healthcare providers. Documenting a pain assessment notifies the patient’s entire healthcare team of the assessment data. This allows the healthcare team to begin to plan interventions and further evaluation if needed. The team cannot initiate pain interventions without good assessment documentation, so this should be a top priority for the nurse.

### Documenting Treatment

All pain management interventions need to be documented according to the policy of each healthcare facility. Pain management interventions can be pharmacological or nonpharmacological. Nonpharmacological treatments can include exercise, mind-body practices, psychological therapy, heat or cold, braces, and rehabilitation (Agency for Healthcare Research and Quality [AHRQ], 2019).

Any administered pain medication should be documented in the patient’s electronic medication administration

record (eMAR). It is important to immediately document the intervention to avoid potential errors such as an unintended repeat dose of medication. Nonpharmacological treatments should also be documented in the patient's medical record. Documentation of all pain interventions ensures all providers are aware of pain management strategies and that the patient is getting timely and effective treatment.

### Documenting Evaluation of Treatment

All pain management interventions need to be evaluated and documented to ensure they are effective. It is important to perform a follow-up assessment in the appropriate time frame. The nurse should be aware of the different mechanisms of action for different forms of pain medications to best evaluate the effectiveness. For example, administration of intravenous pain medication should be evaluated within a shorter time frame than oral pain medication due to the different durations of action. The Joint Commission guidelines state that healthcare facilities should have policies in place regarding timeliness of pain reassessments and evaluation (The Joint Commission, 2020).

The nurse should document a new pain level and any symptoms of pain following any interventions. For example, if a patient reported a pain level of 8 out of 10 before PRN pain medication was administered, the nurse evaluates the patient's pain level after administration to ensure the pain level is decreasing and the pain medication was effective. Effective pain management involves mutual pain goals between the healthcare team and the patient and ongoing reassessment with the patient to assess the effectiveness of pain interventions (ANA Center for Ethics and Human Rights, 2018). The nurse should compare the current pain rating to the patient's stated comfort-function goal. If the patient states that their pain does not meet their comfort-function goal, the nurse should continue to explore pain management strategies and continue to reevaluate.

## 30.5 Pain Management

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe pharmacological therapy in pain management
- Identify nonpharmacological therapy in pain management
- Recognize how patient-controlled analgesia (PCA) is used for pain management

Nurses have a responsibility to provide multimodal pain management (ANA Center for Ethics and Human Rights, 2018). Pain management should include different interventions and focus on helping patients improve their quality of life (National Center for Injury Prevention and Control, 2022).

Pain management requires collaboration with the entire interdisciplinary team. Involving specialists such as neurologists, surgeons, and physical therapists can help manage patients' pain (Dydyk & Grandhe, 2023). Pain can be managed by pharmacological and nonpharmacological therapy. The most effective pain management uses a combination of pharmacological and nonpharmacological interventions.

### Pharmacological Therapy

A type of therapy called **pharmacological therapy** can be very effective in treating pain. Pharmacological therapy is the use of medication to treat a disease, illness, or medical condition. The type of medication depends on the type, duration, and severity of the pain (Ford, 2019). There are three main types of pain medications: opioid analgesics, nonopioid analgesics, and adjuvants. An **analgesic** is a medication used to relieve pain. When administering pain medications, the nurse must consider the patient's goals for pain relief and determine if past medications have been effective. The nurse must also consider if the patient is experiencing any side effects that may impact the patient and be aware of contraindications (AHRQ, 2019). Patients should be involved and engaged in their pain management plan. Research has shown improved patient outcomes when patients work together with the healthcare team to manage their pain.

#### Opioid Analgesics

An **opioid analgesic** is a powerful prescription medication that helps reduce pain by blocking pain signals. Common opioids include codeine, morphine, fentanyl, oxycodone, and tramadol. Different opioids have different amounts of analgesia, ranging from codeine used to treat mild to moderate pain, up to morphine, used to treat severe pain ([Table 30.2](#)). Opioids are commonly administered orally or intravenously, but can also be administered rectally,

subcutaneously, intramuscularly, or through the skin.

Generic Name	Trade Name(s)	Route	Adult Dosages
Codeine with acetaminophen	Tylenol #3	PO	30 mg/300 mg
Hydrocodone with acetaminophen	Lortab, Norco, Vicodin	PO	5 mg/300 mg or 325 mg 10 mg/320 mg or 325 mg 5 mg/500 mg
Oxycodone (immediate release and extended release) or Oxycodone with acetaminophen	Oxycodone (IR), OxyContin (ER) Percocet, Roxicet	PO PO	5–10 mg 5 mg/325 mg
Fentanyl	Duragesic, Sublimaze	Transdermal IM IV	12–100 mcg/hr 0.5–1 mcg/kg 0.5–1 mcg/kg
Hydromorphone	Dilaudid	PO Rectal SubQ, IM, and IV	4–8 mg 3 mg 1.5 mg (may be increased)
Morphine	Duramorph, MS Contin, Oramorph SR, Roxanol	PO and rectal SubQ, IM, and IV	30 mg (may be increased) 4–10 mg (may be increased)

**TABLE 30.2** Common Opioid Analgesics

Opioids have a high risk of addiction and overdose, so it is important to consider other forms of pain management before prescribing opioids (National Center for Injury Prevention and Control, 2022). The Centers for Disease Control and Prevention (CDC) recommends avoiding opioids for pain management in patients younger than 18 years old and to avoid opioids as **first line therapy** for chronic pain (Dowell et al., 2022). First line therapy is medical treatment that is recommended as the best option for the initial treatment of a disease or medical condition.

It is important that patients are informed about the side effects and risks of opioids. Side effects of opioids include the following:

- addiction
- confusion
- constipation
- drowsiness
- itching
- nausea and vomiting
- overdose
- physical dependence
- respiratory depression
- tolerance

Constipation, nausea, and vomiting are common side effects of opioids. Opioids slow peristalsis and cause increased reabsorption of fluid into the large intestine, resulting in slow-moving, hard stools. Nurses should educate patients on preventing constipation with a bowel management program including stool softeners, fluids, well-

balanced diet, and physical activity (as allowed with pain/postsurgical restrictions) to aid in preventing constipation. Because opioids slow gastrointestinal mobility, nausea and vomiting can also occur when taking opioids. Typically, patients will build enough tolerance against nausea and vomiting after taking opioids for a few days. Respiratory depression is one of the most serious potential side effects of opioids. Nurses must closely monitor patients receiving opioids for respiratory depression and administer naloxone to reverse the opioid effects if needed.

As important as pain management is, it is also crucial that healthcare providers are mindful of prescribing opioids to treat pain due to the high risk of addiction and overdose. Addiction is a chronic disease of the brain pursuing reward and/or relief by substance use. Patients who have an addiction have trouble stopping the use of opioids and often struggle with addiction for the rest of their life. Patients can also struggle with **tolerance** and **physical dependence** with opioid misuse. Tolerance is when the body builds up resistance to a medication. Physical dependence is when the patient experiences physical symptoms of withdrawal, such as anxiety, diaphoresis, and muscle cramps, when stopping a medication (National Center for Injury Prevention and Control, 2022).

Healthcare providers must be vigilant to avoid addiction and overdose with opioid use especially with the current opioid epidemic in the United States. Opioids can be very effective in pain management when used appropriately, but healthcare providers must monitor for serious side effects (ANA Center for Ethics and Human Rights, 2018).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Safety: Opioid Analgesic Administration

Disclaimer: Always follow the facility policy for medication administration.

**Definition:** Minimize risk of harm to patients and providers through both system effectiveness and individual performance.

**Knowledge:** Examine human factors and other basic safety design principles as well as commonly used unsafe practices.

**Skill:** Demonstrate effective use of strategies to reduce risk of harm to self or others. The nurse will:

- Avoid distractions and disruptions when preparing and administering medications.
- Have a second nurse witness any wasted opioid medication and document the wasted amount.
- Perform hand hygiene before administering medications.
- Perform a comprehensive pain assessment on the patient prior to medication administration.
- Verify the patient's information prior to medication administration.
- Monitor for adverse effects after medication administration.
- Perform a comprehensive pain assessment after medication administration to assess effectiveness.

**Attitude:** Value the contributions of standardization and reliability to safety.

---

### Nonopioid Analgesics

Nonopioid analgesics are another effective form of pain management. A **nonopioid analgesic** is a type of medication that includes **nonsteroidal anti-inflammatory drugs (NSAIDs)** used for acute and chronic pain relief. Other nonopioid analgesics include acetaminophen, anticonvulsants, lidocaine, tricyclic and tetracyclic antidepressants, and serotonin and norepinephrine reuptake inhibitor (SNRI) antidepressants (National Center for Injury Prevention and Control, 2023). Acetaminophen is used to treat mild pain and fever but does not have anti-inflammatory properties. Acetaminophen is often administered orally but can be administered rectally or intravenously. There is a risk of severe liver damage when taking too much acetaminophen or consuming a large amount of alcohol while taking acetaminophen. Nonopioid analgesics have high risks in certain patient populations such as older adults, pregnancy, and patients with liver, cardiovascular, kidney, and gastrointestinal disease (National Center for Injury Prevention and Control, 2023). It is important for nurses to educate these patient populations about the side effects of nonopioid analgesics and the importance of limiting the amount consumed.

NSAIDs provide mild to moderate pain relief while also reducing fever and inflammation by inhibiting the production of prostaglandins. NSAIDs can be used along with opioids for severe pain. Common NSAIDs include ibuprofen,

naproxen, ketorolac, and aspirin (Table 30.3). Ibuprofen and naproxen are commonly prescribed NSAIDs and can be taken several times a day. Ketorolac can help treat breakthrough pain and is indicated for short-term management of moderate to severe acute pain. Common side effects of NSAIDs include nausea and vomiting, gastrointestinal bleeding, and kidney failure. There is an increased risk of heart attack, heart failure, and stroke if patients take more NSAIDs than prescribed or longer than directed.

Drug Name	Administration Considerations	Adverse/Side Effects
Ibuprofen	<ul style="list-style-type: none"> <li>• Given parenterally and orally</li> <li>• Assess pain prior to and after administration</li> <li>• May take with food or milk if stomach upset occurs</li> <li>• Stay well hydrated to prevent kidney failure</li> <li>• Assess patient for signs of GI bleed</li> <li>• Assess for skin rash</li> <li>• Monitor BUN, serum creatinine, CBC, and liver function test</li> <li>• Do not administer to patients who are allergic to aspirin or other NSAIDs</li> </ul>	<ul style="list-style-type: none"> <li>• Headache</li> <li>• GI bleed</li> <li>• Constipation</li> <li>• Dyspepsia</li> <li>• Nausea</li> <li>• Vomiting</li> <li>• Steven-Johnson syndrome</li> <li>• Kidney failure</li> </ul>
Aspirin	<ul style="list-style-type: none"> <li>• Given orally</li> <li>• Assess pain prior to and after administration</li> <li>• Children under 12 years: do not use unless directed by a provider</li> <li>• Take with a full glass of water and sit upright for fifteen to thirty minutes after administration</li> <li>• Take with food if the patient reports that aspirin upsets their stomach</li> <li>• Do not crush, chew, break, or open an enteric-coated or delayed-release pill; it should be swallowed whole</li> <li>• The chewable tablet form must be chewed before swallowing</li> <li>• Should be stopped seven days prior to surgery due to the risk of postoperative bleeding</li> </ul>	<ul style="list-style-type: none"> <li>• GI upset</li> <li>• GI bleeding</li> <li>• Tinnitus</li> </ul>

**TABLE 30.3** Commonly Used NSAIDs

Drug Name	Administration Considerations	Adverse/Side Effects
Ketorolac	<ul style="list-style-type: none"> <li>• Given orally, parenterally and as an ophthalmic solution</li> <li>• Assess pain prior to and after administration</li> <li>• Therapy should always be given initially by the IM or IV route; then use the oral route as a continuation of parenteral therapy</li> <li>• Stay well hydrated to prevent kidney failure</li> <li>• Assess patient for signs of GI bleed</li> <li>• Assess for skin rash</li> <li>• Monitor BUN, serum creatinine, CBC, and liver function tests</li> <li>• Do not administer before any major surgery</li> <li>• Do not administer to patients who are allergic to aspirin or other NSAIDs</li> </ul>	<ul style="list-style-type: none"> <li>• Drowsiness</li> <li>• Headache</li> <li>• GI bleed</li> <li>• Abnormal taste</li> <li>• Dyspepsia</li> <li>• Nausea</li> <li>• Steven-Johnson syndrome</li> <li>• Edema</li> <li>• Kidney failure</li> </ul>
Naproxen	<ul style="list-style-type: none"> <li>• Given orally</li> <li>• Assess pain prior to and after administration</li> <li>• May take with food or milk if stomach upset occurs</li> <li>• Stay well hydrated to prevent kidney failure</li> <li>• Assess patient for signs of GI bleed</li> <li>• Assess for skin rash</li> <li>• Monitor BUN, serum creatinine, CBC, and liver function test</li> <li>• Do not crush, chew, or split open a delayed-release pill; it should be swallowed whole</li> <li>• Do not administer to patients who are allergic to aspirin or other NSAIDs</li> </ul>	<ul style="list-style-type: none"> <li>• Headache</li> <li>• GI bleed</li> <li>• Constipation</li> <li>• Dyspepsia</li> <li>• Nausea</li> <li>• Vomiting</li> <li>• Steven-Johnson syndrome</li> <li>• Tinnitus</li> <li>• Kidney failure</li> </ul>

**TABLE 30.3** Commonly Used NSAIDs

### Adjuvant Analgesics

An **adjuvant analgesic** is a type of medication that is not classified as an analgesic but has been found to have an analgesic effect along with opioids ([Table 30.4](#)). Adjuvant medications include antidepressants and anticonvulsants such as gabapentin and amitriptyline. Adjuvant analgesics can be very effective for neuropathic pain but may not be as effective for somatic or visceral pain (Jacques, 2022).

Drug Name	Administration Considerations	Adjuvant Effect	Adverse/Side Effects
Amitriptyline	<ul style="list-style-type: none"> <li>• Boxed warning: Increased risk of suicidality</li> <li>• Taper dose when discontinuing; do not stop abruptly</li> <li>• Monitor orthostatic blood pressures and consider fall risk precautions</li> </ul>	Decrease feelings of chronic pain	<ul style="list-style-type: none"> <li>• Immediately report signs or symptoms of suicidality</li> <li>• Anticholinergic effects</li> <li>• Hypotension</li> <li>• May lengthen QT interval; risk for arrhythmias</li> <li>• Sedation</li> <li>• Sexual dysfunction</li> <li>• Altered seizure threshold</li> </ul>
Gabapentin	<ul style="list-style-type: none"> <li>• Administer first dose at bedtime to decrease dizziness and drowsiness</li> <li>• Monitor for worsening depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior</li> <li>• Taper dose; do not stop abruptly</li> </ul>	Decreased neuropathic pain	<ul style="list-style-type: none"> <li>• Increased suicidal ideation</li> <li>• Immediately report fever, rash, and/or lymphadenopathy</li> <li>• CNS depression: dizziness, somnolence, and ataxia</li> </ul>

**TABLE 30.4** Commonly Used Adjuvant Analgesics

Drug Name	Administration Considerations	Adjuvant Effect	Adverse/Side Effects
Prednisone	<ul style="list-style-type: none"> <li>• Never abruptly stop corticosteroid therapy</li> <li>• Use the lowest dose possible to control disorder and taper when feasible</li> <li>• May require concurrent treatment for osteoporosis or elevated blood glucose levels</li> <li>• Regularly monitor for development of symptoms of adrenal suppression</li> <li>• Contraindicated in patients with untreated systemic infections</li> </ul>	Reduce inflammation	<ul style="list-style-type: none"> <li>• Fluid and electrolyte imbalances</li> <li>• Increase in blood glucose</li> <li>• Muscle weakness</li> <li>• Peptic ulcers</li> <li>• Thin, fragile skin that bruises easily</li> <li>• Poor wound healing</li> <li>• Development of Cushing syndrome</li> <li>• May mask some signs of infection, and new infections may appear</li> <li>• Psychic derangements may appear when corticosteroids are used, ranging from euphoria, insomnia, mood swings, personality changes to severe depression</li> </ul>

**TABLE 30.4** Commonly Used Adjuvant Analgesics

Drug Name	Administration Considerations	Adjuvant Effect	Adverse/Side Effects
Baclofen	<ul style="list-style-type: none"> <li>• Given parenterally and orally</li> <li>• Administer orally with milk or food to minimize gastric upset</li> <li>• Assess for muscle spasticity before and during therapy</li> <li>• Observe patient for drowsiness</li> <li>• For intrathecal administration, monitor patient closely during test dose and titration and have resuscitative equipment available</li> </ul>	Relieve muscle spasms and spasticity	<ul style="list-style-type: none"> <li>• Drowsiness</li> <li>• Confusion</li> <li>• Dizziness or lightheadedness</li> <li>• Nausea</li> <li>• Constipation</li> <li>• Muscle weakness</li> </ul>
Lidocaine topical	<ul style="list-style-type: none"> <li>• Given topically on the skin; can be in the form of a cream, ointment, or patch</li> <li>• Patches should not be worn for more than twelve hours in a twenty-four-hour period</li> </ul>	Relieve local pain	<ul style="list-style-type: none"> <li>• Headache</li> <li>• Vomiting</li> <li>• Irritation at site</li> <li>• Numbness</li> <li>• Sudden dizziness or drowsiness</li> <li>• Confusion</li> <li>• Speech or vision problems</li> <li>• Tinnitus</li> <li>• Severe allergic reaction, such as hives, dyspnea, and angioedema of the face, lips, tongue, or throat</li> </ul>

**TABLE 30.4** Commonly Used Adjuvant Analgesics

Antidepressants can help control how pain signals are delivered to and processed by the brain. Amitriptyline is a tricyclic antidepressant that can help treat neuropathic pain. Amitriptyline can cause sedative effects, so it is usually administered at bedtime. Anticonvulsants can block certain types of pain signals and help decrease neuropathic pain (Jacques, 2022). Gabapentin is an anticonvulsant that can also treat neuropathic pain and restless leg syndrome. Side effects of gabapentin include mental health changes, drowsiness, and weakness.

Other medications such as corticosteroids, muscle relaxants, and topical agents can also help reduce pain. Corticosteroids decrease inflammation and topical agents can be directly applied to the skin to decrease pain (Jacques, 2022). Adjuvant analgesics can help reduce pain in a variety of ways but are not always effective on their own.

### Nonpharmacological Therapy

A type of therapy called **nonpharmacological therapy** can be very effective when used in conjunction with pharmacological therapy. The Joint Commission recommends that healthcare providers use at least one

nonpharmacological pain intervention when creating a pain treatment plan (The Joint Commission, 2020). Nonpharmacological therapy is any intervention that helps reduce pain without using medication. Nonpharmacological therapy can include psychological, emotional, and environmental therapies.

Psychological and emotional therapies can be incorporated into the daily lives of patients and can be especially useful in treating chronic pain. Psychological and emotional therapy can include relaxation techniques, music, breathing, art therapy, distraction, meditation, or cognitive behavioral therapy. Changing the environment can also help patients manage their pain. Adjusting lighting, sounds, and temperature to a more relaxing environment has been shown to reduce pain (Ford, 2019). Exercise and physical therapy can also help reduce pain without the side effects of pharmacological therapy. Patients can easily incorporate nonpharmacological therapy such as physical therapy into their daily lives without risks.

### Physical Therapy

Many healthcare providers prefer using **physical therapy** over pharmacological therapy when treating pain (Nall, 2021). Physical therapy involves working with a trained professional to use exercise and movement to improve strength and flexibility. Physical therapy can help chronic conditions such as arthritis, nerve pain, and fibromyalgia ([Figure 30.10](#)) (Nall, 2021).

**FIGURE 30.10** Physical therapy and movement can help patients feel more relaxed and reduce pain through improved strength and flexibility. (credit: “Naval Hospital Jacksonville Physical Therapy 220926-N-QA097-055” by Navy Medicine/Flickr, Public Domain)

Research shows that physical therapy and exercise improves mobility and overall quality of life (Nall, 2021). Physical therapy and exercise can also lead to weight loss, which can reduce joint and back pain. Exercise can also promote relaxation and stress reduction. Yoga combines movement with breathing and meditation. Yoga can help

improve strength, balance, flexibility, and mental health (Nall, 2021).

Physical therapy and exercise do not need to be intense or complicated to be effective. Nurses should educate patients about easy ways to incorporate movement into their daily lives and can help patients find a level of physical therapy that works for them.

### Massage

Massages can help relax patients and provide pain relief by loosening tight muscles. A **massage** is a form of therapeutic touch where a therapist uses touch and pressure to loosen tight muscles and tendons. Touch and pressure block pain signals, which relieves pain and improves the blood flow to tight muscles, which in turn can promote relaxation (Nall, 2021).

Patients should be cautious with massages if they have a skin rash, infection, certain cardiovascular diseases, or are pregnant. Otherwise, there are minimal risks and side effects with massage (Nall, 2021). Sometimes, patients may experience pain during the massage due to the intense pressure of the therapist. Nurses can educate patients to ask their massage therapist to use varying amounts of pressure to provide relaxation and pain relief.

### Guided Imagery

A relaxation technique called **guided imagery** can help ease pain and promote relaxation. It is a technique that uses images or scenes to invoke positive and relaxing feelings. The goal of guided imagery is to stimulate natural relaxation responses to reduce pain, slow breathing, decrease blood pressure and heart rate, and decrease feelings of stress (West, 2022).

Guided imagery can be done with or without direction. Once patients are familiar with guided imagery practice, it is easy to incorporate it into their daily lives. Guided imagery consists of imagining anything the patient deems as relaxing or calming. For example, a patient may imagine being on the beach on a warm, sunny day and listening to the ocean sounds. Another patient may imagine their body fighting off cancer or a chronic illness and being able to function without pain. The image can be whatever the patient chooses, but they should try to engage all their senses during guided imagery (West, 2022). Patients can also use a therapist, an audio recording, or an app to direct them through guided imagery.

The process of guided imagery includes the following steps:

1. Choose a quiet place without distractions.
2. Get in a comfortable position and close your eyes.
3. Focus on whatever image you choose and engage all your senses.
4. Continue to add more details to the scene and visualize the scene for as long as is needed.
5. Gradually open your eyes and reengage with the present environment (West, 2022).

Guided imagery can be especially helpful in patients with chronic pain. Patients who experience pain on a daily basis often seek alternative therapies to help manage their pain. Guided imagery can be an easy method for patients to incorporate into their daily lives and on the go.

## LINK TO LEARNING

[Guided imagery scripts \(https://openstax.org/r/77gdimagescpt\)](https://openstax.org/r/77gdimagescpt) can be used to help promote relaxation and reduce pain. Guided imagery scripts can be tailored toward specific scenarios, such as sleep promotion, pain reduction, or reducing panic attacks.

### Distraction

Another important tool for nurses to use in pain management is **distraction**. Distraction is a method that moves patients' attention away from pain (Ibitoye et al., 2019). Distraction moves patients' attention away from pain by modifying the nociceptive responses to decrease pain. Methods of distraction include music, videos, conversation, games, interactive toys, and controlled breathing. Music specifically can help reduce pain and relax patients. Music is often used as a pain reduction tool before, during, and after surgery. Research has found that listening to music when having surgical procedures can help reduce anxiety and pain (Nall, 2021).

Distraction can especially help reduce pain in pediatric patients. Blowing bubbles, playing games, and watching videos can help reduce anxiety and pain in children. Younger children are more easily distracted, and more invasive interventions can often be avoided if distraction is used effectively in pain management (Trottier et al., 2019).

### Biofeedback

Biofeedback is a technique that uses visual or auditory feedback to control bodily functions such as heart rate and breathing patterns. During **biofeedback** therapy, sensors are used to measure bodily functions and show changes with different adjustment methods. When the body is in pain, physical factors such as heart rate, respiratory rate, and muscle contraction can change. Biofeedback helps a patient recognize these changes and make a conscious effort to relax. Decreasing heart rate and respiratory rate, as well as relaxing muscles, can help stimulate pain reduction in patients. Patients who experience chronic pain are ideal candidates for biofeedback therapy, as patients typically need multiple sessions to see results. Biofeedback is a popular nonpharmacological pain intervention due to its minimal risk and side effects (Mayo Clinic staff, 2023).

Biofeedback machines are available in physical therapy clinics, hospitals, and outpatient clinics. Some biofeedback machines are now available for home use. During biofeedback therapy, electrical sensors will monitor brain waves, body temperature, muscle contraction, heart rate, and respiratory rate. A healthcare provider will monitor these sensors and make suggestions to the patient to try to alter these bodily functions. Over time, the patient can learn to make these alternations without monitoring (Mayo Clinic, 2023).

### Patient-Controlled Analgesia

Hospitalized patients with severe pain may receive **patient-controlled analgesia (PCA)**, which allows the patients to safely self-administer opioid medications using a programmed pump. PCA is used to treat acute, chronic, labor, and postoperative pain. A computerized pump contains a syringe of opioid analgesics and is connected directly to a patient's intravenous (IV) line. Doses of medication can be self-administered as needed by the patient by pressing a button. However, the pump is programmed to only allow administration of medication every set number of minutes with a maximum dose of medication every hour. These pump settings, and the design of the system requiring the patient to be alert enough to press the button, are safety measures to prevent overmedication that can cause sedation and respiratory depression. For this reason, no one but the patient should press the button for administration of medication (not even the nurse). In other cases, the PCA pump delivers a small, continuous flow of pain medication intravenously with the option of the patient self-delivering additional medication as needed, according to the limits set on the pump. PCA is useful for patients who have acute pain due to conditions such as trauma, burns, or pancreatitis (Pastino & Lakra, 2023). Patients with mild chronic pain may be good candidates for PCA.

## REAL RN STORIES

---

### Managing a PCA Pump for the First Time

**Nurse:** David, BSN

**Clinical setting:** Medical ICU

**Years in practice:** 1

**Facility location:** Hospital in a small town in Nevada

I had just started working in the medical ICU at my hospital as a new graduate nurse. Our orientation was about ten weeks, and I was almost to the end of my orientation. I was working with my preceptor but was pretty much doing everything on my own at that point.

We would occasionally get postsurgical patients, and that day I was assigned my first postsurgical patient. I was told this patient had undergone surgery to repair a femur fracture and would be in traction and have a PCA. The patient was coming to the ICU from the operating room (OR) in the next thirty minutes. I was very nervous, but my preceptor reassured me that I could handle this patient assignment.

When the patient arrived, they were screaming in pain and had wires and lines everywhere from the OR. Together with my preceptor and charge nurse, we quickly got the patient into the room and connected to the monitors. We

surveyed the lines and verified the medications that were currently running. The OR nurse and anesthesia gave a quick report as they “had to get moving on the next case.” I was surprised that I did not get a chance to ask any questions. My preceptor said that often happens with postsurgical patients and we can always call the OR if we have questions later.

I then went to look at my patient’s PCA pump. I was nervous because I had never seen a PCA pump and was not sure what it was. I remember hearing about them in nursing school but had no clue what I was supposed to do with it. My preceptor helped me look up the medication dose and rate in the MAR and showed me how to verify that the pump was set to the correct dose. She showed me how to document the dual nurse sign-off and the volume remaining in the pump. She then told me it was important to ensure the patient knew how to use the pump. The patient was fully awake from anesthesia and was able to answer our questions appropriately. My preceptor told me that you cannot let a confused or sedated patient use a PCA pump because they cannot always understand how it works. The patient verbalized our teaching and answered our pain assessment questions.

Throughout the rest of my shift, I frequently checked the PCA and the patient’s pain levels. The patient expressed minimal pain throughout my shift and used the PCA periodically. I was shocked that the PCA managed to control the patient’s pain so well right after surgery. My preceptor explained that PCA was a common form of pain management after surgery because it works so well. Even though setting up and managing the PCA was scary, I am glad I had the experience and the support of my preceptor to learn a new skill.

---

### Benefits of PCA

The ability of the patient to self-administer pain medication has been shown to increase patient satisfaction and deliver timely pain interventions (Pastino & Lakra, 2023). It also reduces the stress of the nurse and patient of having to adhere to a dosing schedule of PRN analgesics that may not be adequate to treat the patient’s pain. PCA may be a good option for patients who are unable to tolerate oral pain medications or for patients who have breakthrough pain and need frequent dosing. The patient can time their own medication according to the pain severity for better pain reduction and control.

### Nursing Considerations for PCA

PCA pumps must have certain orders relating to the bolus dose, basal rate, and lockout time. The bolus dose is the dose that the patient receives each time they press the button on the PCA pump and is used for breakthrough pain. The **basal rate** is the continuous rate of the medication that maintains effective pain management. The lockout time is the amount of time after a bolus dose that the pump will not administer medication to the patient, even if they press the button, to prevent overdose. The PCA doses may be dependent on the type of medication, IV site, patient’s weight, current research, and facility guidelines (Pastino & Lakra, 2023). It is important to review your facility’s guidelines when programming PCA dosing.

There are contraindications for PCA. If the patient cannot understand how the PCA works and follow directions, they would not be good candidates for PCA. Allergies, infection, increased intracranial pressure, chronic kidney failure, and bleeding disorders are also contraindications for PCA (Pastino & Lakra, 2023).

Side effects of PCA use are the same as opioids and include constipation, nausea and vomiting, urinary retention, and pruritus (itching). The most serious potential adverse effect of opioids is respiratory depression. Respiratory depression is usually preceded by sedation. The nurse must carefully monitor patients receiving opioids for oversedation, which results in decreased respiratory rate. Patients at greatest risk are those who have never received an opioid and are receiving their first dose, those receiving an increased dose of opioids, or those taking benzodiazepines or other sedatives concurrently with opioids. If a patient develops opioid-induced respiratory depression, the opioid is reversed with naloxone (Narcan) that immediately reverses all analgesic effect.

Nurses must follow facility guidelines when administering PCA and ensure that the pump is set up correctly. Many facilities have safeguards in place such as a dual nurse sign-off, scanning medications into the electronic medication administration record (eMAR), and guardrails on the pumps to prevent medication errors. To document the amount and frequency of pain medication the patient is receiving, as well as to prevent drug diversion, the settings on the pump are checked at the end of every shift by the nurse as part of the bedside report. The incoming and outgoing nurses double-check and document the pump settings, the amount of medication administered during the previous shift, and the amount of medication left in the syringe.

## UNFOLDING CASE STUDY

### Unfolding Case Study #4: Part 9

Refer back to [Unfolding Case Study #4: Part 8](#) for a review on the patient data.

Nursing Notes	<b>1800:</b> Focused pain assessment performed. Patient reports lower back pain rated 7/10 on numerical pain scale that began last night. Patient states, "I think it's coming from the hospital bed because I can't get comfortable." Patient reports the pain is worse with immobility but improves slightly with ambulation.
Provider's Orders	<b>1830: New orders</b> <ul style="list-style-type: none"><li>• Ketorolac (Toradol) 15 mg IV Q6 hours PRN severe pain</li><li>• Physical therapy referral</li></ul>

4. Generate solutions: What is the rationale for each of the provider's orders?
5. Take action: After administering the ketorolac as prescribed, what adverse effects will the nurse monitor for? What assessment findings might indicate the patient is experiencing these adverse effects?
6. Evaluate outcomes: What assessment findings would indicate effectiveness of the interventions performed?

## Summary

### 30.1 The Pain Process

Pain can be classified and described in many different ways. The duration, location, and cause are all important factors when assessing and treating pain. The physiologic process of pain describes how the brain is alerted to painful stimuli and how it can modify and adjust the amount of pain that is felt in the body. Biological, psychological, and social factors can affect the perception of pain and impact how patients react. The central nervous system can also determine which pain signals are allowed through to the brain. This gate control theory can help nurses understand how pain is perceived under different circumstances.

Nurses must be aware of the factors that can affect pain and patients' perceptions of pain. One patient may perceive pain differently than another patient does, but both are right in their assessment. Nurses must accept the pain as whatever the patient says it is and individualize pain management strategies for each patient.

### 30.2 Responses to Pain

Physiologic, behavioral, and emotional responses to pain are the brain's way of keeping the body safe in signs of danger. The sympathetic and parasympathetic nervous systems allow the body to initiate responses that either fight or run away from a perceived threat. Behaviors, emotions, and vital sign changes such as elevated blood pressure, heart rate, and respiratory rate can all be ways that patients express signs of pain.

Behavioral and emotional responses to pain can vary among patients. Some patients may vocalize their pain or express body movements and social interactions that demonstrate pain. Some patients may experience negative emotions such as fear and anxiety when dealing with pain. Nurses must be aware of all physiologic responses to pain and know that these responses can vary greatly among patients. Physiologic responses to pain are involuntary and are often the first reaction a patient will have to pain. These responses can help healthcare providers assess pain and develop effective strategies for managing pain.

### 30.3 Factors Affecting Pain

There are many factors that play a role in pain. Psychosocial factors can influence a patient's perspective on pain. A patient who associates pain with trauma may have a hard time coping with chronic pain. Physiological factors such as developmental level and age can change a patient's perception and expression of pain over time. A patient's psychological view of pain can influence how effective pain management strategies can be. A patient who catastrophizes their pain may have worse outcomes than a patient who expects their pain medication to be effective. Nurses play an important role in educating patients about these factors. Patients' awareness of these factors and their effect on pain can make a big difference in pain management outcomes.

### 30.4 Pain Assessment

A comprehensive pain assessment must include subjective and objective data. Collecting subjective data involves choosing an appropriate pain rating scale, asking open-ended assessment questions, and accepting the pain is whatever the patient says it is. Collecting objective data involves performing a physical assessment, measuring vital signs, and assessing nonverbal behavior. Each pain assessment may have different ways of collecting subjective and objective data. The nurse should choose the pain assessment tools that are appropriate for each patient.

Pain assessments, interventions, and evaluations should be performed and documented in a timely manner to ensure adequate pain relief is achieved. Documentation of pain management ensures the patient receives timely and effective treatment. Pain management strategies cannot be deemed effective without comprehensive assessment and documentation. Pain management is an ongoing concern for patient care, and a quality pain assessment is the first step to effective pain relief.

### 30.5 Pain Management

There are many different types of interventions that can be used for pain management. Pain management should always include patient involvement and a combination of nonpharmacological and pharmacological interventions. Nurses have a responsibility to provide adequate pain management to all patients and will encounter pain in all types of healthcare settings.

Pharmacological therapy can be very effective in managing pain but must be used with caution. There are many risks and side effects, especially with opioid analgesics. Nurses must be aware of the risks and ensure patients are educated on appropriate dosing and monitoring when taking these medications. Patient-controlled analgesia (PCA) can also be an effective way to manage pain and involve the patient in their care. However, PCA is also not without risks. Nurses must be vigilant when monitoring a patient receiving PCA and ensure the patient meets criteria to be able to understand how to use PCA.

Nonpharmacological therapy can also be an effective pain management strategy, especially when paired with pharmacological therapy. Interventions such as physical therapy, guided imagery, and distraction can be effective pain management strategies without the same risks as pharmacological therapy. Nonpharmacological pain interventions have been shown to be effective in treating all types of pain and allow patients to avoid the side effects and risk of chronic issues such as addiction and overdose from opioid analgesics. Being aware of all types of pain management strategies is essential for all nurses and helps nurses effectively manage pain.

## Key Terms

**acute pain** pain that is short in duration and caused by an acute event

**adjuvant analgesic** medication that is not classified as an analgesic but has been found to have an analgesic effect with opioids

**affective response** the emotional interpretation of pain, such as how uncomfortable the pain is

**algophobia** the extreme fear of pain

**analgesic** medication used to relieve pain

**basal rate** the continuous rate of the medication that maintains effective pain management

**biofeedback** a technique that uses visual or auditory feedback to control bodily functions such as heart rate and breathing patterns

**breakthrough pain** pain that persists along with chronic pain even with pain interventions

**catastrophizing** picturing the worst possible outcome for a situation

**chronic pain** pain that persists for longer than three months

**cutaneous pain** pain that is perceived from the skin and caused by heat, cold, or mechanical or chemical stimuli

**distraction** a method that moves patients' attention away from painful stimuli

**etiology of pain** the specific cause of pain

**fight-or-flight response** the automatic response from the sympathetic nervous system to a perceived stressful or dangerous situation, which triggers the body to either run away from or fight the perceived threat

**first line therapy** medical treatment that is recommended as the best option for the initial treatment of a disease or medical condition

**guided imagery** a relaxation technique that uses images or scenes to invoke positive and relaxing feelings

**idiopathic pain** chronic pain from an unknown origin

**massage** a form of therapeutic touch where a professional uses touch and pressure to loosen tight muscles and tendons

**McCaffrey Initial Pain Assessment Tool** a pain assessment tool that uses visual aids and questions including elements of the PQRSTU mnemonic to provide a comprehensive pain assessment

**modification of pain** a change by the brain in the intensity of the pain signal based on the situation that originated the pain signal

**neuropathic pain** pain caused by neurological damage or dysfunction

**neurotransmitter** a chemical that carries messages between neurons to communicate throughout the body

**nociception** the process by which painful stimuli are detected by nociceptors and send the pain signals from the peripheral nervous system to the brain

**nociceptive pain** pain that originates in the peripheral nervous system from stimulation by heat, cold, or mechanical or chemical stimuli

**nociceptor** a type of sensory receptor in the peripheral nervous system that responds to potentially damaging stimuli by sending nerve signals to the central nervous system

**nonopioid analgesic** medication, including nonsteroidal anti-inflammatory drugs (NSAIDs), used for acute and chronic pain relief

**nonpharmacological therapy** interventions that reduce pain without using medication

**nonsteroidal anti-inflammatory drug (NSAID)** medication that provides mild to moderate pain relief while also

reducing fever and inflammation by inhibiting the production of prostaglandins

**opioid analgesic** powerful prescription medication that helps reduce pain by blocking pain signals

**patient-controlled analgesia (PCA)** a form of pain medication administration that allows hospitalized patients with severe pain to safely self-administer opioid medications using a programmed pump

**pharmacological therapy** the use of medication to treat a disease, illness, or medical condition

**physical dependence** a condition in which a patient experiences physical symptoms of withdrawal when stopping a medication

**physical therapy** the use of exercise and movement to improve strength and flexibility

**physiologic response** the body's involuntary response to a stimulus such as inflammation or changes in heart rate and blood pressure

**placebo effect** an improvement in a condition, such as the lessening of pain, that occurs due to the patient believing a treatment will be effective

**post-traumatic stress disorder (PTSD)** a psychiatric disorder in which a person experiences lingering effects triggered by a past traumatic event

**referred pain** pain perceived at a location other than the site originating the painful stimulus

**somatic pain** pain that originates in ligaments, tendons, bones, blood vessels, and muscles

**tolerance** a decrease in the effectiveness of a drug over time due to repeated use

**transduction of pain** the starting point of the pain process when stimuli activate nociceptors to alert the brain

**transmission of pain** the second step of the pain process when the pain signal is sent from the peripheral to the central nervous system

**visceral pain** pain that is activated when internal organs such as the stomach and kidneys are damaged

**vocalization** the use of sounds, noises, and words to express pain

**Wong-Baker FACES Pain Rating Scale** a visual pain assessment tool using drawings of different faces exhibiting increasing levels of pain

## Assessments

### Review Questions

- What step in the pain process involves the gate control theory of pain?
  - transduction of pain
  - transmission of pain
  - perception of pain
  - modification of pain
- The nurse is providing a class to nursing students on chronic pain management. What example describes chronic pain?
  - a patient admitted to the hospital for a femur fracture
  - a patient experiencing back pain from a car accident last year
  - a patient receiving first aid for burning their hand on the stove
  - a patient experiencing a ruptured aneurysm
- A patient is complaining of right ankle pain that feels “dull and aching.” The nurse documents this as what type of pain?
  - cutaneous
  - visceral
  - somatic
  - referred
- The nurse is providing a class to nursing students about pain. How would the nurse define pain to the students?
  - an unpleasant sensory and emotional experience associated with actual or potential tissue damage
  - an objective experience that is defined by a pain rating scale
  - an unpleasant sensation that can only be treated with medications

- d. an unpleasant sensation for a short duration and in a specific location
5. The nurse is caring for an older adult patient who has been experiencing back pain. The nurse asks the patient to rate their pain and the patient states “I am not in pain. I am fine.” The nurse knows the patient could have what factor impacting their perception of pain?
- medical diagnosis
  - culture
  - age
  - cognitive function
6. The nurse is explaining the sympathetic response to pain to a student who has just started their orientation in the emergency department. What statement does the nurse make about the sympathetic response to pain?
- “It is an involuntary reaction to pain that keeps the body safe from danger.”
  - “It helps the body relax and rest after perceived pain.”
  - “It involves facial expressions and vocal expressions of pain.”
  - “It can include emotions such as fear and anxiety in connection to pain.”
7. The nurse is caring for an infant patient and knows what physical response or sign is most likely going to be present in an infant in pain?
- increased blood pressure
  - decreased heart rate
  - crying
  - withdrawal from touch
8. The nurse is caring for a patient experiencing chronic pain due to bladder cancer treatment. The nurse knows the patient is at risk for what type of behavioral response to pain?
- vocalization of pain
  - social withdrawal
  - algophobia
  - catastrophizing
9. A patient dealing with chronic pain is seeking help with their anxiety. The patient states “My anxiety has gotten so much worse since this pain began.” The nurse can make what recommendation to the patient to treat anxiety in chronic pain?
- cognitive behavioral therapy
  - opioid analgesics
  - avoiding potential painful situations
  - treating the chronic pain
10. The nurse is teaching a class on pain management and is discussing the physiologic response to pain. What would the nurse state is a sign of the sympathetic response to pain?
- lowering blood pressure
  - directing the pancreas to create insulin
  - slowing digestion
  - constricting pupils to limit light
11. The nurse is caring for a patient who is struggling to cope with their chronic pain from cancer treatment. The nurse knows what factor can make a positive difference in the patient’s perception of pain?
- strong social support
  - quitting their job
  - avoidance
  - catastrophizing

- 12.** The nurse is caring for a preschool-aged patient who is admitted for abdominal pain. How would the nurse expect the patient to express their pain?
- catastrophizing
  - accepting the pain is normal
  - physical resistance and anger
  - appear quiet and reserved
- 13.** What is the definition of the placebo effect?
- when a patient thinks of the worst possible outcome for their pain
  - when pain intervention proves to be effective because the patient believed it would be
  - when the patient experiences extreme physical or mental suffering
  - when the patient experiences pain because they expect it
- 14.** The effect of trauma on the perception of pain is what type of factor?
- psychological
  - psychosocial
  - physiological
  - cultural
- 15.** The nurse is caring for an 80-year-old patient who has come into the emergency room to be monitored after a fall at home. The nurse knows the patient is at risk for what factor impacting their pain?
- age
  - trauma
  - distress
  - expectation
- 16.** A 40-year-old patient diagnosed with congestive heart failure is laughing and eating dinner with his visiting family. When asked to rate his pain on a numeric rating scale, the patient rates his pain as an 8 out of 10. What would the nurse conclude is the patient's pain rating?
- It is what the patient says it is.
  - It is less severe due to the patient's behaviors.
  - It is in anticipation of future pain.
  - It is not accurate and the patient is exhibiting drug-seeking behaviors.
- 17.** A patient comes to the emergency department with reports of decreased physical mobility, nausea, lack of appetite, and a "strange ache" in her back. What is the nurse's initial focus?
- starting IV fluids for dehydration
  - performing a comprehensive pain assessment
  - ordering a physical therapy evaluation
  - administering antiemetic medications
- 18.** The nurse notices a 6-year-old patient grimacing and moaning as he walks to the bathroom. The patient does not respond when the nurse asks the patient to rate his pain on the numeric rating scale. What is the nurse's response?
- Accept the patient's lack of response as an indication of no pain.
  - Clarify the patient's pain rating using the FACES Pain Scale.
  - Ask the patient's parents to rate his pain.
  - Ask the patient to rate his pain using the same scale again.
- 19.** For a patient who is cognitively impaired and cannot use a pain scale, what vital sign changes may indicate the patient is experiencing pain?
- decreased blood pressure
  - decreased respiratory rate

- c. increased heart rate
  - d. increased oxygen saturation
- 20.** What should the nurse document when evaluating an intervention for pain?
- a. current pain level and any symptoms
  - b. vital signs
  - c. head-to-toe assessment
  - d. skin assessment
- 21.** What is biofeedback therapy used for?
- a. controlling bodily functions such as heart rate to decrease pain
  - b. controlling pain using a programmed pump
  - c. decreasing pain through exercise and movement
  - d. decreasing pain through positive imagery
- 22.** The nurse is caring for a patient who was recently prescribed opioids following surgery. What is the best nursing intervention to prevent the side effect of constipation?
- a. increasing fluids and exercise
  - b. monitoring for respiratory depression
  - c. using stool softeners as needed
  - d. increasing the patient's diet to promote motility
- 23.** The nurse is caring for a patient with pancreatitis that has been unable to take oral pain medications. What is the best action for the nurse?
- a. administering antiemetic medication
  - b. using massage as a pain intervention
  - c. initiating biofeedback therapy
  - d. requesting a PCA order from the practitioner
- 24.** The patient states they have been consuming acetaminophen frequently for the past several days to reduce their back pain. What side effect would the nurse be concerned about?
- a. gastrointestinal bleeding
  - b. liver damage
  - c. respiratory depression
  - d. constipation
- 25.** What safeguard should the nurse initiate to prevent medication errors when caring for a patient receiving a patient-controlled analgesic?
- a. checking the pump settings with the oncoming nurse
  - b. decreasing the patient's dose to prevent side effects
  - c. monitoring the patient for respiratory depression
  - d. ensuring the pump alarms are at full volume

### Check Your Understanding Questions

1. Describe the steps of how a pain stimulus travels to and is perceived by the brain.

Review the following examples of behavioral responses to pain and identify which type of behavioral response is being demonstrated.

2. An infant crying in their mother's arms after being fed and changed.
3. A patient sitting in the waiting room with their eyes closed and jaw clenched.
4. A patient complaining of knee pain but refusing to let the nurse examine the knee.
5. When conducting a thorough pain assessment, what questions should be asked in addition to using a numeric rating scale?

## Reflection Questions

1. Using the gate control theory of pain, what nursing interventions would be effective for a patient with back pain?
2. What background information might you want to know about your patient who is a veteran complaining of chronic pain?
3. What information would the nurse need to determine pain in a patient who is unable to state their pain rating?

## Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #4: Part 8](#).  
What changes to the patient's vital signs might indicate pain?
2. Refer to [Unfolding Case Study #4: Part 9](#).  
What other nonpharmacological interventions could the nurse use to improve the patient's pain?

## What Should the Nurse Do?

The nurse is caring for a patient who has arrived in the emergency room complaining of pain. The nurse brings the patient into an exam room to begin the assessment. The patient is frowning and is guarding their stomach. The patient states their pain began two hours ago and is “killing me.”

1. What information would the nurse want to know to identify the type of pain the patient is experiencing?
2. What tools and questions could the nurse ask to get more information about the patient's pain?
3. Based on this information, what type of pain do you think the patient is experiencing?
4. The nurse is caring for a patient who is admitted for abdominal pain. The patient's 0800 vital signs were as follows: heart rate 70 bpm, respiratory rate 14 bpm, blood pressure 110/75, oxygen saturation 98 percent on room air. The nurse enters the room for the 0900 assessment and the patient is complaining of pain. The nurse notes the patient's vital signs are now: heart rate 118 bpm, respiratory rate 20 bpm, blood pressure 164/80, oxygen saturation 96 percent on room air. What should the nurse do next?
5. The nurse is caring for a patient who is admitted for ongoing abdominal pain. The patient has just been diagnosed with pancreatic cancer and has a history of high blood pressure, diabetes, and depression. The patient has been in the hospital for several days and has just started chemotherapy. The nurse is educating the patient on the possible side effects of the medication and notes the patient appears quiet and withdrawn. The nurse notes that there is no family at the bedside. The nurse asks the patient if there is anything wrong. The patient starts crying and states “I just don't know how I am going to survive all of this.” What psychosocial factors might affect the patient's perception of pain?

The nurse is caring for an older adult patient with a history of arthritis who is complaining of chronic joint pain in their knees.

6. What pharmacological interventions could the nurse recommend for this patient?
7. What nonpharmacological interventions could the nurse recommend for this patient?

## Competency-Based Assessments

1. Describe how the nurse would recognize the patient is demonstrating a physiologic pain response.
2. Develop a comprehensive pain assessment, including subjective assessment questions and objective assessment criteria, for an adult patient with a history of pancreatitis who is admitted for abdominal pain.
3. Describe the process of the dual nurse sign-off when verifying the patient-controlled analgesic (PCA) pump and how to monitor a patient on a PCA pump for side effects.
4. Describe the appropriate procedure for administering opioid analgesics to a patient.

# CHAPTER 31

## Perioperative Nursing Care

**FIGURE 31.1** Perioperative nursing involves providing safe, competent quality care throughout all stages and phases of the surgical experience to improve patient outcomes. (credit: “Making the cut: Aviano’s surgical team” by Airman 1st Class Ryan Conroy/US Air Force, Public Domain)

### CHAPTER OUTLINE

- 31.1 Surgical Concepts
- 31.2 Preoperative Phase
- 31.3 Intraoperative Phase
- 31.4 Postoperative Phase

**INTRODUCTION** Surgery is an exciting, transformative field that can save lives and improve the quality of a patient’s life. As a nurse providing perioperative care to people undergoing surgery, your most critical responsibility is to work with the other members of the perioperative team to provide a safe and positive surgical outcome for the patient. Another important role is to ensure that the perioperative process is as efficient as possible for all members of the healthcare team.

To provide the best possible care, you need to understand the art and science of surgery. This chapter provides an overview of surgical concepts as well as a discussion of the three stages of perioperative nursing care: preoperative, intraoperative, and postoperative. In this chapter, you learn the important role of the perioperative nurse in providing safe and effective care throughout all stages of the patient’s experience in collaboration with the surgical team.

It is also important to keep in mind that surgery can be a very emotional experience for patients. Often, you will encounter patients who are anxious or afraid. By providing care that is compassionate, competent, and culturally aware, you can help put your patients at ease while ensuring positive surgical outcomes.

## 31.1 Surgical Concepts

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify classifications of surgical procedures
- Recognize surgical advancements and trends in today's health care
- Describe the types of anesthesia used in surgical procedures

The **perioperative period**, which includes the time before, during, and after a surgical procedure, is a busy time for nurses. While each point in the patient's surgical journey has its own tasks, needs, and expectations, there are some general concepts related to nursing that the nurse must understand to effectively navigate through each period.

Surgical techniques and technology have advanced at a rapid pace over recent decades. Nurses certainly do not need to be experts on surgical techniques, but keeping a finger on the pulse of surgical innovation is key to staying current with the ever-evolving perioperative landscape. This chapter provides an overview of several important surgical concepts, including classifications of surgical procedures, types of anesthesia used in surgery, and some recent advancements and trends to consider.

Surgery can be broadly classified into four main types: emergent, urgent, expedited, and elective. Performed immediately to save a life, limb, or organ, an **emergent surgery** often requires resuscitation simultaneously with surgery. An **urgent surgery** is not necessarily immediate but is performed as soon as possible to treat a condition with acute onset or clinical deterioration of life or limb or for organ survival. When a patient is stable, an **expedited (scheduled) surgery** requires early intervention for a condition that is not an immediate threat to life or limb or to save an organ but can lead to significant complications and impair quality of life if left untreated. Scheduled in advance, an **elective surgery** is performed to repair injuries or enhance appearance and function.

The types of anesthesia that can be used during surgery also vary. The choice of anesthesia usually depends on the needs of the individual patient, the requirements of the procedure, and the preferences of the surgical team. The most common types of anesthesia include general, monitored anesthesia care (MAC)/moderate sedation, regional, and local. In **general anesthesia**, a patient receives a potent cocktail of intravenous (IV) and inhalation medications that induce a state of controlled, reversible unconsciousness, amnesia, and analgesia with or without reversible muscle paralysis so the patient does not feel any pain during the surgery. General anesthesia induces amnesia (temporary or permanent loss of memory). In **monitored anesthesia care (MAC)/moderate sedation**, a state of drowsiness is induced and anxiety is reduced while allowing the patient to respond to basic commands and breathe on their own during surgery. In **regional anesthesia**, only the area of the body where the surgery is being performed is numbed through spinal or epidural anesthesia; sedation may also be provided. In **local anesthesia**, only a small, specific area of the body where a procedure will be performed is numbed while allowing the patient to remain fully conscious.

Among the many advancements and trends that are currently taking place in the field of surgery, there are a few in particular that warrant discussion. One surgical advance is the increasing use and refinement of **minimally invasive surgery (MIS)**, a technique that uses one or more small incisions or natural body openings, which causes less pain and scarring. It typically has a shorter recovery time; however, MIS still carries some of the risks of traditional surgery.

Another emerging trend is **robotic-assisted surgery**, which is performed with a computer-controlled robot that allows surgeons to make more precise movements. This technique can improve accuracy and reduce the risk of complications but also has limitations and risks. Technological advances (e.g., telesurgery, artificial intelligence [AI]) are also reaching the operating room (OR) and have the potential to change surgical case workflows. With **telesurgery**, surgeons are able to remotely perform surgical procedures from a distance using robotic systems and telecommunication technology. Using **artificial intelligence (AI)** allows a robot or other computer system to perform tasks that typically require human intelligence.

### Classification of Surgery

The world of surgery is a dynamic and multifaceted realm, encompassing a diverse range of procedures aimed at addressing a wide variety of medical conditions. Understanding the nuances of surgical classifications is paramount for healthcare professionals, ensuring precise and tailored patient care.

The **surgeon**, alongside a multidisciplinary team, considers factors such as patient health, urgency, and the complexity of the procedure when determining the most appropriate surgical approach. Moreover, patient education plays a crucial role in the decision-making process. Transparent communication regarding the nature of the surgery, potential risks, and expected outcomes empowers patients to actively participate in their healthcare journey.

### Emergent Surgery

Imagine a scenario in the emergency department in which a patient presents with a life-threatening hemorrhage that requires immediate intervention or a pregnant person presents with fetal distress. These are situations in which the clock ticks relentlessly, where minutes or even seconds can mean the difference between life and death. Emergent surgery is performed without delay to address critical situations. Emergent surgeries require rapid decision-making and seamless collaboration between all members of the perioperative team. In these uncertain situations, nurses must be prepared to respond immediately to get the patient into the **operating room (OR)** as rapidly as possible. The focus is on immediate stabilization and survival, with little room for delay or meticulous planning. Examples of emergent surgeries include the following:

- Trauma surgery: This field encompasses a range of interventions to repair injuries sustained in accidents, violence, or other traumas, often requiring immediate action to prevent further complications and preserve vital functions.
- Emergency cesarean delivery: When vaginal delivery is deemed unsafe for the birthing parent or child because of complications (e.g., fetal distress, placental abruption), an emergency cesarean delivery becomes the lifesaving intervention for both birthing parent and child.

Balancing the nurse's role as a member of the care team with their responsibilities to the patient during this time-intensive process can be challenging. However, it is integral that the nurse participates in clear, effective, transparent communication with the team, the patient, and the family members. One responsibility of the nurse is to provide support to the patient's loved ones during this confusing and uncertain period, if at all possible. With compassion and clarity, the nurse can guide a patient's family through the whirlwind they are experiencing. If critical patient care precludes the nurse from providing this support, the nurse should call for administrative nursing support.

### Urgent Surgery

An urgent surgery is when an acute condition has occurred, or there is clinical deterioration of life or limb, or organ survival is at risk. Typically, urgent surgery occurs within hours of the decision to operate, and if resuscitation was required, it has been performed and resolved. Examples of urgent surgery include wound debridement plus fixation of a fracture or an exploratory **laparotomy** (a surgical procedure where a large incision is made in the abdomen to expose the abdominal cavity) for bowel perforation or other injuries.

## REAL RN STORIES

---

### Every Second Counts

**Nurse:** Cheri, BSN

**Clinical setting:** Emergency department

**Years in practice:** 4

**Facility location:** New York City

A few weeks ago, I was working in the emergency department (ED) when a teenager was brought in after a motor vehicle accident (MVA). Trying to obtain the pertinent details about the MVA from the emergency medical services (EMS) team was difficult because the patient was screaming as they rolled him in on the stretcher. His leg was visibly deformed and obviously fractured. I also observed the patient appeared to be in excruciating pain, terrified, and possibly in shock. Trying to listen as EMS gave me the information I needed while simultaneously assessing the patient was challenging. In those hectic moments, I recalled my father's advice to "stay cool as a cucumber." In the ED, you see a lot of life-and-death situations, but there are also moments when you know that even if a patient survives a trauma, their life may never be the same again.

I didn't know if the surgical team would be able to save the teenager's leg, but I knew that my job was to get him

stable enough for them to try. I quickly assessed him and got IV fluids started, then made sure we communicated to the OR that an orthopedic surgical consult was urgently needed and that we were prepping the patient for transfer to the OR. I knew those minutes would feel agonizingly slow for the young man. I tried to reassure him, but I could see the fear in his eyes and wasn't sure he was processing what I was saying.

When we transferred him to the OR and provided the patient handover, I knew it was up to others to do their work at that point. I felt grateful for my team, but knew I had to let go of the urge to keep helping and accept not knowing what was going to happen next. As I headed back to the ER, I tried to keep positive thoughts about the patient in my mind. Later, I did find out that he survived, and his leg was saved, though his recovery was going to be very long and challenging. Although it was the skilled work of the surgeon and surgical team that ultimately led to that positive outcome, I know the part I played in caring for the patient also mattered.

---

Surgery to perform an appendectomy for appendicitis is an interesting case because traditionally it was considered an emergent procedure. An **appendectomy** involves surgically removing an appendix. The goal is to remove the appendix before it ruptures and spills infectious material into the abdominal cavity, potentially leading to life-threatening peritonitis. While complicated cases can certainly be emergent, there is some disagreement about whether all cases of appendicitis require immediate surgery. Some research suggests that delaying surgery for up to twenty-four hours may not adversely affect the outcome of either adult or pediatric patients with appendicitis (van Dijk et al., 2018). Considering appendicitis as urgent rather than emergent allows for more efficient identification of a surgeon, **anesthesia provider**, perioperative personnel, and available OR time (Salem, n.d.).

### Expedited (Scheduled) Surgery

Not all surgeries are performed in the face of immediate danger. Some address chronic or progressive conditions that, while not life-threatening in the immediate term, can lead to significant complications and impair quality of life if left untreated. The goal of expedited surgery is to prevent future harm and improve long-term well-being.

Examples of expedited surgeries include the following:

- Tumor removal: Excising cancerous or precancerous growths to prevent their spread and improve patient survival.
- Joint reconstruction: Repairing joints damaged by injury may offer temporary relief and stabilization until a more definitive treatment (like replacement) can be undertaken.
- Open-heart surgery: Repairing damaged heart valves or bypassing blocked coronary arteries to improve blood flow and address cardiovascular issues.

Expedited surgeries are often scheduled in advance, allowing for careful planning, preoperative optimization of the patient's health, and detailed discussions of potential risks and benefits. These procedures, while not as time sensitive as emergent or urgent cases, still play a vital role in preventing future health problems and improving long-term quality of life.

### Elective Surgery

Beyond lifesaving interventions requiring emergent or urgent surgery and addressing pressing medical needs requiring expedited interventions, surgery also offers options for repairing injuries or enhancing appearance and function, allowing individuals to make informed choices about their well-being. An elective surgery is one chosen by a patient to improve their quality of life, address cosmetic concerns, or manage specific health conditions that are not immediately life threatening. Elective surgery is planned and scheduled in advance of routine admission to a hospital or surgery center. The timing of the elective surgery is determined to suit the patient and also the availability of perioperative personnel and an appropriate surgical facility. Examples of elective surgery include the following:

- Elective orthopedic surgery: Repairing sports injuries, correcting deformities, or relieving chronic pain can improve mobility, function, and quality of life.
- Joint replacement: Replacing damaged or diseased joints with artificial implants can restore mobility, alleviate pain, and improve function.
- Cosmetic surgery: Procedures (e.g., breast augmentation, liposuction, facial rejuvenation) can help individuals achieve desired aesthetic enhancements and boost self-confidence.
- Weight-loss surgery: Gastric bypass or other procedures can address obesity and its associated health risks,

leading to improved physical and mental well-being.

Elective surgeries are often personal decisions, requiring careful consideration of potential benefits and risks, long-term implications, and recovery time. These procedures, while not essential for survival, can significantly enhance a patient's physical and emotional well-being, contributing to a better quality of life.

## Surgical Advancements and Trends

In recent years, the field of surgery has experienced a remarkable transformation propelled by a convergence of cutting-edge technologies and pioneering research. These advancements are revolutionizing traditional surgical practices, offering new avenues of treatment, and significantly enhancing the capabilities of healthcare professionals in the OR.

Minimally invasive techniques are at the forefront of innovation in surgery. The shift toward procedures that use smaller incisions, specialized instruments, and advanced imaging technologies has not only reduced the physical impact on patients but has also led to quicker recovery times and decreased postoperative discomfort.

### Robotic Surgery

Minimally invasive surgery (a technique that uses fewer and smaller incisions than traditional open procedures) and robotic-assisted surgery (a procedure performed with robotic systems controlled by surgeons) offer many benefits for both patients and surgeons (Figure 31.2). The advantages of robotic-assisted surgery include the following:

- **Enhanced dexterity:** Imagine nimble fingers navigating tight spaces with unmatched precision. Robotic arms transcend human limitations, providing tremor-free movements and 7-degree freedom (the number of independent movements the robot can make), mimicking the natural dexterity of the human wrist. This translates to precise dissection and manipulation of delicate tissues. Surgeons can access and operate on hard-to-reach areas, minimizing collateral damage and preserving healthy structures.
- **Intricate suturing and reconstruction:** Robotic arms provide unmatched needle control, enabling meticulous closure and faster healing.
- **Magnified vision:** Robotic systems boast high-definition cameras with three-dimensional (3-D) capabilities, offering surgeons a panoramic view of the surgical field where even the tiniest nerve is brought into sharp focus. With the aid of robotics, surgeons can identify anatomical landmarks clearly, minimizing the risk of complications and enhancing surgical decision-making.

**FIGURE 31.2** Robotic-assisted surgery has not replaced the human operating room team, but the innovation has given surgeons new techniques for many common procedures. (credit: “Keesler MDG Airmen perform first robotic surgery in AF” by Senior Airman Jenay Randolph/Air Education and Training Command, Public Domain)

Common robotic-assisted procedures include laparoscopic prostatectomies, hysterectomies, and mitral valve repairs. For instance, a robotic-assisted laparoscopic prostatectomy is a minimally invasive approach for prostate cancer removal. It offers shorter operative times, increased precision, reduced pain, less scarring, shorter hospital

stays, reduced blood loss, and faster recovery compared to traditional open surgery (Chuchulo & Ali, 2023).

That said, there are also very real challenges associated with robotic surgery, including the cost to implement and maintain the systems, the need for specialized training for all team members, a “learning curve” for surgeons to gain experience, and the potential for technical issues that could compromise the efficiency of a procedure or even put patient safety at risk (Chuchulo & Ali, 2023).

### Telesurgery

Robot-assisted remote surgery, or telesurgery, uses advanced robotic technology that allows surgeons to operate on patients from a remote location in real time. This empowers surgeons to provide specialized care to underserved areas, overcome geographical barriers, and potentially reduce healthcare disparities. During telesurgery, the surgeon works in a control room equipped with high-definition 3-D screens and **haptic interfaces** that provide real-time feedback to the surgeon. Haptic interfaces are a type of human-computer interaction technology that is created by using force feedback, or the application of forces or vibrations to the user’s skin, via movement of a limb or the head to simulate bodily tactile sensations and movements, which can mimic the feel of touching natural objects. The surgeon operates a “slave robot” (a robotic system that is directly controlled by the surgeon, often from a console) that mimics the surgeon’s movements with precise dexterity.

Telesurgery is already making strides in various specialties. It is used for brain surgery, where remote neurosurgeons have performed tumor resections and stroke interventions, potentially improving access to specialized care for patients in remote locations. Other examples of common telesurgeries include laparoscopic cholecystectomies, joint replacements, and fracture repairs (Patel et al., 2024).

## REAL RN STORIES

### Like Science Fiction

**Nurse:** Liliana, BSN

**Clinical setting:** Surgery

**Years in practice:** 8

**Facility location:** A teaching hospital in Boston, Massachusetts

I’ll admit it, I was very uncertain about the first telesurgery case I worked. Maybe even more than uncertain—nervous. Really nervous! I mean, it sounded like science fiction, and when you actually see it happening . . . well, it kind of looks like science fiction too. But it’s a modern marvel, and not so much science fiction as a balance of science and art. It takes a really special kind of surgeon to do remote procedures. They need to be able to communicate like they’re in Mission Control and also need to have a real knack for technical problem-solving—doing all this while not being in the room with the team or the patient.

And I think on that first case, it was that realization that really helped me see my role more clearly. It’s always my job to be there for the patient, but in a telesurgery setup, it is even more important. It’s not enough to be present, you have to have “presence.” And that feels even more crucial when you’re one of the only people who is physically in the OR with the patient.

During that first case, the patient was also nervous, and I needed to make sure that I didn’t let my jitters affect the patient at all. The truth was, the surgeon on the case was one of the best in the country, and the fact that this patient could be treated by that surgeon despite the distance was incredible. I could never have fathomed that even ten years ago this was not possible. But your mind starts to run with all the what-ifs. What if the internet goes out? Or the connection intermittently goes in and out? Or the computer decides to do an update and restart right after the first incision? Now, rationally, I understood there were safeties in place for telesurgery just like there would be for an in-person surgery. But since I’d never seen it play out in anything other than a simulation lab, my mind was running wild. However, our on-site surgeon had done so many of the procedures at that point that he remained calm and composed. I think his demeanor helped me feel a little more assured—and it definitely helped me reassure the patient when they groggily asked me if it was time for “lift off.”

The procedure itself was . . . well, actually almost routine. The voice of the specialist surgeon miles away came

through the speakers as though they were in the room with us. The image on the video wasn't quite high definition (HD); however, it was on the higher end of video calls I've been on, that's for sure.

And whether the voice was coming from across the room or across the country, it didn't really change my job. I was still monitoring the patient, communicating with the team, and thinking through my tasks with the same focus that I have every time I'm in the OR.

When it was over, I almost forgot it had been anything new! But when the patient woke up in recovery and made a groggy reference to *Star Trek*, I was happy to report to them that the mission had been a success.

---

In many ways, the role of perioperative nurses in telesurgery is no different from that in any other surgery. The **RN circulator** (a registered nurse whose primary responsibilities include managing the overall environment of the OR to ensure it remains safe, sterile, and efficient) must have **cognitive awareness** during any procedure; however, it is particularly essential when the surgeon is not physically in the room. Cognitive awareness may be defined as an increased level of attention that results in a "positive presence" by being consciously aware of all the components of an interaction. It is more than hearing what the surgeon is saying. Rather, the nurse learns to anticipate what the surgeon is thinking in order to determine what the surgeon needs in the moment and help the surgeon achieve the desired result even though the surgeon is not physically in the room.

Despite its immense potential, telesurgery presents risks and challenges that need to be addressed. For example, any delays in the transmission of data within communication networks, limited touch-based (haptic) feedback, and potential robot malfunctions can be catastrophic for the patient. Delays in data transmission could affect real-time control, and technical glitches or poor connectivity could adversely affect communication. Regulatory requirements may vary between regions, and there could be risks to security and patient privacy. Legal and ethical concerns also need to be addressed, which would include the liability related to remote surgeries. Additionally, implementing and maintaining telesurgery infrastructure requires costly investments, necessitating cost-effective solutions, and resource allocation strategies.

### Artificial Intelligence

Robotic surgery and telesurgery have become far safer and more practical because of advances in AI. These computer systems are trained with algorithms designed to perform tasks that require human intelligence. The effect of AI is multifaceted, encompassing various aspects of surgical care. Examples include the following:

- **Preoperative planning:** There are AI algorithms that can analyze medical images and patient data to predict potential complications, optimize surgical planning, and even suggest the most suitable surgical approach. Certain AI algorithms can analyze patient data to predict individual responses to surgery, allowing surgeons to provide more personalized surgical techniques and optimize treatment plans. For instance, AI has been used with great success in detecting and identifying tumors. This is because AI can analyze medical images to detect cancer cells with higher accuracy than human eyes, potentially leading to earlier diagnoses and better treatment options.
- **Intraoperative assistance:** There are AI-powered systems that can provide real-time feedback during surgery, guiding surgeons by highlighting critical structures, identifying anomalies, and even predicting potential bleeding risks.
- **Postoperative care:** Some AI algorithms can analyze surgical data to monitor patient recovery, predict potential complications, and suggest personalized care plans.

Although the field is constantly evolving and much remains unknown or theoretical, we do have some clear indications of the overarching pros and cons of using AI in health care. From a clinical standpoint, the possible benefits of using AI in medical settings such as the OR include the following:

- **Increased accuracy:** Artificial intelligence can help surgeons make more accurate incisions and reduce the risk of complications.
- **Improved efficiency:** Artificial intelligence can help automate tasks, freeing up surgeons to focus on more complex aspects of the procedure.
- **Reduced risk of human error:** Artificial intelligence can help to prevent human errors, acting as a "safety check" against human factors like fatigue and inattention.
- **Better patient outcomes:** The combination of increased accuracy and precision, efficiency, and safety could

ultimately improve surgical outcomes for patients.

However, there are also some potential risks and challenges associated with the use of AI in surgery:

- **Reliability:** Artificial intelligence algorithms must be thoroughly validated for accuracy, and large language models must be fine-tuned with appropriate, accurate, relevant datasets.
- **Lack of human intuition:** Artificial intelligence cannot exercise the nuanced judgment of experienced surgeons in challenging situations that are not “textbook” or that require “in the heat of the moment” decisions.
- **Data bias:** Artificial intelligence algorithms can be biased based on the data on which they are trained (e.g., garbage in, garbage out).
- **Security:** It may be difficult to protect patient data or even proprietary data from cybersecurity threats introduced by AI.
- **Integration:** Integrating AI seamlessly into existing workflows presents unique challenges and high up-front costs as well as the costs for maintaining the systems to keep up with a quickly evolving industry.
- **Regulation:** It is necessary to establish clear regulations for AI broadly across all industries, particularly in health care.

Healthcare professionals must ensure that AI is ethically, responsibly, and effectively developed to balance the gains with the risks. Artificial intelligence must ensure that patient safety and privacy remain the priority, and patient outcomes are the ultimate guiding force behind implementing new technology.

### Multi-Angle Rear-Viewing Endoscopic Tool

Developed by researchers at NASA’s Jet Propulsion Laboratory, the **Multi-Angle Rear-Viewing Endoscopic tool (MARVEL)** is a thin, flexible endoscope equipped with a unique single-lens system and complementary multi-band-pass filters. This innovative combination allows the endoscope system to achieve 3-D imaging without the bulky need for dual cameras. This offers several key advantages (Shearn et al., 2012):

- **Enhanced visualization:** Unlike traditional endoscopes that offer a limited field of view, MARVEL can bend and rotate its tip, providing surgeons with a panoramic view of hidden anatomical structures, especially in confined spaces like the brain or spine. This improved view reduces the risk of accidental damage to critical structures and improves surgical precision.
- **Minimized tissue trauma:** The small diameter and flexible nature of MARVEL minimize tissue disruption during surgery. This leads to faster recovery time, less pain, and potentially fewer complications for patients.
- **Improved access:** Compared to traditional endoscopes, MARVEL can navigate through complex anatomical pathways with greater ease, reaching previously inaccessible areas and expanding the possibilities for minimally invasive procedures.

Practitioners in several surgical specialties are exploring MARVEL’s versatility and potential advantages. For example, neurosurgeons are using MARVEL for brain tumor resections, aneurysm clipping, and other delicate procedures, gaining improved access to deep and narrow brain regions. The tool’s maneuverability is proving valuable for minimally invasive spinal surgeries, allowing surgeons to see and access spinal structures with minimal tissue disruption. In the area of otolaryngology, MARVEL’s ability to reach hidden areas in the ear, nose, and throat makes it ideal for sinus surgery, tumor removal, and other endoscopic procedures.

Although MARVEL is a promising new technology with a number of potential benefits for surgeons and patients, there are also some potential risks and challenges that must be considered:

- **High cost:** The expense of acquiring and maintaining MARVEL can be financially prohibitive for many facilities.
- **Steep learning curve:** A substantial amount of training and expertise is required to use MARVEL skillfully, and it can be time-consuming to put in the time and effort to learn how to use it.
- **Image quality constraints:** While MARVEL provides better visualization, the actual clarity and detail of the images it produces may fall short when compared to the high-quality images generated by traditional endoscopic equipment.
- **Seamless integration:** Incorporating MARVEL into established surgical workflows could hinder widespread adoption.
- **Patient acceptance:** Some patients may be hesitant or even unwilling to consent to undergoing procedures with new technology like MARVEL.

- **Regulatory oversight:** Currently, there is a lack of comprehensive regulations for new tools like MARVEL. Frameworks need to be developed to ensure that the technology is safe and effective.

Even if they do not yet have the technology at every facility, nurses should be familiar with MARVEL and its potential benefits and have a clear understanding of how it differs from traditional endoscopes. Having a baseline understanding of MARVEL will help nurses provide optimal preoperative care, facilitate efficient intraoperative surgical workflow, and provide excellent postoperative care and patient education.

### 3-D Printing

From printing custom implants to creating lifelike anatomical models for use in surgical planning, **3-D printing** or a manufacturing process that creates 3-D objects from digital files, is becoming more common in surgical practice because it offers several key benefits (Sun, 2018). For example, anatomical models printed from patient data allow surgeons to visualize complex structures, practice surgical approaches, and identify potential challenges before entering the OR. This improved planning leads to reduced surgical time, enhanced surgical precision, and real advancements in personalized implants and surgical tools.

Certain applications for 3-D printing in surgery seem especially promising. These include the following:

- **Orthopedic surgery:** Custom-printed implants for joint replacements or bone fractures ensure a perfect fit, leading to faster healing, improved function, and reduced risk of complications.
- **Craniofacial surgery:** Reconstructive surgery can benefit from patient-specific implants that restore facial features and functionality, improving both physical appearance and self-esteem.
- **Vascular surgery:** In vascular surgery, 3-D-printed stents and other vascular implants can be customized to the specific needs of each patient's blood vessels, enhancing the success and safety of these procedures.

However, the integration of 3-D printing in surgical settings is not without its potential downsides and risks, such as the following:

- **Financial and economic investment:** The initial setup costs and materials can be expensive, and printing complex structures can be time-consuming.
- **Safety and suitability:** Ensuring the safety and biocompatibility of printed materials as well as making sure that printed models accurately represent an individual patient's anatomy are critical areas of challenge that must be addressed.
- **Regulations and standards:** There also need to be clear, evidence-based guidelines for the approval of 3-D-printed medical devices. This may prove difficult because advancements in materials for improved biocompatibility remain ongoing challenges in a field that is changing quickly.

Ongoing research and development are essential for advancing 3-D-printed materials that offer enhanced biocompatibility and open new possibilities for patient-specific treatment.

### Types of Anesthesia

Modern surgery requires not only surgical precision but also sophisticated pain management with anesthesia. The variety of anesthesia types each offer a unique blend of unconsciousness, pain relief, and controlled depth of anesthesia. These include general anesthesia, monitored anesthesia care (MAC)/moderate sedation, regional anesthesia, and local anesthesia ([Table 31.1](#)). The choice of anesthesia is a delicate decision, tailored to the specific needs of the surgery, the patient's health, and the medical team. In addition to the type of surgery being performed, anesthesia providers (e.g., anesthesiologists, certified nurse anesthetists [CRNAs]) carefully evaluate each patient, considering factors such as age, medical history (including bleeding risk), and anxiety levels, to determine the most appropriate approach for a safe and comfortable surgical experience.

Factors to Consider	General Anesthesia	Monitored Anesthesia Care (MAC)/Moderate Sedation	Regional Anesthesia	Local Anesthesia
Pros	<ul style="list-style-type: none"> <li>• Complete unconsciousness: The patient is completely unaware and feels no pain during the procedure, nor will they remember anything about it afterward.</li> <li>• Muscle relaxation: Inducing muscle relaxation is necessary for the surgery to be performed to prevent involuntary movements and muscle contractions that could interfere with the surgical procedure and/or cause injury.</li> <li>• Controlled: Anesthesia providers can precisely control the depth of anesthesia, allowing them to keep a patient unconscious until the procedure is over and bring the patient out of sedation.</li> </ul>	<ul style="list-style-type: none"> <li>• Less disruptive: It allows patients to remain conscious but relaxed.</li> <li>• Quick recovery: The recovery time is shorter compared to general anesthesia.</li> <li>• Versatile: It is suitable for various procedures and diagnostic tests.</li> </ul>	<ul style="list-style-type: none"> <li>• Selective numbing: It numbs a large region while allowing the patient to remain conscious.</li> <li>• Reduced systemic effects: It limits effects to a specific region, reducing overall systemic impact.</li> <li>• Postoperative pain control: It provides extended postoperative pain relief.</li> <li>• Types: <ul style="list-style-type: none"> <li>◦ Spinal anesthesia: a one-time injection of numbing medication.</li> <li>◦ Epidural anesthesia: injected through a catheter placed in the epidural space.</li> <li>◦ Nerve blocks target specific limbs or areas: offer precise pain control with no effect on consciousness unless sedation is added.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Minimal systemic effects: It acts only on the specific area where it is administered.</li> <li>• Quick recovery: Patients can often resume normal activities shortly after the procedure.</li> <li>• Fewer side effects: It is typically associated with fewer systemic side effects.</li> </ul>

**TABLE 31.1** Summary of Types of Anesthesia

Factors to Consider	General Anesthesia	Monitored Anesthesia Care (MAC)/Moderate Sedation	Regional Anesthesia	Local Anesthesia
Cons	<ul style="list-style-type: none"> <li>• Recovery time: The patient needs to fully regain consciousness after general anesthesia, which can prolong recovery time.</li> <li>• Potential side effects: Nausea, vomiting, and respiratory issues can be side effects of anesthesia medications and protocols.</li> <li>• Postoperative disorientation: Some patients may experience confusion or disorientation after waking up from general anesthesia, while others have different reactions, such as tearfulness or agitation.</li> </ul>	<ul style="list-style-type: none"> <li>• Limited depth: It may not provide enough depth of anesthesia for more complex or painful procedures that require a patient to be unconscious.</li> <li>• Potential respiratory depression: Some patients may experience reduced breathing rate with sedation.</li> <li>• Patient cooperation: It requires patient cooperation because the patient will remain conscious during the procedure.</li> </ul>	<ul style="list-style-type: none"> <li>• Potential complications: There are risks associated with nerve blocks or epidurals (e.g., hypotension, bleeding, infection, potential respiratory complications, paralysis).</li> <li>• Limited area of effectiveness: It may not cover all areas for certain complex surgeries.</li> <li>• Monitoring challenges: It requires careful monitoring of the patient's neurological status.</li> </ul>	<ul style="list-style-type: none"> <li>• Limited area: It is effective only in a specific localized area.</li> <li>• Discomfort during administration: It may cause temporary discomfort (e.g., burning, stinging) during injection.</li> <li>• Not suitable for all procedures: It is not suitable for more extensive or deeper surgeries.</li> </ul>

**TABLE 31.1** Summary of Types of Anesthesia

Factors to Consider	General Anesthesia	Monitored Anesthesia Care (MAC)/Moderate Sedation	Regional Anesthesia	Local Anesthesia
Duration and recovery	<ul style="list-style-type: none"> <li>• These vary based on surgery type and medications used.</li> <li>• Typically, this stage lasts for the duration of surgery, and the patient will emerge or “wake up” gradually as the medications wear off.</li> </ul>	<ul style="list-style-type: none"> <li>• Effects are typically short lived, lasting only for the procedure and not lingering for long, although drowsiness may last for a while afterward.</li> </ul>	<ul style="list-style-type: none"> <li>• Spinal: This takes effect almost immediately and may last up to two hours.</li> <li>• Epidural: This takes ten to twenty minutes to provide relief but lasts as long as necessary by repeated injections through the catheter.</li> <li>• Nerve blocks: Pain relief can vary from a few hours, to a few days, to several weeks, months, or even years.</li> </ul>	<ul style="list-style-type: none"> <li>• Duration is generally limited to the time needed for the procedure.</li> <li>• Recovery is rapid, and effects wear off relatively quickly.</li> </ul>

**TABLE 31.1** Summary of Types of Anesthesia

Factors to Consider	General Anesthesia	Monitored Anesthesia Care (MAC)/Moderate Sedation	Regional Anesthesia	Local Anesthesia
Effectiveness and safety monitoring	<ul style="list-style-type: none"> <li>• Basic anesthetic monitoring includes (1) oxygenation (e.g., pulse oximetry), (2) ventilation (e.g., capnography, partial pressure of carbon dioxide in exhaled air over time), (3) circulatory function (e.g., heart rate, blood pressure, electrocardiogram), and (4) temperature.</li> <li>• Depth of anesthesia is assessed by patient response to stimuli (e.g., nociception).</li> <li>• Continual observation of respiratory parameters and end-tidal CO<sub>2</sub> levels is necessary.</li> </ul>	<ul style="list-style-type: none"> <li>• Consciousness level and responsiveness to verbal stimuli (e.g., asking their name) are assessed.</li> <li>• Continuous respiratory rate and oxygen saturation monitoring is performed.</li> <li>• Vital signs (e.g., blood pressure, heart rate, pulse oximetry) are evaluated.</li> </ul>	<ul style="list-style-type: none"> <li>• Neurological function in the targeted region is assessed.</li> <li>• Vital signs (e.g., blood pressure, heart rate) are continuously monitored.</li> <li>• Patient comfort and pain levels are evaluated.</li> </ul>	<ul style="list-style-type: none"> <li>• Pain control and absence of sensation in localized area are assessed.</li> <li>• The patient's comfort level during the procedure is observed.</li> </ul>

**TABLE 31.1** Summary of Types of Anesthesia

Factors to Consider	General Anesthesia	Monitored Anesthesia Care (MAC)/Moderate Sedation	Regional Anesthesia	Local Anesthesia
Potential side effects and management	<ul style="list-style-type: none"> <li>• Nausea and vomiting: Antiemetic medications and essential oil aromatherapy (Farrington et al., 2019) may be used.</li> <li>• Temporary cognitive changes: These typically resolve within a few days with supportive care and reassurance.</li> <li>• Respiratory issues: Respiratory function and mechanical ventilation are closely monitored, if necessary.</li> <li>• Sore throat: Over-the-counter throat lozenges may be recommended.</li> </ul>	<ul style="list-style-type: none"> <li>• Respiratory depression: Breathing issues may occur, particularly in higher doses, requiring continuous monitoring of vital signs; supplemental oxygen may be provided if needed.</li> <li>• Drowsiness: Patients may feel excessively sleepy, requiring observation until the effects wear off.</li> <li>• Hypotension: Decreased blood pressure may require fluid administration or vasoactive medications.</li> </ul>	<ul style="list-style-type: none"> <li>• Hypotension or bradycardia: These are possible effects of spinal or epidural anesthesia due to sympathetic blockade requiring administration of fluids and medications to support blood pressure and heart rate.</li> <li>• Nerve damage or irritation: These are rare but potential complications, especially with nerve blocks, caused by needle/catheter placement; they require close monitoring for any signs of neurological issues.</li> </ul>	<ul style="list-style-type: none"> <li>• Localized pain or discomfort: Topical anesthetics may be applied. The patient may require reassurance during local administration and during the procedure.</li> <li>• Allergic reactions: Immediate treatment of allergic reactions is necessary; alternative anesthetics may have to be used.</li> <li>• Local anesthetic systemic toxicity: Prompt recognition and treatment is necessary; supportive care is administered.</li> </ul>

**TABLE 31.1** Summary of Types of Anesthesia

### General Anesthesia

For major and complex procedures, general anesthesia takes center stage. This potent cocktail of IV and inhalation medications induces a state of controlled unconsciousness, **amnesia** (a temporary or permanent loss of memory), and **analgesia** (pain relief so the patient does not respond to painful stimuli, with or without reversible muscle paralysis). The process of **intubation** involves inserting an endotracheal tube into the mouth or nose and into the trachea to maintain an open airway, support breathing and ventilation, and provide oxygen delivery. This, in addition to monitoring vital signs, remains paramount throughout the procedure. General anesthesia offers complete pain relief, keeping the patient unarousable to painful stimuli during surgery, which provides optimal surgical conditions. However, general anesthesia has potential side effects (e.g., postoperative nausea and vomiting, temporary cognitive changes after surgery) (American Society of Anesthesiologists, n.d.).

### Monitored Anesthesia Care/Moderate Sedation

For shorter and less-invasive procedures, a patient may not need to be completely unconscious. Monitored anesthesia care (MAC)/moderate sedation induces a state of drowsiness and reduces anxiety while allowing patients to respond to basic commands and breathe on their own. This approach offers a balance between pain relief and awareness, making it ideal for procedures like endoscopies and biopsies. However, some patients may still experience some discomfort or remember fragments of the procedure (American Society of Anesthesiologists, n.d.).

## LIFE-STAGE CONTEXT

---

### Age-Related Anesthesia Considerations

Some considerations for the use of anesthesia are based on the patient's life stage, from newborn infants to the oldest patients who need surgery.

#### *Infants and Young Children*

- **Underdeveloped organ systems:** Reduced metabolism and medication clearance in infants can lead to prolonged medication effects and unexpected responses to anesthesia. Weight-based dosing of anesthetic medications in children can help ensure that the safest, most effective therapeutic doses of anesthetic agents and pain medication are given while minimizing risks and medication side effects.
- **Thermoregulation challenges:** Infants are more susceptible to hypothermia during surgery, requiring careful temperature monitoring and warming techniques to prevent complications.
- **Potential for airway obstruction:** Careful attention to airway management is crucial for infants and babies who have smaller and more pliable airways.

#### *Pregnancy*

- **Fetal safety:** The type and timing of anesthesia could affect the developing fetus. Careful medication selection and monitoring are essential to minimize risks to both the pregnant patient and the unborn baby.
- **Physiological changes:** Pregnancy alters the pregnant patient's cardiovascular, respiratory, and gastrointestinal systems, which requires special attention throughout anesthesia management.
- **Pain management:** Balancing pain relief for the pregnant patient as well as the safety of the unborn baby is a priority. Regional anesthesia is often preferred, when possible, to reduce fetal risk.

#### *Older Adults (65 years old and older)*

- **Cardiovascular changes:** Decreased cardiac reserve makes older adults more vulnerable to hypotension and arrhythmias. Careful titration of anesthetic agents, close monitoring, and consistent fluid management are essential.
  - **Respiratory decline:** Reduced lung function and oxygenation capacity in old age can contribute to a higher risk of hypoxia and postoperative respiratory complications. Preoperative optimization of lung function and careful oxygen management are important for older adults who will be undergoing surgery.
  - **Neurological considerations:** Older patients may have preexisting cognitive changes or conditions and, therefore, can be more sensitive to the effects of anesthetic medications. Lower doses with titration to effect and careful monitoring can mitigate the risk of emergence delirium (also known as postoperative delirium) and cognitive dysfunction in older surgical patients (Ramroop et al., 2019).
  - **Altered drug metabolism:** Decreased kidney and liver function are common in older adult populations and can prolong the effects of medications and increase the risk of toxicity. Dosage adjustments may be needed to help prevent these risks.
  - **Polypharmacy:** Older adults are more likely to be on multiple medications to manage chronic diseases, many of which may interact with anesthetic medications. Preoperative medication reconciliation is essential, particularly if a medication may need to be held for a specified time period before a procedure to help avoid interactions or altered effects.
-

## Regional Anesthesia

When the surgical procedure is on a specific region of the body, regional anesthesia may be the best anesthetic option. This approach blocks nerve signals in targeted areas, leaving patients awake and aware during the procedure. Spinal and epidural anesthesia provide partial or complete analgesia by numbing the lower body. Nerve blocks target specific limbs or areas, offering precise pain control with no effect on consciousness unless sedation is added. Regional anesthesia often leads to faster recovery times and fewer side effects compared to general anesthesia but may not be suitable for all procedures or patients with certain medical conditions. Common uses for regional anesthesia include orthopedic surgeries, procedures on extremities, labor and delivery, and some abdominal surgeries (American Society of Anesthesiologists, n.d.).

## PATIENT CONVERSATIONS

---

### Teaching the Patient about Regional Anesthesia

**Scenario:** The nurse midwife is preparing an obstetrical patient in labor who will be receiving regional anesthesia for pain relief.

**Nurse Midwife:** Hi, Kayla. How are you feeling?

**Patient:** Hurts . . . a lot.

**Nurse Midwife:** We are about to start your epidural to help with the pain. I'd like to talk to you about what to expect, is that okay?

**Patient:** Yes . . . please.

**Nurse Midwife:** An epidural is a kind of regional anesthesia. It's not like the general anesthesia that puts you to sleep before a surgery; it just numbs part of your body to help with pain relief.

**Patient:** So, it won't . . . knock me out?

**Nurse Midwife:** Nope, you'll be completely awake. When the anesthesia provider comes in, we will have you sit up or lie on your side and they will use a needle to put a tube into your lower back at the bottom of your spine. It might pinch a little, but they usually put a little numbing medicine in your skin first to help it hurt less.

**Patient:** Does the needle stay in my back?

**Nurse Midwife:** No, the needle is just used to poke through your skin. Then they put in a flexible tube called a catheter. They remove the needle but leave the catheter in place. The catheter allows the anesthesia provider to put in numbing medicine. It will probably take about twenty minutes for the medicine to take effect.

**Patient:** Will I be totally numb?

**Nurse Midwife:** No, the medicine will only numb you from about the waist down. While you will be numb, it is normal to still feel some pressure as the baby moves down the birth canal. You can still move your legs a bit, but you won't feel them like you normally would.

**Patient:** Will I still be able to push?

**Nurse Midwife:** Yes, the muscles you use to push will still work, even with the epidural.

**Patient:** Is it safe?

**Nurse Midwife:** Epidurals are safe; however, all treatments have risks, so I'm glad you asked. We will watch you and your baby closely to make sure that things like heart rate and blood pressure are what we want them to be. Some people take longer to get feeling back than others. It is very important that you remain in your bed. Your legs will be numb so you would fall down. Please ring your bell, it's right here, if you need anything.

Another possible risk is that sometime people get headaches from having the epidural placed. There is also a risk of more serious complications, like blood clots and nerve damage, but these are rare, and we will be monitoring you closely for any signs of a problem. We will help you manage any of these side effects if they happen, and we'll make

sure that adjustments are made if necessary.

**Patient:** What if I end up needing a C-section.

**Nurse Midwife:** Well, if you need a C-section, you'll be one step closer to being ready, since the epidural will already be done. If that happens, we'll talk more about what next steps will take place.

**Patient:** When does it come out? The tube, I mean.

**Nurse Midwife:** After delivery, the catheter can be removed. You'll probably start to notice feeling coming back within a couple of hours, but like I said, it might take a little longer or shorter time. You might have some back pain, and it might feel a little weird to try to pee at first, but this will get better as the numbness goes away.

**Patient:** Thanks . . . so, can we get started?

**Nurse Midwife:** Yes, the anesthesia provider should be here any minute now.

---

### Local Anesthesia

Local anesthesia is a technique that temporarily numbs only a small, specific area of the body. It is administered either topically or via injection near the site of the procedure. This form of anesthesia is commonly used for minor surgical procedures, dental work, skin biopsies, or wound repairs. Although it is not as complex as other forms of anesthesia, there are still potential downsides and risks to consider along with the benefits (American Society of Anesthesiologists, n.d.). Side effects may occur if too much local anesthesia is administered or if the medication is inadvertently injected into a vein instead of tissue. This reaction is called local anesthetic systemic toxicity. The patient may experience ringing in the ears, headache, dizziness, confusion, twitching, heart rhythm and blood pressure disturbances, metallic taste in your mouth, or rarely have a seizure. It is also possible to have an allergic reaction to an anesthetic, which is also rare.

## 31.2 Preoperative Phase

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the tasks involved in the preoperative stage of patient care
- Explain the role of the perioperative nurse

The **preoperative stage** is a critical component of the surgical road map, and it includes all the activities and preparations from the time surgery is decided on until the patient is transferred to the OR. This section covers the tasks involved in the preoperative stage of patient care that include, but are not limited to, conducting preoperative assessments, verifying surgical consents, performing risk assessments for anesthesia, educating the patient about the procedure, and preparing the patient physically and emotionally for surgery. This stage is essentially a touchstone for ensuring patient safety, optimizing surgical outcomes, and minimizing the risk of complications.

The preoperative nurse functions as the patient's advocate and primary point of contact throughout the preoperative period, making sure that all preparations are completed accurately and that the patient is educated and emotionally supported in the time leading up to their surgery. Each task is necessary for identifying potential issues that could affect the surgery or recovery and ultimately ensuring that the patient is in the best possible condition to undergo the procedure. By understanding the tasks and responsibilities involved in preoperative care, nurses can effectively prepare patients for surgery, addressing both their physical and psychological needs.

### Preoperative Care

The journey through surgery does not begin with the first incision; it starts long before, in the crucial stage of preoperative care. To ensure the safest possible surgical experience, preoperative care begins with a comprehensive assessment of the patient's health. The preoperative nurse reviews the patient's medical history, noting any preexisting conditions, allergies, and current medications. The nurse then performs a thorough physical examination or reviews the medical preoperative history and physical (H&P), which helps identify any potential issues that could affect the surgical procedure or influence recovery (American College of Surgeons, n.d.).

Preoperative care also goes beyond just physical preparation. Addressing psychological well-being and identifying

the patient's coping mechanisms and available emotional support can significantly contribute to a positive surgical experience. By meticulously laying the groundwork, preoperative care sets the stage for a smoother surgery and a faster, more successful recovery.

Based on the data collected, the nurse formulates a baseline understanding of the patient's status and determines what appropriate preoperative testing is required. The nurse confirms that all required preoperative documents are present. The nurse also ensures the patient has undergone preoperative bowel preparation if required. Finally, the preoperative nurse performs surgical skin preparation and provides prehabilitation and postoperative instructions.

### Completing Preadmission and Preoperative Testing

Before being admitted for surgery, patients may need certain preadmission and preoperative tests. These assessments unveil vital information about the patient's health, which may influence outcomes and can present challenges to a successful procedure. The **preadmission testing** (or preoperative testing) encompasses a range of examinations, laboratory or diagnostic tests, and procedures (e.g., electrocardiogram [ECG], bloodwork) to evaluate a patient's health status. This testing is completed before a procedure or surgery.

The benefits of preadmission testing are multifaceted. Tests may reveal underlying medical conditions that could pose risks during surgery, allowing for adjustments to the surgical plan or even postponement if necessary. Information gleaned from preoperative tests helps the surgeon tailor the approach to the patient's specific anatomy and health, leading to more precise and effective procedures. Testing that identifies potential issues beforehand can ultimately enhance patient safety (American College of Surgeons, n.d.). Some common tests include the following:

- Blood work:
  - Complete blood count can identify a low red blood cell count (e.g., anemia) and high white blood cell count (e.g., infection).
  - Serum electrolytes (e.g., sodium, potassium) help regulate heart rhythms and other body functions. Identifying serum electrolyte abnormalities in advance of surgery allows time to rectify the problem.
  - Serum glucose levels provide insights into the body's ability to heal, among other things.
  - Coagulation studies (e.g., prothrombin time partial thromboplastin time) help prevent bleeding complications by measuring the activity of the clotting cascade.
- Imaging tests:
  - Chest x-rays help diagnose causes of shortness of breath, chest pain, cough, certain fevers, and abnormal heart and lung appearance.
  - Computed tomography (CT) and magnetic resonance imaging (MRI) scans offer detailed images of organs, bones, and tissues, assisting the surgeon in surgical planning and identifying potential anatomical variations.
- Electrocardiogram and echocardiogram (Echo): Assessing heart function is crucial for surgeries involving anesthesia with the goal of minimizing the risk of cardiac complications.
  - An ECG may identify abnormal rhythms (e.g., arrhythmias, dysrhythmias), heart muscle damage, and causes of chest pain, fluttering heartbeats (palpitations), and heart murmurs.
  - An Echo uses high-frequency sound waves to produce pictures of the heart. Among other things, an Echo can help diagnose heart attack, heart failure, valvular problems, and blood clots.
- Urinalysis is an important aspect of preadmission testing.
  - A urinalysis can help diagnose or rule out certain urological conditions (e.g., kidney and bladder infections). Urinalysis can also determine a patient's hydration status and identify illegal drugs in the body.
  - Urine pregnancy tests are required for women of childbearing years who have not undergone a hysterectomy. This helps ensure patient safety and that of an unborn baby.

### Confirming the Presence of Preoperative Documents

Before surgery, patients must complete a set of preoperative documents. These forms may seem daunting to patients; however, they play a vital role in ensuring a safe and successful procedure. Preoperative documents typically cover various aspects of the patient's health and surgical plan. Some common forms include the following:

- Medical H&P: This form details past surgeries, medications, allergies, and any existing medical conditions. Family and social histories are also obtained, which helps in identifying potential risks and ensuring the

- patient is optimized for surgery. The professional completing the H&P also performs a physical examination.
- Informed consents: These are crucial legal documents that provide a detailed overview of the surgery, including its risks, benefits, and alternatives.
    - An informed consent (see [16.3 Legal Dimensions of Care](#)) is a crucial legal process that goes beyond merely signing a form. It requires a thorough discussion between the healthcare provider and the patient (or their legal guardian) to ensure a complete understanding of the procedure and its risks, benefits, and alternatives. This crucial communication allows the patient to make an informed decision about their care. Although nurses may witness the signing of consent forms, the legal responsibility of obtaining informed consent and confirming the patient's understanding lies with the professional who will perform the procedure (i.e., surgeon, anesthesia provider).
  - Anesthesia assessment: This form gathers information about the patient's tolerance for anesthesia and potential risks. The anesthesia provider completes this assessment.
  - Advance directives: These documents specify the patient's wishes regarding life-sustaining measures in case of complications.

Taking the time to carefully review and complete preoperative documents is essential for a smooth and successful surgical journey. By providing accurate information and fostering open communication, these forms pave the way for safer procedures, faster recoveries, and ultimately, improved patient outcomes.

### Preparing the Bowel

The medical procedure of **bowel preparation (bowel prep)** is designed to clean the colon and rectum before certain medical or surgical procedures (e.g., colonoscopy, colorectal surgery). The goal of bowel prep is to remove stool and debris from the digestive tract, allowing for better visualization of the intestinal lining and reducing the risk of complications (e.g., infection) during the procedure. Bowel preparation typically involves a two-pronged approach:

- Dietary modifications: The day(s) leading up to surgery often require a low-fiber diet or clear liquid diet to minimize stool production. Clear liquids may include water, broth, clear juices, and gelatin. This reduces the volume of material that needs to be removed and lowers the risk of blockages during surgery.
- Medications: Laxatives or enemas may be prescribed to stimulate bowel movements and remove remaining stool.
  - Laxatives are medications that promote bowel movements and help clear the colon. They may be in the form of pills, powders, or liquids. Common laxatives include polyethylene glycol (PEG), magnesium citrate, sodium phosphate, or other prescribed medications.
  - Enemas involve introducing a liquid solution into the rectum to stimulate bowel movements and aid in cleaning the lower part of the colon. Types of enemas may include saline enemas or commercially available bowel prep solutions.

The specific timing of when to start the bowel prep and when to complete it depends on the type of preparation prescribed and the timing of the scheduled procedure. Healthcare providers give the patient clear instructions regarding when to start and complete each component of the bowel prep. It is crucial for patients to follow the provided instructions diligently to ensure effective bowel preparation. While bowel prep can be uncomfortable and may cause temporary diarrhea, its benefits in terms of improved visualization and safety during medical procedures outweigh the temporary inconvenience. Patients should communicate any concerns or difficulties with their healthcare providers, who can provide guidance and potentially adjust the bowel prep regimen based on individual needs.

### Preparing the Skin

Preparing for surgery also involves prepping the skin on and around the incision site to minimize the risk of infection and ensure optimal healing. This meticulous process involves both preoperative and intraoperative measures.

Patients may be instructed on things they need to do at home before arriving at the surgical facility for surgery. For example, patients may be given specific instructions for cleansing the skin or showering before surgery and may be advised to avoid lotions and creams. The preoperative instructions often include using a special antiseptic solution to wash the skin. Common antiseptic solutions used for this purpose include alcohol-based chlorhexidine gluconate or iodine-based solutions. These antiseptics help reduce the number of microorganisms on the skin, decreasing the risk of a **surgical site infection (SSI)**, an infection that occurs at or near surgical incisions within thirty days of the

procedure or within one year in the case of organ or space infections with an implant. When choosing a product, the provider will take the requirements and location of the planned procedure as well as any patient allergies into account. Patients should be provided with clear instructions on how to use the product and know who to contact if they have questions about performing the preoperative routine.

Patients are instructed not to remove hair at the surgical site. Shaving the incision site and the area around it within twenty-four hours before surgery is no longer recommended. Instead, healthcare providers may trim or clip hair if necessary after the patient arrives at the facility, minimizing skin irritation and potential infection risk.

Just before surgery, a healthcare professional will meticulously clean on and around the incision area with specialized antiseptic solutions like chlorhexidine gluconate. This further reduces bacterial burden and prepares the skin for the sterile environment of the OR. Sterile drapes are then used to create a barrier between the surgical site and the surrounding nonsterile areas, minimizing the risk of contamination during the procedure.

### Providing Preoperative Instructions

Preoperative instructions have several important roles:

- **Enabling active patient participation:** Patients become empowered partners in their care and are directly contributing to positive surgical outcomes by following the instructions.
- **Empowering through knowledge:** Patients are provided with the information they need to make informed decisions about their care and feel confident that they will be able to follow the instructions before and after surgery.
- **Minimizing risk:** Closely adhering to preoperative guidelines, such as fasting before surgery and stopping certain medications, reduces the risk of complications during and after surgery.
- **Alleviating anxiety:** Clear explanations about what to expect before, during, and after surgery help ease patients' anxieties and give them more of a sense of control over the situation.
- **Promoting optimal outcomes and patient health:** Preoperative instructions may include guidance on lifestyle changes, medication adjustments, and hygiene practices that will help position patients to be in the best possible shape for their surgery and recovery.

Preoperative instructions cover many topics. These include fasting guidelines, medication management, hygiene practices, clothing and personal items, transportation arrangements, and arrival time:

- **Fasting guidelines:** Clear instructions on when to stop eating and drinking before surgery help minimize the risk of aspiration during anesthesia and decrease the severity of pulmonary complications if aspiration occurs. Historically, patients were instructed to fast after midnight the night before surgery. However, many patients experience problems (e.g., dehydration) with extended fasting, especially if surgery is scheduled for the afternoon (Chon et al., 2017). These guidelines have been updated (Apfelbaum et al., 2017). A common instruction for the timing of preoperative fasting includes the following:
  - **Two hours:** Simple or complex carbohydrate-containing clear liquids are encouraged up to two hours before surgeries requiring general anesthesia, regional anesthesia, or procedural sedation.
  - **Four hours:** Infants may consume breast milk up to four hours before surgery.
  - **Six hours:**
    - A light meal (e.g., toast and clear liquids) may be eaten six hours before surgery.
    - Nonhuman milk and formula should be stopped six hours before surgery.
  - **Eight hours:** Fried or fatty foods and milk may require additional fasting time.
- **Medication management:** The nurse performing the preoperative phone call should use facility guidelines and physician-specific orders to determine whether to continue or discontinue certain prescription and over-the-counter medications in the days leading up to surgery. The goal is to help lower risks associated with bleeding or interactions with anesthetic medications. While each facility and surgeon may have specific protocols, here are a few common examples:
  - **Anticoagulants (blood thinners)** (e.g., aspirin, warfarin, clopidogrel, nonsteroidal anti-inflammatory medications such as ibuprofen) and all vitamins, supplements (fish oil), and herbals should be discontinued for a specified period of time before surgery (e.g., five to ten days before surgery).
  - **Antihypertensive medications:** Certain antihypertensive medications as listed should be held before surgery. If the patient takes the medication at night, instruct the patient to hold the evening dose the

night before surgery. Also, have the patient hold the medication the day of surgery (Wagner et al., 2019). The following should be held before surgery:

- angiotensin converting enzyme inhibitors (ACE-I): benazepril (Lotensin), lisinopril (Prinivil), enalapril (Vasotec)
- angiotensin II receptor blockers: losartan (Cozaar), valsartan (Diovan), irbesartan (Avapro)
- Patients with diabetes:
  - Insulin: Nurses should refer to facility protocol for perioperative management of patients with diabetes. A finger-stick blood sugar should be performed on arrival at the facility on the day of surgery if the patient has diabetes. The nurse should notify the anesthesia provider if surgery start time is delayed for guidance on blood sugar monitoring and IV placement (Khan et al., 2024).
  - Oral antidiabetics: Patients should hold on the day of surgery.
- Weight-loss/central nervous system (CNS) (e.g., phentermine) stimulant medications: Patients should stop taking seven days before surgery (Adams, 2023).
- Anti-attention deficit hyperactivity disorder agents: Agents such as dextroamphetamine (e.g., Adderall) should not be taken the day of surgery (Engelman & Cramer, 2023).
- Hygiene practices: The nurse should instruct the patient on preoperative bathing and skin preparation with antimicrobial soap to help reduce the microbial load on the skin, which can help prevent SSIs.
- Clothing and personal items: The nurse should instruct the patient on what clothing to wear on the day of surgery and to leave valuables at home to prevent the loss or contamination of these items. The patient should be told not to wear cosmetics or use lotions before surgery. The nurse should instruct the patient to remove all jewelry and accessories. This includes removing rings and all body piercings to prevent patient injury from burns, pressure-related tissue injury, and SSIs. Nurses should understand that simply placing tape over the jewelry does not eliminate the risks of wearing them in surgery.
  - When electrosurgery is used during a procedure, body jewelry may conduct the electrical current and cause electrical burns to the surrounding tissue.
  - Metal body jewelry may interfere with ultrasound, CT, and MRI and cause injury to the patient during the procedure.
  - Nursing personnel should learn techniques for safe jewelry removal and to maintain patent piercing tracts. Facilities should ensure the availability of tools needed to safely remove body-piercing jewelry. Nose, tongue, or lip jewelry make airway management and visualization of the airway during intubation difficult and dangerous to the patient. Genital piercing can pose problems during urinary catheter insertion and may result in urethral tears that could require cystostomy or surgical closure.
- Transportation arrangements: To give patients time to plan, the nurse making the preoperative call should gather information about transportation to and from the surgical facility, including any restrictions on driving after certain types of anesthesia. If the patient is having same-day surgery and is undergoing general or regional anesthesia or conscious sedation, a driver is required to take the patient home. Patients may ask if they can take a rideshare (e.g., Lyft, Uber, taxi). However, the rideshare driver cannot be held responsible for transporting the patient into and out of the vehicle. Therefore, rideshares are prohibited unless an adult accompanies the patient and assumes responsibility for the patient.
- Arrival time: Specific instructions on when to arrive at the surgical facility or hospital for preoperative assessments and preparations are needed to guide patients through the schedule for the day. Adequate time ensures steps are completed without rushing.
- Documentation: The nurse should remind the patient to bring essential documents, including photo identification, insurance information, and any preoperative paperwork and consent forms. This helps make the process go more smoothly on the day of the surgery and decreases the likelihood that something important will be forgotten or incomplete.
- Contact information: Emergency contact information should be obtained from the patient as well as instructions on whom to contact if the patient has questions or concerns before the surgery.

### Providing Postoperative Instructions

Providing postoperative instructions is crucial to help prepare the patient in advance for self-care on discharge. Instructions may include the following:

- General information about what to expect after surgery (e.g., postoperative pain management, activity

restrictions and recommendations, potential side effects) helps the patient feel more prepared.

- Instructions for wound care are also important, and patients need to be aware of their responsibility for taking care of their wound after the procedure. This may involve changing bandages regularly or leaving them undisturbed until the follow-up appointment. Patients should also be instructed on how to recognize a potential wound infection as well as what signs and symptoms would warrant calling their provider.
- Additional instructions may include general advice for maintaining good personal hygiene (e.g., hand hygiene before and after touching the wound), adhering to dietary and nutritional instructions, and staying adequately hydrated and well rested. Instructions should be provided for the safe application of ice or heat after surgery if ordered.
- The nurse should provide personalized guidelines to help the patient manage pain and ensure that the patient is knowledgeable about the prescribed pain medications ordered for home use.

### Formats Used for Preoperative Instructions

Using a combination of communication methods helps address the needs of diverse patient learning styles and preferences.

- Written instructions: Printed or electronic documents are often given to patients from the surgeon's office during preoperative visits or via online patient portals.
  - Whenever possible, the nurse should ensure that instructions are written at no greater than a sixth-grade reading level. Stress and fear greatly inhibit learning. Even people with advanced education may have difficulty understanding and remembering surgical information.
  - Visual aids: Infographics, videos, or visual aids can enhance patient understanding and are useful for offering clarification or answering questions.
  - Foreign language: Facilities should be prepared to provide written instructions in the patient's primary language.
- Verbal communication: Healthcare providers, including nurses and surgeons, will verbally reinforce instructions during preoperative assessments or consultations. Patients are encouraged to ask questions, clarifying any concerns and ensuring full comprehension.
  - Facilities should be prepared to provide interpreters in the patient's primary language.
  - As an alternative to in-person translators, nurses should be aware of and prepared to use one of the many online, real-time interpretation services that are now available.

### The Role of the Perioperative Nurse

Nurses are the patient's primary advocate serving as a trusted resource and ensuring patient safety throughout the surgical journey. They explain procedures, address concerns, provide emotional support, ease anxieties, and foster a sense of security. The perioperative nurse may work in any of the three areas of perioperative services:

- Preoperative preparation: A few of the steps of care provided by the preoperative nurse are assessing patients, managing anxieties, and ensuring informed consent has been completed by the surgeon.
- Intraoperative care: The **scrub person** (nurse, surgical technologist) sets up the sterile field and assists the surgeon by passing instruments. The RN circulator manages the overall environment to ensure safety, prepares the patient, and provides necessary supplies. A **perioperative first assistant** (e.g., **registered nurse first assistant [RNFA]**, certified surgical first assistant [CSFA], surgical physician's assistant [PA], perioperative nurse practitioner [NP]) with advanced education and training helps the surgeon with tasks such as holding retractors and suturing.
- Postoperative recovery: Perioperative nurses assess and care for patients in the postanesthesia care unit (PACU) (formerly referred to as the recovery room), manage pain, monitor vital signs, anticipate and treat postoperative complications (e.g., airway management, cardiovascular interventions), and provide essential early postoperative care.

The perioperative nurse's role is not merely technical; it is deeply human. The nurse navigates the emotional tides of patients and families, offering reassurance and compassion during a vulnerable time. Their expertise, adaptability, and unwavering dedication are the bedrock of safe and successful surgery.

### Performing the Preoperative Assessment

The nurse's role in **preoperative assessment** includes conducting a comprehensive physical and psychosocial

evaluation. The nurse is responsible for reviewing past surgeries, medications, allergies, and any preexisting conditions and identifying potential risks. The nurse then tailors a patient-specific nursing care plan.

The nurse assesses the patient's overall health, pain levels, and potential anatomical variations that might affect the procedure. It is also the responsibility of all surgical team members at every step of the process to confirm the patient's identity and the type and site of the surgery to be performed to ensure that the correct location is established before the patient goes to the OR. The nurse should also recognize the emotional weight of surgery. Addressing anxieties, providing emotional support, and ensuring informed consent are crucial aspects of a holistic assessment.

## CULTURAL CONTEXT

---

### Cultural Considerations During the Preoperative Assessment

The nurse should be aware of the unique individual needs of each patient and pay particularly close attention to how a patient's culture may influence their beliefs and practices about surgery and recovery. Providing culturally aware care during the preoperative stage helps build trust, establishes therapeutic rapport, improves understanding, and contributes to better patient outcomes. Here are a few ways that nurses can incorporate a patient's cultural considerations into their assessment.

#### Language and communication:

- Identify the patient's primary/preferred language: Ask, "What language do you prefer to speak?" Never make assumptions about a patient's language based on appearance or name.
- Provide interpreters: When possible, use certified medical interpreters for patients with limited proficiency in the primary language of the healthcare setting. Translating medical and legal language requires specific skills. Therefore, do not have patient family members translate because this can lead to misunderstandings. If a medical interpreter is not available, assistive technology that helps translate in these situations may be useful.
- Translate materials: Give instructions and documents in the patient's preferred language, if possible. Check with your facility to see if they have a trusted translation service for medical documents or if documents can be printed in multiple languages.

#### Health beliefs and practices:

- Be open to learning from patients: Ask, "Are there any cultural or religious beliefs I should be aware of regarding your health or upcoming surgery?" For example, a patient might request a moment of prayer or a ritual cleansing before surgery.
- Respect traditions: Some patients may use traditional remedies or have specific beliefs about illness and healing. For example, a patient from a culture that uses traditional medicine might be apprehensive about conventional surgical procedures or anesthesia. Acknowledge these beliefs with respect, and find ways to incorporate them into the care plan.

#### Decision-making and family:

- Identify decision-makers: In some cultures, decisions are made collectively with their family or specific people within the family. Ask the patient who should be involved in discussions.
- Support family involvement: Facilitate family participation in the preoperative process, if desired by the patient. If not, make sure you have a clear understanding of who should not be involved in the patient's care.

#### Religious practices:

- Spiritual needs: Ask about any religious practices or rituals that the patient would like to be accommodated before, during, or after surgery. For example, some patients may refuse blood transfusions because of their religious beliefs, and this must be considered in surgical planning. Nurses should be prepared to discuss alternatives to blood transfusion that may be available, for instance, implementing options for preoperative optimization of hemoglobin levels, employing cell salvage (a procedure whereby blood lost during or after surgery is collected and then transfused back to the patient) intraoperatively and postoperatively, and

supporting hematopoiesis (the process by which blood cells are produced to maintain the levels of circulating blood cells in the body) throughout perioperative care.

- Dietary restrictions: Be knowledgeable of any fasting practices (e.g., Ramadan) or dietary restrictions (e.g., kosher, halal) that may need to be factored into preoperative and postoperative instructions.

Modesty and privacy:

- Respectful draping: Provide options for gowns or draping that align with cultural preferences and norms around modesty.
- Gender considerations: Some patients may have a clear preference to be treated by healthcare providers of the same gender identity, if possible. Nursing managers should make every effort to facilitate these interactions in accordance with patient preferences.

Nonverbal communication:

- Observe cues: Be aware that nonverbal cues (e.g., eye contact, body language) may have different meanings across cultures. Do not assume that your perception based on your cultural background is the same for your patient. For example, in American culture, avoiding eye contact may be seen as shyness or even evasiveness. However, for Muslim patients, it may be a sign of deference and respect.
- Avoid assumptions: Do not assume that a patient's silence implies agreement or understanding. It is critical that you create a safe space for questions and clarification.

Complementary and alternative medicine (CAM):

- Ask about CAM use: Ask patients if they use herbs, supplements, or traditional healing practices. Do this not only so you can include them in care, when possible, but also so you can be alert for how they might interact or affect traditional treatments or medications used during surgery.
- Prioritize collaboration, not judgment: Work with patients, families, and other healthcare providers to integrate any safe and beneficial CAM practices into the patient's care plan.
- Cultural sensitivity: When providing care, cultural sensitivity requires open communication, respect, and a willingness to learn. What is considered acceptable in some cultures may be considered abhorrent in others. Nurses cannot look at the norms of one culture through the lens of their own culture.

The nurse's keen observation skills and ability to build rapport with patients are invaluable assets. They can detect subtle cues of discomfort, unearth hidden concerns, and ensure the patient feels heard and understood. The preoperative nurse then communicates this information to the surgeon, anesthesia provider, and RN circulator to ensure a collaborative approach to care.

### Implementing Preoperative Nursing Interventions

Although the facility and surgical team will have specific requirements for the nurse to follow to prepare patients for surgery, there are some items that are expected components of the preoperative nursing assessment checklist ([Table 31.2](#)) (Stony Brook Medicine, n.d.).

Stage	Nurse's Role	Things to Consider
General information	Confirm patient identification, reason for surgery, allergies, medications, and advance directives.	Direct patient to appropriate resource if insurance questions arise.
Medical and surgical history	Document chronic and acute medical conditions, past surgeries, anesthesia history, and family history.	Determine which, if any, conditions may affect the perioperative course.

**TABLE 31.2** Components of the Preoperative Nursing Assessment Checklist

Stage	Nurse's Role	Things to Consider
Physical assessment	Assist with gowning, confirm surgical site, establish IV access, obtain baseline vitals, and perform relevant system assessments (cardiovascular, respiratory, neurological, skin, musculoskeletal). Encourage voiding.	Ensure patient's personal belongings are secure.
Psychosocial assessment	Assess anxiety levels, support systems, coping mechanisms, and understanding of the procedure.	Consider cultural, spiritual, and religious beliefs/practices that may be relevant to surgery and postoperative care.
Preoperative preparation	Verify NPO (nothing passed orally) status (no eating or drinking for a set period of time before surgery), review laboratory/diagnostic tests, perform skin preparation if needed, document prostheses/devices, and confirm removal if necessary.	Ensure hair removal from linen and surgical garments if applicable.
Education and discharge planning	Reinforce preoperative instructions, demonstrate postoperative exercises, discuss postoperative expectations (pain management, recovery, wound care, activity restrictions, follow-up), and identify patient's support system.	Preoperative exercises (e.g., have the patient demonstrate correct use of the incentive spirometer) can improve postoperative compliance and recovery.

**TABLE 31.2** Components of the Preoperative Nursing Assessment Checklist

This document provides an [example of a task checklist \(https://openstax.org/r/77taskchecklist\)](https://openstax.org/r/77taskchecklist) that preoperative nurses may encounter.

### Providing Pain Management

While pain medication plays a crucial role in preoperative care, the nurse's involvement in pain management extends far beyond simply administering medications. They take a patient-centered approach, employing various interventions to minimize discomfort and promote a calmer, more positive surgical experience.

When possible, nurses may recommend medications or nerve blocks before the onset of significant pain. As the patient's advocate, the nurse may be called on to collaborate with providers to determine if this proactive approach is appropriate for the patient and would help reduce postoperative discomfort and improve recovery time. It is important for nurses to recognize that anxiety and fear can exacerbate pain perception. Nurses should provide emotional support, address concerns, and employ relaxation techniques like guided imagery or deep breathing to manage anxiety and reduce pain (Stanford Medicine, n.d.).

Nurses should educate patients about nonpharmacological pain management techniques that can be used both before and after surgery. These strategies can reduce pain, decrease how much pain medication is needed, and alleviate stress. While pain management must be tailored to the patient, there are some general nonpharmacological pain management strategies the nurse should be aware of and able to suggest to patients:

- Deep breathing and relaxation techniques: Practicing deep breathing exercises, mindfulness techniques, or guided meditation may help manage anxiety and may even decrease sensitivity to pain.
- Distraction methods: Distraction techniques such as listening to music, watching a favorite show, or engaging in light conversation may help divert attention from pain or discomfort.
- Cold and heat therapy: The safe use of cold packs or heating pads can help reduce inflammation and pain, depending on the specific procedure and surgeon's recommendations.

- **Proper positioning:** Positioning that supports the body, reduces pressure on surgical sites, and promotes comfort can go a long way to helping patients be more at ease physically and mentally. Provide pillows or other positioning aids for comfort as well as to help prevent pressure sores.

What works for one patient may not work for another, so it is up to the nurse to work with the patient and advocate on their behalf to ensure their pain is managed and to adapt to changing needs for pain management throughout the surgical journey and on to recovery.

### Teaching Coping Strategies

A key aspect of preoperative interventions involves teaching patients coping strategies to navigate the anxiety and stress associated with the upcoming procedure (Stanford Medicine, n.d.; Tsegaye et al., 2023). Nurses should take a personalized approach, tailoring guidance to each patient's individual needs and preferences. They may do the following:

- **Identify coping mechanisms:** Encourage patients to explore their existing coping skills, whether it is deep breathing, mindfulness techniques, spending time with loved ones, or engaging in hobbies.
- **Introduce new strategies:** Introduce relaxation techniques like guided imagery, progressive muscle relaxation, or visualization exercises if a patient lacks coping mechanisms.
- **Promote positive self-talk:** Encourage the patient to challenge their own negative thoughts and replace them with affirmations; this can significantly reduce anxiety and pain levels and improve preoperative well-being.
- **Provide resources:** Connect patients with additional resources, such as support groups, educational materials, or online resources to enhance their coping toolbox.

The effectiveness of these strategies is backed by research. Studies have shown that educational conversations between the patient and healthcare providers can help prepare surgical patients and significantly reduce anxiety (Aust et al., 2016). By facilitating or providing teaching, nurses not only lessen the emotional burden of surgery but also play a crucial role in optimizing the overall surgical experience.

## PATIENT CONVERSATIONS

---

### Coping with Pain

**Nurse:** Hi, I'm Maria. I will be your preoperative nurse this morning. Can you tell me your name, birthday, and the surgery you are having today?

**Patient:** Yes, I'm Veronica LaBate and my birthday is July 6, 1972. I am having a right knee replacement.

**Nurse:** Thank you. How are you feeling? Do you have a few minutes to talk with me about your surgery?

**Patient:** Sure. Honestly, I'm a little bit nervous. Well, maybe a lot nervous. I've heard the recovery can be . . . pretty rough.

**Nurse:** Feeling nervous is normal. That's why having a chat now is helpful. We want to make sure that any concerns or questions you have get answered. By "rough," are you worried about how long it will take to heal? Or that you'll be in pain?

**Patient:** Oh, I'm scared of the pain. I know it's going to hurt some, but what if I wake up and it hurts a lot?

**Nurse:** Managing pain is a very important part of what the team will do for you, and it starts before we even get to the OR. We can talk about it now, actually. Let's start by talking about how to measure your pain. We use a pain scale to help you tell us about your pain. It goes from zero, which is no pain at all, to ten, which is the worst possible pain you could ever imagine. When I had surgery last year, I reminded myself that ten pain is like standing on a sidewalk and a car runs over you. That helped me be objective about my pain so I could compare the pain number I gave my pain before surgery with the pain number I gave the pain after surgery. Does that make sense?

**Patient:** Yes, I think I understand.

**Nurse:** So, how would you rate your pain or discomfort right now?

**Patient:** My knee just aches right now. I guess I would say it's a two out of ten.

**Nurse:** OK. When you wake from surgery, your recovery nurse will ask you to rate your pain. Remember what it felt like now and what ten might be like compared to your postoperative pain. So, let's get back to your fear of pain after surgery.

**Patient:** Well, I know you'll give me medicine, but I don't even like taking a Tylenol for a headache. I'm pretty nervous about those painkillers people get addicted to, and I think I'll try to tough it out without them.

**Nurse:** Medicine is part of pain management, and it has an important role in helping keep your pain controlled during the surgery and afterward. It's important that you're not in so much pain that you can't rest and heal properly, but we want to balance that with the side effects and risks that come with medicine. Luckily, you don't just have to rely on pain medicine alone to cope. Can you think of any nonmedical ways you deal with pain?

**Patient:** Well, when my knee aches a heating pad usually helps.

**Nurse:** Heat therapy is what we call a nonpharmacological pain management technique. There will be some techniques that you can use after your surgery to help you cope with the pain, and sometimes they work well enough that you don't need as much pain medicine. For example, deep breathing exercises and relaxation techniques can significantly help with pain and anxiety.

**Patient:** Really? How?

**Nurse:** Well, deep breathing gets more oxygen flowing through your body and brain and can help you relax and loosen your muscles, which can naturally ease pain. Mindfulness or guided imagery can help distract your mind from the pain, which can sometimes make it more manageable. Some people find that listening to music or watching movies also helps distract them.

**Patient:** Will I be able to use my heating pad?

**Nurse:** Cold or heat therapy can be very effective. Cold therapy is great for reducing swelling and inflammation, while heat therapy can relax muscle tension and improve blood flow, helping with pain relief. We'll find out for sure from your surgeon whether these will be appropriate options for you, depending on your surgery.

**Patient:** That all sounds fine, but what if I do all those things and I'm still in a lot of pain?

**Nurse:** Well, if at any point the pain is worse or not something you feel you can manage, we want you to let us know right away. It's important for your recovery that we manage your pain. At that point, we may want to adjust the amount or type of your medicine so that it helps more. It can also help to change positions and move around to avoid putting extra pressure on your wound, which can hurt and delay healing.

**Patient:** How will I remember all this after I get home?

**Nurse:** Before you're discharged, we'll give you detailed instructions on managing your pain at home, including how to take your medicine safely and a list of these other techniques we talked about that you might want to try. Plus, we will make sure it's clear how and when you should contact your surgeon if you have any concerns about your pain levels.

**Patient:** That makes me feel a bit better, actually. Not just knowing I have options but that I can call someone if I get home and am hurting and don't know what to do.

**Nurse:** We definitely want you to feel informed and empowered, but don't worry—you won't be going through this alone.

---

### Attending to Family Needs

The preoperative stage is often a whirlwind of emotions for not only the patient but also their family members. Navigating anxieties, managing logistics, and providing support all fall within the scope of the preoperative nurse's role, ensuring a positive experience for both the patient and their loved ones.

Nurses should employ active listening and open communication, addressing specific fears and questions to create a foundation of trust and understanding. It is also important to explain the procedure, potential complications, and

recovery process, which empowers families to be active participants in their loved one's care. Clear communication reduces anxiety and facilitates informed decision-making. Family members often grapple with their own anxieties. Nurses can offer emotional support, provide resources like support groups, and connect them with other families facing similar experiences.

By attending to both the emotional and practical needs of families, nurses play a crucial role in creating a supportive environment for patients during preoperative interventions. This holistic approach not only fosters a positive experience for the entire family but also contributes to a smoother and more successful surgical journey for the patient.

### Initiating the Perioperative Records

Perioperative nurses, acting as guardians of information, play a critical role in initiating and maintaining accurate and comprehensive patient records. These records are not mere paperwork; they are the vital narratives of a patient's surgical journey, informing future care, ensuring safety, and contributing to medical advancements. From the moment the patient arrives at the facility to when they go to the OR, preoperative nurses meticulously record every step of the process, including vital signs, medications administered, procedures performed, and unexpected events. This detailed record serves as a real-time account of the preoperative stage, allowing for immediate adjustments and ensuring accurate communication between the different perioperative stages.

The RN circulator continues to maintain the patient's record by documenting intraoperative activities (e.g., time-outs performed, position and positioning aids used, hypothermia interventions, counts, medications on the sterile field, wound irrigation, electrosurgical dispersive pad placement) and patient outcomes (e.g., surgical procedures performed, skin integrity, wound status, final count status). As the patient recovers, PACU nurses continue to document vital signs, pain levels, interventions provided, and any complications.

This ongoing record tracks the patient's progress, identifies potential issues early, and helps tailor recovery plans for optimal outcomes. Maintaining consistent formats and adhering to established documentation protocols ensures clarity, completeness, and legibility of records. This allows for efficient information sharing between healthcare providers and facilitates accurate data analysis for research and quality improvement initiatives. By meticulously documenting every aspect of the perioperative journey, nurses play a crucial role in safeguarding patient safety, informing future care, and advancing the field of medicine. Their dedication to accurate and comprehensive records ensures that every scalpel stroke, every suture, and every heartbeat is not just witnessed but also remembered for the benefit of patients now and in the future.

### Administering Preanesthetic Medication

Preoperative nurses, acting as medication safety champions, ensure the safe and effective delivery of preanesthetic medications. These critical medications promote a safe, comfortable surgical experience. Nurses conduct thorough patient reviews, considering factors like allergies, medical history, and medication interactions. This comprehensive analysis ensures the selection of the most appropriate preanesthetic medication for each individual patient, minimizing risks and optimizing outcomes. Preanesthetic medications serve several purposes, including the following (Aegis Anesthesia, 2023):

- **Anxiolysis:** An **anxiolytic**, like benzodiazepines (e.g., midazolam), reduces anxiety and promotes a calming effect. This can help alleviate preoperative fears and create a more relaxed state.
- **Sedation:** Certain medications (e.g., benzodiazepines, opioids) induce a state of relaxation and sedation. This helps minimize distress and discomfort during the induction of anesthesia.
- **Amnesia:** Some preanesthetic medications, particularly benzodiazepines because of their rapid onset and short duration of action, are used to promote temporary memory loss or amnesia. This helps patients forget the events surrounding the induction of anesthesia and the procedure itself.
- **Analgesia:** Opioid analgesics like fentanyl may be administered preoperatively to provide pain relief and reduce the perception of pain during the preoperative process, surgery, and postoperative recovery period.
- **Antisialagogue and anticholinergics:** Medications called **antisialagogues** and anticholinergics, like glycopyrrolate, reduce salivation, minimizing the risk of aspiration during the procedure and preventing bradycardia.
- **H2 blockers or proton pump inhibitors:** These medications (e.g., omeprazole [Prilosec]) are given to reduce gastric acid secretion and minimize the risk of aspiration in patients at risk.

- Antiemetic: Medications can be administered intravenously (ondansetron [Zofran]) and transdermally (scopolamine patches) for their antiemetic properties to prevent postoperative nausea and vomiting.

It is essential to administer preanesthetic medications according to the appropriate schedule to ensure the medication has sufficient time to take effect before the induction of anesthesia. Continuously monitoring the patient's vital signs, including blood pressure, heart rate, respiratory rate, and oxygen saturation, is crucial during and after the administration of preanesthetic medications to make sure they remain a safe and effective treatment. Prior to the administration of preanesthetic medications, it is also important for the patient to sign the necessary consent forms and to urinate, ensuring they are physically and legally prepared for the procedure.

Nurses follow strict protocols and guidelines for medication administration, adhering to the eight rights of medication administration: right patient, right medication, right dose/concentration, right route, right time, right documentation, right reason, and right patient response (Comerford & Durkin, 2021). Meticulous adherence to the eight rights helps to prevent errors and helps ensure the intended effects of the medication are realized. Nurses proactively address any emerging issues, adjusting medication regimens or notifying the surgical and anesthesia team, if necessary.

## 31.3 Intraoperative Phase

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the roles of the surgical team
- Identify key components of the surgical environment
- Analyze potential intraoperative complications

The **intraoperative stage** begins as soon as the patient is transferred to the OR and concludes when the patient is transferred to the PACU. This stage is a highly coordinated effort by a multidisciplinary professional team that includes surgeons, anesthesia providers, perioperative nurses, and surgical technologists, with each member playing a unique and equally vital role.

Perioperative nurses are fully aware of their surroundings and understand the space in which they will be working. The OR environment is a carefully controlled and sterile setting that is designed to minimize the risk of infection and optimize patient outcomes. From the specialized equipment, the design and layout of the space, and the intricate protocols and procedures, every aspect of the perioperative space is carefully orchestrated to optimize patient care and team efficiency.

However, even the most well-designed OR with advanced tools and strict protocols cannot make up for the presence of skilled providers who can work together. The surgical team must be vigilant and responsive to potential complications. Effective communication with informed and swift decision-making and a deep understanding of the patient's unique circumstances are crucial for mitigating risks and addressing any unforeseen challenges that may arise.

The nurse must understand the roles and responsibilities of the surgical team, understand the key components of the surgical environment, and recognize potential intraoperative complications that can occur. Nurses must understand the dynamic and complex nature of surgical care and be equipped with the knowledge necessary to contribute effectively to the surgical team.

### Surgical Team and Assigned Roles

Each member of the surgical team contributes to how a surgery unfolds, and it is their actions that will ultimately ensure patient safety and optimal patient outcomes. The RN circulator orchestrates the flow of the OR. They manage supplies and equipment, ensure sterile technique, anticipate the surgeon's needs, coordinate communication, document the surgery's progress, and advocate for the patient's well-being throughout the procedure. The surgeon is trained to perform surgical procedures and bears the ultimate responsibility for the surgery and the actions of the other surgical team members. The skilled experience of the scrub person (e.g., scrub nurse, surgical technologist) allows close collaboration with the surgeon by preparing and organizing surgical instruments, anticipating the surgeon's next move, and maintaining a sterile field. The anesthesia provider ensures the patient's comfort and safety throughout the procedure by administering anesthesia and monitoring vital signs.

Perioperative first assistants are specifically trained to assist the surgeon directly by retracting and suturing tissues, providing additional instrumentation, and anticipating needs, among other things.

Each member of this surgical team, with their unique skills and expertise, contributes to the harmonious performance of a successful operation. By understanding and appreciating their roles, nurses can better collaborate with the team, ensuring the highest quality of care ([Table 31.3](#)).

Surgical Team Role	Responsibilities	Key Points
RN circulator	<ul style="list-style-type: none"> <li>• Assesses and educates preoperative patients</li> <li>• Prepares and maintains the sterile operating room (OR) environment</li> <li>• Collaborates with the scrub person, anesthesia provider, and surgeon</li> <li>• Monitors the sterile field to prevent contamination</li> <li>• Ensures an accurate <b>surgical count</b> to prevent <b>retained surgical items (RSIs)</b></li> <li>• Manages the intraoperative “<b>time-out</b>”</li> <li>• Tracks surgical progress and provides supplies as needed</li> <li>• Collects and processes specimen, applies dressings, and transfers the patient to the postanesthesia care unit</li> </ul>	<ul style="list-style-type: none"> <li>• Acts as patient’s primary advocate</li> <li>• Orchestrates the flow of the surgical environment</li> <li>• Collaborates with the surgical team</li> <li>• Acts as a vigilant guardian intraoperatively</li> <li>• Tracks progress</li> <li>• Ensures transition to postoperative care</li> </ul>
Scrub person	<ul style="list-style-type: none"> <li>• Assists the RN circulator in OR setup</li> <li>• Assembles and passes instruments and supplies to the surgeon</li> <li>• Labels medications and fluids on sterile field</li> <li>• Manages specimens on the sterile field</li> </ul>	<ul style="list-style-type: none"> <li>• May be an RN or a surgical technologist</li> <li>• Scrubs in during surgery</li> </ul>
Surgeon	<ul style="list-style-type: none"> <li>• Performs preoperative evaluation, discusses surgical options with the patient, and determines the surgical approach</li> <li>• Obtains informed consent</li> <li>• Leads surgical team and makes critical decisions during surgery</li> <li>• Maintains communication with anesthesia provider and other team members</li> <li>• Monitors patient’s recovery and provides follow-up care</li> </ul>	<ul style="list-style-type: none"> <li>• Retains ultimate responsibility for surgery</li> <li>• Leads a diverse team</li> <li>• Ensures clear communication</li> </ul>

**TABLE 31.3**

Surgical Team Role	Responsibilities	Key Points
Anesthesia provider	<ul style="list-style-type: none"> <li>• Conducts preoperative medical history and physical examination</li> <li>• Discusses anesthesia options and obtains informed consent</li> <li>• Administers anesthesia and monitors vital signs during surgery</li> <li>• Provides postoperative pain management orders</li> </ul>	<ul style="list-style-type: none"> <li>• May be a physician (anesthesiologist) or certified nurse anesthetist</li> <li>• Manages perioperative care</li> <li>• Monitors vital signs</li> <li>• Ensures postoperative pain management</li> </ul>
Perioperative first assistant	<ul style="list-style-type: none"> <li>• Assists surgeon during surgery by handling tissues, retracting, and using instruments</li> <li>• Anticipates surgeon's needs and provides technical support</li> <li>• Collaborates with surgeon to plan procedure and may meet patient preoperatively</li> <li>• Assists with wound closure, specimen collection, and patient transfer</li> </ul>	<ul style="list-style-type: none"> <li>• May be certified surgical first assistant, registered nurse first assistant, surgical physician's assistant, or perioperative nurse practitioner</li> <li>• Anticipates needs of the surgeon</li> <li>• Facilitates informed consent (surgeon responsible)</li> <li>• Assists with closure and transfer</li> </ul>

TABLE 31.3

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### National Patient Safety Goals and Surgery

The Joint Commission established National Patient Safety Goals (NPSGs) to promote patient safety and minimize risks in healthcare settings. There are several NPSGs that the nurse will need to consider that are of particular relevance to surgical care (The Joint Commission, 2024).

- **Correct site, correct procedure, correct patient:** This goal emphasizes the crucial steps taken to verify the exact surgical site, procedure, and patient identity before the surgery begins. This is often achieved through a “time-out” during which the entire surgical team pauses and confirms all the pertinent details at three points during the surgical process: before induction of anesthesia, before the first incision is made, and before the patient leaves the OR (World Health Organization, n.d.).
- **Prevention of wrong-site surgery:** Specific protocols and checklists are used to ensure that every surgery is performed on the intended body part, thereby greatly reducing the chances of a surgery being performed on the wrong site or the wrong procedure being done on the wrong patient. The nurse must be aware of the protocols and procedures at their facility that promote a culture of safety, such as marking the surgical site preoperatively and confirming the site several times before the surgery begins.
- **Communication:** Effective communication between surgeons, anesthesia providers, nurses, and other team members is one of the most essential components of patient safety during surgery. Clear communication ensures that all team members know and understand the surgical plan, are prepared for any potential issues, and are equipped to make necessary adjustments throughout the procedure.
- **Safe medication practices:** Adhering to safe medication practices, such as accurate medication labeling, proper dosage administration, and heightened vigilance for potential medication interactions, is essential to patient care before, during, and after surgery.
- **Infection prevention:** Maintaining a sterile environment is one of the most vital features of surgical safety. The

NPSGs emphasize the importance of practicing proper hand hygiene, using sterile technique, and administering antibiotics, when appropriate, to minimize the risk of SSIs.

## Key Components of the Surgical Environment

The OR is a meticulously controlled environment designed to minimize patient risk during surgical procedures. To keep this environment highly effective, it is important to be conscious of proper practices and protocols for maintaining **sterility** (state of being free from living microorganisms), mitigating fire hazards, and preventing occupational health risks.

**FIGURE 31.3** The operating room is designed and run in a manner that prioritizes safety and efficiency. (credit: “Clinical Center Operating Room” by National Institutes of Health Clinical Center/Flickr, CC BY 2.0)

### Surgical Asepsis and Sterile Technique

Surgical site infections are potentially serious infections that may occur in surgical wounds or around incisions within thirty days of the procedure or within one year in the case of organ or space infections with an implant. These serious infections remain a persistent adversary, jeopardizing patient recovery and adding a significant economic burden. Microorganisms lurk on patient skin, in the air, and on instruments, posing a constant threat to the vulnerable surgical wound. Meticulous adherence to aseptic techniques and rigorous sterilization protocols are crucial to minimizing this risk (Anderson & Sexton, 2024; WHO, n.d.).

The absence of all living microorganisms within any type of invasive procedure is **surgical asepsis**; this is achieved through rigorous sterilization processes and meticulously maintained through sterile technique. A set of specific practices and procedures employed to maintain sterility of the sterile field (e.g., equipment, instruments, drapes) is **sterile technique**.

Individual responsibility is paramount in preventing SSIs, which is demonstrated through having a **surgical conscience**. A surgical conscience is a moral code of integrity that compels a person to speak up when an infraction has or is thought to have occurred, to prevent patient harm (e.g., contamination increasing the risk of an SSI). Possessing a surgical conscience means that any time doubt exists about a product’s sterility or whether a behavior resulted in contamination, the person speaks up and takes appropriate action without fear or concern of embarrassment or criticism, even when no one else is watching. (Holm, 2023, p. 116)

Maintaining a sterile environment requires the following:

- **Hand hygiene:** The cornerstone of aseptic practice is thorough handwashing and gloving prior to surgery, which is crucial for minimizing microbial transfer.
- **Sterile field creation:** Designated areas draped with sterile barriers define the sterile field where instruments and supplies are being used and are kept free from contamination.
- **Maintaining sterile field integrity:** Movements within the sterile field are restricted and controlled to avoid

accidental breaches. Instruments are transferred using specific techniques like “no-touch” or hands-free technique methods. This also helps minimize the risk of sharps injuries during surgery.

- **Constant vigilance:** Continuous awareness of potential contamination risks and immediate corrective actions is essential to maintain sterility throughout the procedure.

Rigorous adherence to sterile technique significantly lowers the risk of SSIs, which can lead to prolonged hospital stays, increased healthcare costs, and even patient death. By minimizing the risk of infections, sterile practices contribute to faster healing times, better surgical results, and overall improved patient safety and satisfaction. This requires constant vigilance, meticulous attention to detail, and unwavering adherence to established protocols.

### Surgical Attire and Surgical Zones

Typical **surgical attire** is part of personal protective equipment (PPE) and includes scrubs, surgical gowns, gloves, masks, head coverings, shoes, and face shields that are worn to prevent personal and environmental contamination. Scrubs are loose-fitting garments made of tightly woven material, designed to prevent shedding of lint. The material may be made of an antimicrobial fabric that may help decrease bacterial contamination of scrubs. Scrub caps cover hair completely; beard coverings are used when necessary. Shoe covers are not required if the shoes are worn only in the surgical suite. If the shoes come from outside the surgical suite, shoe covers are worn that enclose footwear. Impervious shoe covers may be worn if exposure to fluids is anticipated, such as procedures with copious amounts of irrigation (e.g., arthroscopy). Surgical gowns are sterile disposable garments worn over scrubs to provide an additional barrier against contamination. Different levels of sterile and impermeable gowns exist for various procedures and risk levels. Hands should be covered by sterile, single-use gloves. Double gloving is advised when scrubbed in for all procedures because pinpoint holes occur caused by wear and tear during the procedure. Double gloving also may be employed for high-risk procedures, such as intubation. Masks filter microorganisms, while face shields prevent splashes and splatter.

Personal items (e.g., jewelry, stethoscopes, ID badges, lanyards, briefcases) can become contaminated with bacteria so should be cleaned regularly according to facility policy. Scrubbed personnel must not wear rings, watches, bracelets, or necklaces that can fall outside the sterile scrubbed attire.

The OR is segmented into **surgical zones**, each with distinct functions and attire requirements. This serves to safeguard against the silent threat of infection. This stratification orchestrates a flow of sterility, protecting the vulnerable surgical site from the outside world. The zones are as follows:

- The **unrestricted zone** is the outer layer of the OR, where nonsterile activities like patient admission and transport occur. Street clothing is allowed, with personnel donning scrubs and shoe covers for basic hygiene before entering the semirestricted zone. The unrestricted zone includes the admissions area, offices, changing areas, break rooms, and supply receiving and storage.
- The **semirestricted zone** is an intermediate zone between the unrestricted and restricted zones, where personnel are clothed in surgical attire. This area includes the preoperative and postanesthesia care units and medication rooms.
- The **restricted zone** is the innermost sanctum encompassing the OR suite itself where surgery is performed and includes the actual OR rooms, the scrub sink areas, substerile rooms, central core, and steam sterilization areas. Access is strictly limited to personnel in at least surgical attire plus head covering and mask.

### Health Hazards Linked to the Surgical Environment

While the OR evokes images of sterile precision and lifesaving interventions, it also harbors its own share of hidden health hazards. From fire risks, exposure to invisible anesthetic gases, and ergonomic and psychological stresses to surgical smoke, laser risks, and exposure to blood and body fluids, these risks demand proactive management to ensure the well-being of both patients and healthcare personnel.

### Fire Risks and Prevention

Understanding and mitigating fire risks in this high-stakes environment is paramount, demanding constant vigilance and proactive measures. Any fire requires three elements: fuel (e.g., surgical drapes, alcohol-based cleaning agents), an oxidizer (e.g., oxygen, nitrous oxide), and an ignition source (e.g., electrosurgical equipment, lasers). All three elements of the fire triangle are readily available in the OR, creating a potentially volatile mix. Electrosurgical units and lasers can generate sparks sufficient to ignite nearby fuel sources. A technique or device to stop bleeding by burning tissue, typically with electricity, is called **electrosurgery**. Electrosurgery can be monopolar, bipolar,

argon-enhanced coagulators, or ultrasonic. Faulty equipment, electrical malfunctions, and static discharge further contribute to the potential ignition sources.

## LINK TO LEARNING

This algorithm demonstrates the steps required for [mitigating fire risks in the OR \(https://openstax.org/r/77ORfirerisks\)](https://openstax.org/r/77ORfirerisks) using a multipronged approach.

### Anesthetic Gases

Anesthetic gases and vapors, while essential for surgery and pain management, can pose health risks when personnel are exposed over time. Chronic exposure to an **occupational anesthetic gas (OAG)** has been linked to reproductive issues, neurological disturbances, and even cancer in some studies (Occupational Safety and Health Administration, 2000). Critical control measures include implementing closed-circuit anesthesia systems designed to minimize the release of gases and vapors into the room, using scavenging devices that help capture and remove gases and vapors that escape the closed system, and promoting proper ventilation.

### Ergonomic Stress

Repetitive movements and standing for long periods of time in the OR can take a cumulative toll on perioperative personnel. Musculoskeletal disorders, particularly in the neck, back, and shoulders, are prevalent among surgeons and OR personnel. Ergonomically designed furniture, adjustable equipment, and promoting frequent postural changes are vital for mitigating these risks.

### Psychological and Emotional Stress

Witnessing trauma and dealing with patient mortality can take a psychological toll on healthcare personnel in the OR. Compassion fatigue, burnout, and post-traumatic stress disorder (PTSD) are not uncommon experiences. Offering access to mental health resources, fostering a supportive work environment, and implementing resilience training are crucial in safeguarding the well-being of perioperative personnel.

### Surgical Smoke

During surgery, **surgical smoke** is generated by thermal destruction of tissue via electrosurgical and radio-frequency devices, lasers, ultrasonic scalpels, power tools, and other heat-destructive devices during surgery. Surgical smoke harbors a hidden threat of potentially harmful chemicals (e.g., bioaerosols, hydrogen cyanide, benzene, formaldehyde) and particulate matter (e.g., dead and live cellular material [e.g., blood fragments, viruses]). Nanoparticles, which make up 80 percent of surgical smoke, can transmit viable bacteria and human papillomavirus (HPV) when inhaled, entering the person's bloodstream and traveling to organs (The Joint Commission, 2020). Patient exposure to surgical smoke is short-term and relatively low-risk. However, daily exposure of surgical personnel to surgical smoke causes multiple health problems. These include headaches, watering of the eyes, upper respiratory tract irritation (e.g., cough, sore throat, sneezing, rhinitis), nausea, drowsiness, dizziness, ocular and visual problems, and also increased pregnancy complications for female scrubbed personnel (The Joint Commission, 2020). This hidden threat underscores the urgency of implementing effective smoke evacuation systems and employing smoke plume management techniques like smoke shields and suction devices to protect both patients and perioperative personnel from the unseen dangers lurking within surgical smoke.

### Laser Risks

With their concentrated beams of light for cutting or cauterizing tissue, the **laser** has revolutionized surgery, enabling minimally invasive procedures with greater precision and reduced blood loss. To avoid danger, lasers must be used while following meticulous safety protocols and with a deep understanding of potential risks in the surgical environment. Laser hazards in the OR include the following:

- Direct tissue damage: Unintentional exposure to the laser beam can cause severe burns to skin, eyes, and internal organs, for both patients and perioperative personnel.
- Fire hazards: Laser contact with drapes, instruments, or flammable materials can spark fires, posing a significant threat in the oxygen-rich surgical environment.
- Eye injuries: Accidental laser reflections off instruments or even patient skin can cause permanent eye damage to anyone not wearing proper eyewear.

- Airborne contaminants: Lasers vaporize tissues during surgery, creating plumes containing potentially harmful particles and chemicals that can be inhaled by the patient and perioperative personnel.

### Exposure to Blood and Body Fluids

Blood and body fluids can be vectors for viruses, bacteria, and parasites. Some major threats include the following:

- Hepatitis B virus: This causes liver inflammation and damage, with chronic infection potentially leading to cirrhosis and liver cancer.
- Hepatitis C virus: Although often asymptomatic initially, chronic infection can lead to liver cirrhosis, liver failure, and even increased risk of liver cancer.
- Human immunodeficiency virus (HIV): This can lead to AIDS, significantly weakening the immune system and leaving individuals at-risk for opportunistic infections.

Sharps injuries (e.g., needlesticks, scalpel cuts) and other injuries from contaminated instruments pose a direct route of pathogen transmission. Even without needles, blood and body fluids can splash or become aerosolized, increasing the risk of inhalation or contact with mucous membranes. Broken or damaged skin on healthcare workers can provide another entry point for pathogens. Exposure to blood and body fluids remains a significant occupational hazard in the surgical environment. However, a safer environment can be created for perioperative personnel by prioritizing universal precautions, consistently using proper PPE, implementing guidelines for sharps safety (e.g., exposure control plan, engineering controls, work practice controls, administrative controls, PPE, sharps disposal), and promoting education and training to minimize the threat posed by these silent, infectious agents (Association of periOperative Registered Nurses [AORN], 2021b).

Addressing health hazards in the OR demands a comprehensive approach. Implementing best practices for fire safety minimizing OAG exposure, promoting ergonomic principles, prioritizing mental health support, and adhering to infection control practices are vital for safeguarding the health and well-being of those who safeguard others. By acknowledging and proactively managing these challenges, we can ensure the OR remains a safe environment for both patients and healthcare team members.

### Potential Intraoperative Complications

Despite meticulous planning and skilled surgeons and perioperative personnel, the inherent unpredictability of human biology can introduce challenges during surgery. These intraoperative complications, while not the norm, are a reality for which surgeons and patients must prepare. These complications include hemorrhage, anesthesia awareness, aspiration, allergic reactions and anaphylaxis, cardiac arrest, hypoxia, hypothermia, malignant hyperthermia, and positioning injuries.

#### Hemorrhage

One common operative concern is excessive bleeding, which may turn into hemorrhage. This can be caused by various factors (e.g., traumatic injury requiring surgery, unexpected anatomical variations, intraoperative tissue damage, preexisting medical conditions). To manage bleeding, surgeons employ a range of techniques, including electrocautery and sutures, working swiftly to maintain stable blood pressure and ensure oxygen delivery to vital organs. Excessive bleeding may be treated with administration of fluid or one or more of a variety of blood products.

Should blood and blood product administration become necessary, the RN circulator and anesthesia provider work together to ensure patient safety. Before blood product administration, the nurse confirms that typing and compatibility screening have been performed within the past seventy-two hours. The RN circulator obtains the supplies and equipment necessary for blood administration (e.g., blood tubing with a blood filter, a mechanical blood delivery pump or pressure bag for rapid, emergent blood administration). Blood is administered via an 18-gauge or larger catheter along with normal saline to avoid clot formation. Microdrip tubing is never used because it destroys red blood cells. Nothing else may be administered through the same IV line. The anesthesia provider and RN circulator perform the mandatory two-person verification process for blood product transfusions before blood is administered (Holm, 2023).

#### Anesthesia Awareness

The experience of consciousness and even pain during surgery with possible recall of events while under general anesthesia is called **anesthesia awareness**. While estimates vary, this unsettling occurrence affects roughly 1 in

1,000 to 1 in 15,000 patients undergoing general anesthesia. This spectrum of awareness can range from vague sensations and muffled sounds to vivid memories of the surgical process and excruciating pain (Kim et al., 2021).

The precise causes of anesthesia awareness remain complex and multifaceted. Factors like genetics, individual variations in medication metabolism, inadequate medication dosing, and interactions with specific medications can all contribute to this unwanted awakening during general anesthesia. Additionally, certain patient characteristics (e.g., obesity, pregnancy) and certain medical conditions (e.g., lung disease) may increase the risk. The psychological effect of anesthesia awareness can be profound. Patients often grapple with feelings of fear, vulnerability, and betrayal of trust. Vivid memories of the surgery can lead to anxiety, depression, and PTSD, significantly affecting their quality of life.

Anesthesia awareness is rare, and although its cause may not be fully understood, anesthesia providers employ interventions to help prevent its occurrence. Interventions to prevent anesthesia may include addressing the varying anesthetic requirements for different patients, ensuring that sufficient anesthetic medication is administered, and ensuring that the anesthesia machine has undergone appropriate preventive maintenance to help prevent malfunction.

## LIFE-STAGE CONTEXT

---

### Anesthesia Awareness in Children

Any patient can experience anesthesia awareness, which is the experience of consciousness and even pain during surgery while under general anesthesia. However, it can be particularly challenging when it occurs in children. Although some studies have suggested young patients might be more at risk for experiencing anesthesia awareness, assessing it in children also presents unique challenges because of communication barriers, trauma and stress, and a child's limited understanding.

Children have unique needs during surgery related to the state of their physical and emotional development. It is crucial for the surgical team to understand that anesthesia awareness may be a possibility in a pediatric patient and take steps to decrease the risk of it occurring.

It is also critical that a child's accounts of anesthesia awareness not be dismissed, even if it may not have truly occurred. The child's experience of confusion, disorientation, and fear can still be traumatizing. It is vital that the anesthesia provider and RN circulator report any incidence to the PACU nurse assigned to recover the patient after surgery. When the parent is brought into the PACU to be with the patient, the PACU nurse should carefully, and with sensitivity, explain to the parent the anesthesia awareness incident and help them speak to the anesthesia provider if necessary.

---

### Aspiration

Instructing patients to be NPO (nothing by mouth) before surgery helps reduce the risks associated with vomiting and aspiration during surgery. However, sometimes patients may not have fasted according to instruction, and in emergencies, a patient may not have had the opportunity to fast at all before the procedure. Although antiemetics can help reduce nausea and vomiting during surgery, it is still possible and carries the serious risk of aspiration. The surgical team must be aware of patient- and surgery-related factors that can contribute to the risk of aspiration and be prepared to respond appropriately to keep the patient safe. For instance, the RN circulator must stand beside the head of the patient with gloves on and be prepared to assist the anesthesia provider during induction of anesthesia and intubation. Furthermore, during local or sedation procedures, the nurse should monitor the patient for signs of nausea (e.g., swallowing, sweating) that could precede an episode of vomiting. The nurse may need to turn the patient's head or suction the patient's oral cavity to keep the patient safe if intraoperative nausea and vomiting occur. The nurse may also be responsible for documenting the occurrence and the steps taken in response; the event should be communicated during the handover report so that appropriate postoperative follow-up care can be provided.

### Allergic Reaction and Anaphylaxis

Allergic reactions in the surgical environment can range from mild discomfort to life-threatening emergencies (e.g., anaphylaxis) posing a significant challenge for both patients and healthcare professionals. Surgical allergies

encompass a range of reactions, triggered by various substances encountered during surgery. These can include the following:

- **Anesthetic medications:** Certain medications used for general anesthesia (e.g., neuromuscular blockers, muscle relaxants) can trigger allergic responses.
- **Latex:** Gloves, drapes, and other equipment and supplies made of latex can cause itchy rashes, wheezing, and even anaphylaxis in sensitized individuals. Many perioperative departments in the United States have put together a latex-free cart to be used for patients with diagnosed latex allergies. However, to avoid this risk in patients with undiagnosed latex allergies, many perioperative departments have removed all latex products to completely eliminate this surgical risk.
- **Antibiotics:** Preoperative and intraoperative antibiotics are crucial for infection prevention, but some individuals may have allergic reactions to specific types of antibiotics.
- **Iodine:** Some contrast agents contain iodine, as does povidone iodine 10 percent, a common skin preparation solution. Historically, practitioners have believed that patients with an allergy to shellfish (which normally harbor iodine) should not be exposed to iodine to minimize the risk of an iodine reaction. However, recent evidence indicates that a seafood allergy actually may be related to fish protein, not iodine (AORN, 2021a).
- **Blood products:** Transfusions used during surgery might trigger allergic reactions in some patients, especially those with preexisting sensitivities.

## REAL RN STORIES

### A Lesson about Latex

**Nurse:** Celia, RN

**Clinical setting:** Operating room at a community hospital

**Years in practice:** 12

**Facility location:** Outside Orlando, Florida

I tell this story to all the new nurses on the surgical floor because I truly believe it could save a life. Or, if not a life, then a lot of itching. A few years ago, I was on a pretty routine case—a 17-year-old with ovarian torsion who was having a laparoscopy. During the preoperative assessment, the patient had denied allergies, but her mother had piped up and said, “Well, kiwi makes her mouth itchy, so she won’t eat them anymore.” I noted it in the chart and didn’t think too much about it—oral allergy syndrome is pretty common, especially with fruit.

But throughout the process of getting her prepped, she just seemed to be getting more and more uncomfortable. She was in a lot of pain but had some medications in the ED before she came to us. The anesthesia provider thought she’d feel better when the sedative kicked in. She’d never had surgery before, not even stitches for a bumped knee as a kid, so she was very nervous.

It wasn’t until we wheeled her into the OR and were scrubbed in that things took a turn, though. By then, she’d had a lot of gloved hands on her body—around her mouth, on her abdomen. I was focused on the checklist and time-out, so I didn’t see the redness at first. As the surgery got going and the anesthesia provider was monitoring her vital signs, we noticed her heart rate accelerating a little. I looked her over and noticed that what might have started out as faint redness on her abdomen was spreading and looking more like welts and hives. Just as I was about to speak up, the anesthesia provider did, because he’d noticed that her nose had started to run a bit, and her eyes were tearing.

The anesthesia provider clicked into her chart just as the surgeon asked, “What does her chart say about allergies?” “None known,” I offered, “Well, except her mother says kiwi makes her mouth tingle.” I knew almost as soon as I’d said it that I must have missed something, because the anesthesia provider immediately said, “Kiwi is highly cross-reactive with latex. She’s having an allergic reaction to the gloves, I’d bet on it!”

Well, we got lucky. The reaction was pretty mild and easy to control when everyone’s gloves were changed out. The patient had a successful procedure and uneventful recovery. But I made a big note in her chart that she had very likely had a latex allergy and ensured that the PACU nurse was aware of the allergic response and was prepared to include it in the patient’s discharge teaching to include suggesting seeking out latex allergy testing. And like I said,

it's the first tidbit I give to new nurses!

---

### Cardiac Arrest

Cardiac arrest is sudden cessation of heartbeat and cardiac function, caused by an electrical disturbance or a lethal rhythm resulting in the loss of effective circulation. Causes of cardiac arrest that occurs perioperatively include myocardial infarction, dysrhythmias, anaphylaxis, malignant hyperthermia (MH), respiratory arrest, and massive blood loss. In most facilities, the RN circulator is required to have Basic Life Support, Advanced Cardiac Life Support, and/or Pediatric Advanced Life Support certification. If a cardiac arrest occurs, the RN circulator calls for assistance, requests the code cart, and directs another team member to begin compressions. Compressions circulate the blood until someone arrives with the defibrillator. Defibrillation stuns the heart and briefly terminates its electrical activity. This is the most likely intervention that will resuscitate the patient because it allows the normal intrinsic heart pacemakers to resume electrical control of the heart.

Roles in the OR are assigned depending on who and the number of people who arrive to help. Often, the ACLS-trained anesthesia provider assumes the role of team leader. However, if the patient requires airway or cardiac intervention (e.g., intubation, medications) immediately, another person may take over as leader. As soon as the defibrillator is brought to the room, the nurse applies the defibrillator pads and prepares to deliver a shock when instructed to do so by the team leader. Two other roles are to administer medications and document medication administration and other events with times and the patient's responses. Another nurse continues the role of RN circulator by providing supplies and maintaining the counts if surgery continues during resuscitation (Holm, 2023).

### Hypoxia

A state in which the body's tissues are deprived of adequate oxygen is known as hypoxia. It can pose a significant challenge during surgery, with potentially devastating consequences if left unrecognized. Hypoxia in the surgical setting can manifest in various ways, depending on its cause and severity. Some potential presentations include the following:

- Decreased alertness and responsiveness: Patients might appear drowsy, confused, or disoriented.
- Rapid or shallow breathing: The body attempts to compensate for the oxygen deficit by increasing respiratory rate.
- Changes in vital signs: Heart rate and blood pressure may rise initially, followed by a drop in severe cases.
- Skin discoloration: Bluish or grayish skin tone, particularly around the lips and nail beds, can indicate a critical lack of oxygen.

Preventing hypoxia is fundamental in safeguarding patients in the OR. Strategies include the following:

- Preoperative assessment: Preoperative nurses can help by identifying patients at risk based on medical history and respiratory function tests.
- Optimizing oxygenation: After identifying the risk of hypoxia, the preoperative nurse can initiate oxygen therapy and introduce incentive spirometer use preoperatively. This helps ensure adequate preoperative oxygen levels and facilitates use postoperatively in the PACU.
- Standardized protocols: Nurses in all perioperative settings should understand and implement airway management guidelines, monitoring for and responding to hypoxic events.
- Continuous training: Regularly educating on hypoxia recognition and management is particularly important for perioperative personnel.

### Hypothermia

A drop in core body temperature below 96.8°F (36°C), or hypothermia, can have significant consequences during surgery and potentially affect patient outcomes. Hypothermia in the surgical setting is not merely an issue of discomfort. Hypothermia triggers a cascade of physiological changes that can affect vital functions. In an attempt to conserve heat, the body constricts blood vessels, reducing blood flow to vital organs. The body's involuntary attempt to generate heat through muscle contractions (shivering) can increase oxygen demand and metabolic rate. Low temperature can disrupt the heart's electrical rhythm, leading to irregular heartbeats and potentially jeopardizing blood circulation. Additionally, impaired blood flow and reduced oxygen delivery to tissues can hinder wound healing and increase the risk of infection.

Several factors can contribute to hypothermia in the OR:

- **Exposure:** Cold OR temperatures, inadequate patient warming, and open surgical sites can lead to significant heat loss.
- **Anesthesia:** Certain anesthetic medications can cause vasodilation, lower the cold threshold in the hypothalamus, and suppress the body's shivering response and temperature regulation.
- **Fluid administration:** Large volumes of cool IV fluids can rapidly cool the body core.
- **Underlying medical conditions:** Patients with preexisting conditions like thyroid disorders or malnutrition may be more susceptible to hypothermia.

Actions to prevent hypothermia that the perioperative team can implement include passive insulation and active warming methods. Passive insulation includes blankets, drapes, and surgical garments. Active warming methods include forced-air warming devices; water-circulating devices; conductive/resistive warming; radiant warming; and using warmed anesthesia gases, IV fluids, insufflation gases, and irrigation fluids. Some of these measures should be implemented by the preoperative nurse as prewarming actions.

### **Malignant Hyperthermia**

A rare, inherited, hypermetabolic disorder of skeletal muscles called **malignant hyperthermia (MH)** can be fatal if not identified and treated quickly. It is triggered by certain anesthetic medications, most commonly inhalant medications and muscle relaxants. During the preoperative assessment, the RN circulator should ask the patient if they or any immediate family member has ever had a problem with anesthesia. A family or personal history of a “bad reaction to anesthesia” or statements such as “my uncle died in surgery, but no one knows why” indicate the need for further questioning by the anesthesia provider. Another indication of MH susceptibility is a history of a muscular or neuromuscular disorder (e.g., muscular dystrophy).

The MH reaction presents with a cascade of symptoms, including masseter muscle rigidity, hyperkalemia, and muscle breakdown (rhabdomyolysis). This results in a hypermetabolic reaction during which body heat can reach beyond life-sustaining temperatures (e.g., 106°F [41.1°C]), which can quickly lead to organ damage and death if not recognized and treated immediately. The first action if MH is suspected is for the anesthesia provider to discontinue the triggering agent. The scrubbed team should rapidly finish surgery or pack the surgical wound. Meanwhile, other perioperative team members should quickly obtain the MH cart and begin reconstituting dantrolene sodium (e.g., Dantrium, Ryanodex), the specific antidote for MH. Other team members institute prompt cooling measures: administer cold IV fluids; pack the patient's neck and head, groin, axilla, and any open cavities with ice; change the forced-air blanket to cool air; and provide supportive care, which is crucial for successful MH management. Patient stabilization is demonstrated by a decrease in end-tidal carbon dioxide (CO<sub>2</sub>), muscle rigidity, and heart rate.

Intravenous dantrolene sodium is continued for at least twenty-four hours and titrated to alleviate symptoms. The surgeon and anesthesia provider inform the patient and family members of the event and counsel first-degree family members to undergo genetic testing for MH susceptibility. While rare, MH awareness and appropriate OR protocols remain critical for ensuring patient safety during surgery.

## **CLINICAL JUDGMENT MEASUREMENT MODEL**

### **A Patient Experiencing Malignant Hyperthermia**

Malignant hyperthermia is a rare, potentially life-threatening genetic predisposition to uncontrolled muscle breakdown (hypermetabolism) typically triggered by certain anesthetic medications, most commonly inhalant medications and muscle relaxants. This crisis can quickly cause organ damage and death if steps are not swiftly taken to correct it. The nurse can use the Clinical Judgment Measurement Model framework to assess for and respond to cases of MH.

1. **Recognize cues:** Identify the key signs and symptoms of MH (e.g., masseter muscle rigidity, metabolic acidosis, and extremely high temperature [e.g., 106°F {41.1°C}]).
2. **Analyze cues:** Interpret clinical data, including muscle contractions while under general anesthesia, rapidly elevating temperature, and patient and family history (e.g., problems with anesthesia; family member died during surgery, but the cause is not remembered; a history of a muscular or neuromuscular

- disorder), to assess the severity of the condition and potential for complications.
3. **Prioritize hypotheses:** Determine the most immediate threats to patient health, such as the unsustainably high temperature. By prioritizing, the nurse can focus on providing immediate care interventions to prevent life-threatening complications and death.
  4. **Generate solutions:** Develop a treatment plan: The RN circulator should immediately notify the charge nurse to obtain additional support while the anesthesia provider stops the flow of the triggering agent, the surgeon and scrubbed team stop surgery if at all possible (e.g., close or pack the wound), the RN circulator assigns another nurse to reconstitute and administer dantrolene sodium according to the anesthesia provider's orders, and other team members institute rapid cooling actions (e.g., providing the anesthesia provider cold IV fluids, pack the patient in ice).
  5. **Take action:** Clearly communicate the plan and implement steps until the patient is stabilized. The nurse provides a handover report to the receiving PACU nurse of the patient's need for additional or higher-level care. The surgeon and anesthesia provider notify the patient's family members about the event and counsel them regarding genetic testing for MH susceptibility.
  6. **Evaluate outcomes:** The PACU nurse takes over monitoring the patient's response to treatment, adjusting the plan as necessary based on the possibility of symptom reoccurrence.
  7. **Reflect on the process:** Reflect on your clinical decision-making process, outcomes, and what could be improved if you encounter the situation again in the future. Think about the appropriateness and effectiveness of the interventions and the timeliness of the response.

### Positioning Injuries

Positioning injuries are unintended complications that arise from patient positioning during surgery, which could lead to nerve damage, pressure sores, or compartment syndrome. The human body is a complex network of nerves, blood vessels, bones, muscles, and soft tissue, all susceptible to pressure and strain. During surgery, prolonged or improper positioning can compress these structures, leading to the following:

- **Nerve damage:** Nerve compression can cause tingling, numbness, weakness, and even paralysis in the affected area. Common sites of nerve injury include the arms, legs, and head.
- **Pressure sores:** Prolonged pressure on bony prominences like the heels, elbows, and back can disrupt blood flow and lead to tissue breakdown, forming painful and potentially infected sores.
- **Compartment syndrome:** In severe cases, prolonged pressure can lead to compartment syndrome, a life-threatening condition where blood flow is so restricted that tissue damage and even muscle death can occur.

Recognizing the potential for positioning injuries is crucial to preventing them. A proactive approach includes identifying patients at risk via a thorough physical examination and medical history review, selecting the most appropriate surgical position based on the procedure and patient factors, regularly checking for signs of pressure, and repositioning the patient as needed throughout the surgery.

The nurse will take steps to prevent positioning injuries, such as the following:

- Carefully padding and supporting bony prominences with positioning devices (e.g., gel pads) to distribute pressure evenly.
- Assessing skin integrity regularly and monitoring for signs of pressure, discoloration, or impaired circulation during long procedures as well as during the postoperative and recovery period.
- Repositioning the patient at regular intervals, adjusting positioning devices, and relieving pressure points as often and as much as possible.
- Ensuring adequate padding and support for the head, neck, and extremities as much as possible to maintain proper body alignment and avoid nerve compression given the positional requirements of the surgical procedure.
- Communicating concerns about positioning or potential pressure points to the surgical team as soon as possible and collaborating to identify solutions that ensure patient comfort and safety. Documenting steps taken to prevent or mitigate pressure injury should also be detailed and thorough to assist with recovery care planning.

## 31.4 Postoperative Phase

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe the phases of postoperative care
- Summarize the role of nurses in postoperative care
- Recognize special considerations when providing postoperative care

The phases of postoperative care start when the patient leaves the OR, arrives in the **postanesthesia care unit (PACU)**, previously known as the recovery room, and continues through to the completion of their recovery. Ongoing nursing management during postoperative care includes maintaining the patient's airway and ensuring cardiovascular and CNS stability. The PACU nurse must monitor the patient for signs of hypotension and shock, hemorrhage, hypertension, and arrhythmias. The nurse also must manage the patient's pain, resolve any problems with postoperative nausea and vomiting (PONV), and implement measures to prevent infection. Special considerations when providing postoperative care include considerations for older adult patients, patients with a higher weight, and patients who have developmental needs.

### Stages and Phases of Postoperative Care

Postoperative recovery is broken down into three stages: immediate, intermediate, and convalescence.

- The **stage 1—immediate** postoperative stage is the period of time the patient is in the PACU, which may last a few hours or up to a day depending on the type of surgery and the patient's health and response to surgery and anesthesia. There are two phases of care in the immediate postoperative stage:
  - The **phase I recovery** stage is the immediate postanesthetic period during which the PACU nurse ensures the patient's full recovery from anesthesia and return of vital signs to near baseline.
  - The **phase II recovery** stage focuses on preparing patients for discharge from the facility, which includes providing education regarding the postoperative instructions and prescribed discharge medications.
- The **stage 2—intermediate** postoperative stage begins when the patient is transferred out of the PACU, whether it be to another location in the hospital, to the home, or to a convalescent facility. The focus of this stage is on wound management, physical therapy for regaining mobility, and ongoing pain management. This stage can range from days to weeks depending on the surgery and healing progress.
- The **stage 3—convalescence** postoperative stage begins at home, where the focus shifts to gradual rehabilitation and resumption of normal activities, following the surgeon's instructions for wound care, medication, and activity limitations. This stage can take weeks or months, varying greatly based on the individual.

### Admission to the Postanesthesia Care Unit

Admission to the PACU marks a critical stage in the continuum of care, where seamless communication and comprehensive assessments play a pivotal role. The handover process involves the transfer of essential patient information from the surgical team to the postoperative care team. When surgery is complete, the RN circulator and anesthesia provider transport the patient to the PACU. The RN circulator performs a face-to-face, handover report directly to the PACU nurse. The handover report during admission to the PACU is crucial to ensure accurate and timely communication of critical details. This includes information about the surgical procedure, anesthesia administered, intraoperative events, and any immediate postoperative concerns. Effective communication during handover facilitates continuity of care, allowing the postoperative care team to promptly address the patient's needs and ensure a smooth transition from the OR to the recovery unit.

In addition to the handover process, medication review is a crucial component of admission to the PACU for ensuring appropriate postoperative pain management and addressing any medication-related concerns. Further, a **medication reconciliation** should occur before discharge. This comprehensive review of the patient's medication history should include medications being taken at home, including ones that the patient should have been taking but may not be, as well as any medications administered in the preoperative area, OR, and PACU. This medication review is compared with any newly prescribed medications with the goal of identifying potential problems and resolving discrepancies. The medication reconciliation process aligns with the goals of patient safety and is in line with recommendations from the American Society of Anesthesiologists and the American Society of PeriAnesthesia

Nurses.

## LINK TO LEARNING

Review the [statement of the American Society of PeriAnesthesia Nurses for medication management \(https://openstax.org/r/77MedMgmtPreOP\)](https://openstax.org/r/77MedMgmtPreOP) during the perioperative period.

Family updates form an integral part of the recovery process, fostering transparency and emotional support. Keeping families informed about the patient's status, the outcome of the surgical procedure, and any postoperative care plans helps alleviate anxiety and enhances collaboration between healthcare providers and the patient's support system. Family-centered care is increasingly recognized as an essential aspect of the perioperative experience, contributing to improved patient satisfaction and outcomes.

### Immediate Postoperative Assessment

The first moments after surgery, the patient is contending with the fading effects of anesthesia and taking the initial steps toward recovery. The immediate postoperative assessment holds immense significance for guiding the course of healing and identifying potential complications ([Table 31.4](#)).

Focus Area	Assessment Points
Airway	Clear airway, adequate oxygenation, signs of obstruction, respiratory rate and effort, hypoxia
Breathing	Rate, depth, rhythm of breaths, abnormal breath sounds, oxygen saturation levels
Circulation	Heart rate, blood pressure, capillary refill time, bleeding, compromised circulation to surgical site or extremities
Consciousness and neurological status	Level of consciousness, orientation, responsiveness, neurological function, signs of delirium or confusion
Pain	Pain assessment using appropriate scales, location, intensity, characteristics of postoperative pain
Temperature	Monitoring for hypothermia, hyperthermia, malignant hyperthermia
Surgical site	Redness, swelling, abnormal discharge, infection prevention, wound healing, intact dressings, presence of drains, amount of drainage from wound and/or drain
Gastrointestinal function	Bowel sounds, postoperative nausea and vomiting, tolerance of oral intake
Urinary function	Urinary retention, urine output, color, discomfort indicating bladder distension
Psychosocial status	Emotional state, anxiety, support and coping strategies, open therapeutic communication

**TABLE 31.4** Immediate Postoperative Assessment

Effective communication plays a crucial role in this process. The patient's voice becomes an invaluable tool, providing insights into their experience and any emerging concerns. Open communication between the patient, nurses, and physicians fosters a collaborative environment, ensuring timely and appropriate interventions. Based on the findings, the healthcare team determines the appropriate level of care, be it continued monitoring in the PACU, transfer to a hospital room or to a rehabilitation or skilled nursing facility, or discharge home (American Society of

Anesthesiologists, n.d.).

### Determine Readiness for Discharge

Determining readiness for discharge after a surgical procedure is a critical aspect of postoperative care, ensuring that patients can safely transition from the hospital to home and continue their recovery with minimal complications. A comprehensive assessment that considers various factors is crucial in making informed decisions regarding discharge. The nurse should assess these key criteria (Alper et al., 2023):

- Vital signs: The patient should have stable vital signs including heart rate, blood pressure, respiratory rate, temperature, and oxygen saturation levels.
- Pain management: Effective pain control demonstrates understanding of the pain management plan (e.g., oral medications, nonpharmacological strategies).
- Gastrointestinal function: The patient should have return of typical bowel function, tolerance of oral intake, and ability to maintain hydration.
- Urinary function: The patient should be able to void independently and maintain adequate urine output and does not exhibit urinary retention or discomfort.
- Surgical site: The patient's surgical site should show no signs of infection, dressings should be intact, and there should be no wound complications or issues with skin integrity (e.g., dehiscence, evisceration) noted.
- Mobility and activity: The patient should be mobile, ambulating with minimal dizziness, and demonstrate understanding of activity restrictions during recovery.
- Respiratory status: The patient should demonstrate adequate respiratory function without distress and effective coughing and deep breathing.
- Psychosocial and mental well-being: The patient should display mental clarity, signs of coping with recovery, and adequate social support.
- Medication management: The patient should be provided education on prescribed medications and side effects and ability to self-administer (or a caregiver who can administer) medications.
- Follow-up plan: Postdischarge follow-up appointments are scheduled and instructions have been provided regarding when to call the provider or seek care for questions or concerns before a follow-up appointment.
- Discharge instructions: Patient and caregivers demonstrate understanding of postoperative care instructions, such as wound care, activity, and dietary restrictions if required.
- Transportation arrangements: The patient has safe transportation home and availability of assistance for the first twenty-four to forty-eight hours.
- Home environment: The patient has a safe home environment for recovery with necessary medical supplies and equipment.
- Patient education: The patient or caregiver has knowledge of postoperative wound care, dietary recommendations including fluid requirements, therapeutic activity, pain management, signs of complications, and clear understanding of when to contact the provider or seek medical care if concerns emerge during recovery.
- Help from caregiver: The patient has a responsible support person available who has been educated on patient care needs.
- Emotional and psychological well-being: The patient shows emotional readiness for discharge and connection to appropriate support services.

The nurse also needs to consider the broader spectrum of postdischarge care options beyond sending a patient home. If patients are being discharged to another level of care or even temporarily to a skilled nursing facility, the nurse will need to collaborate with other professionals to ensure that the patient's transition to the next phase of recovery is smooth. Considerations for the nurse include the following:

- Case management and social workers: These professionals will assess the patient's social, emotional, and financial needs and then develop a comprehensive discharge plan. They coordinate with the patient's physician, other healthcare providers, and the patient's family to ensure that the plan addresses all aspects of the patient's recovery, including transportation, medical equipment needs, and follow-up care. They also act as liaisons that connect patients with community resources and ongoing support.
- Home health services: Patients may be returning home but still require medical care, in which case, home health services can offer a continuum of care. Home health includes nursing services, physical therapy,

occupational therapy, and other rehabilitative services that are delivered at the patient's home. This option may suit a patient who is well enough to leave the hospital but would benefit from continued healthcare support at home.

- **Rehabilitation facilities:** Patients who require intensive rehabilitation before they can safely return home are often discharged to a rehabilitation facility. They will receive focused therapy and care that helps restore functional independence and mobility. This level of care is often necessary after orthopedic surgeries or neurological procedures.
- **Skilled nursing facilities (SNFs):** Some patients, especially older adults and those with several comorbidities, may need extended care services at an SNF. In this setting, the patient can receive both medical care as well as help with daily living activities. An SNF can be an important “bridge” between the hospital and home or, in some cases, a transition to long-term care.

The nurse should carefully consider the patient's needs in the discharge planning process to ensure patient satisfaction and recovery and optimize resource utilization and decrease the chances of hospital readmission. Patients have unique needs when they leave the hospital, and personalized care planning that is comprehensive and takes a coordinated approach is key to making sure the patient gets the appropriate level of care and support necessary for their recovery.

## Ongoing Nursing Management during Postoperative Care

Ongoing nursing management is crucial during postoperative recovery. This includes maintaining the patient's airway; monitoring for changes in cardiovascular and CNS status; and treating hypotension, shock, hemorrhage, hypertension, or arrhythmias if they should occur. The PACU nurse is responsible for managing pain, preventing PONV, and implementing steps to prevent infection. Continuous assessment, effective communication, and proactive interventions to promote optimal outcomes during this critical period can ensure early identification and prompt management of any complications that may arise postoperatively.

### Maintaining the Patient's Airway

Maintaining a patent airway is a critical component of postoperative care, ensuring that patients can breathe effectively and minimizing the risk of respiratory complications. A significant concern following surgery is **atelectasis**, the partial or complete collapse of one or more areas of the lungs. Postoperatively, patients often experience reduced respiratory effort due to the effects of anesthesia and pain medications, which can lead to shallow breathing and inadequate lung expansion. This diminished effort, combined with immobility and discomfort that limit deep breathing and effective coughing, increases the risk of atelectasis. Additionally, the inflammatory response triggered by surgery can cause the accumulation of fluid or mucus in the airways, obstructing proper lung inflation.

Continuous monitoring of respiratory parameters (e.g., respiratory rate, oxygen saturation) is important to promptly detect any signs of airway compromise in the postoperative period. The nurse must carefully document the findings, including baseline levels, significant variations or changes, and any interventions required. The nurse must document according to facility protocols and should always initial and date/time their assessments when added to the patient's chart.

## REAL RN STORIES

### An Organized Room Saves a Life

**Name:** Matt, RN

**Clinical setting:** Postanesthesia care unit at an urban hospital

**Years in practice:** 5

**Facility location:** Chicago, Illinois

I was working an evening shift in the PACU a few months ago and had just finished my initial assessment on Mrs. Frank, a 68-year-old patient who had undergone major abdominal surgery earlier in the day. Her vital signs were stable, and she seemed to be recovering well from the anesthesia. I was just about to step away from the bed to document my assessment findings when I heard a faint moan from the bed.

Mrs. Frank's eyes were full of alarm, and I noted that her oxygen saturation levels were rapidly dropping. I immediately recognized the signs of airway compromise and raced back to her bedside.

First, I positioned Mrs. Frank upright to help her airway stay open, then grabbed the suction equipment that I had ensured was set up and easily within reach at the beginning of my shift. Using the suction catheter, I was able to clear the thick secretions that were blocking her airway, and she was able to start breathing easily again. I administered supplemental oxygen and monitored her to make sure that her oxygen saturation levels were improving.

As I was debriefing with myself and reflecting on the situation, I was thankful that the suction equipment had been available at the bedside. I was glad that diligently preparing the room to make sure that everything had a place and was in its place was an ingrained habit that I had learned early in my career. It's easy to overlook the importance of having a properly organized patient room, but in those moments when every second counts, being able to get what you need without delay can make a huge difference to a patient.

---

Nurses are crucial in assessing and addressing airway challenges, and their competence in using appropriate interventions is extremely important. To ensure optimal respiratory function in the postoperative period, nurses must prioritize maintaining a patient's airway patency through proper positioning, suctioning as needed, and monitoring respiratory rate. Elevating the head of the bed (if appropriate) and encouraging early ambulation can further promote a patient's recovery. When necessary, respiratory support devices like continuous positive airway pressure or bilevel positive airway pressure devices should be considered, and nurses must prepare for emergencies by familiarizing themselves with airway management procedures and equipment.

### Ensuring Cardiovascular Stability

Cardiovascular stability is a crucial aspect of postoperative care. Nurses should understand cardiovascular parameters and early detection of complications (e.g., arrhythmias, hemodynamic instability). Nurses should be prepared to implement prompt interventions (e.g., administering prescribed medications, titrating vasoactive medications) when cardiovascular instability occurs. A multidisciplinary approach, involving nurses, physicians, and other relevant healthcare providers, is vital for timely decision-making and intervention in response to changes in the patient's cardiovascular status.

### Monitoring Central Nervous System Status

Monitoring the CNS status during postoperative care is essential to ensure patient safety and detect any neurological complications early in the recovery process. Nurses should conduct regular neurological assessments (e.g., level of consciousness, pupillary response, motor function) to promptly identify any signs of CNS dysfunction.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Safety: When and How to Perform a Central Nervous System Examination

Performing a CNS examination postoperatively is critical for detecting early signs of neurological deterioration. The assessment gives the nurse the information they need to initiate interventions and prevent complications. Following are several circumstances in which a CNS examination would be performed for a patient after surgery:

- baseline assessment: at admission to the preoperative area before surgery to establish a baseline for the patient's neurological function
- postoperatively: to monitor for neurological changes after surgery, particularly after surgery involving the CNS
- change in neurological status: any reported or observed change in a patient's level of consciousness, motor function, sensory function, or cognitive ability
- head injury: to monitor for complications in a patient with a traumatic brain injury (TBI)
- neurological disorders: ongoing monitoring of patients with previously diagnosed neurological conditions

The components of a CNS examination vary on the patient's needs and the facility where surgery is being performed, and whether the nurse needs to perform a more comprehensive or focused assessment. In general, the nurse will assess the following:

- level of consciousness: using a standardized scale (e.g., the Glasgow Coma Scale [GCS])
- pupillary response: size, shape, reactivity to light, and accommodation
- motor function: muscle strength, coordination, and the presence of abnormal movements
- sensory function: sensation to light touch, pain, temperature, and vibration
- cranial nerves: function of the twelve cranial nerves
- reflexes: deep tendon reflexes, other reflexes
- coordination and gait: balance, coordination, and gait (if patient is ambulatory)

Proper documentation of the findings facilitates ongoing monitoring and improved continuity of care, which are key to patient safety in the postoperative stage.

Recognizing changes in cognitive function or motor abilities is paramount, as is collaborating with other healthcare providers to address any emerging issues promptly. This collaborative approach is crucial for preventing and managing complications related to the CNS. Additionally, educating patients and their caregivers on what to observe and report helps in the early detection of neurological complications, facilitating timely intervention.

### Preventing Hypotension and Shock

Nurses working in the PACU are eagle-eyed observers, constantly attuned to the subtle shifts in a patient's physiology. Through regular blood pressure checks, pulse oximetry monitoring, and meticulous fluid balance charting, they can detect early signs of impending hypotension (e.g., altered consciousness; cool, clammy skin). Normal blood pressure is considered 120/80 mm Hg. Nurses are alert to a blood pressure below 90/60 mm Hg, which might be a concern depending on the patient's intraoperative course and status of recovery.

Identifying the cause of postoperative hypotension is fundamental in treatment. Typical causes of postoperative hypotension include intraoperative anesthetic medications that were administered or hypovolemia as a result of severe blood or fluid loss. Preventive measures include careful monitoring of fluid balance, administration of fluids or blood products as needed, and appropriate management of anesthetic medications. Fluid management begins by accurately monitoring intake and output. This guides the administration of IV fluids, ensuring enough circulating volume throughout the body. Early mobilization and pain management play crucial roles as well, because stagnant patients and unchecked pain can trigger blood vessel dilation, which worsens hypotension.

### Intervening in Hemorrhage

In the aftermath of surgery, during which the body mends itself from the incisions, preventing hemorrhage is especially important. From the moment the patient arrives in the PACU, the PACU nurse begins observing and monitoring the patient's vital signs for any hint of trouble. Blood pressure, heart rate, and oxygen saturation can give clues to bleeding. Frequent wound checks are vital for identifying swelling, redness, or drainage that can reveal bleeding (e.g., pooling of blood under the patient).

After determining that a patient may be hemorrhaging, the PACU nurse prepares to intervene. The nurse notifies the charge nurse who reaches out to the surgeon and anesthesia provider while the PACU nurse remains with the patient. The nurse prepares to administer additional fluids or blood products and anticipates a return to the OR.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Analyze Cues and Take Action: Postoperative Internal Hemorrhage

Mrs. Yen, a 54-year-old postoperative patient, has been in the PACU for thirty minutes after having undergone an abdominal hysterectomy. Based on your assessment findings, you use the Clinical Judgment Measurement Model to analyze and take action to provide care for the patient.

#### Recognize Cues

- restlessness, slight agitation
- increased heart rate compared to the patient's baseline
- blood pressure low to normal and dropping
- pale, cool skin
- surgical dressing or drains with moderate amount of fresh, bright red blood

- tight abdomen

#### Analyze Cues

- You recognize the cues in your assessment as potential signs of early hemorrhage.
- Based on your knowledge of postoperative complications, your experience as a nurse, and what you know about abdominal surgery, you analyze the cues to see which ones may have important implications for the patient's care.

#### Prioritize Hypotheses

- Your priority hypothesis is that Mrs. Yen could be experiencing internal bleeding at the surgical site. You know that immediate action is required, so you will use this hypothesis to come up with a plan.

#### Generate Solutions

- Notify the surgeon immediately.
- Closely monitor vital signs.
- Prepare for potential interventions (e.g., blood tests, fluids, return to OR).

#### Take Action

- You contact the surgeon and communicate your assessment findings clearly and efficiently.
- You continue to monitor the patient's vital signs.
- You prepare for additional interventions as ordered by the surgeon.

#### Evaluate Outcomes

- The surgeon arrives and assesses Mrs. Yen and confirms a bleed. The patient will return to the OR for treatment.
- As you reflect on your role in the patient's care, you understand that your recognition of cues, analysis, and actions may have prevented more serious complications for the patient.

The PACU nurse implements measures to help prevent hemorrhage by ensuring postoperative pain is appropriately managed. By maintaining optimal pain control, the nurse helps stabilize the patient, enabling the patient to participate in early mobility and pulmonary hygiene exercises that are vital for preventing blood clots and other postoperative issues. The nurse provides a pillow or blanket for the patient to press on the abdomen when performing pulmonary hygiene exercises (e.g., turn, cough, deep breathing, use of an incentive spirometer). While necessary to help prevent postoperative pulmonary complications, excessive coughing, particularly without splinting, may dislodge clots. Early mobilization, getting patients up and moving, promotes blood flow and prevents complications of inactivity, while meticulous attention to fluid balance ensures optimal blood volume.

#### Treating Hypertension and Arrhythmias

Hypertension and arrhythmias during postoperative recovery are critical issues that require careful monitoring and management to prevent adverse outcomes. Nurses should watch subtle shifts in a patient's physiology. Regular blood pressure checks, pulse oximetry monitoring, and meticulous ECG interpretations are potential clues to cardiovascular complications. Increasing blood pressure readings and changes in consciousness may be signs of distress; variations in pulse regularity may indicate arrhythmias.

Fluid management with accurate intake and output monitoring informs the need for IV fluid administration to ensure optimal blood volume without taxing the heart. Postoperative pain can trigger hypertensive episodes, so pain management is critical. Early mobilization encouraging movement aids in venous return, and maintaining electrolyte balance ensures the electrical stability of the heart.

#### Managing Pain

Effective pain management during postoperative care is crucial for ensuring patient comfort, promoting recovery, and minimizing complications associated with inadequate pain control. Patients in phase I of recovery may be unable to tell the nurse that pain is becoming intolerable. The PACU nurse watches for early signs of unmanaged pain (e.g., grimacing, guarding, sighing, clenched fists, furrowed brows, changes in vital signs).

Intravenous pain medications are often used in the immediate postoperative period because they provide fast relief and can be used before the patient is able to tolerate food and fluids. Titration of pain medicines based on the patient's individual response is important to prevent overly sedating the patient, which can result in respiratory depression. Even with regular pain medication administration, patients can have breakthrough pain. It is important to have a plan to remedy the situation quickly. This may include as-needed (PRN) or shorter-acting medications until a more effective schedule can be achieved.

Intravenous pain medications may be delivered via **patient-controlled analgesia (PCA)** for postoperative pain management. This method allows patients to self-administer small doses of IV pain medication within safe, preprogrammed limits that are based on patient-specific factors (e.g., age, health). Nurses must educate patients on how to use the PCA device and about the safety features that help prevent overdose. The nurse closely monitors the PCA device for safety and effectiveness and watches for potential side effects (e.g., oversedation, respiratory depression), especially in the early stages of patient use. Regular assessment of pain levels and PCA usage patterns informs the nurse on needed adjustments to the pain management plan and helps the nurse evaluate the effectiveness of the intervention (Pastino & Lakara, 2023).

As the patient stabilizes and can tolerate oral intake, the nurse transitions the patient to oral pain medications. Oral medications are a key step in preparing for discharge because these are the pain relief medications the patient will be self-administering when they are at home. However, the nurse needs to ensure that the transition is carefully managed to maintain adequate pain control.

The nurse should also discuss nonpharmacological pain management strategies with the patient, which will be integral to their long-term pain management. These include positioning and splinting techniques; deep breathing, meditation, guided imagery, and self-hypnosis exercises; distraction (e.g., listening to music, watching TV) techniques; using heat or ice therapy safely; and offering therapeutic touch. Nurses monitor the effectiveness of pain management interventions and the side effects of medications and potential interactions.

The nurse works with other professionals involved in the patient's care (e.g., physical therapists) to schedule pain medications strategically. Ideally, the medications should provide optimal pain relief during activities that promote mobilization and recovery. The nurse communicates concerns to physicians, advocating for adjustments or additional interventions when needed.

### Treating Postoperative Nausea and Vomiting

Postoperative nausea and vomiting affects roughly 30 percent of patients (Gan et al., 2020). This distressing combination of gagging, dry heaves, and full-blown emesis not only disrupts comfort but also carries potential complications like dehydration, electrolyte imbalances, and aspiration pneumonia. It is especially crucial to prevent PONV after abdominal surgery because the act of retching and vomiting can stress the abdominal wall and might lead to wound dehiscence. Understanding the complex mechanisms and the crucial role of nurses in managing PONV is essential.

Contributing factors include the type and duration of surgery, patient-specific characteristics (e.g., female gender, history of PONV episodes), and the influence of anesthetic agents. The underlying pathways involve the CNS and the gastrointestinal tract, triggered by stimuli like opioid medication administration, and inner ear disturbances.

Risk assessment tools like the Apfel score help identify patients at high risk for PONV, allowing for targeted interventions. Antiemetics also play a crucial role. Serotonin (5-HT<sub>3</sub>) receptor antagonists (ondansetron [Zofran]), glucocorticoids (dexamethasone [Decadron]), and NK1 receptor antagonists (aprepitant [Emend]) are the first line of defense, often administered preemptively. Nonpharmacological interventions like acupressure applied to the wrists, ginger, and aromatherapy with peppermint offer a multimodal, patient-centered approach.

### Preventing Infection

Preventing infections is especially important for postoperative patients. Nurses are responsible for consistently adhering to infection prevention interventions. The first line of defense is meticulous hand hygiene. Nurses must adhere to handwashing protocols before, during, and after every patient interaction. This simple yet powerful act significantly reduces the risk of transmitting pathogens, thus helping prevent infections.

Monitoring for potential surgical infections includes performing regular wound checks and astutely observing for redness, swelling, or drainage; monitoring vital signs for spikes in temperature; and reviewing laboratory results

(e.g., white blood cell count). Early detection allows for prompt intervention, preventing minor issues from escalating into serious complications.

Proper care of the surgical wound is another key step for infection prevention. Proper catheter care for patients with urinary retention, ensuring optimal blood sugar control for patients with diabetes, and promoting early mobilization to improve circulation all contribute to a hostile environment for pathogens. Additionally, administering appropriate prophylactic antibiotics further bolsters the defenses.

Before discharge, nurses must provide clear, actionable instructions on wound care that emphasize the importance of the following:

- Keeping the wound site dry: Patients need to avoid getting the incision site wet for a specified period, as directed by the surgeon.
- Leaving the dressing intact: The initial dressing should be left in place until the follow-up appointment or as otherwise instructed by the surgeon.
- Observing the wound: Patients need to know the signs of infection (e.g., redness, swelling, increasing pain, drainage, fever). They need to be told when and how to contact the surgeon to report any signs of infection.

### Special Considerations When Providing Postoperative Care

Postoperative care demands a nuanced and tailored approach to accommodate diverse patient populations and unique healthcare needs. Special considerations in postoperative care involve recognizing and addressing factors that may influence recovery and outcomes, extending beyond the standard protocols. For instance, older adults may have distinct physiological and cognitive challenges that require specialized attention (e.g., management of comorbidities, cognitive impairment, polypharmacy). Additionally, the American Association of Critical-Care Nurses (AACN, n.d.) Clinical Practice Guidelines highlight the necessity of specialized care during the postoperative stage for patients with bariatric considerations (e.g., wound care, mobility, respiratory support). Developmental considerations in postoperative care are paramount, particularly when caring for pediatric patients whose unique developmental stages require tailored approaches to recovery.

#### Gerontological Considerations

The biological, psychological, and cultural science of old age and the aging process of adults throughout their lives is known as **gerontology**. On the other hand, **geriatrics** is the study of the diseases of older adults. Providing postoperative care to older adults requires a nuanced approach that acknowledges the unique challenges and strengths of the older adult population. Nurses play a crucial role in navigating age-related changes and tailoring interventions to ensure a smooth and successful recovery journey.

Older adult patients often have decreased organ function, slower wound healing, and altered pain perception compared to younger individuals. These factors necessitate adjustments in medication dosages, monitoring protocols, and pain management strategies. Cognitive decline and delirium are more prevalent in older adults after surgery, adversely affecting communication, medication adherence, and the overall recovery progress. Management of comorbidities and **polypharmacy** (occurs when a person is on many medications, particularly on numerous medications for the same condition) can be challenging.

Nurses must employ patient-centered communication, simplify instructions, and provide consistent reassurance to address these challenges. Additionally, preexisting limitations in mobility and independence can be exacerbated by surgery, increasing the risk of falls and complications. Early mobilization and rehabilitation become crucial interventions to maintain function and prevent deconditioning. By embracing these gerontological considerations and tailoring postoperative care plans, nurses can empower older adult patients to navigate the recovery journey successfully. Their vigilance, adaptability, and unwavering dedication pave the way for a positive and dignified healing experience for older adults.

#### Bariatric Considerations

Patients with a higher weight require customized interventions, considering factors such as wound care, mobility, and respiratory support, to address the unique challenges associated with obesity. Weight-loss surgery, or **bariatric surgery**, is a category of surgical procedures of the stomach and intestines to induce weight loss. Nurses must employ patient-centered communication and instructions and provide consistent reassurance to address these challenges. Although offering significant benefits for weight management and overall health, bariatric surgery

presents unique challenges in the postoperative period. The nurse should be informed about the various types of bariatric procedures, including the following:

- Roux-en-Y gastric bypass: This method creates a small stomach pouch and reroutes the small intestine, effectively restricting food intake and reducing nutrient absorption; considered the “gold standard” of bariatric surgery.
- Sleeve gastrectomy: This is a restrictive procedure where most of the stomach is removed, and a narrow “sleeve” remains that limits the amount of food a patient can consume.
- Adjustable gastric band: In this procedure, an inflatable, adjustable band is placed around the upper part of the stomach, making a small pouch that effectively restricts food intake.
- Biliopancreatic diversion with duodenal switch (BPD/DS): This is a complex procedure to create a small stomach sleeve and bypass most of the small intestine.

Nurses play a crucial role in ensuring a smooth and successful recovery for these patients, necessitating a nuanced approach that accounts for the specific physiological and psychological changes following surgery (Amiri et al., 2019). Bariatric procedures often involve rerouting the digestive tract, leading to altered food absorption and nutrient deficiencies. Therefore, nurses need to monitor for and address potential nutritional deficiencies, particularly iron, vitamin D, and calcium. Some patients experience **dumping syndrome** after gastric bypass surgery, when food gets “dumped” directly from the stomach pouch into the small intestine too rapidly without being digested, causing nausea, vomiting, abdominal cramping, and diarrhea. Nurses play a crucial role in educating patients on dietary modifications and proper food intake to manage dumping syndrome.

By understanding the unique challenges of bariatric surgery and implementing these tailored care considerations, nurses can help patients navigate the postoperative journey successfully. Their knowledge, empathy, and holistic approach play a vital role in ensuring long-term weight management, improved health, and a positive quality of life for bariatric patients.

### Developmental Considerations

Developmental considerations in postoperative care are paramount, particularly when caring for pediatric patients whose unique developmental stages require tailored approaches to recovery. Their developing bodies, cognitive abilities, and emotional needs necessitate a nuanced approach that goes beyond simply applying adult-focused protocols:

- Physiological differences: Children are not just “small adults.” They have smaller body mass, different medication metabolism, and increased vulnerability to pain, making medication doses and pain management strategies distinct from adults.
- Cognitive development: Younger children may struggle with understanding their situation, leading to anxiety and fear. Nurses need to adapt communication, using simple language, visuals, and age-appropriate explanations to reduce distress.
- Emotional vulnerability: Separation anxiety, fear of pain, and difficulty expressing emotions are common in children during the postoperative period. Nurses need to be empathetic when providing comfort, reassurance, and emotional support to the patient and parents throughout the recovery process.

## PATIENT CONVERSATIONS

### Pediatric Patient Undergoing Surgery

**Scenario:** The nurse is caring for 6-year-old patient Stella, who just had a tonsillectomy. The patient’s mother, father, and 8-year-old brother Joey are in the room. The nurse is preparing to talk to them about what they need to know before discharge.

**Nurse:** Hi, Stella, are you ready to go home?

**Patient:** (looks at mother, whispering) Um . . .

**Patient’s mother:** She doesn’t want to talk because she’s afraid it will hurt more.

**Nurse:** [To Stella] Your throat will be sore for a while as it's healing, and you might not feel like talking much. That's okay.

**Patient's mother:** Joey thought she could use an app to sort of talk for her if she's not feeling up to it? Do you think that will help?

**Nurse:** The wonders of technology, right? That's smart thinking, Joey. You must be a good older brother!

**Patient's father:** But she shouldn't be totally silent, right? Won't it hurt her voice if she doesn't use it at all?

**Nurse:** It's not really a use it or lose it situation, because her voice will need a few weeks to start feeling back to normal. It's important that she pays attention to her body and doesn't overuse it, which could delay the healing process.

**Patient's mother:** I'm worried that she won't eat because she's afraid of pain.

**Nurse:** That's a common concern. How stocked up are you on popsicles and ice cream? (Stella perks up) Do you like ice cream and popsicles, Stella?

**Patient:** (nodding and whispering) Uh-uh.

**Nurse:** Foods and drinks that are cool will feel good in your throat. You need to eat and drink every day to help your throat get better. Just be sure to avoid red popsicles and juice, which may make it challenging to distinguish between the red dye and bleeding from the incision site.

**Patient's brother:** I told her she can't have Doritos and she got mad at me.

**Nurse:** Well, you're right about one thing; chips are a pretty crunchy, sharp, and salty snack. They might be more irritating than something smooth, cool, and soft. But Stella, you don't have to give up Doritos forever. You just need to take a break while your throat is healing.

**Patient's mother:** Her grandmother said she needs to do saltwater gargles, but is that just an old wives' tale?

**Nurse:** Believe it or not, there is some truth in that old remedy! But we'll see what the surgeon says. Some kids have a hard time gargling, so they just end up swallowing it. Usually, the surgeon will want you to avoid anything that might disrupt the healing tissues for at least a week.

[To Stella] Stella, it's very important that you take it easy while your throat is still sore. I want you to think about what kinds of things you like to do at home to relax. Do you like to read books or watch favorite movies? Or color?

**Patient:** (nodding and whispering) Color.

**Nurse:** Coloring would be a great activity to do to rest and yet keep busy when you get home. And you might feel like taking more naps. That's okay, too. Sleep will help your body heal.

**Patient's father:** Can we just give her the liquid kid Tylenol? She doesn't have to swallow a pill right?

**Nurse:** We'll check on the surgeon's prescriptions. Liquid Tylenol is usually fine, especially if she's had it before. But if it's not enough to control her pain, the surgeon might prescribe a liquid pain medication or a tablet. You can often cut these up to make them easier to swallow, or mash the tablet and put it in a food like applesauce to make it easier to swallow.

**Patient's mother:** Oh, we've got plenty of applesauce. We stocked up!

**Nurse:** That's great.

[To Stella] I think you're ready to go home, Stella. But if you feel worried or are hurting, it's important to tell your parents. They can give us a call, and we'll come up with a plan to help, okay?

**Patient:** (nodding and whispering) Okay.

**Patient's mother:** Thank you. We're a little nervous!

**Nurse:** It sounds like you've planned ahead and have some great teamwork going on. Of course, we're here to help if

you have any questions after you're home.

---

Developmentally focused postoperative care for children prioritizes age-specific communication and uses simple language and play-based interventions to alleviate anxiety and improve understanding of the surgical experience and recovery. Active parental involvement is also important. The nurse can empower caregivers to participate in care and provide emotional support. Encouraging age-appropriate activity and addressing specific developmental needs, such as skin-to-skin contact for infants or distraction techniques for older children, promotes a recovery plan that considers the child's unique emotional and physical needs.

## Summary

### 31.1 Surgical Concepts

Surgical procedures are classified as emergent, urgent, expedited (scheduled), and elective. Emergent surgeries are performed immediately to save a life, limb, or an organ. Urgent surgeries are performed for a condition with acute onset or clinical deterioration of life, limb, or organ survival. Expedited surgeries are when a patient is stable but requires early intervention for a condition. Elective surgeries are scheduled in advance and are not performed to save a life.

During the last couple of decades, surgical advancements have been made exponentially to include robotic surgery, telesurgery, surgical uses of AI, Multi-Angle Rear-Viewing Endoscopic tool (MARVEL), and 3-D printing. In many ways, these advancements have made surgery safer and more available to a greater number of people. However, there are risks, and many are exorbitantly expensive and therefore prohibitive.

There are several types of anesthesia used in medical procedures and surgeries: general anesthesia, MAC/moderate sedation, regional anesthesia, and local anesthesia. Each type of anesthesia has advantages, disadvantages, potential side effects, and appropriate applications based on the procedure to be performed, patient factors, and required depth of anesthesia. The nurse must be aware of how anesthesia providers evaluate and monitor patients to ensure safe and effective anesthetic management for procedures.

### 31.2 Preoperative Phase

The preoperative stage encompasses a broad spectrum of activities aimed at preparing the patient for surgery. The nurse is tasked with key steps, like conducting detailed medical and medication reviews to identify any factors that might influence surgical outcomes or anesthesia plans. This stage also involves the nurse providing patient education, including managing expectations regarding postoperative pain and recovery as well as discussing preoperative fasting and medication adjustments. The nurse also assesses the patient's nutritional status, psychological well-being, and any cultural or religious considerations that may affect care. The nurse then coordinates with the surgical team to ensure all preoperative documentation, including informed consents and advance directives, is collected and managed. All of the data come together as part of a comprehensive pain management plan that incorporates both pharmacological and nonpharmacological strategies tailored to the patient's needs and preferences.

The perioperative nurse acts as an advocate for the patient, ensuring that their cultural, spiritual, and emotional needs are respected and integrated into the care plan. By establishing a rapport with the patient and their family, the nurse helps by alleviating anxiety, addressing concerns, and facilitating a smooth transition to the intraoperative stage.

All of the nurse's tasks in the preoperative stage are integral to patient safety, optimizing surgical outcomes and enhancing the overall patient experience. Taking a holistic approach to preoperative preparation demonstrates the importance of thoroughness, empathy, and collaboration in achieving successful surgical outcomes for patients.

### 31.3 Intraoperative Phase

The intraoperative stage is the core of the surgical experience, where all the planning and preparation come into play. Successful surgery ultimately comes down to the effective collaboration of a multidisciplinary team, each member with a distinct role, who can carry out their work with skill and diligence.

Patient safety during surgery is the priority, and the nurse's role is vital in realizing that goal. The patient is at their most vulnerable when they are unconscious and completely reliant on medical science and the key players in the OR. The nurse, then, must act as the patient's eyes and ears, ensuring that the patient has a voice even when they are unable to speak for themselves. Understanding and mitigating potential complications like anesthesia awareness, malignant hyperthermia, intraoperative vomiting and aspiration, and positioning injuries are all aspects of providing competent care. Nurses must be able to recognize these risks, advocate for the patient, and work with the team to implement appropriate interventions—which, at times, may be life-and-death decisions.

## 31.4 Postoperative Phase

The postoperative stage is focused on promoting healing, preventing complications, and facilitating a smooth transition back to normal routines. The role of the nurse is to provide vigilant monitoring, advocate for the patient, coordinate care, and educate patients to empower them in their own recovery.

There are distinct stages of postoperative recovery including the immediate (phase I and phase II), intermediate, and convalescent stages of recovery. The key responsibilities of nurses throughout these stages are assessing vital signs and system functioning, managing pain, preventing infection, encouraging mobility, and preparing the patient for discharge and long-term recovery.

The nurse must also factor in special considerations for providing care to patients after surgical procedures, such as pain medication management, discharge planning, specific requirements for bariatric surgery patients, and the unique developmental needs of geriatric and pediatric patients. The nurse must be equipped to recognize potential complications, develop a plan, intervene effectively, and provide support for a patient's ongoing recovery.

### Key Terms

**3-D printing** manufacturing process that creates three-dimensional (3-D) objects from digital files

**amnesia** temporary or permanent loss of memory

**analgesia** pain relief so the patient does not respond to painful stimuli during surgery

**anesthesia awareness** the experience of consciousness and even pain during surgery with possible recall of events while under general anesthesia

**anesthesia provider** a physician (anesthesiologist) or advanced practice RN (certified RN anesthetist [CRNA]) who is specialized in administering anesthesia and managing perioperative care

**antisialagogue** medication (e.g., glycopyrrolate) that reduces salivation, minimizing the risk of aspiration during surgery

**anxiolytic** a type of drug that reduces anxiety

**appendectomy** surgical removal of an appendix

**artificial intelligence (AI)** a robot or other computer system designed to perform tasks that typically require human intelligence

**atelectasis** partial or complete collapse of lung tissue affecting gas exchange

**bariatric surgery** surgical procedures on the stomach or intestines to induce weight loss

**bowel preparation (bowel prep)** a medical procedure that involves the cleansing of the gastrointestinal tract, particularly the colon, in preparation for certain medical procedures or surgeries

**cognitive awareness** a level of attention that results in a positive presence by being consciously aware of all the components in an interaction

**dumping syndrome** after gastric bypass surgery, food gets “dumped” directly from the stomach pouch into the small intestine too rapidly without being digested, causing nausea, vomiting and abdominal cramping, and diarrhea

**elective surgery** a nonemergent surgical procedure scheduled in advance to repair injuries or enhance appearance and function

**electrosurgery** a technique or device that uses electricity to stop bleeding by burning tissue

**emergent surgery** surgery that is performed without delay to address critical situations such as potentially life-, limb-, or organ-threatening conditions

**expedited (scheduled) surgery** a planned, nonemergency surgical procedure for a chronic or progressive condition that, while not life-threatening in the immediate term, can lead to significant complications and impair quality of life if left untreated

**general anesthesia** a potent cocktail of IV and inhalation medications that induce a state of controlled, reversible unconsciousness, amnesia, and analgesia with or without reversible muscle paralysis; the patient remains unarousable to painful stimuli

**geriatrics** the study of the diseases of older adults

**gerontology** the biological, psychological, and cultural science of old age and the aging process of adults throughout their lives

**haptic interface** a type of human-computer interaction technology that is created by using force feedback via movement of a limb or the head to simulate bodily tactile sensations and movements, which can mimic the feel

of touching natural objects

**intraoperative stage** the period during a surgical procedure from arrival in the OR to closure and transfer to the PACU

**intubation** insertion of an endotracheal tube into the mouth or nose and into the trachea to maintain an open airway, support breathing and ventilation, and provide oxygen delivery

**laparotomy** a surgical procedure where a large incision is made in the abdomen to expose the abdominal cavity

**laser** concentrated light beam used in surgery for cutting or cauterizing tissue, enabling minimally invasive procedures with greater precision and reduced blood loss

**local anesthesia** numbing of a small, localized area through topical or injected anesthetic medications

**malignant hyperthermia (MH)** a rare, life-threatening inherited, hypermetabolic disorder of skeletal muscles in reaction to certain anesthesia medications or a history of a muscular or neuromuscular disorder

**medication reconciliation** a comprehensive review of the patient's medication history: medications being taken at home, including ones that the patient should have been taking but may not be, and any medications administered in the preoperative area, OR, and PACU; this medication review should occur before discharge and is compared with any newly prescribed medications with a goal of identifying potential problems and resolving discrepancies

**minimally invasive surgery (MIS)** a surgical technique using one or more small incisions or natural body openings

**monitored anesthesia care (MAC)/moderate sedation** drug-induced state of depressed consciousness while maintaining reflexes

**Multi-Angle Rear-Viewing Endoscopic tool (MARVEL)** a flexible, robotic endoscope providing a panoramic view for surgeons of hidden anatomical structures, especially in confined spaces like the brain or spine

**occupational anesthetic gas (OAG)** anesthetic gas and vapor that, while essential for surgery and pain management, pose health risks when personnel are exposed over time

**operating room (OR)** a meticulously controlled environment designed to minimize patient risk (e.g., surgical site infections) during surgical procedures

**patient-controlled analgesia (PCA)** a pain management system that allows the patient to self-administer small doses of IV pain medication within safe, preprogrammed limits, which are based on patient-specific factors like age and health

**perioperative first assistant (also, registered nurse first assistant [RNFA], certified surgical first assistant [CSFA], surgical physician's assistant [PA], perioperative nurse practitioner [NP])** scrub person with advanced education and training who helps the surgeon with tasks such as holding retractors and suturing

**perioperative period** the entire surgical experience to include all stages of surgery

**phase I recovery** the immediate postanesthetic period during which the PACU nurse ensures the patient's full recovery from anesthesia and return of vital signs to near baseline

**phase II recovery** preparing patients for discharge from the facility, which includes providing education regarding the postoperative instructions and prescribed discharge medications

**polypharmacy** the use of multiple medications simultaneously to treat one or more medical disorders

**postanesthesia care unit (PACU)** area where patients recover from anesthesia after surgery; previously known as the recovery room

**preadmission testing** a range of examinations, laboratory or diagnostic tests, and procedures tailored to the specific patient and surgery to be performed that are completed before a procedure or surgery to evaluate a patient's health status

**preoperative assessment** conducting a comprehensive physical and psychosocial evaluation that includes reviewing past surgeries, medications, allergies, and any preexisting conditions and identifying potential risks

**preoperative stage** a critical component of the perioperative experience that includes all the activities and preparations from the time surgery is decided on until the patient is transferred to the OR

**regional anesthesia** numbing of a specific body region through spinal or epidural anesthesia

**registered nurse first assistant (RNFA)** a perioperative RN with advanced education and training who helps the surgeon with tasks such as holding retractors and suturing

**restricted zone** OR suite with actual OR rooms, the scrub sink areas, substerile rooms, central core, and steam sterilization areas; access restricted to personnel wearing surgical attire, hair covers, and masks

**retained surgical items (RSIs)** surgical item unintentionally left inside a patient, which poses a severe risk to patient safety and causes an unacceptably poor patient outcome

**RN circulator** a registered nurse who is not scrubbed in but whose primary responsibilities include managing the

overall environment of the OR to ensure it remains safe, sterile, and efficient; the overarching roles of the RN circulator include being the primary patient advocate; orchestrating the environment and ensuring sterility; and collaborating with the anesthesia provider and scrub personnel

**robotic-assisted surgery** a surgical procedure performed with a robotic system controlled by a surgeon

**scrub person** the person (RN, technologist) who scrubs in during surgery to assemble and pass instruments and supplies to the surgeon and surgical team, label medications and fluids on the sterile field, count all required items, and manage specimens

**semirestricted zone** includes the preoperative and postanesthesia care units and medication rooms; personnel are clothed in surgical attire

**stage 1—immediate** the immediate stage of postoperative care is the period of time the patient is in the PACU, which may last a few hours or up to a day; stage 1 recovery is divided into phases I and II

**stage 2—intermediate** the intermediate postoperative stage begins when the patient is transferred out of the PACU to a hospital room, to a convalescent facility, or to home; this stage can range from days to weeks depending on the surgery and healing progress

**stage 3—convalescence** the convalescence stage begins when the patient is home and includes gradual rehabilitation and resumption of normal activities; this phase can take weeks or months, varying greatly based on the individual

**sterile technique** a set of specific practices and procedures employed to maintain sterility of the sterile field (e.g., equipment, instruments, drapes)

**sterility** state of being free from living microorganisms (e.g., germs, spores)

**surgeon** a medical provider trained to perform surgical procedures who bears the ultimate responsibility for the surgery and members of the surgical team

**surgical asepsis** the absence of all microorganisms in any type of invasive procedure, achieved through rigorous sterilization processes and meticulously maintained through sterile technique

**surgical attire** personal protective equipment used to prevent personal and environmental contamination; determination of what to wear (e.g., scrubs, surgical gowns, gloves, masks, hair coverings, shoes, face shields) depends on the area of surgical suite and the risk of contamination

**surgical conscience** a moral code of integrity that compels a person to speak up when an infraction has or is thought to have occurred, to prevent patient harm

**surgical count** the process of counting all item that may possibly be retained in a patient during a surgical procedure to identify and prevent count discrepancies and the occurrence of retained surgical items

**surgical site infection (SSI)** infection that occurs at or near a surgical incision within thirty days of the procedure or within one year in the case of organ or space infections with an implant

**surgical smoke** contains potentially harmful particles that are produced by thermal destruction of tissue when using electrosurgical and radio-frequency devices, lasers, ultrasonic scalpels, power tools, and other heat-destructive devices in the operating room

**surgical zone** segmented area in the surgical suite with distinct function and attire requirements; a zone may be unrestricted, semirestricted, or restricted

**telesurgery** remotely performing surgical procedures from a distance using robotic systems and telecommunication technology

**time-out** a specific verification process that occurs as a short pause just before induction of anesthesia, before the initial surgical incision, and before the patient leaves the OR to confirm that the team is about to perform (and has performed) the correct procedure on the correct body part of the correct patient

**unrestricted zone** where nonsterile activities like patient admission and transport occur; includes the admissions area, offices, changing areas, break rooms, and supply receiving and storage; street clothing is allowed

**urgent surgery** typically occurs within hours of the decision to operate for an acute situation, and if resuscitation was required, it has been performed and resolved; although urgent, time is available to allow for more efficient identification of a surgeon, anesthesia provider, perioperative personnel, and available operating room time

## Assessments

### Review Questions

1. What anesthesia type induces a state of drowsiness and reduces anxiety without complete unconsciousness?

- a. general anesthesia
  - b. monitored anesthesia care (MAC)/moderate sedation
  - c. regional anesthesia
  - d. local anesthesia
2. A nurse is preparing a patient for a procedure to remove a wart. The wart is not painful and does not affect the patient's ability to function. How would this surgery be classified?
- a. expedited
  - b. emergent
  - c. elective
  - d. urgent
3. The nursing student is discussing the appropriate use of general anesthesia with their preceptor. What statement should the student make to demonstrate they have an accurate understanding of general anesthesia?
- a. General anesthesia numbs a small area of the body while allowing the patient to remain conscious.
  - b. General anesthesia may be used with sedation.
  - c. General anesthesia makes patients drowsy while allowing them to breathe on their own during surgery.
  - d. General anesthesia puts patients into a deep sleep and induces amnesia.
4. A patient in a rural area is having a hysterectomy performed remotely, in real time, by a doctor who is two hours away in an urban hospital. What type of surgery makes this possible?
- a. MARVEL
  - b. telesurgery
  - c. minimally invasive surgery
  - d. artificial intelligence
5. What new technology offers neurosurgeons improved access to do brain tumor resections in deep and narrow regions of the brain?
- a. robotic-assisted surgery
  - b. telesurgery
  - c. MARVEL
  - d. artificial intelligence
6. What is the purpose of preadmission testing?
- a. to educate a patient about the purpose of their procedure or surgery
  - b. to ensure the patient's colon and rectum are clean before a procedure or surgery
  - c. to evaluate a patient's health status before a procedure or surgery
  - d. to ensure the patient has provided informed consent for the procedure or surgery
7. Why is fasting before surgery important?
- a. Fasting helps clean the patient's colon and rectum before surgery.
  - b. Fasting helps minimize the risk of aspiration during anesthesia.
  - c. Fasting helps determine if a patient is strong enough to survive surgery.
  - d. Fasting helps minimize the chances of a patient developing an infection after surgery.
8. What is the role of the nurse during preoperative preparation?
- a. Prepare instruments and assist the surgeon while maintaining a safe environment.
  - b. Manage the patient's pain, monitor vital signs, and treat postoperative complications.
  - c. Provide essential early postoperative care.
  - d. Assess patients, manage anxieties, and confirm informed consent.
9. How can distraction methods help with pain management?

- a. With distraction methods, activities such as listening to music can help divert attention from pain or discomfort.
  - b. With distraction methods, activities such as guided meditation can help manage anxiety and decrease pain.
  - c. With distraction methods, therapies such as cold packs and heating pads can help with inflammation and reduce pain.
  - d. With distraction methods, positioning provides comfort and helps patients be more at ease physically and mentally.
- 10.** What are the eight rights of medication administration?
- a. right patient, right medication, right dose/concentration, right surgeon, right time, right supplements, right reason, and right patient response
  - b. right patient, right medication, right dose/concentration, right dietary requirements, right time, right documentation, right supplements, and right patient response
  - c. right patient, right medication, right dose/concentration, right fluid intake, right dietary requirements, right documentation, right time, and right patient response
  - d. right patient, right medication, right dose/concentration, right route, right time, right documentation, right reason, and right patient response
- 11.** Which surgical team member directly supports the surgeon by retracting tissues, providing additional instrumentation, and anticipating needs?
- a. RN circulator
  - b. anesthesiologist
  - c. Certified Registered Nurse Anesthetist (CRNA)
  - d. Registered Nurse First Assistant (RNFA)
- 12.** Which surgical team member has tasks before, during, and after surgery, including acting as a patient advocate, preparing the OR and maintaining sterility, and collaborating with other team members, including the management of “time-outs”?
- a. RN circulator
  - b. anesthesiologist
  - c. Certified Registered Nurse Anesthetist (CRNA)
  - d. Registered Nurse First Assistant (RNFA)
- 13.** In the perioperative suite, what surgical zone includes the preoperative and postanesthesia care units and medication rooms?
- a. unrestricted
  - b. semirestricted
  - c. restricted
  - d. substerile
- 14.** What surgical innovation also poses hazards in the OR, including direct tissue damage, fire hazards, eye injuries, and airborne contaminants?
- a. lasers
  - b. surgical smoke
  - c. anesthetic gases
  - d. electrosurgery
- 15.** Preventing hypoxia is fundamental to safeguard patients in the OR. Why?
- a. With hypoxia, the body’s core temperature drops below 96.8°F (36°C), which can have devastating consequences.
  - b. With hypoxia, the body experiences a severe allergic reaction, which can have devastating consequences.

- c. With hypoxia, the body experiences excessive bleeding, which can have devastating consequences.
  - d. With hypoxia, the body's tissues are deprived of adequate oxygen, which can have devastating consequences.
- 16.** During what stage or phase of postoperative care is the focus on wound management, physical therapy, and ongoing pain management?
- a. stage 1—immediate
  - b. stage 2—intermediate
  - c. stage 3—convalescence
  - d. phase I recovery
- 17.** Abnormal blood pressure, heart rate, and oxygen saturation readings plus swelling and redness around a wound are clues of what problem?
- a. hypotension and shock
  - b. hemodynamic instability
  - c. hemorrhage
  - d. hypertension and arrhythmias
- 18.** What are the early signs of unmanaged pain?
- a. guarding, sighing, clenched fists, furrowed brows
  - b. increased blood pressure and changes in consciousness
  - c. restlessness, agitation, pale skin, tight abdomen
  - d. clammy skin, altered consciousness, difficulty breathing
- 19.** What bariatric procedure is complex, creating a small stomach sleeve to bypass most of the small intestine?
- a. sleeve gastrectomy
  - b. Roux-en-Y gastric bypass
  - c. biliopancreatic diversion with duodenal switch
  - d. adjustable gastric band
- 20.** After gastric bypass surgery, food may pass directly from the stomach pouch into the small intestine without being digested. What is this syndrome called, and why is it a problem?
- a. It is called dumping syndrome, and it is a problem because it can cause nausea, vomiting, abdominal cramping, and diarrhea.
  - b. It is called comorbidity syndrome, and it is a problem because it can cause nausea, vomiting, abdominal cramping, and diarrhea.
  - c. It is called dumping syndrome, and it is a problem because it can cause high blood pressure and dizziness.
  - d. It is called comorbidity syndrome, and it is a problem because it can cause high blood pressure and dizziness.

### Check Your Understanding Questions

1. What is the difference between scheduled and elective surgery?
2. What is the difference between local and regional anesthesia?
3. What is the goal of bowel preparation, and what is the two-pronged approach to achieve bowel preparation?
4. During preoperative preparation, what are the nurse's responsibilities regarding skin preparation?
5. What is the main purpose of surgical asepsis and sterile technique in the OR?
6. What is the difference in roles between an RN circulator and a scrub person?
7. What is the purpose of a surgical time-out?

8. What should the nurse assess to determine if a patient has the psychological readiness required to be discharged?

### Reflection Questions

1. Reflect on the challenges and demands placed on healthcare professionals during emergent surgeries. How does the urgency impact decision-making and collaboration?
2. What role does artificial intelligence (AI) play in enhancing surgical decision-making?
3. How does preadmission testing help ensure that patients are prepared and have a successful surgery?
4. How does the nurse's ability to build rapport with patients contribute to a holistic preoperative assessment?
5. Reflect on the potential health hazards associated with the surgical environment. How can healthcare institutions proactively address and mitigate these risks to ensure the well-being of both patients and healthcare personnel?
6. Reflect on the developmental considerations for dealing with children in postoperative care. What should nurses remember when dealing with children as patients?

### What Should the Nurse Do?

1. A patient is scheduled for a surgical procedure to have a large mole removed from the back of their hand. What type of anesthetic should the nurse be prepared to assist with to prepare the patient for this procedure, and how will the nurse know if the anesthetic is working?
2. A patient cut their ankle while doing yard work and needs several stitches. The patient was given a regional anesthetic and is upset because they cannot feel their foot, the area around the ankle, or the lower part of their leg. What should the nurse do?
3. A patient is scheduled for surgery early the next morning and refuses to follow the fasting guidelines. The nurse overhears the patient order a cheeseburger that they intend to eat shortly before going to sleep for the night, which will be less than eight hours before their surgery. What should the nurse do?
4. During a patient's preoperative assessment, the nurse notices that the patient seems nervous and uncomfortable. What should the nurse do?
5. About an hour after surgery begins, a first-year surgical intern opens the door of the OR. The intern is not wearing a surgical gown or gloves, and they are wearing shoes from outside the OR without shoe covers. The intern starts to step inside the OR. Why is this a problem, and what actions should the RN circulator take to correct the problem?
6. During surgery on a urology patient, the surgeon plans to use electrosurgery for part of the procedure. To ensure that this part of the surgery is handled safely without creating a fire risk, what should the RN circulator ensure happens before the electrosurgery device is triggered?
7. While overseeing a new nurse's work, the head nurse finds that the new nurse's immediate postoperative assessment of a patient provides details about the patient's circulation, pain, temperature, and surgical site. But no other information is included in the assessment. Why is this a problem, and what should the head nurse do to correct this?

### Competency-Based Assessments

1. Imagine you are working in a surgical department and are tasked with developing a presentation to help stakeholders decide whether the facility should transition to robotic surgery. What advantages and disadvantages should you highlight?
2. Explain the process that preoperative nurses should use to teach coping strategies and help patients deal with the stress and anxiety that they may experience when preparing for surgery.
3. Consider why hypothermia is a critical concern in the OR. Create a presentation that discusses the factors that can contribute to hypothermia, and how the perioperative team can prevent hypothermia.

4. A critical component of postoperative care is maintaining a patient's airway. Describe the interventions that may be needed to maintain a patient's airway.
5. Providing postoperative care to older adults often requires a nuanced approach that acknowledges unique challenges and strengths of the older adult population. What differences in older adults make this necessary?

## CHAPTER 32

# Self-Concept

**FIGURE 32.1** Thoughts and feelings about ourselves shape what is known as self-concept. (credit: modification of “mirror image” by Clare Black/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

32.1 Foundations of Self-Concept

32.2 Factors Affecting Self-Concept

**INTRODUCTION** Self-concept is an important aspect of patient care. Patients with a positive self-concept are more likely to participate in care and health prevention, have more engagement in self-care, and have better self-management of chronic diseases (Alqahtani & Alqahtani, 2022). A healthy self-concept is also important for nurses to successfully perform in their role. While a healthy self-concept is developed and maintained throughout the life span, there are many factors that can affect self-concept. This chapter introduces the foundations of self-concept, including its components, measurement, and development. It also discusses psychological, physiological, cultural, and behavioral factors affecting a healthy self-concept. A good understanding of self-concept can help the nurse better understand a patient’s cognitive, behavioral, and psychological processes and provide more patient-centered care.

## 32.1 Foundations of Self-Concept

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify components of self-concept
- Explain the measurements of self-concept
- Describe the development of self-concept

Understanding **self-concept**, the various components that collectively contribute to an individual’s perception of

themselves, involves recognizing its multifaceted nature. Measuring self-concept involves employing various assessment tools and methodologies to quantitatively (measurable data, typically involving numbers and statistics) and qualitatively (descriptive data, typically involving observations and non-numerical insights) evaluate various aspects of an individual's self-perception. Objective measurements may include standardized self-report questionnaires, such as the **Rosenberg Self-Esteem Scale**, which assesses global self-esteem. Qualitative measurements involve exploring personal narratives, reflective journals, and interviews, offering deeper insights into the subjective aspects of self-concept. Through these assessments, learners develop an understanding of the diversity in self-concept measurements and the importance of considering both quantitative and qualitative approaches to capture the richness and complexity of an individual's self-perception.

Self-concept is a dynamic construct, an abstract concept or theoretical entity that is not directly observable but is inferred from measurable behaviors or responses, that evolves over the life span. Its development is influenced by numerous factors, including social interactions, cultural contexts, personal experiences, and feedback from significant others. During childhood, interactions with family members and peers significantly impact the formation of self-concept. Adolescence introduces identity exploration, contributing to a more complex understanding of oneself. Adulthood involves continued refinement as individuals navigate relationships, work, and societal expectations. Learners exploring the development of self-concept delve into the psychological and sociological theories that clarify the intricate processes shaping one's self-perception over time. Understanding this development is crucial for healthcare professionals, educators, and counselors to provide effective support and interventions tailored to an individual's evolving self-concept.

### Components of Self-Concept

The construct of self helps us, as individuals, identify and relate within the world around us. How we communicate with others, maneuver through life, and describe ourselves are aspects of our concept of self. Humanistic psychologist Carl Rogers was instrumental in defining the paradigm (a distinct set of concepts, theories, methods, and standards that defines a scientific discipline or intellectual approach) of self-concept through three intertwined components: self-image, self-esteem, and **ideal self** (attributes that individuals aspire to possess) ([Figure 32.2](#)). The overall value and worth one assigns to oneself is one's **self-esteem**, while **self-image** involves the mental and emotional view of one's physical appearance and abilities. Personal characteristics, roles, and affiliations that define an individual are one's **self-identity**. Additionally, **social identity**, the concept of self that is formed through connections with societal groups, influences self-concept. Rogers defined this as "the organized, consistent set of perceptions and beliefs about oneself" (McLeod, 2024). Our personal identity and self-concept, according to Rogers, develop throughout the life span beginning in childhood and are molded by experiences, perceptions, and evaluation of others.

**FIGURE 32.2** Self-concept is a three-dimensional aspect of an individual incorporating the ideal self, self-image, and self-esteem. (credit: modification of “Würfel” by “Schlurche”/Wikimedia Commons, CC BY 3.0)

The concepts of ideal self, self-image, and self-esteem are interrelated components that together form an individual’s self-concept and are fundamental in developing personal identity, body image, and role performance. The ideal self, encompassing goals, ambitions, and desired traits and abilities, is often shaped by personal values, societal standards, and aspirations. Self-image, including personal views of one’s appearance, abilities, and personality, are influenced by feedback from others, experiences, and personal reflections. Self-esteem is the evaluative component, reflecting how one feels about oneself based on the alignment between self-image and ideal self. High self-esteem occurs when there is congruence between the two, while discrepancies can lead to psychological distress resulting in anxiety, poor self-esteem, and body dysmorphic disorders. The following sections explore how personal identity, body image, self-esteem, and role performance contribute to the overall self-concept, examining the roles each plays in shaping our comprehensive understanding and evaluation of ourselves.

### Personal Identity

The sense of individuality and uniqueness that distinguish a person from others is one’s **personal identity**. It involves the recognition and internalization of personal traits, values, and beliefs, contributing significantly to how individuals perceive themselves within the broader context of society. This aspect of self-concept evolves as individuals experience personal growth and self-discovery and navigate the complexities of relationships and societal expectations.

### Body Image

An individual’s perception and evaluation of their physical appearance make up one’s **body image**. This aspect of self-concept is heavily influenced by societal standards, cultural norms, and personal experiences. A positive body image correlates with a healthy self-concept, promoting self-acceptance and overall well-being. On the contrary, negative body image can lead to self-esteem issues, impacting mental health. As healthcare professionals engage with individuals, understanding the intricacies of body image within the context of self-concept becomes crucial for providing holistic and sensitive care.

## CULTURAL CONTEXT

---

### Cultural Considerations and Body Image

Cultural considerations related to body image are crucial to understanding how individuals perceive and interact with their bodies within different cultural contexts. Cultural norms, values, beliefs, and practices significantly influence how body image is constructed and experienced across diverse societies. In many cultures, societal standards of beauty and attractiveness play a central role in shaping perceptions of body image. These standards can vary widely between cultures and may be influenced by factors such as historical traditions, religious beliefs, media representation, and socioeconomic status. Nurses should gather information from their patients and their families that helps assess each patient's views on body image. Here are a few specific cultural examples to illustrate the diversity of beliefs and attitudes toward body image:

- **Western cultures (United States, Western Europe):** In Western cultures, there is often an emphasis on thinness as a beauty ideal, especially for women. Media portrayals frequently feature slim, toned bodies as the standard of beauty, influencing individuals to strive for a particular body size and shape. However, there is growing awareness and advocacy for body positivity and acceptance of diverse body shapes and sizes within Western cultures, challenging traditional beauty standards and promoting self-acceptance (Eisenberg et al., 2005).
- **East Asian cultures (China, Japan, South Korea):** In East Asian cultures, there is often a preference for thinness as well, but with variations. In countries like China, Japan, and South Korea, there may be a cultural ideal of “slimness with curves,” where a slender body is desired but with some emphasis on certain curves and proportions. Moreover, fair skin is often associated with beauty and elegance in many East Asian cultures, leading to the popularity of skin-lightening products and practices (Noh et al., 2018).
- **Latin American cultures:** In Latin American cultures, there is often a greater acceptance of fuller body types, and curves are often celebrated as symbols of beauty and femininity. This cultural preference for a curvier figure is reflected in media representations and beauty ideals. Additionally, there may be cultural rituals and celebrations, such as the quinceañera, where young women aged 15 years are celebrated and embraced for their natural beauty and femininity, regardless of body size or shape (United Nation Children's Fund [UNICEF], 2023).
- **Pacific Islander and Polynesian cultures:** In Pacific Islander and Polynesian cultures, there is often a cultural appreciation for larger body sizes, which are associated with health, fertility, and prosperity. This cultural attitude toward body size is reflected in traditional dances, where fuller figures are celebrated and admired (Brewis et al., 1998).
- **African cultures:** In various African cultures, there is often a preference for larger body sizes, especially among women, which are associated with beauty, health, and fertility. Fuller figures are often celebrated and desired, reflecting cultural ideals of femininity and attractiveness (Naigaga et al., 2018).

These examples illustrate the diversity of cultural attitudes toward body image, emphasizing the importance of understanding and respecting cultural differences when addressing body image concerns in diverse populations.

---

The connection between body image and mental health is evident, with higher body dissatisfaction posing a risk for mental health problems such as depression, anxiety, and suicidal thoughts. A survey conducted by the Mental Health Foundation in 2019 revealed that over one-third of adults felt anxious or depressed due to body image concerns, and one in eight experienced suicidal thoughts or feelings (Mental Health Foundation, 2019). These findings align with research associating body dissatisfaction with a poorer quality of life, psychological distress, and an increased likelihood of depression symptoms. Furthermore, the report emphasizes the link between body image and mental health disorders like **body dysmorphic disorder (BDD)** (a mental health condition characterized by obsessive preoccupation with perceived flaws or defects in physical appearance that are not observable or appear minor to others) (Figure 32.3) and eating disorders (Mental Health Foundation, 2023). While body image concerns are identified as a risk factor for such mental health conditions, the report underscores that addressing body image extends beyond specific disorders, emphasizing the need for comprehensive mental health interventions and preventive measures.

**FIGURE 32.3** Body dysmorphic disorder occurs when individuals have a distorted or impaired self-image, perceiving themselves as having a different body form than reality. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Concerns and worries about body image are prevalent among young people, with a survey by BE REAL indicating that 79 percent of 11- to 16-year-olds in the United Kingdom find their appearance important, and over half often worry about it (Mental Health Foundation, 2023). The Mental Health Foundation's survey of young people aged 13 to 19 years further reveals that 35 percent frequently feel worried about their body image. Despite affecting all genders, girls are more likely to report dissatisfaction, with 46 percent expressing frequent worry compared to 25 percent of boys (Mental Health Foundation, 2023). Body image concerns in young people are identified as the third biggest challenge causing harm, following lack of employment opportunities and educational failure. The impact of body dissatisfaction extends beyond psychological distress, influencing risk-taking behaviors, such as dieting, cosmetic surgery consideration, and steroid use among adolescents. Studies in the United States showed similar findings. In 2021, the YouGov Body Image Study found that 51 percent of Americans feel pressured to achieve specific body types, and 62 percent of those in relationships worry about how their partners perceive them (YouGov, 2021).

### LINK TO LEARNING

The National Organization for Women provides some [facts about body image \(https://openstax.org/r/77NOWbodyimage\)](https://openstax.org/r/77NOWbodyimage) on their website. Do any of these facts surprise you? How might these facts impact the care you provide to your patients?

The factors contributing to poor body image in children and young people are multifaceted. Pressure to conform to an “ideal” body type, shaming and bullying from peers and family, and emotional distress associated with a mindset of nonconformity all contribute to body dissatisfaction. Such ideals differ between genders, with young women pressured to be the typical thin, hourglass body type, and young men expected to be tall and muscular. These expectations are internalized through exposure to media representations of ideal bodies. The survey indicates that 25 percent of young people attribute their worries about body image to celebrities and 19 percent attribute them to TV shows (Mental Health Foundation, 2023). Social media exacerbates these concerns, with 40 percent of young people reporting that social media images cause them worry (Mental Health Foundation, 2023). Peer influence also plays a significant role, with friends contributing to worries about body image for 40 percent of young people (Mental Health Foundation, 2023). Family dynamics, parental behavior, and bullying further impact body image in children and adolescents, with appearance-based bullying linked to detrimental effects on mental health and body image (Mental Health Foundation, 2023).

## LIFE-STAGE CONTEXT

---

### Body Image in Adulthood

In adulthood, the components of self-concept, particularly related to body image, play a crucial role in overall well-being. Increased body dissatisfaction has been correlated with higher rates of depressive symptoms, psychological distress, and development of disordered eating (e.g., skipping meals, restrictive eating, excessive exercise) and eating disorders (e.g., anorexia, bulimia, binge eating). Conversely, positive body image in adults is associated with better overall well-being and quality of life. A Mental Health Foundation survey highlighted that 34 percent of adults reported feeling anxious, and 35 percent reported feeling depressed due to concerns about their body image (Mental Health Foundation, 2023). Moreover, a concerning one in eight adults experienced suicidal thoughts or feelings related to their body image. The survey also revealed that body image concerns were associated with behaviors such as photo editing (7 percent) and contemplating cosmetic procedures like surgery, fillers, or Botox (8 percent) (Mental Health Foundation, 2023).

The impact of body image in adulthood extends beyond emotional well-being and is interconnected with relationships and sexual health. Positive body image has been linked to more positive sexual experiences, especially for women, while body image concerns may contribute to self-consciousness and negatively impact sexual experiences and responses. The survey indicated that one in five adults reported that their sex life had been negatively affected by their body image, and 15 percent mentioned a negative impact on their relationships in the past year (Mental Health Foundation, 2023).

Several factors influence body image in adulthood, similar to childhood, with internalization of “ideal” body types and social comparisons playing pivotal roles. The media, including advertising and social media, contributes significantly to body dissatisfaction, with approximately one in five adults expressing concerns about their body image due to images in advertising and social media. Peer interactions, workplace dynamics, pregnancy, new parenthood, and physical appearance further contribute to shaping body image perceptions in adulthood. Understanding these factors is crucial for devising interventions and support mechanisms to promote positive body image and mental well-being in adults (Mental Health Foundation, 2023).

---

### Self-Esteem

Self-esteem, perhaps one of the most recognized components, represents the overall subjective evaluation of one’s worth and value. It is a composite of various factors, including achievements, interpersonal relationships, and societal comparisons. Healthy self-esteem is associated with resilience, positive coping mechanisms, and the ability to navigate life’s challenges. In contrast, low self-esteem may contribute to feelings of inadequacy, anxiety, and vulnerability. Recognizing the dynamic nature of self-esteem within the broader framework of self-concept is essential for healthcare professionals and behavioral counselors to support individuals in fostering a positive self-image.

### Role Performance

How individuals perceive and execute their roles in different contexts within the family, work, or social environment is called **role performance**. This component integrates personal identity, body image, and self-esteem into action, influencing behavior and interactions. Effective role performance contributes to a sense of purpose, fulfillment, and positive reinforcement of self-concept. Understanding the interconnectedness of these components provides valuable insights for professionals aiming to empower individuals in developing and maintaining a healthy self-concept across diverse life stages and circumstances.

### Measurements of Self-Concept

Trying to understand how people see themselves and how this can change in different situations can be challenging. To glean an accurate depiction, there are a few things healthcare providers should consider. For example, a patient may find it hard to determine their ideal self if they are in a fairly stable environment that does not require them to question themselves or consider new things about themselves. There are also differences in how comfortable people are in finding new things about themselves and their surroundings. Those who are somewhat flexible or feel comfortable in uncertain situations are more likely to change how they perceive themselves compared to someone

who prefers stability and organization.

To understand how people see themselves, healthcare providers also should consider how people define themselves in certain areas of their lives. For example, some people base their identity heavily on close relationships, and changes in those relationships can lead to changes in how they view themselves. Determining a common scale on which to study and measure these changes can be daunting and often unreliable. To do this well, it is suggested to use different methods, consider how the study relates to real-life situations, and make sure the study is as close to a natural setting as possible. [Table 32.1](#) presents some examples of self-concept tools commonly used by providers in different settings.

Test	Description	Format
Self-Concept and Identity Measure (SCIM)	Assesses consolidated identity, disturbed identity, and lack of identity	The questionnaire contains twenty-seven statements that aim to measure self-concept across six different aspects: <ul style="list-style-type: none"> <li>• physical</li> <li>• social</li> <li>• temperamental</li> <li>• educational</li> <li>• moral</li> <li>• intellectual</li> </ul>
The Personal Self-Concept Questionnaire (PSQ)	A shorter measurement tool that provides an accurate representation of self-concept overall	The questionnaire is made up of twenty-two statements, divided into four subcategories: <ul style="list-style-type: none"> <li>• self-fulfillment</li> <li>• autonomy</li> <li>• honesty</li> <li>• emotional self-concept</li> </ul>
The Five-Factor Self-Concept Questionnaire (AF5)	Assesses five specific dimensions: academic, social, familial, emotional, and physical *Developed in Spain and used primarily with Spanish-speaking patients	Thirty items, six for each dimension Rating using a continuous response on a ninety-nine-point scale ranging from one (complete disagreement) to ninety-nine (complete agreement)
The Piers-Harris Children's Self-Concept Scale	A self-reporting tool that assesses self-concept in children and adolescents; can be used as a research tool, to monitor change in self-concept over time, and as a screening tool for identifying individuals who need further testing or treatment	This is a sixty-question tool where the child circles "yes" or "no" to answer questions, covering six subcategories: <ul style="list-style-type: none"> <li>• behavioral adjustment</li> <li>• intellectual and school status</li> <li>• physical appearance and attributes</li> <li>• freedom from anxiety</li> <li>• popularity</li> <li>• happiness and satisfaction</li> </ul>

**TABLE 32.1** Self-Concept Tools

Test	Description	Format
The Rosenberg Self-Esteem Scale	A widely used self-report instrument for evaluating individual self-esteem	A ten-item scale that measures global self-worth by measuring both positive and negative feelings about the self. The scale is believed to be unidimensional. All items are answered using a four-point Likert-type scale format, ranging from strongly agree to strongly disagree.
The <i>Dimensions of Self-Concept (DOSC)</i>	A self-report survey for measuring noncognitive factors that are associated with self-concept or self-esteem in the school setting	Seventy to eighty questions (depending on grade level) that measure the following: <ul style="list-style-type: none"> <li>• level of anxiety</li> <li>• aspirations</li> <li>• academic interest and satisfaction</li> <li>• leadership and initiative</li> <li>• identification versus alienation</li> </ul>

**TABLE 32.1** Self-Concept Tools

Self-knowledge, self-expectations, and self-evaluation play crucial roles in the measurement and understanding of self-concept. Together, these components contribute to comprehensive measurements of self-concept by capturing both descriptive aspects (self-knowledge) and evaluative aspects (self-expectations and self-evaluation). By integrating these dimensions, researchers and practitioners can assess and understand how individuals perceive themselves across different contexts and domains, informing interventions aimed at promoting positive self-concept and psychological well-being.

### Self-Knowledge

A philosophical term, **self-knowledge** is used to identify one's own recognition of mental state—what one believes, feels, perceives, and desires. Self-knowledge serves as the cognitive foundation on which self-concept is constructed, providing the content and data that individuals use to formulate their perceptions and evaluations of themselves. Self-knowledge is genuine information one possesses about oneself, and components of self-knowledge encompass emotional states, personality traits, relationships, behavioral patterns, opinions, beliefs, values, needs, goals, preferences, and social identity. Self-knowledge results from self-reflective and social processes, deriving not only from introspection but also from five sources: the physical world, social comparisons, reflected appraisals, introspection, and self-perception (Wilson, 2021). Additionally, Schaffner (2020) includes **cognitive-behavioral therapy (CBT)** (a structured talk therapy that focuses on problematic thinking and behaviors and helps to create healthy thinking, behaviors, and coping skills) and mindfulness techniques as sources of self-knowledge.

Self-concept measurements rely on individuals' awareness and understanding of themselves. Self-knowledge provides the foundational data about one's traits, values, abilities, and experiences, which are essential for assessing how individuals perceive themselves in various domains. For example, self-knowledge informs responses to questionnaires or assessments that inquire about personal characteristics and behaviors.

Understanding oneself is crucial for healthy functioning and promoting realistic decision-making regarding key aspects of life. Lack of self-knowledge can adversely affect life partner choices, education and career decisions, and lifestyle choices. Deficits in self-knowledge may lead to exaggeration of subjective strengths, impacting life satisfaction and academic performance negatively. The importance of self-knowledge for psychological growth includes satisfying the desire to learn from experiences, preventing discord between self-perceptions and the perceptions of others, releasing oneself from unconscious notions, facilitating proactive responses, and serving as a necessary first step for positive change. Furthermore, self-knowledge promotes emotional balance; reduces work frustration, insecurity, and envy; decreases stress; enhances responsibility for emotions; fosters empathy and compassion; and shapes understanding of others (Wilson, 2021).

Self-knowledge also plays a crucial role in nursing and healthcare contexts, as it helps nurses manage stress related to patient care and workplace dynamics, fostering a deeper understanding of their own emotions and reactions. Self-knowledge also supports nurses in taking responsibility for their emotional responses, which is vital in maintaining professional boundaries and providing empathetic care to patients. By understanding their own strengths, limitations, and values, nurses can cultivate empathy and compassion toward patients and colleagues alike. This self-awareness also contributes to a deeper understanding of patients' perspectives and needs, thereby improving overall patient care and outcomes in healthcare settings.

### Global Self

The concept that we are all part of a collective being is called **global self**, like a global family where our actions have far-reaching impacts. It emphasizes the interconnectedness of people and cultures around the world. Various types of global self are highlighted, including cultural global self, shaped by exposure to diverse cultures; environmental global self, emphasizing responsible interaction with the planet; social global self, focusing on global friendships and community impact; digital global self, reflecting our online presence and connections; and economic global self, recognizing the influence of our purchasing choices on the world economy. These types encourage a holistic understanding of our role in a global context, extending beyond geographical and cultural boundaries.

### Self-Expectations

Expectations are personal beliefs about what should or will happen. They include influential and challenging **self-expectations** regarding what individuals should do, think, or feel. These expectations, often shaped by societal influences, cultural norms, and personal values, guide behavior and judgments. While some expectations can be positive, providing motivation to face challenges and pursue dreams, unrealistic expectations may lead to conflict, frustration, and self-doubt. Self-awareness in managing expectations is significant, particularly when unrealistic self-expectations contribute to negative self-beliefs and potential mental health issues, like anxiety and compassion fatigue. Balancing needs, desires, values, and beliefs is integral, emphasizing the importance of cultivating realistic expectations for nurturing a healthy self-esteem and experiencing fulfillment in life.

Self-concept measurements often include assessments of individuals' expectations and aspirations for themselves. These expectations reflect their ideal self, encompassing goals, desires, and future-oriented aspects of identity. By measuring self-expectations, researchers and practitioners gain insights into how individuals perceive their potential and aspirations relative to their current self-perceptions.

The broader impact of expectations extends beyond self-expectations to include expectations of others. Individuals can unintentionally set expectations for themselves based on assumptions of how others will react, potentially leading to feelings of failure and resentment. Unrealistic expectations in various aspects of life, from striving for constant happiness to setting standards based on societal perceptions and social media influences, can have a negative impact on the quality of life. While setting high expectations often stems from a desire for a perfect outcome, acknowledging and learning from mistakes is crucial for personal growth and success. By highlighting the importance of recognizing strengths and weaknesses as a means of cultivating self-awareness, people are able to manage expectations effectively, building a more satisfying life.

## REAL RN STORIES

---

### When High Expectations Lead to Burnout

**Nurse:** Beth, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 2

**Facility location:** Inner city Washington, DC

I had just landed my dream job at a prestigious hospital downtown and had high self-expectations. I wanted to be a “rock star” nurse and save lives, just like you see on TV. I was super busy throughout all of my shifts and hardly had time to eat at work; however, I kept pushing through because I needed to be the rock star nurse my patients needed. My personal life was deteriorating (my husband and I were like distant roommates), and I dreaded going home, so I would pick up more shifts at the hospital. I was always so tired when I got home, all I wanted to do was

sleep. I hardly talked to my friends or did anything fun because I worked so much and was utterly exhausted all the time. I didn't realize it at the time, but I pushed myself way too hard and quickly became burned out.

One day while I was at work, I passed out. As embarrassing as that was, it was my wake-up call. I was forced to take time off from work and face the real world as well as my personal problems. During my mandatory time off, I had conversations with my husband, and we decided to separate. I also began to see a therapist and take medication for depression. When it was finally time for me to return to work, I had developed a stronger sense of work-life balance and developed healthy self-expectations. It's still a work in progress, but I've decided to make myself a priority.

### Ideal Self

The concept of the self encompasses different aspects, including the actual self, ideal self, and ought self. The **actual self**, or real self, represents the attributes believed to be possessed by an individual, as perceived by oneself or others (Figure 32.4). On the other hand, the ideal self consists of attributes one or others aspire for the individual to possess, while the **ought self** refers to the internalized expectations and standards that individuals believe they should or must adhere to in order to meet external demands, social norms, or moral obligations.

These different facets of the self can lead to internal conflicts, manifesting as disparities between the actual self and the ideal or ought self. Such discrepancies can serve as motivational factors, prompting individuals to undertake actions for self-improvement. For example, imagine a registered nurse who sees herself as compassionate and dedicated to patient care (actual self). However, their ideal self-image includes becoming a nurse practitioner specializing in oncology. Meanwhile, their ought self involves meeting the expectations of their healthcare team and adhering to clinical protocols and patient safety standards. The gap between their current role as a nurse and their ideal self as a nurse practitioner may motivate them to pursue further education, seek certification, and gain clinical experience in oncology. Simultaneously, balancing their ought self with patient care demands and clinical responsibilities requires them to integrate compassionate care with procedural adherence and team collaboration.

**FIGURE 32.4** When our real self and ideal self overlap, harmony occurs. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Moreover, conflicts between the ideal and ought selves can induce heightened stress, particularly when individuals, such as professional women with both career aspirations and maternal duties, perceive a misalignment between their ideal vision and perceived obligations. The resulting actual self may fall short of meeting expectations in either realm. These disparities extend beyond cognitive unease, influencing emotional, behavioral, and communicative responses. When assessing the actual self in comparison to ideal self and external expectations, distinct patterns of emotional and behavioral consequences emerge. *Mismatch with personal ideals* may evoke feelings of disappointment and frustration, as exemplified by the financial discipline scenario. Similarly, *discrepancies with others' ideals* can elicit emotions such as shame and embarrassment, as experienced when academic performance falls short of expectations. *Conflicts with perceived duties or obligations* may lead to agitation and fear of potential repercussions, exemplified by the dilemma of following familial expectations versus personal aspirations. Last, *incongruence with one's own sense of duties* may evoke feelings of guilt and inadequacy. For example, in nursing, when a nurse's actual self, ideal self (aiming for specialized expertise in critical care), and ought self (fulfilling hospital protocols and team expectations) are not aligned, it can evoke feelings of guilt and inadequacy. The nurse may feel guilty when unable to dedicate enough time to specialized patient care during demanding shifts, leading to a sense of inadequacy in meeting both patient needs and professional standards. This overview outlines the four potential discrepancies between selves and the associated emotional outcomes, emphasizing the intricate interplay between internal and external expectations on individuals' well-being and self-perception.

## False Self

Donald Winnicott, a pediatrician and psychoanalyst, stressed how important it is to keep our mental energy strong when there is constant pressure to fit in. His focus was on the individual's ability to be "alive" and spontaneous, and how these qualities can be lost when we start to take on what society expects from us (Ehrlich, 2021). This pressure ultimately causes issues of frustration, anger, and sadness. Winnicott believed that the **false self**, pretending to be someone we are not, begins in infancy due to unmet maternal needs.

The pervasive impact of shame, marked by a sense of inherent inadequacy and unworthiness, often compels individuals to construct a false self in the pursuit of acceptance. The fear of rejection and humiliation drives an individual to garner approval, perpetuating anxiety and a diversion of embracing one's genuine, authentic self. In a quest for safety, individuals alter their identities and expend a considerable amount of energy to meet perceived expectations for love and acceptance. This self-imposed pressure to conform leads many to showcase attributes such as intelligence and skill, beauty, or accomplishments, at the cost of authenticity. Shame and authenticity share an intertwined relationship, influencing self-perception and external presentation. When rooted in the belief of personal flaws, shame disconnects individuals from innate, spontaneous joy, inhibiting the development of self-worth. Recognizing the presence of shame enables individuals to break free from destructive influence, empowering the true self despite external judgments. The journey toward authenticity is viewed as an ongoing process of mindful self-awareness, disentangled from the corrosive influences of shame and inner criticism, allowing individuals to navigate complexities, acknowledge existence without being defined by it, and ultimately spread their wings to savor the richness of life (Amodeo, 2020).

## Self-Evaluation

In psychology, **self-evaluation** refers to the process by which individuals assess and judge their own thoughts, feelings, behaviors, and overall sense of self. It involves reflective thinking about one's own characteristics, performance, and experiences. Self-evaluation can encompass various aspects, including self-esteem, self-worth, self-perception, and self-reflection.

Key components of self-evaluation include the following:

- **Self-esteem:** The overall positive or negative evaluation of oneself. It reflects an individual's feelings of self-worth and confidence. For example, despite facing a challenging shift, a nurse may experience high self-esteem when they maintain composure and effectively manage multiple patient care tasks, feeling confident in their abilities as a caregiver.
- **Self-perception:** How individuals perceive themselves in terms of their abilities, competencies, and characteristics is **self-perception**. A nurse's self-perception as a compassionate caregiver, for instance, may be affirmed when they receive positive feedback from a patient's family for their attentive and empathetic approach during a difficult shift.
- **Self-reflection:** Thoughtful contemplation about one's actions, motivations, and personal growth is **self-reflection**. It involves assessing one's values, goals, and the alignment between behaviors and personal standards. For instance, a nurse may engage in self-reflection after a particularly demanding shift, considering how their communication with patients and families could be improved to provide clearer information and emotional support during stressful times.
- **Self-awareness:** Recognizing and understanding one's emotions, thoughts, and behaviors is **self-awareness**. A nurse's self-awareness, for example, allows them to recognize feelings of frustration and burnout during a busy shift, prompting them to take breaks and seek support from colleagues to better manage stress and maintain quality patient care.

Self-evaluation can be influenced by various factors, including social comparisons (comparing oneself to others), cultural norms, feedback from others, and personal experiences. It plays a significant role in shaping an individual's self-concept and can impact mental well-being.

Self-concept measurements involve evaluating how individuals assess their own qualities, abilities, and behaviors. This self-evaluation component reflects their self-esteem (positive or negative feelings about oneself) and the alignment between their perceived self and ideal self. Self-evaluation measurements assess the degree of satisfaction or dissatisfaction individuals feel about their self-perceptions, which is crucial for understanding their overall self-concept. Psychologists often study self-evaluation processes to understand how individuals perceive

themselves, how they cope with successes and failures, and how these perceptions influence behavior and mental health. The ability to engage in constructive and realistic self-evaluation is considered essential for personal development and psychological well-being (Song, 2021).

### Significance

When people assess themselves, they tend to think of their ideal selves—an almost perfect version of who they want to be. This idealized view can lead to biased evaluations. Even if individuals cannot always act like their ideal selves, they often rate themselves more positively during self-evaluation. It is common for people to think less critically of themselves than they do of others. Understanding that these evaluations can be biased helps individuals form a more balanced self-concept. People may overestimate their abilities, and when they face failure, they tend to attribute the reasons to external factors rather than themselves (Song, 2021).

Recognizing that individuals might sometimes misjudge their capabilities allows them to develop a clearer self-concept. Social comparison, where people constantly compare themselves to others, can lead to assimilation in self-evaluations, making an individual's assessment more like their peers. Providing people with a realistic view of their capabilities helps them gain a better understanding of what they can do and reduces assimilation to some extent.

### Competence

The degree of effectiveness and proficiency individuals perceive in themselves is called **competence**. It involves not only objective assessments of performance but also subjective evaluations relative to personal standards and aspirations. Individuals gauge their competence in academic, professional, social, and personal spheres, reflecting on their achievements, strengths, and areas for improvement. Positive self-perceptions of competence foster confidence, motivation, and a sense of efficacy, empowering individuals to pursue their goals and navigate life's challenges with resilience. Conversely, perceived deficits in competence may lead to feelings of inadequacy, self-doubt, and **impostor syndrome** (a psychological pattern in which individuals doubt their skills, talents, or accomplishments and have a persistent internalized fear of being exposed as a “fraud”), hindering personal growth and well-being.

### Virtue

The moral dimension of self-evaluation, **virtue**, encompasses individuals' reflections on their character, values, and ethical conduct. It involves assessing the alignment between one's actions, intentions, and moral principles, as well as the perceived consistency with societal or cultural norms of virtuous behavior. Positive self-evaluations of virtue contribute to feelings of moral integrity, self-respect, and authenticity, fostering a sense of purpose and meaningful connection with others. Conversely, negative self-perceptions in this domain, such as feelings of guilt, shame, or moral conflict, may arise when individuals perceive a disconnect between their actions and their values, leading to inner turmoil and existential questioning.

### Power

An individual's perception of their ability to influence or control outcomes, resources, or other individuals within their social environment is called **power**. It encompasses both personal agency and social influence, spanning domains such as work, relationships, and community involvement. Positive self-evaluations of power cultivate feelings of autonomy, assertiveness, and efficacy, enabling individuals to assert their needs, pursue their goals, and advocate for change. However, perceived powerlessness or lack of control may engender feelings of frustration, helplessness, or vulnerability, undermining individuals' sense of agency and impeding their ability to effect change in their lives and communities. Recognizing and leveraging personal sources of power can empower individuals to assert themselves confidently, navigate power dynamics effectively, and strive for greater equity and justice in society.

## Development of Self-Concept

Just as forming strong connections is a crucial milestone in infancy, a significant step in childhood is developing a positive sense of self. Initially, babies do not recognize themselves in a mirror until they are approximately 18 months old. Between ages 24 and 36 months, children can point to themselves in pictures, demonstrating self-recognition (Archer, 1992).

From ages 2 to 4 years, children become more social after establishing a self-concept. They enjoy playing with other

kids but might find it challenging to share their belongings. Through play, they explore gender roles and can label themselves as a girl or boy. By the age of 4 years, children can cooperate, share, and separate from parents with less anxiety, displaying autonomy by initiating tasks and carrying out plans. Success in these areas contributes to a positive self-concept. At 6 years old, children identify themselves in terms of group memberships, like being a first grader. They start comparing themselves to peers, recognizing their strengths and areas for improvement. This self-awareness continues into adolescence, where teens form their identities and internalize messages about their strengths and weaknesses, contributing to their ability to positively impact society. Developing a positive self-concept is vital for healthy growth, influencing confidence, academic performance, independence, and a willingness to try new activities.

### Reflected Appraisal

The process by which our self-concept is affected by what other people think of us is called **reflected appraisal**; how we see ourselves is influenced by how others see us. Sociologist Charles H. Cooley described reflected appraisal as a concept called the “looking glass self” (Figure 32.5) (Cooley, 1902). In his assumption, Cooley suggested that how we understand others’ perception of us impacts the development of our self-concept. In other words, social interactions, especially those that are important to us, play an integral role in the development of our sense of self. Words used to describe us, such as smart or athletic, have an effect on how we aspire to encompass these characteristics as well as how we portray ourselves. When asked to describe ourselves, we often will use these same words as they are now part of our self-concept. In contrast, words such as “withdrawn” or “lazy” can negatively impact the way we portray ourselves, as self-concept has been affected in a negative way.

**FIGURE 32.5** The concept of the “looking glass self” represents the dynamics of reflected appraisal. (modification of “The looking glass self” by “Rcragun”/Wikipedia, CC BY 3.0)

According to **symbolic interactionism**, the way we see ourselves is influenced by how others see us. Self-concept is developed during childhood and continues to be refined through adolescence. The foundation of self-concept is based on three basic conditions: (1) a connection between children’s self-perceptions and their perceptions of how others see them (reflected appraisals), (2) a link between children’s reflected appraisals and others’ actual appraisals, and (3) a relationship between children’s self-perceptions and others’ actual appraisals. The model suggests that actual appraisals of significant others influence reflected appraisals, which, in turn, affect self-perception (Hergovich et al., 2002). For example, mothers, fathers, and teachers have an impact on different areas of self-concept, mothers generally being more influential.

### Social Comparison

Human nature drives individuals to measure themselves against others, assessing looks, success, friendships, and social status. In 1954, psychologist Leon Festinger suggested that we evaluate ourselves in comparison to others,

and those judgments influence our self-concept. This concept is known as **social comparison theory**. Some influence our self-concept more than others. *Upward social comparison* occurs when we compare ourselves with those we see as better than us. These comparisons tend to focus on the desire to improve ourselves. *Downward social comparison* occurs when we compare ourselves with those we see as worse off than us. These comparisons often focus on making us feel better about ourselves and our abilities.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Understanding Social Comparison in Health Care

Social comparison theory suggests that individuals evaluate themselves and their abilities by comparing themselves to others. In healthcare settings, patients may engage in social comparison with peers, benchmarks, or societal norms, influencing their perceptions of health, treatment adherence, and satisfaction with care.

- Patient perceptions:
  - Patient-centered care: Recognize patients' unique perspectives and experiences, acknowledging the impact of social comparison on their self-perception and well-being.
  - Communication: Foster open dialogue with patients, encouraging them to express concerns or challenges related to social comparison and providing empathetic support.
  - Teamwork and collaboration: Collaborate with interdisciplinary teams to address patients' psychosocial needs and develop personalized care plans that consider the influence of social comparison dynamics.
- Treatment adherence:
  - Evidence-based practice: Implement evidence-based strategies to enhance treatment adherence, considering the role of social comparison in influencing patient behavior and decision-making.
  - Quality improvement: Identify opportunities to improve patient education and support systems to mitigate the negative effects of social comparison on treatment adherence and health outcomes.
- Satisfaction with care:
  - Patient-centered care: Tailor care approaches to meet patients' individual needs and preferences, fostering a sense of autonomy and empowerment that mitigates the impact of social comparison on satisfaction with care.
  - Informatics: Utilize health informatics tools to monitor patient satisfaction metrics and identify areas for improvement in addressing social comparison dynamics within healthcare delivery systems.
- Implications for practice:
  - Encourage healthcare professionals to be mindful of the influence of social comparison dynamics on patient behavior and well-being.
  - Foster open communication and supportive relationships with patients, addressing individual needs and preferences to minimize the effects of social comparison.
  - Promote a strengths-based approach to care that emphasizes each patient's unique journey and progress, helping patients focus on their own goals and achievements rather than comparing themselves to others.

By recognizing the role of social comparison in patient care, nurses and healthcare professionals can adopt strategies to support patients effectively, enhance treatment adherence, and improve overall satisfaction with care. Through empathy, understanding, and patient-centered approaches, healthcare providers can mitigate negative effects of social comparison and foster positive patient outcomes.

---

### Stages

Development of a positive self-concept is important to healthy development. Children with a positive self-concept tend to be more confident, do better in school, act more independently, and are more willing to try new activities (Ferrer & Fugate, 2003; Maccoby, 1980). Formation of a positive self-concept begins in Erikson's toddlerhood stage, when children establish autonomy and become confident in their abilities. Development of self-concept continues in elementary school, when children compare themselves to others. When the comparison is favorable, children feel a sense of competence and are motivated to work harder and accomplish more. Self-concept is reevaluated in Erikson's adolescence stage, as teens form an identity. They internalize the messages they have received regarding

their strengths and weaknesses, keeping some messages and rejecting others. Adolescents who have achieved identity formation are capable of contributing positively to society (Erikson, 1968).

## PATIENT CONVERSATIONS

---

### Developing Self-Concept

**Scenario:** A parent asks his child's nurse if he can speak to the nurse privately. After the child is led outside by another nurse, the parent explains that the child just turned 12 years old and is experiencing problems in school that are affecting her self-concept. In particular, the child is struggling to earn passing grades in math, and following a recent growth spurt, she lacks the coordination needed to do well in gym class.

**Nurse:** Have you talked to the child about these problems?

**Parent:** No. I'm not sure what to say. I talked to her teacher, and the teacher said that all children have problems occasionally. The teacher suggested that I should be patient and let the problems sort themselves out. But my daughter seems depressed, and in recent weeks, she has refused to socialize with her friends. She also claimed to be sick one day last week and again this week, missing school as a result. That's why I brought her to see you. If she's sick, she needs to be treated. But I'm concerned that her real problem is frustration with math and gym classes, and she's feeling down on herself. What should I do?

**Nurse:** Twelve can be a difficult age as children prepare to become teenagers. I recommend talking to your daughter and encouraging her to tell you why she seems down. Tell her that everyone goes through times in life when things seem challenging and even scary. Tell her about times in your life when you felt down. Make sure she understands that you understand and that it's okay for her to tell you about any problems that she is having.

**Parent:** Aside from talking to her, what else should I do?

**Nurse:** It is important to make sure she feels safe and secure. Focus on her accomplishments and praise her for things that she does well. If you feel comfortable doing it, mention the math and gym classes and explain that everyone has areas in their lives where they struggle and even fail. Make sure she understands that it's okay to fail, and you still love her. Also, offer to help her. Maybe a tutor can help her understand math, and if you play basketball or another sport with her, maybe you can help her improve her coordination. Help her set realistic goals in these areas that are achievable, and then give her the tools she needs to reach those goals.

**Parent:** Thank you for listening and offering suggestions. I will try these things.

---

### Self-Awareness (Infancy)

During infancy, the development of self-concept begins with the foundation of self-awareness. Infants gradually become aware of their own bodies and sensations, distinguishing themselves from their environment. This initial stage is marked by simple sensory experiences, such as recognizing their own movements, sounds, and bodily sensations. Infants may display rudimentary forms of self-recognition, such as looking at their own hands or exploring their reflections in a mirror. When babies encounter a mirror, their first instinct is to hit it, not realizing it is a reflection of themselves. This early stage signifies a lack of self-recognition, where babies do not yet comprehend that the image in the mirror is a reflection of themselves. However, newborns do have an innate ability to differentiate between their image and the background as well as between themselves and their surroundings, indicating an early sense of self as a distinct entity.

Around 2 months old, babies start manipulating the mirror image, or gaining awareness of how their bodies relate to the environment. This stage is critical as it marks the beginning of understanding their physical presence in the world. An example is being able to estimate the distance to an object and then reaching for it. Studies indicate that even though newborns can mimic facial expressions, it is around 2 months of age that they learn to manipulate their bodies in response to the environment (Krisch, 2023). As they enter into 3 and 4 months of age, they begin to demonstrate their ability to imitate an adult sticking out their tongue in a specific direction and reach for objects around them. These behaviors reflect a growing recognition of their own actions and their effects on the environment, reinforcing their developing self-concept.

Caregivers play a crucial role in nurturing self-awareness during infancy through responsive interactions and sensitive attunement to the infant's cues and needs. By providing loving care and attention, caregivers help infants develop a sense of security and trust in their own bodies and surroundings, laying the groundwork for further exploration and self-discovery.

### **Self-Recognition (18 Months)**

Just as attachment is the main psychosocial milestone of infancy, the primary psychosocial milestone of childhood is the development of a positive sense of self. How does self-awareness develop? Infants do not have a self-concept, which is an understanding of who they are. If you place a baby in front of a mirror, the baby will reach out to touch their image, thinking it is another baby. However, by about 18 months, a toddler will recognize that the person in the mirror is themselves. How do we know this? In a well-known experiment, a researcher placed a red dot of paint on children's noses before putting them in front of a mirror (Amsterdam, 1972). Commonly known as the mirror test, this behavior is demonstrated by humans and a few other species and is considered evidence of self-recognition (Archer, 1992). At 18 months old, they would touch their own noses when they saw the paint, surprised to see a spot on their faces. By 24 to 36 months old, children can name and/or point to themselves in pictures, clearly indicating self-recognition.

This newfound self-recognition reflects cognitive advances and an emerging sense of identity. Toddlers start to understand that they have personal attributes and characteristics that distinguish them from others. This awareness lays the groundwork for the development of self-esteem and self-concept, as children begin to form judgments about themselves based on their perceptions and experiences.

Caregivers and parents continue to play a crucial role during this stage by providing positive reinforcement and encouragement. They validate the child's emerging sense of self by acknowledging and celebrating their achievements, preferences, and individuality. By offering praise, affection, and support, caregivers contribute to the development of a positive self-image and self-esteem in the child.

Additionally, social interactions with peers become increasingly important during this stage, as children start to compare themselves to others. Through play and exploration with peers, toddlers learn more about their own abilities, preferences, and social roles. These interactions provide valuable opportunities for self-discovery and understanding as children navigate social dynamics and learn to negotiate their place within their peer group.

### **Self-Definition (3 Years)**

By the age of 3 years, children enter a stage of self-concept development known as self-definition, where they begin to form a more coherent and elaborate understanding of themselves. During this crucial period, children start to describe themselves in concrete terms, using characteristics such as age, gender, physical attributes, and preferences to define their identity.

Language skills play a significant role in this process, as children become increasingly adept at expressing their thoughts, feelings, and perceptions. They may use phrases like, "I am a big boy/girl," "I like to play with dolls/cars," or "I have brown hair and blue eyes" to describe themselves to others. These self-descriptions reflect their growing awareness of personal attributes and preferences, as well as their ability to distinguish themselves from others.

Caregivers and educators continue to play a vital role in supporting children's self-definition during this stage. By providing opportunities for self-expression, validation, and positive reinforcement, adults help children develop a positive self-image and self-esteem. Encouraging children to talk about their interests, accomplishments, and feelings fosters a sense of autonomy and confidence in their identity.

Social interactions with peers also contribute to the development of self-definition. Through play, cooperation, and conflict resolution, children learn more about their own abilities, strengths, and limitations in relation to others. They begin to understand their social roles and develop a sense of belonging within their peer group, further shaping their self-concept.

At this stage, children's self-definition is still largely concrete and based on observable characteristics. However, it lays the groundwork for more complex aspects of self-concept to emerge in later stages of development. As children continue to grow and mature, their self-definition will become more nuanced and multifaceted, incorporating factors such as personality traits, values, beliefs, and aspirations. Through ongoing exploration, reflection, and social interaction, children gradually construct a richer and more comprehensive understanding of themselves and their

place in the world.

### **Self-Concept (6 to 7 Years)**

Between the ages of 6 and 7 years, children undergo significant development in their self-concept, which encompasses their beliefs, perceptions, and evaluations of themselves. During this stage, children begin to internalize and integrate various aspects of their identity, including their abilities, personality traits, social roles, and relationships with others.

One key aspect of self-concept development during this stage is the emergence of social comparison and self-evaluation. Children become more aware of how they stack up against their peers in terms of academic performance, athletic abilities, social skills, and other domains. They may start to compare themselves to others and form judgments about their own competence and worth based on these comparisons. For example, 10-year-old Layla may say, “I’m kind of shy. I wish I could be more talkative like my friend Alexa.”

At the same time, children’s self-concept becomes increasingly influenced by feedback from others, including parents, teachers, peers, and media. Positive reinforcement and encouragement from significant others can bolster children’s self-esteem and confidence, while criticism or negative feedback may lead to feelings of inadequacy or self-doubt.

Children also begin to develop a more differentiated and nuanced understanding of themselves, recognizing their strengths and weaknesses across different domains. They may identify specific interests, talents, and preferences that shape their sense of identity and self-worth. Additionally, children become more aware of societal norms and expectations, which can influence their beliefs about what it means to be “good,” “smart,” or “successful.”

During this stage, caregivers and educators play a crucial role in supporting children’s self-concept development. By providing opportunities for success, offering constructive feedback, and fostering a supportive and inclusive environment, adults can help children develop a positive and realistic sense of self. Encouraging children to explore their interests, set goals, and pursue their passions can also contribute to their self-confidence and self-esteem.

## **32.2 Factors Affecting Self-Concept**

### **LEARNING OBJECTIVES**

By the end of this section, you will be able to:

- Identify factors across the life span affecting one’s self-concept
- Recognize psychological factors affecting one’s self-concept
- Explain physiological factors affecting one’s self-concept
- Describe cultural and behavioral factors affecting one’s self-concept

Self-concept is a multifaceted perspective that individuals develop to understand themselves and their place in the world. The development of self-concept begins in infancy, and core components of self-concept are established in childhood. But like other features of the human body and mind, self-concept evolves and changes throughout individuals’ lives.

Self-concept is influenced by psychological, physiological, cultural, and behavioral factors, which may motivate change in one or more of the components of self-concept, including self-esteem, self-image, self-identity, and social identity. As these components evolve, overall self-concept changes. Understanding how these factors can influence each component of self-concept helps healthcare professionals, educators, and counselors provide more effective care and support throughout individuals’ lives.

### **Factors Across the Life Span**

As individuals go through life, their self-concept is constantly interacting with their environment and is impacted by everything individuals do. The factors that affect self-concept include internal influences, such as emotions and physical health, as well as external influences, like social interactions and even the physical locations where individuals live and work. When these interactions and influences are positive, self-concept typically changes in a positive manner. Likewise, negative interactions and influences tend to motivate negative changes in self-concept.

### **Developmental Changes**

Self-concept begins to develop in infancy as babies become self-aware, and by age 6 or 7 years, most children have

a basic self-concept. In developmental psychology, personal development is distinguished by distinct stages of life when individuals typically reach turning points. During each stage, self-concept evolves as individuals navigate life's challenges and changes. The stages of life identified by developmental psychologists include the following (Cherry, 2023; Malavanti, n.d.):

- **Infancy (birth to 12 months):** This stage is characterized by learning to trust others to meet basic needs, such as affection and nourishment.
- **Early childhood (toddler to preschool, 1 to 5 years old):** This stage is characterized by learning how to do tasks independently. The quality of early-attachment relationships with caregivers can shape a child's sense of security, trust, and self-worth. Parental warmth, responsiveness, and supportiveness contribute to the development of positive self-esteem and self-confidence. Early interactions with peers and caregivers provide opportunities for children to learn about themselves and their social roles, influencing their self-concept.
- **Middle childhood (6 to 11 years old):** This stage is characterized by gaining self-confidence, maturing physically, and learning how to take initiative. Children begin to compare themselves to others in various domains, influencing their self-evaluation and self-worth. During this stage, children also develop guilt when they violate boundaries, or their actions result in failure.
- **Adolescence (12 to 17 years old):** This stage is characterized by experimentation as teenagers overcome confusion about their roles and develop stronger identities. Physical changes, as well as exposure to social media and online interactions during puberty can affect adolescents' body image, self-esteem, and overall self-concept, including perceptions of popularity and attractiveness. Adolescents engage in identity exploration and self-discovery, experimenting with different roles, values, and beliefs.
- **Young adulthood (18 to 35 years old):** This stage is characterized by establishing relationships with others, including societal bonds. Intimate relationships, family dynamics, and social support networks contribute to adults' sense of belonging and self-worth.
- **Middle adulthood (36 to 64 years old):** This stage is characterized by becoming part of a family unit, establishing a sense of purpose, and making contributions to society. Life events such as marriage, parenthood, divorce, or loss can prompt reassessment of one's identity and values, influencing self-concept.
- **Older adulthood (65 years old and older):** This stage is characterized by reflection and assessing life. Transitioning into retirement can prompt reflection on one's life achievements, roles, and identity outside of work. Physical health, cognitive changes, and age-related challenges can influence older adults' self-concept and perceptions of aging. In addition, older adults may contemplate their legacy, contributions to society, and sense of purpose, shaping their self-concept in later life.

### Previous Failures or Successes

As individuals age and live through each stage of life, they succeed at some things while failing at others. During childhood, this may include successes or failures in school, such as receiving high grades or struggling academically, which can shape children's beliefs about their intelligence and capabilities. Children also may have positive and negative experiences in social relationships, such as making friends easily or being bullied, that influence how they perceive their social skills and likability.

As children become adolescents, being accepted or rejected by peers can profoundly affect their self-esteem and sense of belonging. Adolescents also explore their identities. If they find a supportive social group that accepts their identity and makes them feel like they belong, this can enhance their self-concept. Likewise, if they do not feel that they fit in with a group, they may experience identity confusion or insecurity.

In adulthood, career successes, such as job promotions and awards, can boost self-confidence and contribute to a positive self-concept, while failure to achieve career goals can foster disappointment and a negative self-concept. In their personal lives, adults who have fulfilling relationships are more likely to have higher self-esteem than those who experience rejection and relationship breakups.

For older adults, a fulfilling retirement that allows for leisure, hobbies, and social engagement can contribute to a positive self-concept, while difficulties adjusting to retirement, including financial struggles, may lead to feelings of loss or diminished self-worth. If older adults have health challenges, overcoming these to lead a rewarding life can bolster their self-concept, while chronic illness or disability can lead to depression and feelings of inadequacy.

At all stages of life, success bolsters self-concept, fostering feelings of competence and worth. Failures, on the other

hand, may be distressing, causing feelings of inadequacy and diminished self-concept.

An important part of this is **self-efficacy**, which refers to an individual's belief that they can control their own capabilities and circumstances to achieve success. According to Albert **Bandura's self-efficacy theory of motivation**, individuals with a high sense of self-efficacy have a great deal of self-confidence based on their mastery in previous situations and the positive feedback they received about their performance. Likewise, people who experience more failures and receive less positive feedback typically have less self-confidence and self-efficacy (Lopez-Garrido, 2023).

Individuals' sense of self-efficacy influences their self-esteem that, in turn, affects their self-concept. Thus, when individuals are satisfied with their achievements and feel successful, they have a higher level of self-efficacy, which promotes higher self-esteem and leads to a more positive self-concept. Likewise, dissatisfaction and failures typically motivate individuals to have lower levels of self-efficacy, which leads to lower self-esteem as well as a more negative self-concept.

## Psychological Factors

Self-concept is also affected by psychological factors, including emotional experiences and self-awareness. The Big Five personality traits are psychological indicators that shape self-concept, particularly self-image, which is a critical component of self-concept (Figure 32.6). These traits affect how individuals experience life and perceive their physical appearance and abilities. The Big Five personality traits include the following (Lim, 2023):

- The trait **openness to experience** includes characteristics such as creativity and intellectual curiosity. Individuals who are more open to experience are more likely to appreciate abstract thinking, have more vivid imaginations, and feel more comfortable with personal emotions.
- The **conscientiousness** trait includes characteristics such as self-discipline, goal setting, productivity, and competence. When individuals have a high level of conscientiousness, they tend to be more capable of planning and organizing their lives to achieve objectives.
- With **extroversion**, characteristics observed include sociability and openness. Individuals with a higher level of extroversion tend to be more assertive and outgoing. They also may demonstrate higher levels of energy and friendliness than those who are more introverted.
- The **agreeableness** trait includes characteristics such as empathy, respectfulness, and ability to trust others. Individuals with a higher level of agreeableness tend to be more compassionate and focused on the positive attributes of others.
- With **neuroticism**, the focus is on emotional stability. Individuals with a higher level of neuroticism tend to experience more depression, anxiety, anger, and vulnerability. They also tend to be more impulsive and self-conscious.

Each of the Big Five personality traits functions independently of the other traits. The levels of each trait are measured along a continuum, and personality tests can determine whether individuals exhibit a low or high score for each trait. Generally, individuals who score higher on openness to experience, conscientiousness, extroversion, and agreeableness, while scoring lower on neuroticism, tend to have more positive self-concepts (Lim, 2023).

**FIGURE 32.6** The Big Five personality traits of openness to experience, conscientiousness, agreeableness, neuroticism, and extroversion are psychological contributors to self-image, which is a critical component of self-concept. ### Life Crisis or Stressors

All individuals experience stress, which refers to the emotional, psychological, and physical changes that our body undergoes in response to stimuli. Stress is another factor that can affect self-concept.

Some common sources of stress include relationships, parenting, work, finances, physical health, and social interactions. Even when individuals are not experiencing problems in these areas, just the pressure to keep everything in balance can cause stress. On a daily basis, things that may seem minor, like sitting in traffic, meeting work deadlines, getting a child to school on time, and remembering to return a sibling's telephone call can be sources of stress. In addition, any change in life is likely to cause stress. This includes positive changes, such as a promotion at work or buying a new car, as well as negative changes, such as losing a close friend or gaining too much weight.

Stress can be categorized into the following types (Scott, 2022):

- Short-term stress encountered in daily life is **acute stress**.
- Acute stress that happens routinely, causing ongoing frustration, is **episodic acute stress**. Examples of this include things like dealing with people who are always late for appointments, frequently repairing a toilet that will not stop running, and mediating between children who argue often.
- Ongoing stress caused by long-term problems, such as a debilitating medical condition, that create continuing issues is **chronic stress**.
- Fun and excitement caused by adrenaline in response to positive life events, such as getting married or winning a competition, is eustress. While eustress is regarded as a positive source of stress that helps individuals stay energized, it needs to be moderated because too much fun and excitement can be

overwhelming.

- A state of extreme discomfort, suffering, or mental anguish is distress. It can manifest as emotional, psychological, or physical pain caused by various stressors, challenges, or adverse circumstances. Distress often involves feelings of anxiety, sadness, or unease that impact a person's ability to function effectively in daily life.

Stress affects well-being and can impact individuals both physically and mentally. Some of the physical problems experienced in response to stress include headaches, muscle tension, body pains, digestive system issues, racing heartbeats, and reduced energy. The mental problems in response to stress may include difficulty sleeping, mood swings, irritability, anxiety, and depression.

If these problems are prolonged, they may have a negative impact on individuals' self-concept. This is particularly true for stress-related mental issues like anxiety and depression. Such issues tend to make individuals feel insecure and less optimistic. This may negatively affect their self-esteem and self-image, which are both important components of self-concept. Thus, stress is a factor that can adversely affect self-concept.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Referring a Patient for Mental Health Counseling

The nurse is gathering the medical history of a patient who has headaches and neck tension but no other symptoms. The nurse plans to give the patient some acetaminophen (per provider's orders), along with instructions to use an ice pack until the headache and tension improve and then get some rest.

The nurse notices the patient is nervous and talks about being too busy at work because of a staffing shortage. The patient is working ten to twelve hours per day while taking care of two small children and an aging parent. The patient's busy schedule, compounded by caregiving responsibilities and work demands due to staffing shortages, creates significant distress. While discussing these challenges, the patient starts crying. The patient's nervousness and tears underscore the psychological toll of these stressors on the patient's self-concept. The patient may feel overwhelmed, inadequate, or unable to meet all their responsibilities, which can diminish self-esteem and confidence. These feelings can distort self-perception, leading to a negative self-concept characterized by doubt and emotional strain.

The nurse recognizes that the patient's headaches and neck tension likely are a response to stress. After giving the patient acetaminophen, the nurse takes action by asking the clinic's psychologist to talk to the patient and help identify ways the patient can better manage stress. By providing pain relief and involving the clinic's psychologist, the nurse takes proactive steps to address both the physical symptoms and the underlying psychological impact of stress. This approach aims to support the patient in developing effective coping strategies and improving stress management skills.

### Grief and Loss

Throughout life, individuals experience loss. Loved ones pass away. Friends move to another state. Jobs are taken away when a company downsizes. Favorite restaurants go out of business. Graduation day arrives and school is over. These situations and many others cause individuals to lose people and things that are important to them, forever altering their lives.

Such losses, particularly when someone dies, are likely to trigger grief, which is deep emotional discomfort and sorrow. Grief is another factor that affects self-concept. As individuals go through the five stages of grief as identified by the Kübler-Ross model—denial, anger, bargaining, depression, and acceptance—they experience physical and mental issues (see [Kübler-Ross's Five Stages](#) for more information).

For example, grief may cause individuals to have physical problems such as body aches and pains, loss of appetite, fatigue, higher blood pressure, insomnia, dehydration, forgetfulness, confusion, and brain fog. Emotionally, individuals may experience anxiety, hostility, guilt, despondency, and loneliness, as well as anger and depression. When grief is caused by the loss of a loved one, some individuals even experience **identity confusion**, which is the feeling that part of them also died when their loved one died (Bellet et al., 2020).

If these symptoms persist, grieving individuals may change the way they regard themselves and their lives, including their feelings about the future. This change in perspective is likely to alter individuals' self-concept.

For example, some individuals may experience identity reconstruction as they struggle to make sense of the changed circumstances caused by their loss. If the individual loses something central to their self-concept and self-worth, such as a partner or a job, they may even lose their sense of identity.

Sometimes, loss triggers feelings of guilt, regret, or inadequacy as individuals blame themselves for perceived failings or shortcomings that made them unable to prevent the loss. Such feelings can cause individuals to have negative self-evaluations leading to diminished self-worth and eroded self-esteem.

Grief often prompts individuals to confront existential questions about the meaning and purpose of life, their beliefs, values, and mortality. This existential questioning can profoundly impact self-concept as individuals grapple with their place in the world and their sense of self in the face of loss and mortality.

Loss also can disrupt social connections and support networks, leading to feelings of isolation and loneliness. Social roles and identities tied to the lost relationship or context may also be affected, further complicating individuals' sense of self within their social environment.

Individuals may adopt various coping strategies to manage grief, which can influence their self-concept. Some may seek support from others, engage in self-reflection, or find solace in religious or spiritual beliefs, while others may withdraw or engage in avoidant behaviors that undermine their self-esteem and sense of identity.

Grief may motivate individuals to search for meaning in their loss and find ways to integrate the experience into their self-narrative. This process of meaning-making can lead to personal growth, resilience, and a deeper understanding of oneself, ultimately shaping one's self-concept in more adaptive ways. Through the process of mourning and adaptation, individuals may develop a stronger sense of self, greater compassion, and a deeper appreciation for life, ultimately leading to a more resilient and enriched self-concept.

## PATIENT CONVERSATIONS

---

### What If Your Patient Keeps Crying and Seems Confused?

**Scenario:** The nurse enters the patient's room to begin an assessment and finds the patient crying. When the nurse starts talking, the patient stops crying but does not seem able to focus on what the nurse is saying.

**Nurse:** Hi, my name is Chandler, and I am going to be your nurse today. Please verify your name and date of birth for me.

**Patient:** Where am I?

**Nurse:** You are in the hospital emergency room. Your neighbor found you wandering around outside your house, and you seemed confused. Please tell me your name and date of birth.

**Patient:** My name is Melissa, and I was born in 1959.

**Nurse:** Okay, Melissa, that's good. Please tell me your last name. And what is your birthday?

**Patient:** My last name is Garcia, and my birthday is January 17.

**Nurse:** Good. Melissa, I need to take your vital signs.

**Patient:** (sobbing) Please don't hurt me. Roger is gone, and I can't do this by myself.

**Nurse:** Melissa, I won't hurt you. I promise. Who is Roger?

**Patient:** (crying harder) Roger is my partner. He's gone.

**Nurse:** Did something happen to Roger?

(The patient nods but is crying too hard to speak. The nurse hands the patient a tissue, sits in a chair next to the patient, and occasionally pats the patient on the shoulder while the patient cries. When the patient's crying

subsides, the nurse speaks again.)

**Nurse:** Would you like to tell me about Roger?

**Patient:** (choking back tears) Roger was in a car accident, and he is gone. (The patient begins crying again and then looks at the nurse.) Where am I and who are you?

(The nurse recognizes the patient may need a psychiatric evaluation.)

**Nurse:** My name is Chandler, and you are at the hospital. Please excuse me, I need to make a quick phone call.

**Scenario follow-up:** Patient nods and continues crying. Keeping the patient in view, the nurse steps outside the room and contacts the provider to report the concerns and recommend a mental health evaluation. The nurse goes back inside the room and sits with the patient while she continues to cry. In a few minutes, a psychiatric nurse enters the room and gently leads the patient away to a quiet area to evaluate her for identity confusion related to grief.

---

## Physiological Factors

Physiological factors exert a profound influence on one's self-concept, permeating through mood, cognition, and overall well-being. Neurotransmitters and hormones, such as serotonin and dopamine, regulate mood and emotional states, with imbalances contributing to mood disorders like depression and anxiety, distorting perceptions of oneself and the world. Chronic illnesses, disabilities, or injuries alter physical abilities and appearance, impacting self-esteem and perceived competence. Persistent pain or discomfort from health conditions can lead to frustration and diminished self-worth, eroding self-concept. Disrupted sleep patterns, poor nutrition, and sedentary lifestyles impair cognitive function and emotional regulation, affecting self-perception and confidence. Moreover, genetic predispositions interact with environmental factors, shaping susceptibility to physiological challenges and influencing self-concept.

When individuals' systems function normally and they have no physiological issues, they generally experience better health outcomes. For example, when individuals' renal systems function properly, their kidneys, bladder, ureters, and urethra work in normal ranges to help control fluid in their bodies, guarding against problems such as incontinence and dehydration. Such physical well-being can enhance self-perception by fostering a sense of physical competence and reliability. Mentally, the absence of physiological issues related to the renal system can also positively impact self-concept. Individuals are less likely to experience anxiety or worry related to health concerns, allowing them to focus more on their personal goals, relationships, and overall quality of life.

If individuals have physiological issues with any system in their bodies, they may not feel well. For example, individuals who routinely consume too much caffeine may cause physiological issues for themselves, such as insomnia, caffeine jitters, and irritability. Other physiological issues may be the result of disease, such as respiratory problems that lead to asthma. When individuals experience any problem rooted in a physiological issue, that problem is likely to reduce their energy levels and negatively impact their sense of well-being, which has a negative effect on their self-concept.

### Aging

As individuals age, physiological changes become increasingly prominent, impacting various aspects of their lives and ultimately influencing their self-concept. Physiological factors of aging encompass a spectrum of transformations, from alterations in physical appearance and health conditions to changes in cognitive function and social dynamics. These changes can challenge individuals' perceptions of themselves and their capabilities, leading to shifts in self-esteem, self-image, and overall well-being.

---

## PATIENT CONVERSATIONS

### Reflecting with Your Patient about Aging

**Scenario:** The nurse enters the examination room and finds an older patient rubbing his knee. The nurse notices a cane beside the patient's chair.

**Nurse:** Hello. I'm Tabitha, and I'll be your nurse today. What health concern brings you here today?

**Patient:** My knee is swollen, and it hurts. I can't walk up and down stairs, and I have to use the cane to help me get out of chairs.

**Nurse:** When did the problem start?

**Patient:** It's been an off and on problem for about six months, but this is the worst that it's been. I've never had swelling before, and the pain is worse now than ever before.

**Nurse:** Have you taken any medication to help with the pain and swelling?

**Patient:** I took some ibuprofen, which usually helps. But I can't tell that it's making a difference this time. That's why I decided to come in to see you.

**Nurse:** Okay. Please raise your pant leg so I can examine the knee.

**Patient:** (The patient raises the pant leg so Tabitha can examine the knee.) This is frustrating. I recently turned 74 years old, and I know that this is just part of getting older. I have friends younger than me who have already had knee replacements. They tell me that I need to get one, but even if that's something I have to do, I'm not ready to do it now. Just three years ago, I ran a marathon, and until about six months ago, I took long walks several times per week. I could still jog as recently as last summer. But I guess my age is catching up with me because I just can't move around as well now as I could. I hate to admit it, but I guess I'm becoming an old person, and I'll have to start acting like one, whatever that means. (Patient smiles sadly at the nurse.)

**Nurse:** I understand, and I'm sorry that this is frustrating. We will talk with the provider to see if they can prescribe some medications that are stronger than ibuprofen. We can also set you up with a physical therapist who can show you some exercises to do that can help with mobility. We'll keep you going as well as possible for as long as possible. Also, if you would like to talk to someone about the challenges of aging, we have some excellent counselors. (The nurse smiles at the patient, and he looks grateful.)

**Scenario follow-up:** The patient receives a prescription for a corticosteroid to help relieve the swelling and pain in his knee. In addition, he has an appointment with a physical therapist to help him with exercises to increase mobility. The healthcare provider also encourages the patient to do things at home, such as elevate the knee when it is swollen and use ice and heat to relieve the pain. Finally, the patient makes an appointment with one of the clinic's counselors to talk about coping with changes in the body as we age.

---

One of the most noticeable physiological changes associated with aging is the decline in physical abilities and changes in appearance. Reduced mobility, loss of muscle mass, and changes in body composition can affect how individuals perceive their physical competence and attractiveness. These alterations may trigger feelings of dissatisfaction with one's body image and a sense of loss of independence, particularly if they were once highly active or physically fit. Consequently, individuals may grapple with adjusting to their changing bodies and the implications for their self-concept.

Age-related cognitive decline, such as memory lapses and slower cognitive processing, can challenge individuals' perceived cognitive abilities and competence. Tasks that were once routine and effortless may become more challenging, leading to frustration and doubts about one's mental sharpness and capabilities. This cognitive decline can impact self-concept by undermining confidence and self-assurance, especially in situations that require cognitive agility and quick thinking.

In addition to physical and cognitive changes, managing chronic health conditions becomes increasingly prevalent with age and can significantly impact self-concept. Coping with conditions such as arthritis, diabetes, or cardiovascular disease may require adjustments to daily routines, lifestyle habits, and social interactions. Individuals may experience fluctuations in self-esteem and confidence as they navigate the limitations imposed by their health conditions and confront uncertainties about their future health and well-being.

Transitions in social roles and relationships, such as retirement, empty nesting, and loss of loved ones, can prompt profound adjustments in identity and purpose. Retirement, for example, may lead to a loss of professional identity and a shift in priorities, raising questions about one's sense of purpose and contribution to society. Losses of loved

ones can trigger feelings of grief and loneliness, challenging individuals' perceptions of themselves within the context of their social relationships and support networks.

Attitudes toward aging also play a significant role in shaping self-concept in later life. Positive attitudes, characterized by a sense of acceptance, resilience, and gratitude for the opportunities that come with age, can foster a healthy and adaptive self-concept. Conversely, negative stereotypes and ageist attitudes prevalent in society may contribute to feelings of self-doubt, inadequacy, and diminished self-worth among older adults.

Aging also affects one's self-concept by impacting self-esteem. As self-esteem develops in childhood, it tends to improve considerably between the ages of 15 and 30 years, and then continues to gradually improve before peaking at around age 60 years. For most individuals, self-esteem remains constant during their 60s but then begins a gradual decline after age 70 years. Since self-esteem is a major component of self-concept, the changes in self-esteem caused by aging tend to affect self-concept (Fagan, 2018).

The challenges associated with aging, including physiological changes, declining health, and shifts in social roles, can indeed make the aging process frustrating and emotionally taxing. As individuals grapple with the physical and cognitive changes that come with age, they may experience a range of emotions, from frustration and anxiety to sadness and loss. These feelings can accumulate over time, potentially leading to mental health problems such as anxiety and depression (Kang & Kim, 2022).

### Illness

Physiological factors of illness can significantly influence one's self-concept by challenging perceptions of health, competence, and identity. The physical manifestations of illness often bring with them a multitude of symptoms and limitations that can drastically alter how individuals perceive themselves. Symptoms such as chronic pain, fatigue, or mobility impairments not only challenge one's physical capabilities but also chip away at their sense of autonomy and self-reliance. Tasks that were once mundane may now feel like insurmountable obstacles, leading to feelings of frustration, inadequacy, and a profound sense of loss. Moreover, changes in physical appearance resulting from illness or treatment can trigger a profound upheaval in body image and self-esteem. Individuals may find themselves grappling with feelings of shame, embarrassment, or even disgust as they confront a body that no longer aligns with their sense of self.

Functionally, illness-induced impairments can disrupt not only one's daily routines but also their social roles and relationships. The inability to perform familiar tasks or fulfill expected roles, such as caregiving or financially providing for their families, can leave individuals feeling stripped of their sense of purpose and contribution. Additionally, illness-related functional limitations may prompt shifts in social dynamics, leading to feelings of isolation, alienation, or perceived burdensomeness. The erosion of social connections and the perceived loss of identity within social circles can exacerbate feelings of loneliness and further strain one's self-concept.

Amid the turmoil of illness, individuals may employ various coping mechanisms to navigate the emotional landscape. Adaptive coping strategies, such as seeking social support and acceptance, and finding meaning in illness experiences, can serve as pillars of resilience, buffering against the negative impacts of illness on self-concept. Conversely, maladaptive coping mechanisms, such as denial, avoidance, or self-blame, may exacerbate feelings of distress and further erode self-esteem and self-worth.

The emotional toll of illness extends beyond the physical realm, infiltrating the core of one's being. Fear, anxiety, and despair can permeate every aspect of life, affecting perceptions of oneself and one's capabilities. These negative emotions can take a significant toll on mental health and can potentially result in mood disturbances, such as depression.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Form a Hypothesis: Unveiling the Impact of Illness on Self-Concept

**Scenario:** Imagine a middle-aged patient named John who has recently been diagnosed with multiple sclerosis. Prior to his diagnosis, John saw himself as an active and independent individual, always taking care of his family and excelling in his career. However, with the onset of his illness, John's sense of self undergoes a significant transformation. He begins to feel like a burden to his family, as he now requires assistance with daily tasks that

he once took for granted. Additionally, the physical limitations imposed by his illness prevent him from engaging in activities he used to enjoy, leading to feelings of frustration and helplessness. Over time, John's self-concept shifts as he grapples with the loss of his previous identity and struggles to redefine himself in the context of his illness. Despite these challenges, John gradually learns to accept support from his loved ones and discovers new ways to find purpose and meaning in his life, ultimately reshaping his self-concept to incorporate his experiences with illness.

- **Identifying cues:** John's change in behavior, such as withdrawing from activities he once enjoyed and expressing feelings of frustration and helplessness, are cues that suggest a shift in his self-concept. Additionally, his perception of himself as a burden to his family indicates a negative impact on his self-image. These cues may indicate a struggle to reconcile his previous identity with the challenges imposed by his illness.
- **Analyzing cues:** The cues observed in John's behavior and self-perception suggest a disruption in his self-concept due to the onset of a chronic illness. His withdrawal from activities and feelings of frustration may stem from a loss of independence and the inability to engage in previously valued roles and activities. Furthermore, his perception of being a burden may indicate feelings of guilt and inadequacy, which can further erode his sense of self-worth and identity.
- **Forming hypothesis:** Based on the identified cues and analysis, a hypothesis could be formulated that John's self-concept has been significantly impacted by his chronic illness. The hypothesis may propose that John is experiencing a period of adjustment and identity redefinition as he navigates the challenges imposed by his illness. Furthermore, it may suggest that John's struggle to maintain a positive self-concept is influenced by societal expectations of independence and self-sufficiency, which are challenged by his illness. This hypothesis would guide further assessment and intervention to support John in coping with his illness and rebuilding his sense of self.

## Cultural and Behavioral Factors

Cultural and behavioral factors affect an individual's self-concept, influencing not only how they perceive themselves but also how they navigate their interactions with others and the world around them. Cultural norms and values provide a framework within which individuals develop their understanding of identity, morality, and social roles, influencing behaviors and attitudes from early childhood onward. Meanwhile, behavioral patterns, encompassing a diverse range of actions and interactions, further contribute to the formation of self-concept. These factors interact in complex ways, with socialization processes, family dynamics, media exposure, and individual experiences all playing roles in shaping self-perception. From traditional cultural practices to contemporary influences like social media, these factors collectively shape individuals' sense of identity, belonging, and self-worth, highlighting the dynamic interplay between societal expectations and personal identity. Understanding the impact of cultural and behavioral factors on self-concept provides valuable insights into the complexities of human identity and the ways in which individuals navigate their social and cultural contexts.

### Cultural Norms and Values

Cultural norms and values serve as the guiding principles that shape individuals' understanding of their identity, morality, and social roles within their communities. These norms are often deeply ingrained and transmitted through generations. For instance, in cultures where collectivism is emphasized, individuals may prioritize the needs of the group over personal desires, fostering a sense of interconnectedness and communal identity. In contrast, cultures that value individualism may encourage self-expression, autonomy, and the pursuit of personal goals.

Socialization processes further reinforce cultural norms and expectations, providing individuals with a framework in relation to others. Family, as the primary agent of socialization, plays a pivotal role in transmitting cultural values and traditions to younger generations. Parents, siblings, and extended family members impart cultural knowledge through language, customs, and rituals, instilling a sense of cultural identity and belonging within individuals. Additionally, educational institutions, peer groups, and media representations reinforce cultural narratives and ideals. Through these interactions, individuals internalize societal norms and expectations, incorporating them into their self-concept.

Social media is a significant influencer of self-concept. Through social media, individuals interact more with others,

learning how others behave and organize their lives. Social media also provides an overwhelming collection of information, including material from questionable sources. Social media motivates individuals to compare themselves to others. If these comparisons are favorable, individuals tend to have a more positive self-concept. If the comparisons are unfavorable, individuals may have a more negative self-concept. Social media's impact on users can be powerful, even shaping the way individuals construct their identities (Ruther et al., 2023).

## LINK TO LEARNING

Learning more about [how social media affects individuals \(https://openstax.org/r/77socialmedia\)](https://openstax.org/r/77socialmedia) can provide insight into the cultural and behavioral factors that affect self-concept.

Social comparison processes further refine self-concept by providing individuals with reference points for evaluating their own attributes and achievements and measuring their own worth. For example, in cultures where material wealth and status are prized, individuals may equate success with financial achievement and social recognition, shaping their self-concept around notions of wealth and prestige. Conversely, in cultures that prioritize spiritual fulfillment and communal well-being, individuals may derive their sense of self-worth from their contributions to the community and adherence to ethical principles.

Cultural identity and ethnicity shape self-concept, particularly for individuals from underrepresented groups. Cultural identity encompasses shared beliefs, traditions, and values that provide a sense of belonging and connection to one's heritage. For members of underrepresented communities, cultural identity serves as a source of pride and resilience, offering a sense of solidarity and empowerment in the face of discrimination and adversity. However, experiences of prejudice, discrimination, and marginalization can impact self-esteem and contribute to negative self-perceptions, highlighting the complex interplay between cultural identity and self-concept.

Acculturation and adaptation processes are central for individuals navigating multiple cultural contexts, such as immigrants. Acculturation involves balancing the preservation of one's cultural heritage with the adoption of the dominant culture's norms and practices, leading to a negotiation of identity and the development of hybrid identities that reflect a synthesis of cultural influences. However, experiences of acculturative stress, discrimination, and identity conflict can impact self-concept and mental health outcomes, highlighting the complexities of cultural adaptation.

### Gender Roles and Expectations

Gender roles and expectations exert a profound influence on one's self-concept, shaping beliefs about identity, behavior, and social roles based on perceived gender. From early childhood, individuals are socialized into gendered norms and stereotypes that dictate appropriate roles, behaviors, and interests for males and females. Young males may be encouraged to be assertive, independent, and competitive, while young females may be socialized to be nurturing, empathetic, and accommodating. These gendered expectations are reinforced through various socialization agents, including family, peers, educational institutions, and media representations, perpetuating a binary understanding of gender and reinforcing traditional gender norms. As individuals internalize these societal messages, they construct their self-concept around notions of masculinity and femininity, which influence various aspects of their lives, including career aspirations, interpersonal relationships, and body image. Deviations from gender norms may be met with social sanctions or stigma, leading individuals to conform to societal expectations to maintain a positive self-concept.

## PATIENT CONVERSATIONS

### Empowering Patients: Addressing Gendered Expectations in Self-Concept

**Scenario:** During a routine checkup at the clinic, the nurse notices that a young patient, Sam, seems withdrawn and tense. Sam is fidgeting with his hands and avoiding eye contact as he waits for his appointment.

**Patient:** I've been feeling really overwhelmed lately, but I just can't seem to open up about it.

**Nurse:** It sounds like you're going through a tough time. Would you like to talk about what's been bothering you?

**Patient:** I don't know. . . . It's just that I've always been taught to be strong and not show any weakness. But lately, everything feels like it's piling up, and I'm not sure how to handle it.

**Nurse:** It's okay to feel overwhelmed sometimes. It's natural to need support, regardless of gender. You don't have to carry everything alone.

**Patient:** I know, but it's hard to break out of those expectations. Growing up, I was always told that boys don't cry or ask for help. It's like I've internalized those messages, and now I'm struggling to reach out.

**Nurse:** It's common for societal expectations around gender roles to influence how we perceive ourselves and how we express our emotions. But it's important to remember that seeking help doesn't make you any less strong or capable. In fact, it takes courage to reach out when you're struggling.

**Patient:** Yeah, you're right. I guess I've just been holding onto these beliefs for so long that I didn't even realize how much they were affecting me.

**Nurse:** It's a process, and it takes time to challenge those ingrained beliefs. But know that you're not alone, and I'm here to support you every step of the way.

**Scenario follow-up:** This conversation highlights how societal expectations surrounding gender roles can influence an individual's self-concept and willingness to seek help, even in moments of distress. By acknowledging these influences and providing support, the nurse helps the patient navigate their struggles with greater awareness and resilience.

---

### Social Behavior

Behavioral factors, comprising a diverse array of actions, habits, and interactions, affect one's self-concept. Social behavior, for example, serves as both a mirror and a lens through which individuals view themselves. Positive social interactions, characterized by warmth, acceptance, and affirmation, contribute to feelings of belonging and acceptance, bolstering self-esteem and reinforcing a positive self-concept. Conversely, negative social experiences, such as rejection or ostracism, can inflict wounds upon the psyche, fostering feelings of isolation, unworthiness, and social anxiety. The quality of interpersonal relationships, therefore, plays a pivotal role in shaping self-concept, as individuals internalize feedback from others and construct narratives about their own social worth.

Health behaviors, encompassing actions related to physical and mental well-being, also exert a significant influence on self-concept. Engaging in behaviors that promote health and vitality, such as regular exercise, balanced nutrition, and adequate sleep, fosters a sense of self-efficacy and mastery over one's body and mind. Conversely, neglecting self-care practices or engaging in unhealthy habits may engender feelings of guilt, shame, or self-blame, tarnishing perceptions of self-worth and contributing to a negative self-concept. The connection between physical and psychological well-being underscores the importance of holistic self-care in nurturing a positive self-concept.

Behavioral factors encompass individuals' coping strategies and regulatory mechanisms, which influence how they navigate life's challenges and adversities. Effective coping strategies, such as problem-solving, seeking social support, and engaging in relaxation techniques, enhance resilience and promote a sense of agency in the face of adversity. By contrast, maladaptive coping mechanisms, such as avoidance or denial, may exacerbate feelings of helplessness and undermine self-concept. The ways individuals regulate their behavior in response to stressors, therefore, play a crucial role in shaping perceptions of competence, control, and self-efficacy.

Self-concept is also shaped by how individuals present themselves to others and express their identities. Clothing choices, grooming habits, and nonverbal behaviors serve as outward manifestations of internal self-concept, shaping how individuals are perceived and treated by others. Engaging in activities and hobbies that align with personal interests and values allows individuals to express their authentic selves, fostering a sense of congruence and authenticity in their self-concept. Furthermore, the seeking and processing of feedback from others contribute to the development and refinement of self-concept, as individuals selectively attend to or discount feedback based on their own beliefs and biases.

## Summary

### 32.1 Foundations of Self-Concept

Our personal identity and self-concept, according to Rogers, develops throughout the life span beginning in childhood and is molded by experiences, perceptions, and evaluation of others. The primary components of self-concept are fundamental in developing personal identity, body image, self-esteem, and role performance.

Trying to understand how people see themselves and how this can change in different situations can be challenging. To do this well, it is suggested to use different methods, consider how the study relates to real-life situations, and make sure the study is as close to a natural setting as possible. There are a variety of tools available, depending on the patient situation, that the provider can use to accomplish this. Understanding oneself is crucial for healthy functioning and promoting realistic decision-making regarding key aspects of life.

Just as forming strong connections is a crucial milestone in infancy, a significant step in childhood is developing a positive sense of self. Formation of a positive self-concept begins in Erikson's toddlerhood stage, when children establish autonomy and become confident in their abilities. Development of self-concept continues in elementary school, when children compare themselves to others. Self-concept is reevaluated in Erikson's adolescence stage, as teens form an identity. They internalize the messages they have received regarding their strengths and weaknesses, keeping some messages and rejecting others.

### 32.2 Factors Affecting Self-Concept

As individuals grow and change across their life spans, many factors affect their self-concepts, including psychological, physiological, cultural, and behavioral influences. Processes like developmental changes and aging affect individuals' bodies and minds, changing how they perceive themselves and the world. More personal experiences, such as failure, success, stress, grief, and illness, can have both positive and negative impacts on individuals' mental and physical processes. Personality traits help determine whether individuals approach life with a positive or negative outlook, and cultural influences, including social media, impact individuals' perspectives of themselves and the world. Any of these factors may affect any component of self-concept, including self-esteem, self-image, self-identity, and social identity, motivating changes in overall self-concept.

## Key Terms

**actual self** the attributes that an individual believes they possess, based on personal information as well as input from others

**acute stress** short-term stress encountered in daily life

**agreeableness** one of the Big Five personality traits; includes characteristics such as empathy, respectfulness, and ability to trust others

**Bandura's self-efficacy theory of motivation** individuals with a high sense of self-efficacy have a great deal of self-confidence based on their mastery in previous situations and the positive feedback they received about their performance

**body dysmorphic disorder (BDD)** a mental health condition characterized by obsessive preoccupation with perceived flaws or defects in physical appearance that are not observable or appear minor to others

**body image** a component of self-concept that reflects an individual's perception and evaluation of their physical appearance, based on societal standards, cultural norms, and personal experiences

**chronic stress** ongoing stress caused by long-term problems

**cognitive-behavioral therapy (CBT)** a structured talk therapy that focuses on problematic thinking and behaviors and helps to create healthy thinking, behaviors, and coping skills

**competence** the degree of effectiveness and proficiency individuals perceive in themselves

**conscientiousness** one of the Big Five personality traits; includes characteristics such as self-discipline, goal setting, productivity, and competence

**episodic acute stress** stress that happens routinely, causing ongoing frustration

**extroversion** one of the Big Five personality traits; includes characteristics such as sociability and openness

**false self** pretending to be someone we are not

**global self** idea that we are all part of a collective being, or global family, and our actions have far-reaching impacts

**ideal self** attributes that individuals aspire to possess

**identity confusion** occurs in response to grief when individuals feel that part of themselves also died when their loved one died

**impostor syndrome** a psychological pattern in which individuals doubt their skills, talents, or accomplishments and have a persistent internalized fear of being exposed as a “fraud”

**neuroticism** one of the Big Five personality traits; focuses on emotional stability

**openness to experience** one of the Big Five personality traits; includes characteristics such as creativity and intellectual curiosity

**ought self** the internalized expectations and standards that individuals believe they should or must adhere to in order to meet external demands, social norms, or moral obligations

**personal identity** a component of self-concept that involves the sense of individuality, including personal traits and beliefs, that distinguishes a person from others

**power** an individual’s perception of their ability to influence or control outcomes, resources, or other individuals within their social environment

**reflected appraisal** the influence on our self-concept based on what others think of us

**role performance** how individuals perceive and execute their roles in different contexts within the family, work, or social environment

**Rosenberg Self-Esteem Scale** a widely used self-report instrument for evaluating individual self-esteem

**self-awareness** being able to recognize and understand one’s own emotions

**self-concept** the organized and consistent set of perceptions and beliefs an individual holds about themselves; includes an individual’s self-esteem, self-image, self-identity, and social identity

**self-efficacy** an individual’s belief that they can control their own capabilities and circumstances to achieve success

**self-esteem** the overall positive or negative evaluation of oneself that reflects an individual’s feelings of self-worth and confidence

**self-evaluation** the process by which individuals evaluate their own thoughts, feelings, behaviors, and overall sense of self

**self-expectation** an individual’s perspective on what they should do, think, or feel

**self-identity** personal characteristics, roles, and affiliations that define an individual

**self-image** the mental and emotional view of one’s physical appearance and abilities

**self-knowledge** a philosophical term used to identify how individuals perceive their mental state, based on emotions, personality traits, relationships, behavioral patterns, opinions, beliefs, values, needs, goals, preferences, and social identity

**self-perception** how individuals perceive themselves in terms of their abilities, competencies, and characteristics

**self-reflection** thoughtful contemplation about one’s actions, motivations, and personal growth, based on the evaluation of one’s values, goals, and standards

**social comparison theory** process of evaluating ourselves in comparison to others and using those judgments to influence our self-concept

**social identity** concept of self that is formed through connections with societal groups

**symbolic interactionism** a model positing that the way we see ourselves is influenced by how others see us

**virtue** the moral dimension of self-evaluation, encompassing individuals’ reflections on their character, values, and ethical conduct

## Assessments

### Review Questions

1. How does self-image differ from self-identity?
  - a. Self-image reflects the overall value and worth one assigns to oneself, while self-identity encompasses an individual’s personal characteristics, roles, and affiliations.
  - b. Self-image focuses on one’s physical appearance and abilities, while self-identity encompasses an individual’s personal characteristics, roles, and affiliations.
  - c. Self-image encompasses an individual’s personal characteristics, roles, and affiliations, while self-identity focuses on one’s physical appearance and abilities.

- d. Self-image is formed through connections with societal groups, while self-identity reflects the overall value and worth one assigns to oneself.
- 2.** Why is role performance important?
- Role performance helps with resilience, positive coping mechanisms, and the ability to navigate life's challenges.
  - Role performance helps to overcome feelings of inadequacy, anxiety, and vulnerability.
  - Role performance positively reinforces self-concept and contributes to a sense of purpose and fulfillment.
  - Role performance enables a more accurate perception and evaluation of our physical appearance, which improves body image.
- 3.** According to Brown (2009), what five sources help us develop self-knowledge?
- emotional states, personality traits, behavioral patterns, values, and goals
  - personality traits, behavioral patterns, social comparisons, reflected appraisals, and goals
  - role performance, emotional states, values, goals, and reflected appraisals
  - physical world, social comparisons, reflected appraisals, introspection, and self-perception
- 4.** Which component of self-evaluation focuses on recognizing and understanding one's emotions, thoughts, and behaviors?
- self-reflection
  - self-perception
  - self-awareness
  - self-esteem
- 5.** In the process of reflected appraisal, what affects our self-concept?
- what other people think of us
  - our ability to overcome our false self
  - growth of our ideal self
  - whether we feel part of a collective being
- 6.** Matilda is in middle adulthood. What self-concept factor would she most likely be faced with?
- She is experimenting and overcoming confusion about her role in society and developing a stronger identity.
  - She is establishing relationships with others, along with societal bonds.
  - She is busy, focused on establishing a sense of purpose for life and contributing to society.
  - She is reflecting and assessing her life and recognizing her personal contributions to society.
- 7.** How does self-efficacy affect individuals' ability to succeed or fail?
- Individuals with a low self-efficacy have a great deal of self-confidence and believe they can control their capabilities and circumstances, enabling them to achieve success.
  - Individuals with low self-efficacy also have lower rates of anxiety and depression, which makes it easier for them to succeed.
  - Individuals with high self-efficacy also have higher rates of neuroticism, which makes it easier for them to succeed.
  - Individuals with a high self-efficacy have a great deal of self-confidence and believe they can control their capabilities and circumstances, enabling them to achieve success.
- 8.** As the unit manager, you must decide which nurse on your shift will be in charge during your absence. You need a nurse who is competent, productive, self-disciplined, and can set goals for patients. What Big Five personality trait are you seeking in this nurse?
- extraversion
  - conscientiousness

- c. agreeableness
  - d. openness to experience
9. Your patient is incredibly perky, hyped up about several upcoming personal and social events. What kind of stress is your patient experiencing?
- a. eustress
  - b. episodic acute
  - c. acute
  - d. chronic
10. Your patient just turned 70 years old, and you are concerned that over the next few years, the patient's self-concept will decline. Why are you concerned about this?
- a. After age 70 years, many individuals experience an increase in neuroticism, which tends to negatively impact self-concept.
  - b. After age 70 years, many individuals experience a gradual decline in self-esteem, which tends to negatively impact self-concept.
  - c. After age 70 years, many individuals become extraverted, which tends to negatively impact self-concept.
  - d. After age 70 years, many individuals experience financial difficulties, which tend to negatively impact self-concept.
11. Your patient insists that she can no longer handle life because she feels like a part of herself died too when she lost her partner. What is your patient experiencing?
- a. depression
  - b. physiological change
  - c. chronic stress
  - d. identity confusion

### Check Your Understanding Questions

1. When we experience a discrepancy between our self-concept and reality, what can happen?
2. When we experience an internal conflict between our actual self and our ideal or ought self, how can this benefit us?
3. What is the difference between upward social comparison and downward social comparison, and how do these comparisons affect us?
4. How do the Big Five personality traits affect self-concept?
5. Why are the stages of life and developmental changes important to individuals' self-concept?
6. What are physiological factors and how can they affect self-concept?

### Reflection Questions

1. What is personal identity, and how does it contribute to the concept of self-concept?
2. What is the process of self-evaluation, and why is it important to the concept of self-concept?
3. How is the aging process likely to affect your patients' self-concepts as they enter middle and late adulthood?
4. What impact is social media likely to have on your patients' self-concepts if they spend hours each week engaged on sites such as Facebook?

### What Should the Nurse Do?

1. How should the nurse care for a teenage patient with a higher weight who is being teased at school for their weight?

2. Your patient is a mother of two children, who also works as the vice president at an investment firm. While in the hospital, your patient is cheerful and spent hours relaxing, reading books, and watching television. The patient commented that it was nice not to feel pressured to do things that they ought to be doing at home or work. When you inform the patient that they can go home, they become disheartened. What do you think is going on, and how will you address the patient's change in disposition?
3. How will you use information about developmental changes to help you understand how to care for a teenager who has a poor self-concept and has started smoking cigarettes?

### Competency-Based Assessments

1. Name three of the tools for the measurement of self-concept, and briefly describe each tool. Draw a concept map that compares and contrasts the three tools.
2. List and briefly describe each of the stages of self-concept development.
3. List and explain at least three of the Big Five personality traits. For each trait, indicate how it influences self-concept.

# CHAPTER 33

## Sexuality

**FIGURE 33.1** Providing patient-centered quality care requires the nurse to acknowledge that human sexuality has many variations. These symbols are all variations of symbols used by the LGBTQ+ community to demonstrate unity, pride, shared values, and allegiance to one another. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### CHAPTER OUTLINE

- 33.1 Sexual Identity
- 33.2 Sexual Fulfillment
- 33.3 Factors Affecting Sexuality
- 33.4 The Nurse's Role in Providing Care

**INTRODUCTION** What do sexuality and health care have to do with each other? Studies have shown that sexual minority groups (such as those who identify as gay, lesbian, or bisexual) have poorer health outcomes than heterosexual individuals (individuals who are sexually attracted to a person of a different gender or sex) (Tabaac et al., 2020). Unfortunately, there are a multitude of factors that contribute to less-than-optimal health outcomes in these underrepresented groups. A combination of factors including discrimination, lack of health insurance, limited healthcare access, and lower socioeconomic status affect these underrepresented groups in disproportionate ways (U.S. Department of Health and Human Services, n.d.), leading to poor health outcomes and health disparities. Nurses are in a unique and powerful position to directly impact the health outcomes of at-risk populations by remaining knowledgeable about sexuality and providing care that is inclusive and respectful of all individuals.

### 33.1 Sexual Identity

#### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define biological sex and what it encompasses
- Recognize how gender identity is applied to one's self-identity
- Identify various gender role expressions
- Explain various sexual orientations

The importance of nurses being knowledgeable about patient gender identity, gender role expression, and sexual orientation cannot be overstated. However, just being knowledgeable about the subject is not enough. Nurses must actively work to remain open-minded and nonjudgmental to provide quality care to all patients, regardless of gender

identity, gender role expression, or sexual orientation. Nearly a quarter of **LGBTQIA+** (lesbian, gay, bisexual, transgender, queer/questioning, intersex, asexual, and gender diverse) Americans report being blamed for their health problems by a healthcare provider, as compared to less than 10 percent of non-LGBTQIA+ individuals (Rummler & Mathani, 2022). Additionally, one in every six LGBTQIA+ individuals reports avoiding health care in anticipation of discrimination (Casey et al., 2019). When care is provided in a manner that is closed-minded and/or judgmental, it is discrimination, and it leads to poor health outcomes (Tabaac et al., 2020). These poor outcomes are seen in disproportionately higher numbers in the LGBTQIA+ population, resulting in health disparity, which are preventable differences in the burden of disease, injury, violence, or opportunities to achieve optimal health that are experienced by socially disadvantaged populations (Centers for Disease Control and Prevention, 2023). The key word in that definition is “preventable,” which is why there has been a significant focus in recent years on reducing risk factors in these populations to improve health outcomes (U.S. Department of Health and Human Services, n.d.).

This unit is designed to enrich your nursing understanding of biological sex, gender identity, gender expression, and sexual orientation. By deepening your knowledge in these areas, you will be better prepared to deliver holistic, patient-centered care (PCC) to individuals across the spectrum of sexuality. The goal is to empower you with the insights and sensitivity needed to address the unique needs and concerns of every patient, ensuring that quality care is provided to all. This section of the chapter is designed to enrich your nursing understanding of biological sex, gender identity, gender expression, and sexual orientation.

## Biological Sex

The sex that is assigned to an individual at birth is referred to as one’s **biological sex**. In some cases, you will have patients that prefer to refer to their biological sex as “assigned male at birth” or “assigned female at birth.” This sex assignment is made based on biological factors including chromosomes and physical characteristics (e.g., genitals). At birth, if **ambiguous genitalia** are noted, meaning the genitalia don’t look as expected for a male or female, the child may be classified as “Intersex.” A broad classification term, **intersex** encompasses situations in which a person is born with chromosomes or reproductive or sexual anatomy that does not fully align with being male or female. Some intersex characteristics are recognizable at birth, while others do not present until later in life. The key takeaway about biological sex is to understand that the sex assigned to an individual at birth may not necessarily correspond to the gender they identify with or perceive themselves to be. It is important to be mindful of this when caring for patients and avoid assuming that a person is a certain gender solely based on their assigned biological sex at birth.

### Chromosomal Sexual Development

Biological sex is determined by specific combinations of **chromosomes**, which are threadlike structures containing DNA located in the nucleus of cells. Chromosomes that determine the sex of the individual are referred to as **sex chromosomes** and are designated as X and Y chromosomes. Biological females have two X chromosomes (XX) and biological males have one of each (XY). The biological sex is determined during **fertilization** when a sperm cell fertilizes an egg cell. The egg cell always carries an X chromosome and the sperm carries either an X or a Y, so the biological sex is dependent on which type of chromosome is carried by the sperm. If the sperm carries an X chromosome, the result will be a biological female, and if the sperm carries a Y chromosome, it will be a biological male. It is important to note that although XX and XY are the most common chromosomal configurations for sex, there are some instances where variations may occur. For example, males with XXY sex chromosomes are diagnosed with Klinefelter syndrome ([Figure 33.2](#)). This condition can result in symptoms such as abnormal growth patterns, reduced facial hair growth, enlarged breasts, low sex drive, and infertility. Another example is females with three X chromosomes (XXX), which causes Triple X syndrome. This condition may cause symptoms including infertility, abnormal growth patterns, or early menopause.

**FIGURE 33.2** Klinefelter syndrome occurs when a male is born with XXY sex chromosomes, and manifestations include wider-than-normal hips and enlarged breast tissue. (credit: modification of “Klinefelter’s syndrome” by Unknown author/Wikimedia Commons, CC BY 3.0)

### **Congenital Adrenal Hyperplasia (CAH)**

A genetic disorder, **congenital adrenal hyperplasia (CAH)** affects the adrenal glands, which sit on top of the kidneys. The adrenal glands are responsible for producing several different hormones, including cortisol, aldosterone, and sex hormones (testosterone and androgens). Genetic mutations in CAH result in a lack of certain enzymes needed by the adrenal glands to make hormones. When the body produces less cortisol and/or aldosterone, the body tries to compensate by stimulating the adrenal glands to make more. This stimulation results in an overproduction of sex hormones, which manifests as enlarged external female genitalia in infants and early appearances of pubic hair and acne and rapid growth patterns during adolescence. It is typically treated with hormone replacement therapy to treat the deficient levels of cortisol and aldosterone and antiandrogen medications such as spironolactone to decrease the amount of sex hormones in the body. In severe cases, females may opt to surgically alter the appearance of the enlarged external genitalia for cosmetic or functional reasons.

### **Gender Identity**

Gender is often used interchangeably with biological sex; however, they are two completely different concepts. Sex refers to the biological and physiological characteristics of a male or female such as reproductive organs, hormones, and chromosomes. On the other hand, **gender** is a social construct that includes norms and behaviors associated with being a man or a woman. One’s **gender identity** is defined as “a person’s deeply felt, internal and individual experience of gender, which may or may not correspond to the person’s physiology of designated sex at birth” (World Health Organization, n.d.). In other words, gender identity is the gender that an individual perceives themselves to be, regardless of their biological sex. Gender identity is just as important, if not more so, than biological sex because it encompasses an individual’s internal sense of self, which can directly impact both mental and physical health. It is vital that nurses recognize and understand that a patient’s gender identity may not align with their physical characteristics; however, the patient should be recognized as the gender with which they identify.

For example, if a biological male who identifies as female prefers “she/her/hers” as their pronouns, the nurse should consistently use them in conversation, even if the patient has external physical characteristics that are male. Gender identity is a highly personal and sensitive part of an individual’s life and should be treated with open-mindedness and respect, especially within the healthcare setting.

### Cisgender

Individuals whose gender identity aligns with the biological sex they were assigned at birth as referred to as **cisgender**. For example, an individual who was assigned male at birth and who identifies as a male is cisgender. Historically, cisgender individuals were called “normal,” however, this would indicate that other variations of gender identity are “abnormal,” which is not accurate. There are many variations of gender identity, all of which are normal, so this term has been adopted to help change the societal narrative about there being only one “normal” type. Using this term is a way to demonstrate the use of inclusive language and foster understanding and respect for all individuals.

### Gender Nonconforming

The term **gender nonconforming** is used to describe individuals who display behaviors or appearances that do not align with societal expectations of their sex assigned at birth. An example would be an individual assigned male at birth who enjoys wearing female clothing and makeup. Another example could be an individual assigned female at birth who prefers to keep their hair short and wears masculine clothing. It is important to remember that being gender nonconforming does not necessarily indicate the person’s gender identity. In many cases, the individual may be cisgender but just enjoy expressing themselves in ways that do not align with societal expectations of their sex assigned at birth. This again highlights the need for nurses and other healthcare professionals to maintain an open mind that is free from judgment and allow patients to express themselves authentically, regardless of societal norms.

## LIFE-STAGE CONTEXT

### Navigating Puberty and Gender Identity

As teenagers enter puberty, they embark on a journey of self-discovery that includes exploring their identity, sexuality, and gender expression. For some teens, this period may involve questioning traditional gender norms and embracing a gender identity that differs from societal expectations. The following are some key considerations for teens experiencing gender nonconformity during puberty:

- **Physical changes:** Puberty brings about significant physical changes, such as the development of secondary sexual characteristics such as breast growth, voice deepening, and facial hair. For nonconforming teens, these changes may not align with their gender identity, leading to feelings of discomfort or dysphoria.
- **Emotional challenges:** Adolescence is a time of heightened emotional sensitivity, and navigating gender identity can add an extra layer of complexity. Teens may experience confusion, anxiety, or depression as they grapple with societal pressures and expectations regarding gender roles and expression.
- **Supportive environments:** Creating a supportive and inclusive environment is crucial for teens exploring their gender identity. Schools, healthcare providers, and families can play a pivotal role in offering acceptance, understanding, and resources to help teens navigate this journey with confidence and resilience.
- **Access to resources:** Access to resources such as gender-affirming therapy, support groups, and LGBTQIA+ organizations can provide valuable support and guidance for teens experiencing gender nonconformity. These resources offer a safe space for teens to connect with others who share similar experiences and access affirming care.
- **Respect and affirmation:** Respecting a teen's self-identified gender and using their chosen name and

pronouns are essential for affirming their identity and fostering a sense of validation and acceptance. Providing opportunities for open communication and validation of their feelings can help teens feel understood and supported during this critical time.

- **Legal protections:** Understanding the legal protections and rights afforded to gender nonconforming individuals is vital for ensuring their safety and well-being. Educating teens and their families about their rights in areas such as health care, education, and employment can empower them to advocate for themselves and navigate any challenges they may encounter.

Navigating puberty and exploring gender identity can be a complex and deeply personal journey for teens. By fostering a supportive and affirming environment and providing access to resources and information, we can empower teens to embrace their identity with confidence and live authentically.

---

## Transgender

Individuals whose gender identity does not align with the sex assigned to them at birth as known as **transgender**. For example, an individual who was assigned female at birth but identifies as a man is a Transgender man, whereas an individual who was assigned male at birth but identifies as a female is a Transgender woman. It is important to note that Transgender is a broad term that encompasses many different situations, not just the ones described here. Some other categories of Transgender individuals include those who are gender nonbinary and gender fluid, both of which are discussed in more detail in the following sections. Another term that is sometimes mistakenly used in place of Transgender is transsexual. While many people refer to themselves using this term, it is important to note this term is usually considered outdated and could be offensive to some people because not all transsexual individuals identify as Transgender and vice versa. Use this term only when the individual has used it to identify themselves first.

Transgender people may undertake several processes to express their gender identity or to live in congruence with their gender. These steps or changes are often referred to as "transitioning," but they vary greatly among individuals, and may occur over a relatively long period of time and in no set order. Internal transitioning can be described both as changing the way one thinks about themselves and about how they act when alone. Some transgender people undertake a social transition, in which they may express their identity through choosing a new name and pronouns, changing their style of dress, hair, and other expressions. Legal transitioning may include a legal name change, as well as updating or replacing one's driver's license, passports, and other documents. Some, but not all, transgender people seek and undertake gender-affirming medical care, such as using prescribed hormones, puberty-blockers, voice changes (either through training or surgery), changes to the chest/breast area, changes to genitalia, and other procedures or treatments. Nurses are very likely to care for patients who are considering or undergoing one or more of these transitions, or who have already done so.

## LINK TO LEARNING

Some Transgender individuals may choose to undergo gender affirmation surgery. This procedure involves surgical interventions to alter portions of the body to better align with the individual's gender identity. Learn more about [gender affirmation surgery \(https://openstax.org/r/77genderaffsurg\)](https://openstax.org/r/77genderaffsurg) including procedure details, risks, benefits, recovery, and outlook.

---

## Gender Dysphoria

The term **gender dysphoria** is used to describe the distress experienced by some -- but not all -- individuals when their sex assigned at birth and assumed gender is not the one with which they identify. This is a real health condition that is recognized and defined by the *Diagnostic and Statistical Manual of Mental Health Disorders (DSM 5-TR)*, which is used to assist with diagnosis of mental health disorders by psychologists and psychiatrists (American Psychiatric Association, 2022). Though many transgender, gender nonconforming or questioning people experience challenges and concern about their gender identity, not all experience the distress associated with gender dysphoria. To be classified as dysphoria, significant distress must last for six months, usually with associated impairment in social or other areas of functioning or relationships. Some of the findings in pediatric patients with gender dysphoria per the DSM-5-TR definition include the following:

- a strong desire to be of the other gender or insistence they are the other gender
- a strong preference for playmates of the opposite gender
- a strong dislike of one's sexual anatomy
- people assigned male at birth, a strong rejection of typically masculine toys (e.g., guns, dinosaurs, action figures), games, and activities and avoiding rough play; people assigned female at birth, rejecting typically feminine toys (e.g., dolls), games, and activities

In adolescents and adults, some of the expected findings of gender dysphoria include the following:

- A mismatch between one's expressed gender and primary and/or secondary sex characteristics (or, in young adolescents, the anticipated secondary sex characteristics). For example, an individual assigned female at birth expresses themselves as a male and does not feel that the development of female breast tissue aligns with their gender identity.
- Wishing to be treated as the other gender (or a gender that is different from one's assigned sex)
- Wanting to get rid of one's primary and/or secondary sex characteristics because of a mismatch between one's expressed gender and sex characteristics

Treatment for children with gender dysphoria typically begins with counseling and family therapy to explore the child's feelings about their gender. In adolescents and adults, treatment with hormones may be considered in addition to counseling and therapy.

### Gender Role Expression

Strict societal beliefs that define “acceptable” behaviors for each gender are known as **gender roles**. In most cases, these roles are binary, meaning that they only encompass acceptable behaviors for male and female. An example of a common gender role is that boys should only play with trucks and dinosaurs while girls should play with dolls and have tea parties. Another example would be the traditional beliefs regarding the division of household labor. Traditionally, the female would stay home with the children and handle the cleaning and cooking while males would go to work. In recent years there has been a shift away from these roles for many reasons including nontraditional family dynamics and more women entering the workforce for personal or financial reasons (U.S. Bureau of Labor Statistics, 2023). Despite these shifts, there are still many people who strongly believe in these traditional gender roles, which can make it difficult to change the way society views gender.

The way a person communicates their gender to others is called **gender role expression**. This expression is external, such as by clothing, appearance, and mannerisms. It is important to note that gender role expression may or may not reflect an individual's gender identity. For example, a Transgender female may continue to wear male clothing to work due to fear they will be judged in the workplace if they dressed like a female. When people think about gender expression, they are again usually thinking in binary terms, which in this case would be masculine and feminine. However, there are many other combinations in which a person might express themselves as both genders simultaneously or as different genders at different times, which is described as **gender fluid**. Another example outside of strict masculinity and femininity is called androgynous expression. Individuals who are **androgynous** express themselves in a manner that does not conform to societal expectations of how males or females should look and/or act (Figure 33.3). They may embrace looks or clothing from both genders, making it difficult to determine whether they identify as male or female. The main takeaway is that all individuals possess their own unique form of gender expression, and it does not automatically determine their gender identity, nor should you just assume their identity based on a simple visual examination.

**FIGURE 33.3** An androgynous individual embraces looks or clothing from both genders, making it difficult to determine whether they identify as male or female. (credit: “Genderqueer person” by Franziska Neumeister/Wikimedia Commons, CC BY 2.0)

### Gender Binary

The term **gender binary** refers to the classification of gender into two distinct categories: male and female. Although considered outdated, a number of individuals still believe in this concept. This view about gender asserts that people can only be male or female and that they should conform to societal expectations (gender roles) that are appropriate for their assigned biological sex. This view fails to account for the diversity and complexity associated with gender identity, thus fostering a closed-minded approach to understanding the unique experiences of individuals with “nontraditional” gender identities. This view is inappropriate, but even more so in healthcare settings, as these beliefs can contribute to subconscious biases and subsequently poor health outcomes.

Although some healthcare professionals continue to hold onto this belief and treat patients only according to their sex assigned at birth, others are expanding their knowledge regarding gender care and advocating for better health care for these individuals. A new healthcare-delivery model called **gender expansive health care** is inclusive and affirms gender identity. Many healthcare institutions are beginning to adopt this model by providing continuing education to healthcare professionals about gender care, implementing gender neutral facilities and signage, and using appropriate pronouns and wording when caring for patients (Center for Transgender and Gender Expansive Health, 2023).

### Gender Nonbinary

The term **gender nonbinary** refers to individuals who have a gender identity that does not fit within the traditional binary framework of male or female. People who are nonbinary may identify with a gender that is somewhere along the spectrum between male and female or separate from these categories. Individuals who are nonbinary may express their gender in various ways, which might include a combination of traditionally masculine and feminine traits, or they might present in a way that does not conform to conventional gender norms. Some nonbinary people use specific terms to describe their gender identity, such as genderqueer, genderfluid, agender, bigender, or other terms that best fit their personal experience. Each term may have distinct meanings or nuances that are significant to the individual using them, so it is important for nurses and other healthcare providers to ask patients which terms they prefer and use them appropriately per the patient’s preferences. Nonbinary individuals may use different pronouns that reflect their gender identity, such as they/them, ze/zir, or others. It is important to respect and use the pronouns with which an individual identifies (North Dakota Health and Human Services, n.d.).

## REAL RN STORIES

---

### Gender Identity Discrimination

**Nurse:** Leslie, BSN

**Clinical setting:** Emergency department

**Years in practice:** 3

**Facility location:** Rural community hospital in Kansas

I had just taken a health history on a patient who was being seen for a respiratory illness. During the assessment, I found out the patient was a Transgender male. As I walked through the hall, I ran into the treating provider and pulled him aside to let him know about the patient's preferred pronouns. The provider stated, "So, is she a male or a female? I don't get it. I can't keep up with all these changes. Back in my day, there were only two genders." I responded, "He was assigned female sex at birth, but identifies as a male. So, he is a male."

For hours, I kept replaying that interaction in my head. I found myself regretting not advocating for the patient better. I was proud that I had at least relayed the necessary information for the provider to treat the patient according to his gender identity; however, I knew I could have handled it better. I was so distraught about the situation that I went to talk to my charge nurse about it. She was understanding and recognized that it's difficult to advocate for patients sometimes, especially in situations where it feels like we are correcting providers.

A few hours later, I ran into the provider again. I asked him how his interaction with the patient went, and he said, "It went really well. Thank you for letting me know about his preferred gender identity because I would have had no idea otherwise." I took this opportunity to say, "I appreciate you listening and using his preferred pronouns. I think sometimes it's hard for us to understand others' experiences when we don't necessarily have the same belief system about gender identity, but it's important for us to treat patients according to their preferences. It shows respect and understanding, which is so important in health care."

A few weeks later, I decided to start a hospital-wide committee to increase awareness and education about patient gender identity. And guess who came to the first meeting? The provider. To this day, I have no idea if my words were what moved this provider to join the committee, but I do think it played a small part. And I'm happy to report that he is an active committee member and has since helped teach other providers how to treat patients according to their gender identity without judgment.

---

## Sexual Orientation

The term **sexual orientation** describes who an individual is attracted to sexually, emotionally, and/or romantically. It is important to remember that this term is completely different from gender identity. Gender identity describes who an individual is, whereas sexual orientation describes who that individual is attracted to. There are many variations of sexual orientation, including heterosexual, lesbian, gay, bisexual, asexual, and questioning, among others. These types are discussed in more detail in the following sections.

### Heterosexual

Individuals who are **heterosexual**, also called "straight," are sexually attracted to a person of a different gender or sex. There are several common misconceptions about heterosexuality. First, many people think Transgender individuals cannot be heterosexual. This is not true, because a person's gender identity and sexual orientation are two separate things. If a Transgender man is attracted to women, he is heterosexual, even though his sex assigned at birth was female. Another misconception is that being heterosexual is the only "normal" orientation. Although heterosexuality is the most common sexual orientation, it does not make it any more "normal" than other sexual

orientations. Some people have religious or personal beliefs that do not accept other sexual orientations; however, that does not change the fact they exist and are just as “normal” as being heterosexual.

### Gay and Lesbian

Historically, individuals who identified as gay or lesbian were often labeled as “homosexual.” However, this term is considered outdated and potentially offensive. It should only be used if the individual chooses to describe themselves in this way. The term **gay** is used to describe men who are romantically or sexually attracted to other men. This term is also used more broadly to describe individuals of any gender that are attracted to individuals of the same gender. Women who are romantically or sexually attracted to other women are referred to as **lesbian**.

### Bisexual

Also commonly referred to as “bi” or “bi+,” **bisexual** describes individuals who acknowledge they have the potential to be attracted (romantically, emotionally and/or sexually) to people of more than one gender. It is important to note that the person’s attraction to each gender may not occur at the same time or in the same way and that these levels of attraction can vary significantly depending on the individual. Another important reminder is that individuals who refer to themselves as bisexual do not need to have had sexual and/or romantic experiences with more than one gender, or have had any experiences at all. If an individual identifies as being bisexual, they are.

### Asexual

Sometimes referred to as “ace,” **asexual** describes individuals who do not experience sexual attraction or have a lack of interest in sexual activity. Some asexual individuals still experience romantic attraction and form romantic relationships, whereas others do not. Those who do not experience romantic attraction identify as **aromantic**. Being asexual is different from choosing to abstain from sexual activity for personal or religious reasons; asexual individuals do not have the inner desire to participate.

### Questioning

The term **questioning** refers to a time of exploration and self-discovery about one’s sexual orientation, gender identity, and/or gender expression. Those who are questioning may be unsure about their attraction to others or how they fit within societal expectations of gender roles and identities. Questioning individuals can be of any age and in many cases, this may occur later in life. This is an extremely important process and one that should not be taken lightly. A common misconception about questioning individuals is that they are choosing to be lesbian, gay, or bisexual, which is not true. They are taking the time to explore their internal feelings and attraction to others so that they can become confident in their identity.

## PATIENT CONVERSATIONS

### Patient Questioning Gender Identity

**Scenario:** The patient is a 23-year-old biological male being seen in the community clinic for a wellness exam. The nurse walks into the patient’s room to obtain a health history.

**Nurse:** Hi, my name is Marie and I’ll be your nurse today. Please confirm your name and date of birth.

**Patient:** Sure. It’s James Dobbard and my birthday is 3/29/2001.

**Nurse:** Great, thank you. Before we get started, I want to gather some demographic information. Do you identify as male or female?

**Patient:** Well, that’s kind of hard to explain actually. I’ve been confused about that lately.

**Nurse:** It’s okay to be confused. Do you mind explaining more about your confusion?

**Patient:** I don’t know . . . I guess I’ve never felt completely comfortable being a man. When I was younger, I always liked “girl” toys and enjoyed things such as painting my nails, but my parents forbid me from doing them.

**Nurse:** I’m sorry to hear about that—that must have been difficult.

**Patient:** It was. I tried to just get over it, but as I got older, I still found myself gravitating toward more feminine activities. I enjoy dressing up and putting on makeup. I know that probably sounds weird to you.

**Nurse:** Not at all. It's brave of you to tell me how you're feeling. Do you feel as though you might identify more with being a female?

**Patient:** Yes, I really do, but I'm too scared to say that out loud to anyone in my life because I know I will be judged.

**Nurse:** I'd love to connect you to some local resources and support groups for other individuals who are questioning their gender identity. They may have more insight about your feelings and how to approach the subject with your family and friends. Would you be open to that?

**Patient:** Yeah, that actually sounds great. I would really appreciate it. Thank you, and thank you for not judging me. I can't tell you how relieved I feel now.

## 33.2 Sexual Fulfillment

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the different forms of stimulation used in sexual fulfillment
- Explain sexual behaviors and their assigned categories
- Describe the types of expression used for sexual fulfillment

The state of experiencing satisfaction, pleasure, and contentment in one's sexual relationships, is known as **sexual fulfillment** and is a crucial aspect of overall health and well-being. Though discussing sexual health and habits can be uncomfortable at first, it is important for nurses to gain the experience and knowledge to be able to understand and address patient sexual concerns. By remaining open-minded and nonjudgmental regarding others' sexual preferences, nurses can provide care that is more holistic and promotes optimal patient wellness and outcomes.

### Forms of Sexual Stimulation

Every individual has unique sexual preferences. Thus, achieving sexual fulfillment may vary from person to person. There are several different forms of sexual stimulation that an individual may prefer (or require) to become sexually fulfilled. These forms of sexual stimulation can be classified as either physical or psychological and are discussed in more detail in the following sections.

#### Physical

Physical sexual stimulation involves physical contact, or the touching of parts of the human body ([Table 33.1](#)). Specifically, this involves touching the various **erogenous zones**, which are parts of the body that trigger **sexual arousal** (state of being physically and mentally excited by sexual stimuli, and involves physiological responses such as increased heart rate, blood flow to the genital areas, lubrication in women, and erections in men) when stimulated. These areas include the mouth/lips, ears, neck, breasts/nipples, back, genitals, and the inner thighs ([Figure 33.4](#)).

Type of Stimulation	Description
Kissing	Kissing is direct mouth-to-mouth contact that involves pressing one's lips against another person's lips.
Breast stimulation	Other terms include "nipple stimulation," or "nipple play." Involves biting, sucking, touching, and/or rubbing the nipples and surrounding breast tissue. It is important to note that the amount of breast stimulation that is comfortable varies widely from person to person.

**TABLE 33.1** Different Forms of Physical Sexual Stimulation

Type of Stimulation	Description
Manual stimulation	Manual stimulation involves the use of hands, fingers, or other parts of the body to stimulate the genitals or other erogenous zones. Examples include “fingering,” or placing one’s fingers inside a vagina, using fingers to squeeze nipples, or using hands to stroke a penis.
Oral stimulation	Oral stimulation, also called “oral sex,” involves using the mouth (e.g., mouth, lips, tongue) to stimulate another person’s genitals or anus.

TABLE 33.1 Different Forms of Physical Sexual Stimulation

FIGURE 33.4 Both males and females have similar erogenous zones, which are areas that result in sexual arousal when touched or stimulated. (credit: modification of “Erogene Zonen des Menschen 1” by Mikael Häggström/Wikimedia Commons, CC0 1.0)

### Psychological

In addition to physical touch, some individuals can also be sexually stimulated by other means that can be classified as psychological stimulation. This includes the use of adult movies, magazines, photographs, and certain sounds, such as moaning or sucking noises. With this kind of stimulation, there does not need to be physical contact with another individual to elicit sexual arousal. For many individuals, both physical and psychological stimulation can result in sexual arousal; however, the degree of arousal may vary depending on their specific preferences. It is important to remember that sexual stimulation preferences are specific to each individual and should be approached with an open mind by the nurse and other health professionals.

### Sexual Behaviors

One’s **sexual behavior** refers to acts that an individual engages in to experience sexual arousal, **sexual pleasure** (enjoyable and satisfying physical and emotional sensations experienced during sexual activity), **orgasm** (peak of sexual excitement, characterized by intense physical pleasure and a series of involuntary muscle contractions in the genital area), and/or reproduction of offspring. It encompasses a wide variety of activities and interactions, both

physical and psychological. Sexual behaviors can be classified as either adaptive or maladaptive, each of which is discussed in more detail in the following sections.

### Adaptive

Adaptive sexual behaviors are commonly referred to as healthy sexual behaviors. This involves an individual being able to express their sexuality in ways that enrich their life and do not pose threats to their health. Some examples of adaptive sexual behaviors include the following:

- always giving and obtaining consent before participating in sexual activities
- communicating sexual needs and desires with partner
- listening to and respecting sexual boundaries of self and others
- protecting self and others from sexually transmitted infections (STIs)
- using contraceptives appropriately, if indicated
- being comfortable with sexual identity and orientation

## LIFE-STAGE CONTEXT

---

### Sexual Behaviors in Older Adults

There is a common misconception that older adults are no longer interested in sex. However, studies have shown that older adults who engage in sexual activity have a greater quality of life (Steckenrider, 2023). With the increasing older adult population in combination with increased access to medications and devices to assist with sexual function (e.g., penis pumps, penile implants), it is important for nurses and other health professionals to understand that discussions about sex with the older adult population are warranted and necessary. It is also important to note that older adults engaging in sexual behaviors are still at risk for STIs. For this reason, it is imperative that the care of older adults involve education and discussion about safe sexual practices.

---

### Maladaptive

Maladaptive behaviors occur when an individual does not know how to handle challenges or new situations and acts in problematic ways (Marston, 2022). In some cases, these behaviors can be sexual in nature. Examples of maladaptive sexual behaviors include the following:

- excessive or inappropriate use of **pornography** (materials, such as books, magazines, videos, and websites, that depict explicit sexual content primarily intended to stimulate sexual arousal)
- infidelity (cheating or being unfaithful to a committed partner)
- developmentally inappropriate sexual behavior exhibited by children, particularly under the age of 12
- touching others in inappropriate or unwanted ways

### Common Types of Sexual Expression

Sexual expression refers to both the sexual activities in which individuals engage as well as how they communicate and present their sexuality. This section will discuss masturbation, sexual intercourse, oral-genital stimulation, and a few other less common types of sexual expression.

#### Masturbation

Self-stimulation of the genitals or other areas of the body for sexual arousal or pleasure is called **masturbation**. It can involve the use of hands/fingers, sex toys, or other objects and is a normal part of healthy sexual development. Masturbation can be practiced individually or with a partner, who may or may not choose to participate in the activity. Historically, there have been myths and misconceptions surrounding masturbation, with some people believing that it could lead to various side effects such as blindness, hairy palms, or infertility. In reality, masturbation is a normal and healthy sexual activity that does not cause harm to the body (Ajmera, 2022). Misinformation about masturbation has contributed to stigma and shame surrounding this natural behavior, but education and accurate information can help dispel these myths and promote a more positive understanding of masturbation and sexual health. Masturbation offers many benefits, including

- reduced stress and anxiety,
- increased focus,

- improved mood,
- better sleep, and
- enhanced sex life.

### Sexual Intercourse

In traditional definitions, **sexual intercourse** refers to penetration of the female's vagina by the male's penis. This definition, however, does not account for variations in sexual orientation, so it is often expanded to also include penetration of the anus (of a male or female) by the penis. Some definitions also include penetration of the vagina or anus by a finger, tongue, or inanimate object. Although the definition of what constitutes sexual intercourse may vary, it always involves penetration of the vagina or anus.

### Oral-Genital Stimulation

Also called "oral sex," **oral-genital stimulation**, involves stimulation of an individual's genitals by another individual's mouth, lips, or tongue. The three types of oral sex are

- **fellatio** (oral sex involving the penis),
- **cunnilingus** (oral sex involving the vagina, vulva, or clitoris), and
- **anilingus** (oral sex involving the anus).

Oral sex often may occur before sexual intercourse in what is known as **foreplay**; however, it can also be performed after sexual intercourse or on its own without any intercourse at all. This kind of sexual expression can be pleasurable but is not without risk. Both giving and receiving oral sex increases the risk of obtaining STIs, as they can be spread from mouth-genital contact and vice versa.

### Other Forms of Sexual Expression

There are several other, less common forms of sexual expression ([Table 33.2](#)).

Type of Expression	Description
Voyeurism	<ul style="list-style-type: none"> <li>• Becoming sexually aroused by watching another person (or people) in a state of nakedness or engaged in sexual activity</li> <li>• Traditional definition has a negative connotation because it was used to describe an individual viewing an unknowing/unwilling victim and did not allow for individual to form sexual relationships outside of this preference</li> <li>• More modern definition includes consensual sexual voyeurism that exists within relationships or still allows an individual to form relationships</li> </ul>
Sadism	<ul style="list-style-type: none"> <li>• Sexual arousal from inflicting pain, suffering, or humiliation on others</li> </ul>
Masochism	<ul style="list-style-type: none"> <li>• Sexual arousal from one's own pain or humiliation</li> </ul>
Sadomasochism	<ul style="list-style-type: none"> <li>• Combination of sadism and masochism</li> </ul>

**TABLE 33.2** Other Forms of Sexual Expression

## 33.3 Factors Affecting Sexuality

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe physiological factors affecting sexuality
- Recognize psychological factors affecting sexuality
- Identify psychosocial factors affecting sexuality

Sexuality is a vital component of health and one that should never be overlooked or dismissed as unimportant.

Though discussing sexual health with patients can be uncomfortable at times, it is a key component of providing holistic, patient-centered care (PCC). It is important that nurses and other healthcare providers gain experience and increased comfort with providing guidance and care in accordance with patient sexuality, including their sexual preferences and any concerns regarding sexuality they may have. It is also important to recognize there are many factors, including physiological, psychological, and psychosocial, that may affect an individual's sexuality.

### Physiological Factors Affecting Sexuality

Physiological factors are biological characteristics that can have a significant influence on an individual's sexuality and sexual health. Some of the most common physiological factors that can impact sexuality include developmental changes and certain diseases and medications. Each of these factors is discussed in more detail in the following sections.

### Developmental Considerations

Though sexuality is most often associated with adolescence and adulthood, sexual development begins in early childhood and extends throughout the life span ([Table 33.3](#)).

Life Stage	Considerations
Infancy (birth–1 year)	<ul style="list-style-type: none"> <li>Physical exploration of genitals after developing sufficient motor skills</li> </ul>
Childhood (1–11 years)	<ul style="list-style-type: none"> <li>Developing curiosity about own body and others' bodies</li> <li>Begin to ask questions about own genitals and begin differentiating between male and female anatomy</li> <li>Begin to develop own gender identity</li> </ul>
Adolescence (12–18 years)	<ul style="list-style-type: none"> <li>The process of physical changes that results in development of secondary sexual characteristics such as breast enlargement and menstruation in females and facial hair growth in males begins, known as <b>puberty</b></li> <li>Hormonal changes contribute to development of sexual desire, attraction, and onset of sexual experimentation</li> <li>Period of exploration of sexual identity, preferences, and values, which is often influenced by peers, social media, and cultural norms</li> </ul>
Young adulthood (18–40 years)	<ul style="list-style-type: none"> <li>Exploration of intimate relationships and sexual experiences</li> <li>Sexual identity usually becomes established in this period</li> <li>Period of peak fertility that often involves family planning and new parenthood</li> </ul>
Middle adulthood (40–65 years)	<ul style="list-style-type: none"> <li>Often involves shifts in priorities (e.g., focus on emotional intimacy versus physical attraction)</li> <li>Menopause may impact sexual function</li> </ul>
Later adulthood (65+ years)	<ul style="list-style-type: none"> <li>Sexual development continues; however, function may be impacted by health-related factors such as chronic conditions, medications, and/or physical limitations</li> <li>Intimacy and emotional connection still remain important to most individuals</li> </ul>

**TABLE 33.3** Sexual Development Considerations across the Life Span (Source: Cacciatore et al., 2019.)

### Diseases and Conditions

There is an array of sexual dysfunction disorders that directly impact aspects of sexual functioning, both in males and females. Some of these conditions are discussed in more detail in the following sections. In addition to these specific sexual dysfunction disorders, many other chronic medical conditions may also impact an individual's sexual health. Some of these conditions include diabetes mellitus, cardiovascular disease, and chronic pain, as well as conditions that impact mobility.

#### Sexual Dysfunction Disorders

Difficulty experienced by an individual or a couple during any stage of a normal sexual activity that inhibits one or both partners from achieving sexual satisfaction is known as **sexual dysfunction** (Table 33.4) (Mandal, 2019; Cleveland Clinic, 2020). Sexual dysfunction disorders can have a profound impact on an individual's quality of life.

Disorder	Description
low libido	Lack of or significant reduction in sexual interest and arousal. Common causes include certain medications, mental health disorders, and stress.
erectile dysfunction (ED)	Recurrent inability to achieve or maintain an adequate erection during partnered sexual activities. Common causes include hardening of arteries (e.g., atherosclerosis), neurological disorders, stress, penile trauma, and depression.
female orgasmic disorder	A significant change in female orgasm such as delay, reduction of intensity, or cessation.
delayed ejaculation (DE)	Taking a very long time to ejaculate following penetration.
premature (early) ejaculation	Persistent or recurrent pattern of ejaculation occurring either before or during partnered sexual activity within about one minute following vaginal penetration and before the individual wishes it.
substance/medication-induced sexual dysfunction	A condition in which patients have difficulties with sexual desire, arousal, and/or orgasm due to a side effect of certain medications and/or substances (legal or illicit).
vaginismus	Involuntary vaginal muscle wall spasm during intercourse, resulting in pain. The cause is unknown but previous trauma and/or sexual assault has been suggested as a potential trigger.
priapism	Painful erection that may persist for hours, even with a lack of sexual stimulation. It results when there is blood trapped in the penis that fails to drain adequately.

**TABLE 33.4** Descriptions of Common Sexual Dysfunction Disorders

Disorder	Description
dyspareunia	Persistent or recurrent pain that occurs during sexual intercourse. This pain may occur at the vaginal opening or deep within the pelvis. It can be caused by various factors, including physical conditions such as infections, vaginal dryness, endometriosis, or pelvic floor disorders, as well as psychological factors such as anxiety or past trauma.
vaginal dryness	A condition where the vagina lacks sufficient natural lubrication, resulting in discomfort or pain during sexual intercourse. Vaginal dryness can occur due to various reasons, including hormonal changes (such as during menopause), certain medications, breastfeeding, stress, and certain medical conditions.

**TABLE 33.4** Descriptions of Common Sexual Dysfunction Disorders

### Diabetes Mellites

It may appear that diabetes mellitus would not impact sexual function; however, it can and often does in several ways. First, men with diabetes are three times more likely to experience erectile dysfunction (ED) than men without diabetes (Seid et al., 2017). Because of the chronic inflammation and subsequent damage to blood vessels and nerves seen with diabetes, it is often difficult to accomplish and/or maintain an erection. Additionally, men with diabetes may deal with a lack of sensation in the penis, even with an erection, due to peripheral neuropathy associated with the condition. The same can be said for women with diabetes—because of decreased blood flow and damaged nerves, they often experience less sensation around the vagina during sex, which can make it less enjoyable.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Addressing Diabetes and Sexual Health

John, a 55-year-old male with type 2 diabetes, presents with concerns about ED, which has been affecting his relationship with his partner. The nurse begins by gathering a comprehensive history of John's diabetes, including details about his management regimen, recent changes in medication, and lifestyle factors. A physical examination is conducted to assess for signs of diabetic complications such as peripheral neuropathy or vascular disease, which may contribute to his ED symptoms. Analyzing these cues, the nurse considers the impact of John's diabetes management on his sexual health and orders diagnostic tests to assess diabetes control, cardiovascular risk, and hormonal status. Based on the identified cues and analysis, the nurse forms hypotheses regarding potential diabetes-related causes of ED, such as neuropathy or vascular insufficiency, as well as psychological factors such as depression or anxiety. A collaborative care plan is developed, which includes addressing John's diabetes management goals while providing interventions for ED, such as medication, lifestyle modifications, or referral to a sexual health specialist. By applying a clinical judgment model to John's case, the nurse can systematically address his concerns, optimize his diabetes management, and improve his overall quality of life.

### Cardiovascular Disease

Cardiovascular disease is another physiological condition that can negatively impact sexual function. One of the main reasons is related to the fatigue that often accompanies heart disease. Because diseased cardiac muscle must work harder than healthy muscle, it is prone to early fatigue. This translates to a potential decreased ability to fully participate in sexual activities. Patients with cardiovascular disease may tire early, which doesn't allow them to reach orgasm or achieve sexual satisfaction, or they may lose interest in sexual activity altogether because it seems like it will take too much effort and energy. Additionally, treatment for cardiac disease usually involves medications that reduce the workload of the heart, thus reducing the amount of blood being supplied by the heart to distant areas of the body, such as the genitals. With a diminished blood supply, males may experience erectile dysfunction,

whereas women may have difficulty achieving and/or maintaining sexual arousal.

### Joint or Mobility Conditions

Any medical condition that causes impaired mobility has the potential to impact sexual function. Most sexual activities involve movement and require some mobility, so these kinds of conditions hinder the ability to fully participate. Some examples of conditions affecting mobility that may impact sexual function include

- rheumatoid arthritis,
- spinal cord injury,
- amyotrophic lateral sclerosis (ALS),
- multiple sclerosis (MS),
- stroke, and
- muscular dystrophy.

## REAL RN STORIES

---

### Spinal Cord Injury

**Nurse:** Frankie, BSN

**Clinical setting:** Intensive care unit (ICU)

**Years in practice:** 5

**Facility location:** Inner city of a large metropolitan area in California

For weeks, I had been caring for a 17-year-old patient who experienced a cervical spinal cord injury after diving into shallow water. Originally, it was believed that he would require a permanent ventilator, but he has since been weaned from it and is doing surprisingly well for the type of injury he sustained. He has regained some movement in his arms and fingers but has lost all sensation and function below his navel. He is still having trouble forming verbal words, but he has been using an iPad to communicate.

When I went in to check on him at the beginning of my shift, he asked me if I would have some time to come chat with him about a few things later in my day. I said, “of course,” and was able to make it back a few hours later after getting my other patients settled. When I came back in to chat with him, he typed the following on his iPad, “This is uncomfortable for me to ask, but I feel weird talking about it to my parents. Will I ever be able to have sex?” I was taken aback by the question, only because I had never cared for such a young patient with a permanent injury like this one before. I said, “To be honest with you, I’m not sure. I know that it’s probably unlikely just based on the level of your injury, but I won’t be the one to say no for sure, because I just don’t know. I would be more than happy to relay these concerns to your provider to see if I can get some answers for you though.” He replied in agreement, and I made sure the provider would stop by later that day to chat with him about his concerns.

That afternoon, the provider came by and told the patient that it was highly unlikely that he would be able to have sex, but that until more time had passed and he was given more time to heal, that we just don’t know what will happen. He also said, “There have been a lot of advancements in this area in recent years, so there may be some kind of assistive device that you could use to help you regain some sexual function. Because you have lost sensation below the waist, it’s unlikely that you will be able to feel much, but again, we just don’t know until we have given your body ample time to heal. In the future, if you ever start thinking about having children, there are options available for obtaining sperm, so it’s not completely impossible for you to father biological children, should you desire to.” I could tell that the patient was a little bit upset at these words, but he appeared to remain hopeful that he might regain some function in the future.

---

### Chronic Pain

Chronic pain (pain lasting more than six months), especially when uncontrolled, can negatively impact sexual health in several ways. First, pain can make some sexual positions uncomfortable, or even impossible. For example, chronic conditions such as arthritis and back pain can inhibit flexibility and/or cause discomfort during sexual intercourse. Second, chronic pain often causes fatigue, making it difficult for the individual to have enough energy to participate in sexual activities. Even if they are interested in sex, fatigue may limit their ability to fully participate or achieve an orgasm. Addressing sexual function in the context of chronic pain often requires a holistic approach that

includes treating the pain, addressing emotional concerns, and maintaining open communication with healthcare providers and partners. Therapies such as cognitive behavioral therapy, physical therapy, and couples counseling can be beneficial in managing both pain and its impact on sexual function.

### Medications

There are many medication classes that can have a significant impact on sexual function (Table 33.5). It is important to note that not every single drug in the class of medications causes all (or any) of the listed effects, but they are commonly associated with many of the drugs in that class.

Medication Class	Effect on Sexual Function
Antidepressants	<ul style="list-style-type: none"> <li>• Decreased libido</li> <li>• Delayed orgasm</li> <li>• Erectile dysfunction</li> </ul>
Antipsychotics	<ul style="list-style-type: none"> <li>• Decreased libido</li> <li>• Erectile dysfunction</li> <li>• Difficulty achieving orgasm</li> </ul>
Hormonal medications (e.g., contraceptives, hormone replacement therapy)	<ul style="list-style-type: none"> <li>• Decreased libido</li> <li>• Vaginal dryness</li> </ul>
Antihypertensives	<ul style="list-style-type: none"> <li>• Erectile dysfunction</li> <li>• Decreased libido</li> </ul>
Opioids	<ul style="list-style-type: none"> <li>• Decreased testosterone levels</li> <li>• Decreased libido</li> <li>• Erectile dysfunction</li> <li>• Difficulty achieving orgasm</li> </ul>

**TABLE 33.5** Medication Classes That Can Affect Sexual Function

## UNFOLDING CASE STUDY

### Unfolding Case Study #5: Part 1

Mr. Morales, a 46-year-old male, is being seen in the clinic for an annual wellness examination. During the examination, Mr. Morales reports that he has been having trouble achieving and maintaining erections during sex. He states, “My wife is getting frustrated and so am I. I’m not even that old yet. Why is this happening to me?”

Past Medical History

**Medical history:** Type 2 diabetes, hypertension, depression

**Family history:** Both parents alive and well, mother has hypertension and depression.

**Social history:** Married x twenty years, two teenage children. Wife recently diagnosed with breast cancer.

**Current medications:**

- Fluoxetine (Prozac) 20 mg PO daily
- Metoprolol (Lopressor) 50 mg PO twice daily

1. Recognize cues: Based on the provided information, what cues are most significant for the nurse to recognize?

2. Analyze cues: What might be some contributing factors to the patient's reported erectile dysfunction (ED) symptoms?
3. Prioritize hypotheses: The nurse recognizes the patient's symptoms are consistent with erectile dysfunction (ED) and that it may be partially caused by his current health status and medications. What other information should the nurse obtain from the patient at this time regarding potential causes of his ED symptoms?

## Psychological Factors Affecting Sexuality

In addition to physical factors, psychological factors also have a significant impact on sexual function and health. Human sexuality is influenced by many psychological variables, including but not limited to, mental health, body image, and stress. Nurses play a vital role in recognizing and addressing the psychological dimensions of sexual health and function, thereby promoting holistic well-being for individuals across the life span.

### Mental Health

Mental health and sexual health often go hand in hand. Although sexual dysfunction is often a result of physical conditions (e.g., heart disease, diabetes), they can also have underlying psychological causes. Specifically, depression, anxiety, substance use disorders, and schizophrenia have all been shown to contribute to the development of sexual dysfunction (Sewalem et al., 2022). It is vital that nurses and other healthcare providers treat patients with mental health disorders holistically and not shy away from conversations about sexuality and sexual health. Studies have shown that sexual health needs, especially those of individuals with concurrent mental health disorders, are not addressed appropriately (Hortal-Mas et al., 2022). Though discussing mental health and sexuality can be uncomfortable topics for some, it is imperative that they are addressed appropriately to ensure that all of the patient's needs are being met and holistic, patient-centered care is being provided.

### Body Image

Body image plays a significant role in achieving sexual health and well-being. When individuals have a positive body image, they tend to feel more confident and comfortable with their bodies, which can enhance sexual experiences and intimacy. Conversely, negative body image can lead to feelings of self-consciousness, shame, and insecurity, which may contribute to sexual dysfunction, avoidance of sexual activity, or dissatisfaction with sexual relationships. For example, individuals with poor body image may avoid being seen naked or engaging in certain sexual positions due to feelings of embarrassment or fear of judgment. This avoidance can lead to decreased sexual pleasure and intimacy within relationships. Body image concerns can also affect communication and openness in sexual relationships. Individuals may feel hesitant to express their desires or preferences, fearing rejection or judgment from their partner. This lack of communication can hinder sexual satisfaction and intimacy, as partners may not fully understand each other's needs or feel emotionally connected during sexual interactions. Furthermore, societal standards of beauty and unrealistic media portrayals can exacerbate body image issues, leading individuals to compare themselves unfavorably to idealized images and to feel inadequate. These cultural influences can contribute to body dissatisfaction and impact sexual self-esteem.

## PATIENT CONVERSATIONS

### Body Image Concerns During Sex

**Scenario:** The patient is a 56-year-old female being seen in the clinic for an annual follow-up appointment following a double mastectomy and chemotherapy treatment for breast cancer.

**Nurse:** Good morning, Mrs. Johnson. How are you feeling today?

**Patient:** Good morning. I'm doing okay, thank you. I've been feeling a bit anxious lately, though.

**Nurse:** I'm sorry to hear that. Is there anything specific that's been on your mind?

**Patient:** Well, it's a bit embarrassing to talk about, but I've been feeling self-conscious about my body lately. Since my mastectomy, I can't help but feel insecure about how I look. It's starting to affect my sex life and I can tell my

husband is getting irritated.

**Nurse:** It's completely normal to have concerns about body image, especially after such a significant change. I want you to know that you're not alone, and it's okay to feel this way. Have you and your husband had the chance to discuss these feelings together?

**Patient:** We've touched on it briefly, but I think we're both struggling to find the right words. I worry that he doesn't find me attractive anymore.

**Nurse:** It's understandable that you would feel that way, but I want to assure you that physical appearance doesn't define your worth. Your husband is likely navigating his own emotions surrounding your mastectomy. It might be helpful to have an open and honest conversation with him about your concerns. Would you like some guidance on how to approach this conversation?

**Patient:** Yes, please. I'm not sure where to start.

**Nurse:** I recommend choosing a time when you both feel relaxed and comfortable, perhaps over a quiet dinner at home. Begin by expressing your feelings honestly and openly, using "I" statements to convey your emotions without placing blame. Let him know that you value his support and understanding, and that you want to work together to strengthen your intimacy and connection. Remember, communication is key in any relationship, and sharing your vulnerabilities can bring you closer together.

**Patient:** Thank you so much. That's really helpful advice. I'll try to talk to him tonight.

**Nurse:** You're welcome, Mrs. Johnson. Remember, I'm here to support you. If you ever need someone to talk to or have any questions, don't hesitate to reach out. You're not alone in this.

---

## Stress

Stress can have a significant impact on sexual health, affecting both physical and psychological aspects of sexual function in several ways. First, high levels of stress can cause preoccupation with worries or responsibilities, leaving no physical or mental energy leftover for sexual activity. Second, stress can cause an inability for males to get an erection and for females to achieve orgasm. This is especially true in cases of chronic stress. Chronic stress disrupts hormone balance, increasing cortisol and adrenaline levels, which can inhibit sexual arousal and responsiveness. Lastly, chronic stress is linked to mental health conditions including depression and anxiety, both of which can further exacerbate sexual dysfunction. These conditions can also increase feelings of inadequacy, guilt, or shame related to sexual performance or desire. Chronic stress is a vicious cycle that affects many aspects of life, including sexual health and functioning.

## Psychosocial Factors Affecting Sexuality

Psychosocial factors, which encompass both psychological and social aspects of an individual's life, can profoundly influence sexual health. These factors interact with biological and environmental elements to shape attitudes, behaviors, and experiences related to sexuality.

## Culture

Cultural beliefs, societal expectations, and norms surrounding sexuality can influence how individuals perceive and express their sexuality. Attitudes toward gender roles, sexual orientation, and sexual behaviors are shaped by cultural and societal influences, which can affect sexual identity, self-expression, and access to sexual health resources. In some cultures, such as in many Western countries, there is growing acceptance and support for diverse sexual orientations and gender identities. This acceptance is reflected in laws that protect LGBTQIA+ rights, societal norms that encourage open discussion about sexual orientation, and widespread availability of sexual health resources tailored to LGBTQIA+ individuals. Conversely, in more conservative cultures, such as in some Middle Eastern or African countries, traditional beliefs and societal norms often dictate strict gender roles and heteronormative expectations. Homosexuality may be stigmatized or even criminalized, and gender nonconformity may be met with discrimination or violence. The main takeaway is that nurses and other healthcare professionals must remain open-minded and nonjudgmental to provide culturally competent care that accounts for cultural variations in beliefs about sexuality.

## CULTURAL CONTEXT

---

### Female Genital Mutilation (FGM)

Female genital mutilation (FGM) involves the partial or total removal of the external female genitalia for nonmedical reasons, most often related to cultural or religious beliefs. It has been estimated that more than 200 million females that are alive today have experienced FGM (World Health Organization, n.d.). FGM is nationally recognized as a violation of human rights of girls and women and a severe form of gender discrimination. The World Health Organization (WHO) has developed a goal to rid the world of FGM by the year 2030.

---

### Religion

Religion can have a significant influence on sexual health by shaping attitudes, beliefs, and behaviors related to sexuality. The impact of religion on sexual health varies widely depending on specific religious teachings, cultural practices, and individual interpretations. Religious teachings often provide a moral framework for understanding sexuality and guiding sexual behavior. Values such as **monogamy** (having only one partner at a time) and **abstinence**, or refraining from engaging in sex before marriage, may be emphasized within some religious communities, influencing individuals' choices regarding sexual activity, contraception, and relationships. Some religions may stigmatize certain sexual behaviors or identities, leading to feelings of guilt, shame, or self-judgment among individuals who do not conform to religious norms. Stigmatization of premarital sex, extramarital affairs, nonheterosexual orientations, or gender nonconformity can create barriers to seeking sexual health services and support. It is important to recognize that the impact of religion on sexual health is complex and multifaceted, and individuals' experiences may vary widely within and across religious traditions. Nurses should approach discussions of sexual health with sensitivity to patients' religious and cultural backgrounds, respecting their beliefs and values while providing accurate information and support to promote positive sexual well-being.

### Ethics

There are several ethical factors that may affect an individual's sexuality. First, the importance of informed consent in all sexual interactions cannot be understated. All parties must freely and willingly consent to all aspects of sexual activity without coercion or pressure. Second, the ethical principle of autonomy should be emphasized for all individuals, regardless of their sexuality. Individuals should be able to make informed decisions about their sexual health and relationships, free from outside coercion or judgment. Additionally, ethical sexual behavior involves the individual respecting the autonomy and dignity of themselves and others. It means treating others with kindness, empathy, and understanding, and not sexually objectifying them. Third, ethical considerations related to sexuality mean that nurses and other healthcare professionals must recognize and respect the rights of individuals, regardless of gender, sexual orientation, or any other factor related to one's sexuality. Additionally, it involves challenging power imbalances and advocating for equitable treatment and opportunities for all, both inside and outside of the healthcare system. Lastly, ethical considerations related to sexuality prioritize the safety and well-being of all parties involved. This includes practicing safe sex to prevent the spread of STIs and taking measures to prevent unwanted pregnancies. Ethical sexual behavior also involves being aware of and addressing the emotional, psychological, and physical consequences of sexual activity.

### Lifestyle

Certain lifestyle choices can have an impact on sexual health and functioning ([Table 33.6](#)).

Lifestyle Factor	Impact on Sexual Health
Diet and nutrition	<ul style="list-style-type: none"> <li>• Good nutrition supports overall health, including sexual health.</li> <li>• Maintaining healthy weight can prevent conditions such as heart disease and diabetes, both of which can negatively impact sexual health.</li> </ul>
Smoking and substance use	<ul style="list-style-type: none"> <li>• Smoking has been shown to increase risk of erectile dysfunction in men and decrease fertility in women.</li> <li>• Alcohol and drugs can impair sexual function, decrease libido, and contribute to risky sexual health behaviors.</li> </ul>
Sleep	<ul style="list-style-type: none"> <li>• Chronic sleep deprivation can lead to fatigue and decreased libido.</li> </ul>
Relationships	<ul style="list-style-type: none"> <li>• Communication and emotional connection with a sexual partner can impact sexual satisfaction and health.</li> <li>• Healthy relationships foster intimacy and enhanced sexual experiences.</li> </ul>

**TABLE 33.6** Lifestyle Factors and Impact on Sexual Health

## 33.4 The Nurse's Role in Providing Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe how the nurse acts as an educator
- Recognize how the nurse will be a role model when providing care
- Identify how the nurse is a mandatory reporter

From describing medication side effects to teaching patients about their medical conditions, one of the main roles of the nurse is acting as an educator. This is especially true for sexual health. There are many aspects of sexual health that require the nurse to act as an educator, some of which are described in more detail in the following sections.

### Nurse as an Educator

Providing education related to sexual health can be sensitive and difficult at times, both for the nurse and for the patient receiving it. It is important to remember that sexual preferences and health are highly personal and can be uncomfortable to discuss, even if the nurse and patient have a good relationship. The nurse must possess an extensive knowledge base about sexual health topics including STIs, contraception (methods used to prevent pregnancy resulting from sexual intercourse), and reproduction to provide information to the patient that is accurate and easily understandable. Additionally, the nurse must be able to address any misconceptions about sexual health that the patient may have to help dispel misinformation and promote understanding.

The nurse as an educator must create a safe and supportive environment for the patient to openly discuss their sexual concerns and be able to provide referrals and other resources as needed to fully address the concerns. While acting as an educator, the nurse should acknowledge and respect the patient's cultural and religious beliefs, even if they do not align with the nurse's personal beliefs. Overall, the nurse acts as an educator by empowering patients to take responsibility for their sexual health by providing them with the information and support that they need to make informed decisions about their health. Some of the common topics requiring education to be provided by the nurse include STIs, pregnancy, and fertility, all of which are discussed in more detail in the following sections.

### Sexually Transmitted Infections

An infection that is primarily spread through sexual contact, known as a **sexually transmitted infection (STI)**, may develop after sexual contact with an infected individual ([Table 33.7](#)). These infections can range from asymptomatic to severe depending on the specific type of infection as well as the baseline health status of the infected person. Safe sex practices such as limiting sexual partners or using appropriate protection such as condoms can decrease

the risk for developing STIs. Nurses caring for patients at risk for STIs must not only be able to adequately treat the physical condition and symptoms, but also be able to provide counseling and education regarding effective prevention strategies.

Sexually Transmitted Infection (STI)	Signs/Symptoms
Chlamydia	<ul style="list-style-type: none"> <li>• Abnormal discharge from vagina or penis</li> <li>• Painful urination with itching or burning</li> <li>• Urinary frequency</li> <li>• Pelvic or abdominal pain</li> <li>• Irregular vaginal bleeding</li> </ul>
Gonorrhea	<ul style="list-style-type: none"> <li>• Same symptoms as chlamydia—these STIs often occur together.</li> </ul>
Herpes simplex virus (HSV)	<ul style="list-style-type: none"> <li>• Itching or tingling sensation is noticed a few days before outbreak of sores (called <i>prodrome</i>).</li> <li>• Blisters or sores are present on mouth/lips or genitals.</li> <li>• Flu-like symptoms appear (e.g., headache, fever, chills).</li> </ul>
Human papillomavirus (HPV)	<ul style="list-style-type: none"> <li>• Cases are often asymptomatic, especially if mild.</li> <li>• Genital warts are seen in more severe cases.</li> <li>• Severe types may lead to cancer of cervix, vagina, or anus if left untreated.</li> </ul>
Syphilis	<ul style="list-style-type: none"> <li>• A painless sore called <b>chancre</b>, develops where the bacteria entered the body (e.g., penis, vagina, anus, lips, mouth).</li> <li>• Late-stage symptoms include flu-like symptoms and rash on hands and feet.</li> </ul>

TABLE 33.7 Signs and Symptoms of Common STIs

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Form a Hypothesis: Recognizing a Potential STI

A 22-year-old female seeks care at a sexual health clinic due to lower abdominal pain and vaginal discharge following unprotected intercourse with a new partner. The nurse begins by gathering a comprehensive sexual history, probing for details about recent sexual activity, contraceptive practices, and symptoms experienced. Concurrently, a pelvic examination is conducted to assess for physical cues such as abnormal discharge, cervical tenderness, or lesions indicative of infection. Analyzing these cues, the nurse considers the patient's individual risk factors, including her age, sexual practices, and recent exposure, to determine the likelihood of STI transmission. Diagnostic tests, including nucleic acid amplification tests (NAATs) for common STIs such as chlamydia and gonorrhea, are ordered to confirm the presence of infection. Based on the identified cues and analysis, the nurse forms hypotheses regarding potential STIs such as chlamydia, gonorrhea, or trichomoniasis, considering the risk of coinfection and associated complications. This systematic approach to clinical judgment empowers the nurse to provide targeted, evidence-based care, facilitating timely diagnosis and treatment to optimize patient outcomes in sexual health management.

#### Fear of Pregnancy

Nurses play a crucial role in supporting patients who have a fear of pregnancy by providing them with information, empathy, and resources. Nurses can act as educators by offering detailed information about contraception methods, including their effectiveness, benefits, and potential side effects. They can explain how to properly use contraceptives and address any misconceptions or concerns the patient may have. Nurses can then assist patients

in selecting the most appropriate contraceptive method based on their individual needs, preferences, and medical history. They can also provide guidance on emergency contraception options for situations where contraception has failed or was not used. Most importantly, the nurse should create a supportive and nonjudgmental environment that allows the patient to feel comfortable discussing their fears and concerns related to pregnancy.

### Fear of Infertility

While some patients are fearful of becoming pregnant, others may express fears related to **infertility**, or the inability to conceive a child. Nurses can act as educators in these situations by providing detailed information about fertility, including factors that can affect fertility, common causes of infertility, and available treatment options. They can explain the various diagnostic tests used to assess fertility and discuss potential lifestyle modifications that may improve fertility. Dealing with the fear of infertility can be emotionally challenging for patients. Nurses can offer empathetic support and nonjudgmental listening allowing patients to express their fears, concerns, and emotions openly. Validation of their feelings and providing a safe space for expression can be immensely helpful. Nurses may also empower patients by providing information about fertility preservation options such as egg freezing or sperm banking. This is especially helpful for patients who are facing medical conditions or treatments that could negatively impact their fertility in the future.

### Nurse as a Role Model

In addition to acting as educators, nurses are also often viewed as role models. Specifically, when caring for the sexual health of patients, nurses demonstrate characteristics of a good role model by understanding human sexuality, possessing self-awareness and communication skills, and being able to recognize patient problems and provide competent care.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### Enhancing Patient Safety and Quality Care: Addressing Patient Sexuality

As nurses, it is essential to recognize and address the diverse needs and concerns related to patient sexuality to ensure the provision of safe, competent, and patient-centered care. Incorporating patient sexuality into nursing practice contributes to improved patient outcomes and enhances the overall quality of care. Here's how addressing patient sexuality relates to each of the QSEN competencies:

- **Patient-centered care:** Recognizing and respecting patient sexuality is fundamental to providing patient-centered care. By acknowledging and validating patients' sexual identities, preferences, and concerns, nurses demonstrate a commitment to meeting the individual needs and values of each patient.
- **Teamwork and collaboration:** Collaborating with interdisciplinary teams, including social workers, counselors, and sexual health specialists, allows nurses to address the multifaceted aspects of patient sexuality effectively. By working collaboratively, nurses can ensure that patients receive comprehensive and holistic care that addresses their sexual health and well-being.
- **Evidence-based practice:** Utilizing evidence-based guidelines and best practices in addressing patient sexuality enhances the quality and safety of care. Nurses should stay updated on the latest research and recommendations related to sexual health assessment, counseling, and interventions to provide optimal care based on current evidence.
- **Quality improvement:** Engaging in continuous quality improvement efforts related to patient sexuality involves evaluating current practices, identifying areas for improvement, and implementing strategies to enhance patient outcomes. Nurses can participate in quality improvement initiatives aimed at promoting inclusive and affirming care environments for patients of all sexual orientations and gender identities.
- **Safety:** Ensuring the safety of patients in matters related to sexuality involves creating a supportive and nonjudgmental environment where patients feel comfortable discussing sensitive topics. Nurses must prioritize patient confidentiality, privacy, and emotional well-being while addressing sexual health concerns, thereby promoting a culture of safety and trust within healthcare settings.
- **Informatics:** Leveraging health informatics tools and technologies can facilitate the assessment, documentation, and communication of patient sexuality-related information. Nurses should utilize electronic health records and other informatics resources to capture patient preferences, concerns, and interventions

accurately, thereby enhancing continuity of care and promoting patient safety and satisfaction.

By integrating patient sexuality into nursing practice and addressing it through the lens of the QSEN competencies, nurses can promote patient-centered care, improve patient outcomes, and contribute to a culture of inclusivity, respect, and safety within healthcare settings.

---

### Understanding of Human Sexuality

First and foremost, to act as a role model when caring for the sexual health of their patients, nurses must demonstrate a thorough understanding of human sexuality. To provide high quality patient care, nurses must be knowledgeable about the topic at hand. In this context specifically, nurses must be knowledgeable about concepts related to gender identity, sexual preferences, and clinical symptoms that could be indicative of sexual health disorders. Although most nursing programs offer at least an introduction to these topics, it is important for nurses to participate in continuing education courses to stay abreast of changes in terminology or clinical guidelines to assist them in providing the highest quality care for patient sexual health concerns.

### Self-Awareness

The ability to recognize, understand, and accurately perceive one's own thoughts, feelings, beliefs, attitudes, and behaviors, known as self-awareness, is imperative for nurses, especially in the context of sexuality. By being self-aware, nurses can provide care that is empathetic and respectful. To do this, nurses should reflect on their own attitudes, beliefs, and biases regarding sexuality. Awareness of personal biases enables nurses to provide nonjudgmental care and avoid imposing their values on patients. Nurses may encounter situations that evoke strong emotions or discomfort when discussing sexual health topics. By acknowledging and managing their emotional reactions, nurses can maintain professionalism and provide supportive care to patients without allowing their personal feelings to interfere. Additionally, nurses must establish and maintain appropriate professional boundaries when discussing sensitive sexual health issues with patients. Self-awareness helps nurses recognize and address any boundary issues that may arise to ensure patient comfort and trust. And finally, nurses should engage in regular self-reflection that allows them to assess their performance, identify areas for improvement, and enhance their ability to provide patient-centered care (PCC). Reflective practices, such as journaling or peer supervision, can help nurses deepen their self-awareness and refine their approach to caring for patients' sexual health.

### Communication Skills

Communication skills are crucial for nurses when caring for patients' sexual health as they facilitate open dialogue, build trust, and ensure that patients feel comfortable discussing sensitive topics. First, nurses should practice active listening, which involves giving the patient their full attention while they are speaking, maintaining eye contact, and providing nonverbal cues to show they are engaged and listening to what the patient is saying. When speaking to the patient, nurses should use clear, nonjudgmental language when discussing sensitive sexual health topics. They should avoid using medical jargon or slang terms that may be confusing to the patient. Using inclusive language promotes open communication and helps the patient feel comfortable asking questions about their sexual health. When communicating with patients, nurses should be sensitive to cultural differences related to sexual health. Culturally sensitive care fosters trust and respect, enhancing the nurse-patient relationship and promoting effective communication.

## LINK TO LEARNING

---

Communication skills are important for all nurses to have, especially when caring for patients experiencing sensitive issues related to their sexual health. This video provides some [therapeutic communication techniques](https://openstax.org/r/77TherapComm) (<https://openstax.org/r/77TherapComm>) that may be helpful to use when communicating with patients about sensitive topics.

---

### Recognize Problems

Nurses can recognize problems when caring for patients' sexual health through various means, including observation, assessment, and collaboration. Nurses can observe patients for physical signs or symptoms that may indicate sexual health problems, such as unusual genital discharge, sores, rashes, or discomfort during urination or sexual activity. Additionally, changes in behavior or mood, such as increased anxiety or depression, may also signal

underlying sexual health concerns. Nurses conduct thorough assessments of patients' sexual health by asking relevant questions about sexual activity, contraception use, sexual function, reproductive history, and any concerns or symptoms they may be experiencing. Assessment tools, such as standardized questionnaires or screening tests for STIs or sexual dysfunction, may also be used to gather comprehensive information. Additionally, nurses collaborate with other healthcare professionals to identify and address complex sexual health problems. Interdisciplinary teamwork allows for comprehensive assessment, diagnosis, and management of patients' sexual health concerns, ensuring that they receive holistic, high-quality care.

## UNFOLDING CASE STUDY

### Unfolding Case Study #5: Part 2

Refer back to [Unfolding Case Study #5: Part 1](#) for a review on the patient data.

Nursing Notes	<b>1035:</b> Patient expresses concern about erectile dysfunction. He reports frustration about being unable to participate fully in sexual intercourse with his wife. He reports his wife is also frustrated with the situation, especially given her new diagnosis of breast cancer. He states, "I don't want to start taking Viagra in my 40s. That's just embarrassing. Surely there is something else I can do. My wife thinks I don't want to have sex with her because she has cancer, which isn't even remotely true. My body is failing me."
------------------	--

4. Generate solutions: The nurse prepares to report the patient's concerns to the treating provider. What interventions does the nurse anticipate the provider might order?
5. Take action: The nurse is getting ready to discuss the use of medications to treat the patient's ED symptoms. Thinking about how the nurse can act as both an educator and a role model, how might the nurse go about handling this conversation?
6. Evaluate outcomes: What are some examples of positive patient outcomes that the nurse should assess for after providing the patient with information about treatment options for his ED symptoms?

## Nurse as a Mandatory Reporter

Mandatory reporting laws require that individuals who have contact with at-risk populations report suspected mistreatment or abuse to proper authorities. At-risk populations are defined as children, individuals with disabilities, and older adults. Examples of mandatory reporters include

- childcare providers,
- clergy,
- coaches,
- counselors,
- teachers,
- law enforcement, and
- healthcare providers, including nurses.

These laws cover several kinds of abuse and mistreatment including physical, sexual, emotional, and financial. For this unit, we will focus on the different types of sexual abuse and mistreatment including sexual discrimination, sexual harassment, and sexual assault.

## REAL RN STORIES

### Mandated Reporting—Sexual Abuse

**Nurse:** Gina, RN

**Clinical setting:** Emergency department

**Years in practice:** 12

**Facility location:** Urban level 1 trauma center in California

It was 10:30 p.m. and I was just about to get off work from my 11a–11p shift in the ER when I saw a distressed couple of teenage girls walk in. I walked over to see what was going on. One of the girls couldn't have been more than 15 years old and was super withdrawn, refusing to make eye contact with me. Her friend told me that she had been sexually assaulted by someone she knew but didn't want to give any other information until they were in a patient room.

I got the girls set up in a triage room and got them a warm blanket and some water. At this point, the girl began to tell me what happened. My heart sank as I listened to her recount how she was at a small party with some of her older friends when one of the male friends pulled her aside and began to touch her inappropriately. She asked him to stop multiple times, but he refused. She said he was able to get her pants off and stuck his penis inside of her. At that point, she completely froze up and felt like she couldn't move. She said, "It's all my fault. I could have fought him off, but my body wouldn't move. I did this to myself." I assured her that it was not her fault at all, but she remained adamant that it was. After letting her finish telling me what happened, I let her know that abuse like this must be reported by law to the authorities. She panicked and said, "What if he finds out that I reported him?" I assured her that the authorities would be able to answer that question more thoroughly but that reports like this can be kept anonymous if she chooses not to press charges.

At this point, I excused myself and made a phone call to speak with a sexual assault nurse examiner (SANE) about the situation. The SANE nurse thanked me for my report and said she would be there in fifteen minutes to conduct an examination and help the patient.

---

### Sexual Discrimination

More commonly called "sex discrimination," **sexual discrimination** refers to when an individual is treated less favorably because of their sex, which includes sexual orientation, gender identity/expression, pregnancy, and any other sex-related stereotypes. In many cases, sexual discrimination occurs in the workplace. Some examples of sexual discrimination include the following:

- refusing to hire or promote an individual because they identify as being Transgender
- creating a hostile work environment through unwelcome sexual advances, comments, or behaviors (e.g., inappropriate jokes, indecent gestures)
- denying access to reproductive healthcare services (such as contraception or abortion) based on their a person's sex or gender
- denying housing to an individual because they are gay

### Sexual Harassment

A specific type of sexual discrimination, **sexual harassment** includes unwelcome sexual advances, requests for sexual favors, and other forms of physical or verbal harassment of a sexual nature in any environment, including online. Some examples of sexual harassment include the following:

- offering a promotion to an individual only if they have sex with the manager first
- jokes about an individual's sexual preferences
- sending unwanted sexual photos, emails, or texts
- touching an individual when the contact is not wanted

### Sexual Assault

A **sexual assault** involves sexual contact or behavior, often physical, that occurs without permission or consent from the victim. Although sexual harassment violates civil laws in many cases, sexual assault violates criminal laws. Like other types of assault, the threat of assault and/or using the threat of assault to force someone to perform or submit to an act can both be considered sexual assault. Examples of sexual assault include

- rape,
- forcing a victim to perform sexual acts, and
- fondling or unwanted sexual touching.

A serious global issue called **sex trafficking** involves the exploitation of individuals through force, fraud, or coercion for the purposes of sexual exploitation. Sex trafficking is deeply intertwined with sexual assault because it involves coercing or forcing individuals into sexual activities against their will or under conditions where consent is not gained. Victims of sex trafficking are often manipulated through threats, deception, or physical force to engage in commercial sex acts for the financial gain of traffickers.

### LINK TO LEARNING

---

Healthcare providers must be acutely aware of the [signs and necessary interventions of sex trafficking](https://openstax.org/r/77SexTraficSign) (<https://openstax.org/r/77SexTraficSign>) to identify and aid potential victims.

---

## Summary

### 33.1 Sexual Identity

Biological sex refers to the sex assigned to an individual at birth, either male or female. However, there are several gender variations because the sex assigned at birth does not always correlate with an individual's feelings about their gender. Society has long dictated that individuals should act according to their biological sex, adhering to the appropriate gender role expression; however, there has been an increase in awareness and understanding of gender identity variations over the years. The same can be said for sexual orientation. Nurses are tasked with remaining knowledgeable and open-minded about these variations in gender identity and sexual orientation to provide high-quality, patient-centered care. Nurses must recognize that all variations are normal, and each individual should be treated with respect for their gender and sexual preferences.

### 33.2 Sexual Fulfillment

Sexual fulfillment, which involves satisfaction and pleasure in sexual relationships, is essential for overall health and well-being. Nurses must address patient sexual concerns with open-mindedness and without judgment, as this promotes holistic care and optimal patient outcomes. Achieving sexual fulfillment varies greatly among individuals and can involve physical and psychological forms of sexual stimulation. Physical stimulation includes activities such as kissing, manual stimulation, and oral stimulation, which involve contact with erogenous zones such as the mouth, ears, and genitals. Psychological stimulation can involve adult media and certain sounds, eliciting arousal without physical contact.

Sexual behavior, aimed at arousal, pleasure, or reproduction, includes both adaptive and maladaptive forms. Adaptive behaviors are healthy and enrich life, such as obtaining consent, communicating needs, respecting boundaries, and practicing safe sex. Maladaptive behaviors, which can be problematic, include pornography addiction, infidelity, and inappropriate touching. Sexual expression encompasses various activities such as masturbation, sexual intercourse, and oral-genital stimulation, each with its own benefits and risks. Understanding these diverse aspects of sexuality is crucial for providing comprehensive and empathetic care.

### 33.3 Factors Affecting Sexuality

Sexuality is a vital component of health that should not be overlooked. Nurses must recognize that there are many factors that can have a profound impact on a patient's sexual health. Certain physiological factors including developmental changes, medical conditions, and use of medications can significantly alter sexual functioning. In addition to physical characteristics, there are many psychological factors that can impact sexual health, including mental health, body image, and stress. Additionally, psychosocial factors such as culture, religion, and lifestyle behaviors have the potential to impact sexual health and well-being. Ethical considerations related to sexuality include the importance of informed consent for sexual activity, recognizing and respecting autonomy related to sexual health decisions, and prioritizing the safety and well-being of all parties involved.

### 33.4 The Nurse's Role in Providing Care

There are many aspects of sexual health that require the nurse to act as an educator, including providing education about STIs, pregnancy, and fertility. Additionally, the nurse serves as a role model when caring for patient's sexual health by understanding human sexuality, practicing self-awareness, communicating effectively, and recognizing potential sexual health problems. In addition to these two roles, nurses also serve as mandated reporters, which means that they are required by law to report suspected sexual abuse or mistreatment of at-risk populations to the proper authorities.

## Key Terms

**abstinence** the practice of refraining from engaging in certain activities or behaviors, such as from sex before marriage

**ambiguous genitalia** genitals that do not look as expected for a male or female

**androgynous** gender expression that does not conform to societal expectations of how males or females should look and/or act

**anilingus** oral sex involving the anus

- aromantic** individuals who do not experience romantic attraction
- asexual** relating to or being an individual who does not experience sexual attraction or has a lack of interest in sexual activity
- biological sex** sex assigned to an individual at birth
- bisexual** relating to or being an individual who acknowledges that they have the potential to be attracted (romantically, emotionally and/or sexually) to people of more than one gender
- chancere** a painless sore associated with a syphilis infection that develops where the organism entered the body
- chromosomes** threadlike structures containing DNA that are located in the nucleus of a cell
- cisgender** relating to or being an individual whose gender identity aligns with the biological sex they were assigned at birth
- congenital adrenal hyperplasia (CAH)** a genetic disorder affecting the adrenal glands that causes an overproduction of sex hormones, resulting in enlarged external female genitalia in infants, early appearances of pubic hair, and acne and rapid growth patterns during adolescence
- cunnilingus** oral sex involving the vagina, vulva, or clitoris
- erogenous zones** areas of the body that trigger sexual arousal when stimulated or touched
- fellatio** oral sex involving the penis
- fertilization** the process in which sperm unites with an egg to form a zygote
- foreplay** intimate physical and emotional interactions that occur before sexual intercourse
- gay** a term used to describe men who are romantically or sexually attracted to other men; also used more broadly to describe individuals of any gender that are attracted to individuals of the same gender
- gender** a social construct that includes norms and behaviors associated with being a man or a woman
- gender binary** a classification of gender into two distinct categories (male and female)
- gender dysphoria** distress experienced by some people when their sex assigned at birth and assumed gender is not the one with which they identify
- gender expansive health care** a care-delivery model that is inclusive and affirming of gender identity
- gender fluid** relating to or being an individual who feels as if they are both male and female either simultaneously or at different times
- gender identity** a person's deeply felt, internal and individual experience of gender, which may or may not correspond to the person's physiology of designated sex at birth
- gender nonbinary** a gender identity that does not fit within the traditional framework of being male or female
- gender nonconforming** relating to or being an individual who displays behaviors or appearances that do not align with societal expectations of their sex assigned at birth
- gender role expression** the way a person communicates their gender to others, such as by clothing, appearance, and mannerisms
- gender roles** strict societal beliefs that define "acceptable" behaviors for each gender
- heterosexual** relating to or being an individual who is sexually attracted to a person of a different gender or sex
- infertility** the inability to conceive a child
- intersex** relating to or being an individual whose chromosomes, hormones, or reproductive or sexual anatomy does not fully align with either male or female
- lesbian** relating to or being a woman who is romantically or sexually attracted to other women
- LGBTQIA+** lesbian, gay, bisexual, transgender, questioning/queer, intersex, asexual, gender diverse, and other identities and orientations
- masturbation** self-stimulation of genitals or other areas of the body for sexual arousal or pleasure
- monogamy** having only one romantic or sexual partner at a time
- oral-genital stimulation (also, oral sex)** the stimulation of an individual's genitals by another individual's mouth, lips, or tongue
- orgasm** a peak of sexual excitement, characterized by intense physical pleasure and a series of involuntary muscle contractions in the genital area
- pornography** materials, such as books, magazines, videos, and websites, that depict explicit sexual content primarily intended to stimulate sexual arousal
- puberty** the stage of development during which physical and sexual maturity occurs and individuals become capable of reproduction
- questioning** referring to a time of exploration and self-discovery about one's sexual orientation, gender identity,

and/or gender expression

**sex chromosomes** a specific pair of chromosomes that determine an individual's biological sex

**sex trafficking** exploitation of individuals through force, fraud, or coercion for the purposes of sexual exploitation

**sexual arousal** the state of being physically and mentally excited by sexual stimuli; involves physiological responses such as increased heart rate, blood flow to the genital areas, lubrication in women, and erections in men

**sexual assault** sexual contact or behavior, often physical, that occurs without permission or consent from the victim

**sexual behavior** acts in which an individual engages to experience sexual arousal, sexual pleasure, orgasm, and/or reproduction of offspring

**sexual discrimination** treatment of an individual less favorably because of their sex, which includes sexual orientation, gender identity/expression, pregnancy, and any other sex-related stereotypes

**sexual dysfunction** difficulty experienced by an individual or a couple during any stage of normal sexual activity, including physical pleasure, desire, preference, arousal, or orgasm

**sexual fulfillment** the state of experiencing satisfaction, pleasure, and contentment in one's sexual relationships

**sexual harassment** unwelcome sexual advances, requests for sexual favors, and other forms of physical or verbal harassment of a sexual nature

**sexual intercourse** penetration of the vagina or anus

**sexual orientation** who an individual is attracted to sexually, emotionally, and/or romantically

**sexual pleasure** enjoyable and satisfying physical and emotional sensations experienced during sexual activity

**sexually transmitted infection (STI)** an infection that is primarily spread through sexual contact

**transgender** relating to or being an individual whose gender identity does not align with the sex assigned to them at birth

**transsexual** relating to or being an individual who uses medical interventions such as hormone therapy or gender-affirming surgeries to align their physical characteristics with their gender identity

## Assessments

### Review Questions

- The nurse is caring for a patient with a biological sex of male. What statement about the individual is accurate?
  - The patient was born with a penis.
  - The patient identifies as male.
  - The patient has XX sex chromosomes.
  - The patient is gay.
- What assessment findings would the nurse anticipate for a patient diagnosed with Klinefelter syndrome?
  - overgrowth of body hair
  - increased breast tissue
  - early menopause
  - enlarged genitalia
- What situation represents an individual who is cisgender?
  - A biological male who identifies as female
  - A male who is gender nonbinary
  - An individual who is gender nonconforming
  - A biological female who identifies as female
- The nurse is caring for a patient who is wearing both masculine and female pieces of clothing, making it difficult for the nurse to ascertain the patient's gender identity. What should the nurse do in order to correctly identify the patient's gender?
  - Assume the patient is female.
  - Ask the patient their gender and preferred pronouns.

- c. Ask the patient's family member when the patient is out of the room.
  - d. Avoid using any gender pronouns at all.
5. What example describes a psychological form of sexual stimulation?
- a. sensual dancing
  - b. giving a back massage
  - c. holding hands
  - d. watching a film
6. What example best exemplifies an adaptive type of sexual behavior?
- a. watching pornography daily
  - b. paying for sex from sex workers
  - c. using appropriate contraceptives
  - d. touching a coworker when they ask not to be touched
7. The nurse is caring for a patient who reports that they do not always use condoms during sexual intercourse with strangers. What would the nurse document this as?
- a. maladaptive behavior
  - b. infidelity
  - c. adaptive behavior
  - d. sexual expression
8. The nurse is describing the effects of masturbation to a patient. What effect would the nurse include in the teaching?
- a. hairy palms
  - b. improved mood
  - c. vision loss
  - d. infertility
9. The nurse is caring for a patient who reports they can only be sexually aroused by watching other people engage in sexual activity. What term would the nurse use to document these findings?
- a. voyeurism
  - b. sadism
  - c. masochism
  - d. sadomasochism
10. What characteristic related to sexual health is most likely to be seen in a young adult patient?
- a. beginning of puberty
  - b. menopause
  - c. chronic illness impacting sexual function
  - d. establishment of sexual identity
11. A 55-year-old patient with a history of diabetes mellitus presents to the clinic complaining of difficulty maintaining an erection during sexual activity. Which pathophysiological mechanism is most likely contributing to his erectile dysfunction?
- a. increased testosterone levels leading to desensitization of penile nerves
  - b. chronic inflammation and damage to blood vessels and nerves
  - c. excessive release of nitric oxide causing vasoconstriction
  - d. hyperactivity of sympathetic nervous system inhibiting sexual arousal
12. The nurse is caring for a patient who has recently been diagnosed with depression. The patient expresses concern about how their diagnosis may affect their sexual health and intimacy with their partner. What statement by the nurse best addresses the patient's concerns?

- a. "Depression typically increases sexual desire and responsiveness, so you may notice an improvement in your sexual health."
  - b. "Depression usually has no impact on sexual health, so you shouldn't worry about any changes in your sexual function."
  - c. "It's common for individuals with depression to experience changes in their sexual desire and responsiveness. We can discuss coping strategies and treatment options to help manage any difficulties you may encounter."
  - d. "You should avoid discussing your concerns about sexual health with your partner, as it may cause unnecessary stress and strain on your relationship."
- 13.** The nurse is providing education to a group of patients about lifestyle factors that can impact sexual health. What statement accurately describes the relationship between diet and nutrition and sexual well-being?
- a. "Maintaining a healthy weight through proper nutrition can prevent conditions such as heart disease and diabetes, which can negatively affect sexual health."
  - b. "Poor nutrition has no significant impact on sexual health."
  - c. "Eating a diet high in saturated fats and sugars can increase libido and sexual arousal."
  - d. "Nutritional supplements have been shown to cure erectile dysfunction and improve sexual performance."
- 14.** The nurse is providing education to a group of adolescents about STIs. What statement by one of the adolescents indicates a need for further education?
- a. "I can tell I have chlamydia if I have a painful rash on my hands and feet."
  - b. "Flu-like symptoms can occur during an outbreak of herpes simplex virus (HSV)."
  - c. "Genital warts are a common symptom of human papillomavirus (HPV)."
  - d. "A chancre, which is a painless sore, is characteristic of syphilis."
- 15.** The nurse is counseling a patient diagnosed with genital herpes simplex virus (HSV). What statement by the patient indicates understanding of the teaching?
- a. "After I take my medication, the herpes virus is gone from my body forever."
  - b. "Herpes involves the development of chancres on my skin."
  - c. "I should avoid sexual contact during an outbreak to prevent transmission."
  - d. "Herpes is caused by a bacterial infection."
- 16.** How can nurses effectively recognize problems when caring for patients' sexual health?
- a. by solely relying on observation of physical signs or symptoms
  - b. by conducting thorough assessments of patients' sexual health and utilizing standardized questionnaires
  - c. by avoiding collaboration with other healthcare professionals to address complex sexual health issues
  - d. by focusing solely on the patient's verbal communication about sexual concerns
- 17.** A nurse working in a pediatric clinic suspects sexual abuse in a child based on physical signs observed during an assessment. What is the nurse's appropriate action in accordance with mandatory reporting laws?
- a. Refer the child to counseling services for further evaluation.
  - b. Document the findings and inform the child's caregiver.
  - c. Report the suspected abuse to the appropriate authorities as mandated by law.
  - d. Conduct further assessments to confirm the suspicion before taking any action.
- 18.** What would you recognize as an example of sexual assault?
- a. attempted rape
  - b. making lewd jokes
  - c. denying a promotion based on gender
  - d. sending a nude photo

## Check Your Understanding Questions

1. What is the difference between biological sex and gender identity?
2. What terms related to gender identity and sexual orientation should be used only after an individual has used them to classify themselves to avoid using offensive language?
3. What is sexual expression and why is it important for sexual fulfillment?
4. What are some of the common side effects of medications that impact sexual health and functioning?
5. What is the difference between sexual harassment and sexual assault?

## Reflection Questions

1. How would you provide care to a Transgender patient? Would you do anything different as compared to caring for a cisgender patient?
2. How do you think traditional gender roles can play a role in the development of gender dysphoria?
3. You're caring for a Transgender male patient and overhear another staff member saying something inappropriate about their gender identity. How would you handle the situation?
4. What do you think might cause an individual to display maladaptive behaviors?
5. You are caring for a patient who reports they like to engage in asphyxiation (intentional restriction of oxygen to a sexual partner's brain, often through choking). What should you do?
6. What effects do you think social media can have on body image and sexual health?
7. An unwanted pregnancy can be scary and cause severe anxiety. What are some strategies you could use when discussing a positive pregnancy test with a patient who did not wish to become pregnant?
8. Think about how you might use self-awareness when caring for a patient's sexual health and provide an example.

## Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #5: Part 1](#).  
If the patient from the case study also reported that he was experiencing a lot of stress at his job, how might that be contributing to his ED symptoms?
2. Refer to [Unfolding Case Study #5: Part 2](#).  
In addition to ED symptoms, the patient also reports a new onset of painful urination and increased urinary frequency. The treating provider orders several STI tests. Based on the symptoms, which type of STI should the nurse suspect?

## What Should the Nurse Do?

1. The nurse suspects sexual abuse of an older adult patient. What should the nurse do?
2. A nurse who is pregnant has just received word that she was not hired for a nursing job that she recently interviewed for. She has reason to believe that she was not hired because she is pregnant. What should the nurse do?

## Competency-Based Assessments

1. Write a sample nurse-patient dialogue that displays respect for the patient while obtaining their gender identity and sexual orientation.
2. Create a patient pamphlet that compares adaptive and maladaptive sexual behaviors.
3. Write a script between a nurse and a patient that addresses mental health or body image issues that the patient is experiencing that are negatively affecting their sexual health.

## CHAPTER 34

# Stress, Adaptation, and Homeostasis

**FIGURE 34.1** Stressful circumstances and experiences can manifest in various ways, including nervousness, anxiety, difficulty coping, and strained relationships. (credit: modification of “Canva - Woman Feeling Emotional Stress” by “MismibaTinashMadando”/Wikimedia Commons, CC BY 1.0)

### CHAPTER OUTLINE

- 34.1 Stress and Adaptation
- 34.2 Effects of Stress on Health and Wellness
- 34.3 Factors Affecting Stress and Adaptation
- 34.4 Adaptation Theories and Models

**INTRODUCTION** For nurses, stress can be beneficial in providing patient care: it provides an edge of vigilance while managing all the facets of caring for patients who are at their sickest and in the most chaotic circumstances. Stress can have a negative effect on patient health, contributing to pathophysiological changes and causing problems, possibly even mortality.

Stress happens for a variety of reasons in all sorts of settings. Whether the stress response is helpful or a contributor to harmful changes depends on the individual’s response to the stressor. In stressful situations, the body responds by releasing certain chemicals in an effort to provide the necessary physiological tools to confront whatever the challenge is. Those who manage stress in a positive manner ultimately tend to feel a sense of accomplishment; when stress is managed poorly, and especially in the setting of chronicity, those same signs and symptoms can cause detrimental changes.

## 34.1 Stress and Adaptation

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the experience of stress
- Recognize concepts of stress and adaptation that affect health
- Describe the maintenance of physiological and psychological homeostasis

A physiological response by the body to a stimulus, or **stressor**, is called **stress**. The physiological changes involved in the stress response can be beneficial, life sustaining, and lifesaving, particularly in the face of danger. Acute stressful events are short lived, with prompt resolution and return to a steady state with little or no long-lasting results. Chronic stress, on the other hand, involves sustained effects of the stress response and no relief from the stimulated sympathetic nervous system, which can be detrimental to health.

The stress response, including its activation and subsequent resolution (or not), is a complex process involving multiple body systems, with resultant normal or pathophysiological changes. This module delves more deeply into the experience of stress: the normal response, positive reactions to it, including effective **adaptation** (the body's changes in response to stress), and negative results that can cause health problems. The body has an innate drive for **homeostasis**, or physiological balance. Stress can support or challenge this steady state.

### Experience of Stress

People experience stress in different ways, based on factors such as past experiences, support systems, and overall attitudes. Whether the stress is from something perceived as positive or negative, however, the physiological responses involve the same basic chemical actions and reactions ([Figure 34.2](#)).

- When a person recognizes a stressor, their hypothalamus releases corticotropin-releasing hormone (CRH), which causes the anterior pituitary gland to secrete adrenocorticotropic hormone (ACTH).
- The ACTH causes the adrenal glands to release corticosteroids, most notably cortisol (a glucocorticoid), and to activate the autonomic nervous system (ANS), specifically the sympathetic nervous system (SNS).
- The SNS releases catecholamines: norepinephrine (noradrenalin), epinephrine (adrenaline), and dopamine. These chemicals generate the fight-or-flight response: heart rate and blood pressure increase, bronchioles dilate, and glycogen in the liver is converted to glucose.

Under normal circumstances, when the stressor has been resolved, the effects of SNS stimulation are opposed by its counterpart, the parasympathetic nervous system (PSNS). The stress hormones dissipate, and body processes normalize.

**FIGURE 34.2** The stress response begins with the release of corticotropin-releasing hormone (CRH) and adrenocorticotropic hormone (ACTH), triggering the secretion of corticosteroids and generating the fight-or-flight response. (credit: modification of “Response to stress” by Campos-Rodríguez R, Godínez-Victoria M, Abarca-Rojano E, Pacheco-Yépez J, Reyna-Garfias H, Barbosa-Cabrera RE, Drago-Serrano ME/ Wikimedia Commons, CC BY 3.0)

### Distress

Stress that is perceived negatively is called **distress**. It manifests in many ways, including **anxiety** (a feeling of unease, worry, or nervousness), sadness, pain, and varied vague symptoms that make isolating the cause difficult. The signs and symptoms of stress are similar to those of a stimulated SNS, such as tachycardia, hypertension (HTN), tachypnea, bronchiole and pupillary dilation, and release of glucose. Distress may be acute and relative to a particular event, such as a frightening encounter. Other causes of acute distress may include temporary illness or injury and the feelings of loss when a friend moves away.

Chronic stress develops when the distress is long lasting and unresolved. Medically, chronicity refers to something that develops slowly and is apt to worsen over time (Whitlock, 2023). Chronic stress tends to be responsible for the negative physiological changes associated with the stress experience, such as chronic occurrences of HTN, gastrointestinal upset, anxiety disorder, and heart failure (HF). Chronic distress can also damage or reduce the function of various body systems, including the immune system, increasing the risk of infection or autoimmune disorders. People who do not have supportive systems of family or friends are more prone to chronic stress, as a caring environment and positive relationships decrease levels of stress hormones.

### UNFOLDING CASE STUDY

#### Unfolding Case Study #5: Part 3

Refer to [Chapter 33 Sexuality](#) for Unfolding Case Study Parts 1 and 2 to review the patient data. Mr. Morales, a 46-year-old male, is being seen in the clinic for an annual wellness examination. During the examination, Mr.

Morales reports that he has been having trouble achieving and maintaining erections during sex. He states, “My wife is getting frustrated and so am I. I’m not even that old yet. Why is this happening to me?”

Past Medical History	<p><b>Medical history:</b> Type 2 diabetes, hypertension, depression</p> <p><b>Family history:</b> Both parents alive and well, mother has hypertension and depression</p> <p><b>Social history:</b> Married twenty years, two teenage children. Wife recently diagnosed with breast cancer.</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Fluoxetine (Prozac) 20 mg PO daily</li> <li>• Metoprolol (Lopressor) 50 mg PO twice daily</li> </ul>
Assessment	<p><b>1000:</b></p> <p><b>Neurological:</b> Alert and oriented x4</p> <p><b>Respiratory:</b> Clear lung sounds, normal breathing pattern</p> <p><b>Cardiovascular:</b> Tachycardia, bounding pulses, trace edema noted in bilateral lower extremities</p> <p><b>Abdominal:</b> Bowel sounds present in all four quadrants, no pain or tenderness noted</p> <p><b>Musculoskeletal:</b> Full range of motion in all joints, bilateral muscle strength of extremities equal</p> <p><b>Integumentary:</b> Skin warm, dry, and intact</p>
Flow Chart	<p><b>1030:</b></p> <p>Blood pressure: 155/92 mm Hg</p> <p>Heart rate: 103 beats/min</p> <p>Respiratory rate: 20 breaths/min</p> <p>Temperature: 98°F (36.6°C)</p> <p>Oxygen saturation: 99 percent on room air</p> <p>Pain: No pain reported at this time</p>
Nursing Notes	<p><b>1035:</b></p> <p>Patient expresses concern about erectile dysfunction (ED). He reports frustration about being unable to participate fully in sexual intercourse with his wife. He reports his wife is also frustrated with the situation, especially given her new diagnosis of breast cancer. He states, “I don’t want to start taking Viagra in my 40s. That’s just embarrassing. Surely there is something else I can do. My wife thinks I don’t want to have sex with her because she has cancer, which isn’t even remotely true. My body is failing me.” When asked about other potential contributing factors, patient reports experiencing a significant amount of stress at work lately, and worry about how he will afford his wife’s cancer treatments.</p>

1. Recognize cues: Based on the assessment findings and nursing notes, what cues are the most important for the nurse to recognize?
2. Analyze cues: What physiological effects might the patient be experiencing due to his recent reported stress?

### Eustress

Positive stress, or **eustress**, is stress that initiates a positive response or feeling. Whether a person experiences eustress or distress typically depends on their perception of the stressor, which may itself reflect personality and attitude toward the stressor. Persons who are naturally optimistic tend to perceive stressful events positively, as opportunities for growth. In contrast, pessimists tend to assume stressful events will have negative outcomes, leading to distress (Conde Moreno & Ramalheira, 2022; Lindberg, 2019; Moore, 2019; Villines, 2024).

## LINK TO LEARNING

This video describes [eustress \(https://openstax.org/r/77Eustress\)](https://openstax.org/r/77Eustress) or positive stress. As you watch it, think of examples of positive stressors you have encountered and how they made you feel.

The experience of eustress is essential for healthy development, as it supports the brain's ability to respond to events in beneficial ways. The source of eustress may be psychological or physiological, and results tend to be constructive, with associated feelings of accomplishment and excitement. For example, think of a student studying for an exam they are confident they will pass; an exam is a stressor, but the student's positive perception converts the stress into energy, excitement, and focus. These positive effects are episodic and short lived, without long-term, harmful effects, so eustress is associated with acuity. [Figure 34.3](#) contrasts eustress and distress.

**FIGURE 34.3** Eustress is stress that elicits a transient, positive feeling or response. Distress describes negative stress and can be either acute or chronic. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## Concepts of Stress and Adaptation

An individual's ability to cope with stress allows for adaptive results. These may be effective, promoting health and wellness, or ineffective, causing unhealthy behaviors. Adaptation includes the body's own physiological changes following exposure to a stressor. These adaptive changes are necessary for survival and ultimately a return to homeostasis; however, individuals can also play a more active role in adaptation by learning and practicing stress management techniques and coping strategies.

### Stressors

When a person is threatened or senses looming danger, that threat or danger is perceived consciously or subconsciously as a stressor. Stressors can be categorized by the extent to which they involve substantial changes in one's life: are they catastrophic events, frequent annoyances, or the various irritations and inconveniences that are omnipresent in daily life? Significant life changes are not necessarily negative; they can be joyful or represent the achievement of a goal. For example, a new job or promotion is typically a welcome change that comes with benefits such as increased income, but it also entails additional responsibilities and stress ([Table 34.1](#)). Stressors can be physical or psychological or both.

Type of Stressor	Examples
Significant life change	Marriage, divorce, new job, loss of job, move, birth or adoption of a child, injury/illness/surgery, death of a loved one or friend, change of school or political environment
Catastrophic event	Natural disaster (hurricane, tornado, blizzard, volcanic eruption, forest fire), act of war, life-threatening illness or injury, mental health crisis
Frequent annoyances	Heavy traffic, weather change, equipment malfunctions, changes to plans, forgetting lunch, running out of gas, experiencing a flat tire
Omnipresent irritations	Smog, bad roads or walking paths, distance to school or work

**TABLE 34.1** Stressors

### Physiological Stressors

Physiological stressors are physical stimuli that initiate the body's innate stress response. The following are some examples of physiological stressors:

- illness or injury
- malnutrition
- temperature extremes
- pain

Nursing care and anticipated treatment orders for physiological stressors focus on relieving symptoms and restoring homeostasis. Considering the listed items, restoration of homeostasis is attempted by treating the particular illness or injury, initiating parenteral feedings, avoiding or preparing for extreme temperatures, and implementing treatment for pain.

## PATIENT CONVERSATIONS

### Nursing Care for Physiological Stressors

**Scenario:** Mrs. Feldman has come to the emergency department because she's had "stomach flu" for two days, and she's feeling very weak. She's been vomiting several times a day, and can't even keep down sips of water or ginger ale. After the emergency physician has entered orders, the nurse returns to the patient's room with a medication and syringe.

**Nurse:** Mrs. Feldman, you've been throwing up so much, you're very dehydrated. Now, one of the problems is you can't have anything to drink right now, or you'll just keep throwing up.

**Patient:** I'm so miserable.

**Nurse:** I'll bet you are. The medication I brought for you should help you feel better soon. It's called ondansetron, and it is injected into your IV so you don't have to drink or swallow anything. It should help you stop throwing up.

**Patient:** Good. I've been vomiting so much, my throat burns.

**Nurse:** I can ask the doctor for some lozenges to soothe your throat. The vomit has acid in it, so it's no wonder your throat feels burned. Meanwhile, I've been worried about your blood pressure. You're so dry, your blood pressure has been low. Because you can't drink, you're getting what's called a "bolus" of IV fluid, to replace some of what's been lost. Once that finishes, I'll restart your other IV, with more fluids and also the electrolytes and some glucose (sugar) you need.

**Patient:** I can't wait to feel better. I even feel a bit dizzy when I sit up.

**Nurse:** That doesn't surprise me. When you're dehydrated like this, your blood pressure can drop too low when you

change positions: like sitting up after lying down or standing up after sitting or lying down. So, I want you to make changes like that very slowly. And when some of this fluid starts to work, you'll need to pee. I don't want you to go all the way to the bathroom, though, so I'll bring a commode and put it next to your bed. Don't get up by yourself. Here's your call light. You need to have your nursing assistant, Sean, or me here to help you to the commode.

**Patient:** Okay. I'll call when I feel I need to pee.

**Nurse:** I'll be back in about fifteen minutes. Your bolus IV should finish up about then, and I want to see if you're feeling a little better when that's done.

### Psychosocial Stressors

Stressors can also have psychosocial origins. While psychosocial stressors are rooted in a psychological threat and subsequent imbalance, the same physiological results associated with the stress response occur as when the source is a physical stressor. The following are some examples of psychosocial stressors:

- grief
- job pressure/job loss
- addiction
- interpersonal strain or conflict
- mental illness
- ineffective coping

Consider this situation: a person is experiencing cravings for a particular addictive substance but is unable to acquire the substance and fulfill the need. Psychosocial stressors for this patient include mental health diagnoses, including ineffective coping and addiction. Because of the inability to access the desired substance of abuse, the patient experiences a withdrawal syndrome, which initiates a physiological stress response, such as tachycardia, HTN, and anxiety.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Prioritize a Hypothesis: Alcohol Withdrawal

A patient came to the day surgery for a laparoscopic cholecystectomy. The patient experienced more blood loss than anticipated and was admitted to the surgical floor to receive fluid bolus and blood transfusion. The patient normally drinks eight to ten beers or four to five vodka tonics each evening; however, because of preoperative nausea and abdominal pain, he had not consumed alcohol for two days prior to admission. Today is postoperative day two, and the patient tells the nurse he "feels a little nervous." His hands are shaky. The patient describes his pain as four on a zero to ten scale. The nurse reviews the chart and finds vital signs are as follows:

- temperature: 99.3°F (37.4°C)
- heart rate: 118 beats/min
- blood pressure: 196/124 mm Hg
- respiratory rate: 23 breaths/min
- oxygen saturation: 96 percent on room air

The nurse considers each vital sign and concludes that since the patient's last alcoholic beverage was almost four days ago, the low-grade fever, tachycardia, slight tachypnea, and hypertension are likely physiological indicators that he is withdrawing from alcohol. The patient's nervousness is a psychological indication of rising anxiety, also likely related to alcohol withdrawal. At this point, however, the nurse is most concerned about the patient's blood pressure.

Knowing that the patient's body is responding to the stress of a withdrawal syndrome, the nurse plans to call the healthcare provider to update on current physical and mental status. The nurse anticipates orders for IV hydralazine to bring the blood pressure down. Also, the nurse will ask about starting the alcohol withdrawal protocol, using the Clinical Institute Withdrawal Assessment for Alcohol (CIWA) scale for objective monitoring, and obtaining a prescription for chlordiazepoxide to help with the psychobiological factors of alcohol addiction

and withdrawal.

Because there are physiological signs and symptoms occurring because of substance use and withdrawal, they have to be addressed as part of the treatment plan, along with psychosocial therapies. Psychosocial treatment may include mental health and behavioral therapy to directly address appropriate diagnoses and improve coping skills, as well as medications to support psychosocial treatment and prevent and/or treat withdrawal syndrome.

### Adaptation

Adaptation describes the body's response to stress. Some of these changes are positive and result in the development of effective coping mechanisms and resilience. However, sometimes the body adapts to stress in negative ways, leading to sustained stress responses and development of chronic disorders.

Because adaptation can be adaptive and effective or maladaptive and ineffective, the focus of nursing care is to help patients adapt to stress in positive ways that lead to healthy changes. Nurses play key roles in helping patients identify stress and stressors, minimize maladaptive behaviors, learn coping skills, and increase effective adaptation.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Generate Solutions: Alcohol Withdrawal

Continue to consider the patient withdrawing from alcohol.

What are the desired outcomes?

- Patient will report feeling less nervous.
- Patient's blood pressure will be maintained at less than 140/80.
- Patient's pain will continue to be adequately controlled with PO analgesics.

What interventions can achieve those outcomes?

- Chlordiazepoxide: 75 mg PO; to be increased per prescription order if needed, based on the CIWA protocol
- Hydralazine: 20 mg IV bolus
- Ibuprofen: 800 mg PO Q8 hours

### Maintenance of Homeostasis

Homeostasis describes a steady, balanced, or uniform state in the body. This equilibrium is desirable, and the body tries to return to it when it is challenged and taken off-balance. Activation of the SNS by stress disrupts the steady state that is homeostasis. When nurses treat stressed patients, what they are mainly treating are symptoms of alterations to homeostasis, as well as the body's compensatory mechanisms as it attempts to resolve the perceived threats and return to a steady, stable state.

The process of the body making ongoing changes in response to stress is called **allostasis** (Guidi et al., 2021). These adaptive processes involve frequent physiological adjustments when a loss of equilibrium has occurred in order to reestablish and sustain normal function. Effective adaptations result in positive coping and outcomes representative of a return to homeostasis. While healthy function involves regular adjustments to the body's internal environment, recurrent stress leads to chronic effects of the stress response and maladaptive physical alterations from normal (Figure 34.4).

**FIGURE 34.4** When stressful events build up, allostasis occurs. (Abbreviations: BMI, body mass index; CRP, C-reactive protein; DBP, diastolic blood pressure; DHEA, dehydroepiandrosterone; HR, heart rate; HRV, heart rate variability; SBP, systolic blood pressure; WHR, waist-to-hip ratio.) (modification of "Allostatic load sketch" by "Jwdietrich2"/Wikimedia Commons, CC BY 4.0)

### Physiological Homeostasis

Physiological homeostasis is a state of equilibrium in which the body's physical systems are in balance. When the body is not in a state of homeostasis, it initiates feedback mechanisms intended to return the body to equilibrium. The feedback can be negative or positive, depending on what factor is out of normal range and whether it is high or low. An example of negative feedback is hypotension. When the brain receives signals that blood pressure is too low, it initiates the stress response, releasing the hormone cortisol and the catecholamines epinephrine and norepinephrine. These cause vasoconstriction and tachycardia, thereby raising blood pressure and cardiac output. In addition, the release of the mineralocorticoid aldosterone causes the body to retain sodium and, therefore, water, improving the fluid volume deficit.

Another example of negative feedback is the opposite situation: hypertension. Under normal circumstances, elevated blood pressure causes responses such as vasodilation, to expand blood vessels, and increased urinary excretion, thereby decreasing blood pressure and returning the body to homeostasis.

### LINK TO LEARNING

This video explains [homeostasis and feedback mechanisms \(https://openstax.org/r/77Homeostasis\)](https://openstax.org/r/77Homeostasis) in the body. While the previous examples about hypotension and hypertension both involve negative feedback, the video also illustrates positive feedback.

### Local Adaptation Syndrome

To this point, this chapter has explained the stress response as a generalized reaction involving organs, neurotransmitters, hormones, and systemic results. This whole-body response to stress is known as the general adaptation syndrome (GAS). The stress response can also be isolated to a particular region, and when this is the case, it is called the local adaptation syndrome (LAS). The GAS is discussed in more depth in [34.4 Adaptation Theories and Models](#).

The generalized and localized syndromes respond similarly to stressors, although there are differences besides locality or extent of reaction. Essentially, the LAS is a smaller version of the GAS, in which the body attempts to minimize the negative effects of stress by isolating it. In either case, the ideal response is adaptive, with a return to homeostasis. In certain circumstances, the response may become so severe that it results in the systemic effects of the GAS. The LAS tends to be associated with reflex reactions and the inflammatory processes described in the following paragraphs.

### Reflex Pain Response

Reflex responses are an example of the LAS in which the central nervous system reacts to pain. The reflex arc allows the central nervous system to bypass the longer, normal processes involved in coordination of movement by the neuromuscular system. While the conscious processes of muscle movement may not appear to take much time, the reflex response further minimizes reaction time, allowing for a nearly immediate, involuntary, and protective reaction (Figure 34.5).

**FIGURE 34.5** The reflex arc involves a painful stimulus (stressor), which causes a sensory response in a sensory nerve, which travels to the spinal cord, then through a connector neuron, and on to a motor nerve, which stimulates the effector muscle(s) to remove the body from the stressor. (photo: modification of “The pain is brutal for these Marines 150306-M-IN448-048” by Sgt. Matthew Callahan/Wikimedia Commons, Public Domain; illustration: attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Inflammatory Response

The LAS is closely associated with the inflammatory process. Stressors tend to cause inflammatory agents to be produced, and the stress responses (GAS and LAS) involve production of anti-inflammatory chemicals, including the powerful glucocorticoids. The five cardinal signs of inflammation (erythema, edema, warmth, pain, and loss of function) are integral in the protective and adaptive reactions that prevent further injury and aid return to homeostasis.

Examples of stressors that can cause an LAS reaction include injuries like lacerations, which involve bleeding and subsequent clotting. The injury, like a small razor cut, initiates the LAS (or if large, the GAS). Signs of inflammation often quickly include pain, erythema, sometimes some loss of function, and edema soon after. Internal responses

include vasoconstriction and the clotting process, both of which help minimize bleeding. Healing responses close the wound and form scar tissue. Vasoconstriction, clotting, and wound repair are restorative processes of the LAS. The GAS produces a larger inflammatory reaction. Such systemic responses are seen in disorders categorized by immune or autoimmune diagnoses.

Selye (1956/1976) describes the LAS reaction triggering the inflammatory process in response to invasion and infection by mycobacterium tuberculosis (TB): the inflammatory response as stimulated by the LAS creates a physical barrier around a collection of the bacteria, isolating and preventing their spread (latent TB). While this process relative to TB is not flawless, as it does not always trap and confine all the bacteria, the body's own response to the bacterial assault is remarkable.

### Psychological Homeostasis

Homeostasis is also helpful in maintaining psychological well-being and avoiding stress. Whether the impetus for activation of the stress response is a physical or mental stressor, the resultant release of catecholamines, steroids, and other chemicals is the same. The stressor initiates the stress response, and if not relieved, development of adaptation-related disorders becomes a risk. The mechanisms for restoring homeostasis after psychological stressors initiate a stress response may be either psychological or physical. The following paragraphs discuss the relationship between the mind and body, anxiety, coping and defense mechanisms, and the fight-or-flight response, as ways of restoring homeostasis.

### Mind-Body Interaction

The actions and interactions of the mind and the body are complex. It can also be challenging to describe where each begins and ends in relation to the other. The stress response is a perfect example of such a close relationship between the two body systems, as a stressor initially affecting either the mind or the body will result in the same cascade of physiological events. Dr. Jean Watson (2024) has been involved in the development of Caring Science in nursing, and in understanding the relationship between mind, body, and spirit. Dr. Watson connects these aspects of the person as a whole and relates the three components so closely as to connect them in written form, without spaces, as “mindbodyspirit.”

When the stressor is psychological, there may be initial signs and symptoms of mental distress, such as anxiety (discussed further in the next section), even before the SNS response may also present with some of the same manifestations. Signs and symptoms of exposure to a psychological stressor may conversely appear as physical, in the form of anginal chest pain or gastrointestinal upset, for example. Effective adaptation may involve both the mind and body (and potentially spirit) through behavioral and cognitive stress management efforts, in conjunction with physiological therapies as indicated. An example of such coordinated efforts of restoring homeostatic balance is a patient who experiences a psychotic crisis episode, with symptoms reflecting a loss of connection from reality. Psychotic symptoms may include disordered thoughts and actions and hallucinations, as well as physical symptoms. Physical symptoms reflect the patient's experiences of psychosis, so if the patient is experiencing upsetting and anxiety-producing events, vital signs are apt to demonstrate stress.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Patient-Centered Care

**Definition:** Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs (QSEN, 2022).

The PCC Competency (QSEN, 2022) Knowledge (K), Skills (S), and Attitudes (A) are exemplified through a patient scenario.

The patient is brought to the emergency department by ambulance after being found walking naked on a main shopping street at 0315. Vital signs:

- temperature: 96.5°F (35.7°C)
- heart rate: 124 beats/min
- blood pressure: 206/124 mm Hg

- respiration rate: 22 breaths/min
- oxygen saturation: 97 percent on room air

Labs: Positive for cocaine, methamphetamine, and tetrahydrocannabinol (THC). Complete Blood Count: normal. Comprehensive Metabolic Panel: pending.

**Knowledge:** “Demonstrate comprehensive understanding of the concepts of pain and suffering, including physiologic models of pain and comfort” (QSEN, 2022).

- Psychobiological effects of use of stimulant and depressant drugs
- Priority symptoms:
  - Malignant HTN
  - Hypothermia
  - Tachycardia

**Skills:** “Assess presence and extent of pain and suffering” and “Assess levels of physical and emotional comfort” (QSEN, 2022).

- Urgent focused physical and emotional assessment, followed by comprehensive assessment when stable.

**Attitude:** “Appreciate the role of the nurse in relief of all types and sources of pain or suffering” (QSEN, 2022).

- Restore psychological and physiological homeostasis
  - Hydralazine to lower blood pressure
  - Warm room and blankets to raise temperature
  - Case management for available resources
  - Psych consult for longer-term treatment
    - Inpatient versus outpatient substance use treatment
    - Appropriate mental health drug therapy

---

## Anxiety

A certain level of occasional anxiety is considered normal and can be protective. Anxiety may also occur as a result of the stress response. Some symptoms of anxiety as a stress response include feelings of nervousness, restlessness, impending doom, hyperventilation, tachycardia, difficulty focusing, gastrointestinal upset, and insomnia.

Anxiety disorders are associated with intense manifestations of fear and anxiousness, or even extreme anxiety referred to as panic (Cleveland Clinic, 2020). Anxiety can therefore be its own mental health disorder and stressor, or a symptomatic result of another stressor and the stress response. While there is still some mystery to the etiology of anxiety disorders, there are some people who are more liable to be affected by it, and certain events can contribute to anxiety (Cleveland Clinic, 2020). Family history of anxiety disorder is also important as a potential contributor to occurrence of an anxiety disorder, as there is often a familial pattern to its diagnosis.

Certain medical diagnoses are associated with occurrence of anxiety. These medical problems include chronic obstructive pulmonary disease (COPD), heart disease and HTN, gastrointestinal symptoms, and chronic pain syndrome (Cherney, 2023). Patients who are experiencing a critical physical episode, such as myocardial infarction, often have a feeling of impending doom. Patients with COPD who are in the midst of a severe exacerbation of the disease are also usually very anxious, as air hunger is a frightening experience. These patients frequently do not have any personal or family history of anxiety. It is physiologically stress-induced, with the disease process as stressor.

## LINK TO LEARNING

The Anxiety Network’s suggestions for [statements to assist with various circumstances when anxiety is likely](https://openstax.org/r/77AnxietyStatment) (<https://openstax.org/r/77AnxietyStatment>) may help you with patients, and they may be personally helpful for you as well.

## Coping

An adaptive mechanism for managing stress is known as **coping**, which can reflect effective adaptation or ineffective, maladaptive results. Coping encompasses adaptations in both the cognitive and behavioral realms that help people decrease negative emotions such as sadness, anger, or fear (Wilson, 2023). People begin to develop coping strategies from early exposures to stress and build on such techniques with subsequent stressful experiences. Because negative consequences of stress are often cumulative, they emerge after repeated, chronic experiences. Adaptation-related disease processes are typically exemplified by chronic illnesses such as HTN, DM, and COPD, although children can also develop problems related to maladaptive coping.

Early childhood is an optimal time for positive coping mechanisms to be identified, encouraged, and developed. However, there are many circumstances and many children for whom such an environment is not present. Adverse childhood experiences (ACEs) involve stress responses that begin in childhood and, for many affected without appropriate, effective interventions, potentially lead to a multitude of health problems.

## LINK TO LEARNING

In this video, California's Surgeon General [Dr. Nadine Burke Harris explains more about ACEs \(https://openstax.org/r/77Nadine\)](https://openstax.org/r/77Nadine) and discusses their effects. Pay particular attention to the significance of these experiences, her recommendations for screening, and her goals for prevention.

During stressful situations, nurses can work with patients and their families to set goals as a coping mechanism. Patients may need help realizing that some behaviors are contrary to their effective adaptation, and they may benefit from counseling regarding changes from maladaptive actions toward positive coping strategies.

Wilson (2023) identified several mechanisms for positive coping, which include the following:

- sincerity
- openness
- optimism
- resilience
- establishing and using social support systems

There are many strategies recommended for developing positive coping skills. Of course, the choice of method(s) should be individualized. Coping, like stress, is not one-size-fits-all. Some strategies identified include the following (Peterson, 2021; Wilson, 2023):

- Participate in active relaxation.
- Regulate emotions.
- Rethink how stressors are approached.
- Create supportive interpersonal relationships.
- Reframe emotions through positive self-talk.
- Seek positive activities.
- Participate in religious/spiritual routines.

Certain behaviors are considered maladaptive, and nurses can assist patients in identifying them, as well as guiding them to change the negative coping strategies to techniques more likely to have positive outcomes. Patients' goals are rarely intentionally focused on deleterious behaviors; the ineffective strategies may have been developed years previously and subconsciously continued to develop over time. Following are some examples of maladaptive coping mechanisms:

- avoidance
- procrastination
- self-harm
- anorexia or bulimia nervosa
- risky behaviors
- self-deprecation

### Defense Mechanisms

In the animal world, defense mechanisms are naturally occurring physical or behavioral traits that offer protection or safety from threats. Some translate to human defenses and reactions to stressors. An example is changing one's size—to make oneself appear larger or smaller than normal in order to present a more alarming presence or hide. Another example in some species is to live in a herd; for humans, being surrounded by a community or support group is a similar protective mechanism.

The purpose of defensive mechanisms as a means of coping is protection, in this case, from anxious feelings, self-esteem challenges, and events or experiences the person does not want to face or directly cope with (Cherry, 2022). Defense mechanisms may be effectively adaptive, although they are often related to maladaptation, or unhealthy behaviors. Higher-level adaptation, associated with positive coping, may be found with sublimation, suppression, humor, and altruism. Certain methods avoid maladaptive results and thereby assist in restoring homeostasis (Cherry, 2022). These include improved self-awareness, establishing and using effective coping strategies, and seeking mental health care if and when needed ([Table 34.2](#)).

Defense Mechanism	Description	Example
Acting out	Avoiding feelings by not acknowledging or sharing them but instead displaying the feelings through actions	Avoiding verbal confrontation by pounding fists on a table, or head on a wall
Altruism	Avoiding feelings by lack of direct acknowledgment; helping others as a way of satisfying internal needs	Volunteering at a preschool as a way to alleviate low self-esteem
Avoidance	Not facing a situation, person, or item by minimizing encounters	Refusing to return to a room where a negative experience occurred
Compensation	Overachievement of a strength to compensate for a weakness or failure	Excessive efforts in mathematics to compensate for poor understanding of grammar
Denial	Denying an event or item's existence	A person who has experienced abuse as a child denies that it happened
Displacement	Assigning emotions (e.g., anger) to a person or object other than the focus of the emotion	Kicking a pet after an argument with a spouse
Dissociation	Separating oneself from a negative or stressful experience	A person does not recall the events after being the victim of a sexual assault
Fantasy	Avoiding reality by retreating to a self-created inner, fictional reality	Creation and inhabitation of a self-world, away from specific stressor(s)
Humor	Identifying humorous facets of an experience	Making a joke during a crisis situation

**TABLE 34.2** Defense Mechanisms

Defense Mechanism	Description	Example
Intellectualization	Avoiding emotional response for extreme intellectual pursuit and/or understanding	Performing excessive research into a particular diagnosis to avoid personal connection to it
Projection	Transferring certain qualities to another person	Feeling inadequate in caring for children and older adult parents, but criticizing one's sibling for not regularly visiting parents
Rationalization	Justifying behavior with a logical explanation	Being fired from a job and explaining that the "boss had it out for me all along"
Regression	Returning to behaviors of the past	A school-age child sucking their thumb
Repression	Subconsciously removing negative experience(s) from consciousness	Not recollecting a traumatic car accident

**TABLE 34.2** Defense Mechanisms

### Fight-or-Flight Response

When someone is said to have a rush of adrenaline, the image of bungee jumpers or skydivers usually comes to mind. But adrenaline, also known as epinephrine, is an important chemical in coordinating the body's fight-or-flight response. To respond to a threat—to fight or to run away—the sympathetic system causes divergent effects as many different effector organs are activated together for a common purpose. More oxygen needs to be inhaled and delivered to skeletal muscle. The respiratory, cardiovascular, and musculoskeletal systems are all activated together. Additionally, sweating keeps the excess heat that comes from muscle contraction from causing the body to overheat. The digestive system shuts down so that blood is not absorbing nutrients when it should be delivering oxygen to skeletal muscles.

How extreme the responses are differs based on the perceived significance and danger of the stressor. Someone whose resistance and resilience abilities are diminished by underdeveloped coping skills or constant stressful assaults may be overwhelmed by a stressor that a person with better coping skills would find a minor inconvenience. A stress response may also be consciously acknowledged or remain unrecognized. Patients who can recognize physical signs of stress are able to actively attempt behavior modifications to reduce stress and minimize negative results ([Figure 34.6](#)). Unrecognized stress and acute disruption of homeostasis can lead to physical and mental illness.

**FIGURE 34.6** A person feeling stressed may experience any or all associated symptoms of stress. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## 34.2 Effects of Stress on Health and Wellness

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the effects of stress on basic human needs
- Explain effects of long-term stress
- Identify how unmanaged stress can evolve into a crisis

Stress can affect basic human needs related to physiology, safety and security, love and belonging, self-esteem, and the potential for self-actualization.. This list of basic human needs is recognizable as Maslow’s hierarchy of needs.

Long-term, or chronic, stress can have significant effects on body functions, actions, and relationships, and has impacts on body systems, especially the immune system. Stress that is not managed effectively through resistance and adaptation is described as having depleted adaptive resources. When this happens, the stress response has progressed through the stages of the GAS to that of exhaustion. Such a loss of abilities to resist stress leads to crises. This unit explores the effects of stress on basic human needs and how unmanaged stress can be detrimental to function.

### Effects of Stress on Basic Human Needs

Humans have certain needs they must meet to survive and ultimately thrive. The most common theory related to such physiological and psychological requirements is Maslow’s hierarchy of needs. Maslow’s hierarchy of needs is composed of five levels: physiological, safety and security, love and belonging, self-esteem, and self-actualization. These are frequently illustrated as a pyramid, with self-actualization as the pinnacle of human potential ([Figure 4.5](#)).

While there is a natural tendency to expect that lower-level needs are met prior to attempting or achieving those needs at the higher levels, Maslow determined this may not be the case (1943/2000). Instead, he described a “degree of relative satisfaction,” whereby some needs are met in each category, with percentage of achievement (if it were measured) lessening as one climbs the pyramid. Maslow estimated that in the general population, more of

the most basic needs tend to be met, with fewer achieving most or all of the self-esteem or self-actualization concepts.

Stress is encountered throughout life, from fetal development through the process of death, with the stress response and adaptive capabilities existing long before the person is able to identify such experiences. Although usually transient, stress is essentially omnipresent as part of human growth and development, and in the motivations toward necessary and desired achievements, such as basic human needs.

### Physiological Needs

When the effects of stress reach a life-threatening point, a patient becomes critically ill. The patient care setting is most often an intensive care unit (ICU) and includes multiple providers, such as pulmonologists and other specialist physicians, ICU nurses, therapists (e.g., respiratory, physical, speech, occupational), dietitians, and spiritual care providers. The goal of care is to return homeostasis by meeting basic physiological needs such as adequate neurological, cardiovascular, and pulmonary function. Maladaptive resistance apparent in these systems is often the root cause of chronic diseases evident in other organs.

For those patients who are not critically ill but show signs of chronic adaptation-induced disorders, treatment focuses on managing the condition(s). This includes primary care and specialist consultations aimed at symptom and disease-progression improvement or stabilization of the symptoms associated with chronic stress. Chronic stress manifests as a breakdown of systems affected by ANS (specifically sympathetic) overstimulation. When stress is chronic, there is a lack of relaxation, or physiological downtime. The harmful effects appear in both physical and psychological changes and behaviors.

Some examples of long-standing effects of increased cortisol, norepinephrine, and epinephrine include hypertension (HTN), tachycardia, headache, hyperglycemia, hyperlipidemia, gastrointestinal upset, and anorexia. Kidney damage may ensue from effects of chronic HTN and hyperglycemia; cardiovascular effects are also common, secondary to HTN, coronary artery disease, and subsequent issues such as myocardial infarction, HF, and peripheral vascular disease. These diagnoses, symptoms, and effects can be related to basic human physiological needs. Following are some examples:

- Nutrition: Diagnoses may change a person's recommended diet to restrictions of electrolytes and water; weight-loss (cardiovascular) or weight-gain (COPD) diets may be indicated.
- Weakness and fatigue: Organ dysfunctions may cause disability, as the patient becomes unable to tolerate activities. Job loss may ensue, leading to loss of shelter and financially based needs like clothing or food.
- Reproduction (or sexual pleasure, which appears more directly under love and belonging): Physical activity can be impaired to the point of sexual intercourse becoming uncomfortable, complicated, or impossible.

### Safety and Security

Similar to physiological needs and consequential negative effects of stress on the ability to meet them, safety and security can be affected by health and wellness changes. Development or exacerbation of anxiety is a possible effect of an overactive SNS or as a result of other systemic pathophysiological changes. The impact of anxiety on a person's behaviors and subsequent ability to establish or maintain a safe and secure environment can be significant. The following are some examples:

- Safety and security: may be affected by physiological or psychological changes (e.g., job loss leading to loss of shelter)
- Resources: an inability to provide for other financially based resources (e.g., health insurance, transportation, positive activities)
- Anxiety: may affect perception of safety; person may make poor decisions

### Love and Belonging

Anxiety and long-term results of chronic stress, such as weakness and fatigue, can hinder the physical ability to participate in meaningful, intimate relationships, broader social friendships, and activities. Isolation, loss of lower levels of need achievement, and difficulty establishing connections are possible consequences of negative stress effects.

Sexuality and performance of sexual intercourse can be impacted, as effects of diagnoses like HTN or diabetes take their toll. Meanwhile, increased physical needs increase the need for love and belonging even more. Patients may

not only need help with care, they may also need more emotional presence and support. They may lose their sense of belonging and of their normal roles, increasing feelings of inadequacy.

### Self-Esteem

The aging process itself is associated with normal physiological changes, such as loss of muscle mass and related strength, slowing of neurological responses, and hearing and vision changes. Stress-induced chronic illness and some of the effects of particular disorders may involve weight gain (e.g., hyperlipidemia, DM, HF, weight loss [e.g., COPD, anorexia]) or disability. Any or all of these situations are likely to have negative effects on establishing or maintaining self-esteem. Additionally, physiological changes can affect patients' roles in their families or social circles as well as their ability to fulfill their obligations. Isolation is also a likely consequence of stress effects related to self-esteem.

### Self-Actualization

Unmet needs on any of the other levels of human needs ultimately impact self-actualization. This is the pinnacle of the needs, the utmost in fulfillment, or fulfillment of potential (McLeod, 2024). As Maslow put it, "What a man *can* be, he *must* be" (1943/2000). It has been noted that few people achieve this level of human needs, as it requires advancing beyond the normal state of homeostasis to a unique level of creativity and elevated homeostasis through "peak experiences" (McLeod, 2024).

For many, chronic disease from stress adds further barriers to achieving a level of self-actualization. For example, when someone is experiencing a common combination of adaptation-related ailments, COPD, heart disease, and DM, it becomes difficult to seek out and focus on higher levels of homeostasis when the body is battling hard merely to achieve normal functions while struggling with oxygenation, perfusion, and hormonal regulation. That said, some people find that physical challenges and established disabilities provide the opportunity to develop themselves intellectually. Some who are limited physically manage to reach heights of fulfillment and achievement that doubtless place them in the realm of the self-actualized.

## Effects of Long-Term Stress

Maladaptive physical and mental changes are not typically associated with occurrences of eustress or with short-term episodes of distress. The short and positive stress response and the adaptive resistance response can ultimately take a toll on the body, but such changes tend to be considered naturally age related over a lifetime. The types of stress that are normally connected to negative implications to health and wellness are those that are chronic.

As outlined by the GAS, the acute phase of the stress response mounts the various physiological reactions brought about by the release and effects of hormones and neurotransmitters in efforts to return the body to homeostasis. During the resistance phase, the body physiologically remains on the alert for the stressor. If coping mechanisms are effective, effective adaptation returns the system to a homeostatic state. Ineffective adaptation, however, leads to the third phase, that of exhaustion, whereby metabolic resources are ultimately depleted. Prolonged exposure to stressors continues this cycle and leads to chronic changes to various organs and systems and dysfunction of the immune system.

### Negative Effects on the Body Systems

Long-standing, or chronic, stress has similarly long-standing impacts on the human body. Such effects are attributed to negative or ineffective adaptation during the resistance stage of the GAS. Such a loss of the ability to restore homeostasis allows for breakdown of body systems, including the immune system. This is reflective of the exhaustion phase of the GAS, as the resources associated with resistance and adaptation are diminished. Effects are seen in what Selye described as "diseases of adaptation" (1956/1976, p. xvii).

As Selye researched the chemicals released as a result of stressful experiences, he determined a difference between diseases caused by microbial invasion or toxins, for example, and those resulting from an adaptive response to stressors. Selye attributed several diseases or disorders to the reactions of chronic exposure to corticoids and pituitary hormones. His research dates back to the 1920s during his medical school education, and while there have been many developments in medicine since that time, he identified several disease processes as related to stress, which have been supported as such over the years. Some of the terms he used are no longer used to refer to the ailments, but the disorders are still recognized as related to chronic stress. Examples, using current

terminology, include the following:

- hypertension
- arteriosclerosis
- myocardial infarction
- cardiac hypertrophy
- edema
- nephritis, nephrosclerosis
- proteinuria
- inflammatory diseases/disorders

The following are some additional disorders and habits that have been recognized as frequently being related to stress:

- hyperlipidemia
- nutritional imbalances
- obesity
- alcohol and other substance misuse
- smoking
- COPD
- sedentary habits
- DM

In addition to cortisol, it is important to consider another corticosteroid, aldosterone, which is not a glucocorticoid but a mineralocorticoid. Release of aldosterone is not typically associated with the stress response in the way that cortisol and glucocorticoids are, but certain stressors may result in its secretion. An example is a patient who is hypovolemic (e.g., from blood loss or severe dehydration) and presents with hypotension.

In an effort to correct the low blood pressure and restore homeostasis, the stress response is initiated, including stimulation of the renin-angiotensin-aldosterone system. By a series of responses in various organs (liver, kidneys, lungs), the enzyme angiotensinogen interacts with renin to form angiotensin I, which is activated to produce angiotensin II by an enzyme reaction (angiotensin-converting enzyme) primarily in the lungs. Angiotensin II is a powerful vasoconstrictor, which prompts secretion of aldosterone from the adrenal cortex. Therefore, by two mechanisms, vasoconstriction and sodium retention with subsequent water retention, homeostasis is achieved, as seen by a normal blood pressure.

## REAL RN STORIES

---

### Physical Adaptations

**Nurse:** Margaret, MSN, RN

**Clinical setting:** Medical/surgical

**Years in practice:** 8

**Facility location:** Denver, Colorado

I was teaching a Med-Surg I clinical. As I approached one of the students for a check-in, I said, “Tell me about your patient this morning. Does she have COPD?” The student looked alarmed and replied, “How did you know? Yes!”

“Over the years, I’ve filled a photo album in my mind with the patients I’ve taken care of. There have been many at various stages of COPD, and sadly for your patient, she looks like them. You’re just starting your photo album, and she will probably be one of the pictures.” We proceeded to talk about the physical characteristics so often apparent in patients with COPD and the pathophysiology contributing to the changes. The student explained that her 72-year-old patient had been smoking since she was 15 years old, having quit five years ago. She smoked two packs a day most of that time. The student proudly stated, “She has a 104 pack-year history.”

The patient’s body had made modifications over the years, specifically decreased oxygen and increased carbon dioxide, as it adapted to stressors such as chronic acidosis and chronic hypoxemia. I noted the patient’s barrel chest

(a chest that has been chronically enlarged by hyperinflation, with a resultant round shape) and explained that was part of the adaptation process as her body became accustomed to an inability to fully exhale the carbon dioxide. The student had noticed the patient's use of accessory muscles of the neck and shoulders as she employed pursed-lip breathing to consciously inhale and exhale.

These physical assessment findings gave us the opportunity to discuss the long-term effects the patient was experiencing from a chronically activated stress response. What was the stressor, back when she was 15 years old, that started her exposure to tobacco smoke? Was it a desire to “fit in,” leading to peer pressure and smoking, or was it a painful breakup from an early love, or struggles with math class, or frequent arguments at home? Was there even an emotional cause, or did she just want to try a cigarette and then enjoyed the results? From our vantage point, many years and many packs of cigarettes later, the original cause was not as important as the psychophysiological changes of all the years of stress, leading to cascading events and alterations to her body. We watched a frail woman, not overly aged at 72 years, but aged by years of the impacts of stress, sitting in a hospital bed, with the head at 60 degrees, while she spent critical calories simply breathing and could barely rally the energy necessary to pick at her breakfast tray or sip from a can of Ensure.

### Negative Effects on Immunity

The stress response involves a process beginning with the body's recognition of the stressor, leading to the hypothalamus's release of CRH. Circulating CRH causes adrenocorticotropic hormone (ACTH) secretion from the anterior pituitary gland. ACTH stimulates the release of corticosteroids from the adrenal glands. The most notable is the glucocorticoid cortisol. Mineralocorticoids are also secreted from the adrenal glands; aldosterone is such a steroid. Its release is associated with fluid and electrolyte balance.

The stress effect on immunity involves both glucocorticoids and mineralocorticoids. Glucocorticoids have anti-inflammatory properties, and they reduce the immune response. There is a balancing act involved with patients who experience chronic maladaptive disorders, as the stress response has already been implicated in the release of cortisol, epinephrine, and norepinephrine. Patients' bodies eventually lose the ability to compensate, with resultant disorders like DM and HTN demonstrating the long-term exposure to glucocorticoids and catecholamines.

Meanwhile, the mineralocorticoid aldosterone has also been synthesized more often as a compensatory mechanism, with effects of sodium and water retention, and signs and symptoms of fluid volume excess (e.g., HTN) again, as well as development over years of cardiovascular disorders including myocardial infarction and HF. This entire cycle of chronic results of general adaptation finally has patients reach the exhaustion phase, when the lack of resources and the long-term damage finally catch up. Immune system function decreases, patients become more prone to infections, or autoimmune diseases may develop. At this stage of the GAS, exacerbations of diseases like HF or COPD can cause major setbacks, with lengthy hospitalizations, rehabilitation or skilled nursing needs, or mortality.

## UNFOLDING CASE STUDY

### Unfolding Case Study #5: Part 4

Refer to [Unfolding Case Study #5: Part 3](#) for a review of the patient data.

Provider's Orders	<b>1115:</b> Full laboratory workup including BMP, CBC, lipid panel, and hemoglobin A <sub>1C</sub> .
Lab Results	<ul style="list-style-type: none"> <li>• BUN 21 mg/dL</li> <li>• Creatinine 1.1 mg/dL</li> <li>• Glucose 139 mg/dL</li> <li>• WBC 15,000/mm<sup>3</sup></li> <li>• Total cholesterol 245 mg/dL</li> <li>• HDL cholesterol 50 mg/dL</li> <li>• LDL cholesterol 110 mg/dL</li> </ul>

3. Prioritize hypotheses: What connections can you make between the patient's self-reported stress and his lab results?
4. Generate solutions: Based on the patient's lab results, what interventions do you anticipate being ordered by the provider?

### Development of Poor Health Habits

Some people are surrounded by the necessary items to face and withstand stressful situations. Particularly optimistic individuals are able to frame stressful circumstances as eustress, and while the physiological response involves the same chemical reactions, the temporary nature combined with resilience minimizes the negative effects and allows for more positive adaptations. Unfortunately, many people are not in such affirmative environments, and they have developed coping mechanisms that are ultimately destructive. There are those who are born into settings filled with poor coping abilities. Long-standing decisions about nutritional choices, cooking habits, and the importance of exercise are examples of settings and behaviors that surround people and impact health.

When poor health is established, this in itself is a stressor, and it can place the patient firmly within the cycle of chronic stress, maladaptation, and ultimately exhaustion. Feeling ill can wear a person down; even an optimistic person can feel the burden and sadness ensuing from an illness or a chronic diagnosis. Such depression and not feeling well can be apparent through a lack of energy and motivation.

The following are some examples of ineffective coping mechanisms:

- overeating (food as a source of comfort)
- anorexia (not eating as a method of control)
- substance use disorders (alcohol, drugs use as means of escape)
- smoking (as a way of reducing stress)
- isolation (feeling too physically or mentally unwell to participate in social activities)

Unfortunately, these maladaptive coping methods perpetuate or worsen stressful circumstances and associated disorders; if not replaced by positive coping techniques and improvements in health and wellness, they may lead to detrimental effects within family units.

### Negative Effects on the Family

Stress-related effects cause an assortment of challenges and problems for families. Physical and psychosocial effects impact not only the patient but families as well. The toll from maladaptive coping may mean family members have to do more for the patient in completion of activities of daily living and in supporting the patient with work or lack thereof. Often, people who have developed poor coping strategies are in an environment where others around them also do not employ positive coping methods. This leads to dysfunctional behaviors, such as enabling each other's actions and further reinforcing chronic stress and its negative effects.

Manifestations of negative family effects related to stress include addictive behaviors, frustration and anger, relationship strain, interpersonal violence, and mental health diagnoses. The earlier part of the chapter presented some of the effects of ACEs that result from the environment surrounding a child and described how they cause chronic activation of the stress response. Some examples are a child living with someone with a mental illness, substance misuse or addiction, having a parent or caregiver who is incarcerated, violence, or parents with marital strain or dysfunction. The contribution of ACEs to the development of physical and mental health problems is significant, especially when more than one ACE is experienced. Diagnoses that have been identified with ACEs include DM, liver and heart diseases, stroke, cancers, and autoimmune diseases.

Because of the multigenerational influence of ACEs, recommendations focus on prevention of the experiences. Preventive measures as outlined by the Centers for Disease Control and Prevention (CDC) are designed to minimize the behaviors and environments that contribute to ACEs, thereby reducing the negative impacts caused by chronic stress on families. The CDC (2022) strategies include the following:

- strengthening economic supports to families

- promoting social norms that protect against violence and adversity
- ensuring a strong start for children
- teaching skills
- connecting youth to caring adults and activities
- intervening to lessen immediate and long-term harms

## LINK TO LEARNING

---

This video “We Can Prevent ACEs” describes [one person’s experience in breaking the cycle of ACEs](https://openstax.org/r/77BreakCycleACE) (<https://openstax.org/r/77BreakCycleACE>) and ideas for ongoing prevention. Watch the video, and note the positive changes; consider how you, as a nurse, can incorporate your awareness of ACEs into practice.

---

## Crisis

Stress and the responses of a person experiencing it can range from mild to severe reactions, up to and including a point of crisis. A **crisis** is described as an inability to cope with a stressful situation, or a state reflecting loss of psychological homeostasis. Adaptive coping mechanisms are established over time as children consciously or subconsciously learn ways to handle stressful situations. At various places in this chapter, the notions of positive and negative maladaptive strategies have been discussed. People who have not developed positive methods for managing stress are more apt to face crises, whereby they become overwhelmed as stressors spiral out of control and techniques established over time for stress adaptation no longer work.

In addition to stages of crisis, there are different types identified. The types of crises include maturational, situational, and adventitious. As nurses interact with patients, awareness of not only the person’s physical state but also their psychosocial status is important. Exploring life events while talking to patients is important, as during such discussion, the nurse can identify occasions that may have been stressful for the patient or that might cause stress in the future. During such discussion, the nurse can also assess the patient’s psychological and physical state, noting any of the characteristics or manifestations of the different levels of crisis and stress ([Table 34.3](#)), and plan care accordingly.

	<b>Crisis Phase 1: Normal Stress and Anxiety</b>	<b>Crisis Phase 2: Rising Anxiety</b>	<b>Crisis Phase 3: Severe Stress and Anxiety</b>	<b>Crisis Phase 4: Crisis</b>
Characteristics	Person is exposed to causal stressor (annoyance or inconvenience of life).	Regular coping mechanisms fail to relieve the stressor.	<ul style="list-style-type: none"> <li>Person uses novel internal and external resources to cope.</li> <li>New techniques for coping are surveyed and employed to reduce stress.</li> </ul>	Lack of resolution leads to critical point of maladaptive efforts to cope.
Manifestations	<ul style="list-style-type: none"> <li>Stress response initiates; anxiety begins.</li> <li>Person is reasonable; emotions and behavior are under control.</li> </ul>	<ul style="list-style-type: none"> <li>Anxiety increases.</li> <li>Thinking is impaired; feelings of confusion and helplessness prevail.</li> <li>Person may experience tachycardia, tachypnea, voice changes to higher pitch and fast speech.</li> <li>Person may be restless and have nervous habits (e.g., tapping of feet or hands).</li> </ul>	<ul style="list-style-type: none"> <li>If new techniques are successful, anxiety resolves, and homeostasis is reestablished.</li> <li>If new techniques are unsuccessful, anxiety continues to increase; functions such as reasoning, communication, and behaviors are impaired.</li> <li>Person may display a panting appearance to tachypnea.</li> <li>Person may clench fists, pace, and sweat.</li> </ul>	<ul style="list-style-type: none"> <li>Person may experience intolerable anxiety to the point of panic and unorganized, disturbed thought processes (possible psychotic thoughts).</li> <li>There is urgency for relief of emotional discomfort.</li> <li>There is a potential for harm.</li> </ul>

**TABLE 34.3** Crisis Phases**Maturational**

The first crisis type is maturational crisis. The term **maturational** indicates these are the sorts of events that happen in a person's life, and while they are normal occurrences, for some people they can cause a crisis. This may be influenced by other events in the person's life that add to the level of stress, pushing the person to a stress point that reaches critical levels.

Patients who have developed positive adaptation and coping mechanisms tend to take such occasions in stride,

coping with the extra busyness of the affair skillfully and without (or with minimal) anxiety, the experience reflecting eustress. For those whose coping techniques are maladaptive, however, such events as a wedding or the birth or adoption of a child can climb to the point of anxiety and on to crisis levels as previously used coping systems are not effective enough to address the rising stress level.

### Situational

While maturational crises are common occurrences that are considered normal life events, a situational crisis results from an incident that comes as a surprise. A situational crisis is exemplified by being fired or laid off from a job, moving for a new job, or a death in the family. Even those who can typically withstand added stress may find themselves overwhelmed by all the emotions and added stress involved in such a significant circumstance.

Some who have remarkable support systems and their own internal strength and coping can minimize even situational stress. Many, though, are impacted by situational stress, and without interventions assisting them with new coping mechanisms and means of adapting, the response carries them into higher levels of anxiety and disequilibrium. Patients in the higher stages of crisis are likely to require more interventions, additional support, and exploration of novel methods of adaptation in order to overcome the combined psychophysiological distress and restore homeostasis.

### Adventitious

Crises such as those resulting from traumatic incidents like a flood, hurricane, terrorist attack, or violent crime are categorized as adventitious. These are crisis events that take a person (or group) by surprise. An adventitious crisis may affect one person or several, and perhaps even an entire community or region. This type of crisis may not advance through the levels as shown in [Table 34.3](#) but may appear already as a high-level crisis and be accompanied by a complete failure of previously used coping techniques.

As with the other types of crises, there is a loss of psychophysiological homeostasis. In the case of an adventitious crisis, it may be more complicated to restore equilibrium, as the level of devastation may impact an individual patient in a more significant manner, for example, in the case of a victim of a violent crime. Or, as in the case of natural disasters like hurricanes and tornadoes, there may be such tremendous damage and so many people may be impacted that support systems and resources are depleted. See [Table 34.4](#) for characteristics and examples of different categories of crises.

Category	Characteristics	Examples
Maturational/ developmental	<ul style="list-style-type: none"> <li>Stressors are part of normal life: growth and development.</li> <li>Somewhat predictable; they commonly occur at certain developmental milestones.</li> <li>Vulnerability to crisis is related to personal equilibrium/homeostasis.</li> </ul>	<ul style="list-style-type: none"> <li>Birth</li> <li>Puberty and adolescence</li> <li>Marriage</li> <li>Death</li> </ul>
Situational	<ul style="list-style-type: none"> <li>Stressors are unexpected and sudden.</li> <li>Stressors are unpredictable.</li> <li>Equilibrium/homeostasis is threatened by the event.</li> </ul>	<ul style="list-style-type: none"> <li>Traumatic accident</li> <li>Illness (self or loved one)</li> <li>Job loss</li> <li>Financial hardship</li> <li>Move</li> <li>Divorce</li> </ul>
Adventitious/ social	<ul style="list-style-type: none"> <li>Stressors are unanticipated and rare.</li> <li>They may include multiple losses.</li> <li>They may result from major disasters (natural or man-made).</li> <li>There is a severe threat to equilibrium/homeostasis.</li> </ul>	<ul style="list-style-type: none"> <li>Natural disasters (e.g., flood, forest fire, earthquake, tsunami, tornado, hurricane)</li> <li>Terrorism/attack</li> <li>Riots/violent crime</li> <li>War</li> </ul>

**TABLE 34.4** Crisis Categories

## 34.3 Factors Affecting Stress and Adaptation

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine sources of stress throughout the life span
- Recognize personal factors affecting stress and adaptation

Effects may be strictly physical, with signs of elevated cortisol and activation of the autonomic (particularly sympathetic) nervous system. As stress manifests, strain on the body results from release of cortisol and catecholamines and from the stimulation of the fight-or-flight response. Personal factors that affect stress and adaptation include the individual's adaptation abilities, health status, support system (or lack thereof), and socioeconomic status.

### Sources of Stress

Exposure to stressors begins very early in development and lasts throughout the life span. An elevation of cortisol levels in infants was found to be related to factors such as maternal anxiety, history of depression, and the mother's attitude and attachment to the baby (Hernández-Martínez et al., 2019). Adaptations are a part of normal stress exposures, and such mechanisms are experienced throughout all stages of growth and development. Adaptation and coping techniques can be positive and have positive, perhaps even lifesaving, results, or they can be maladaptive, with negative results. Such negative impacts can become devastating, especially if healthier skills are not learned and used, leading to maladaptive consequences becoming chronic or lethal. In the following paragraphs, developmental and situational sources of stress are considered.

#### Developmental Stress

There are certain developmental milestones anticipated in the normal human life cycle. Such events tend to be associated with stress, whether physiological, psychological, or both. The first exposures to stress appear during fetal development, with the fetus exposed to stressors of the uterine environment and to maternal emotional

influences. Changes in levels of infant cortisol relate to prenatal exposure to factors, such as overall maternal emotional status with specific mention of the feelings toward the pregnancy, and factors after delivery, such as the maternal-infant bond (Hernández-Martínez et al., 2019).

Fetal exposure to stress, anxiety, and depression results in low levels of cortisol, while parental neglect, abuse, bonding disorders, mental health disorders in parent(s), and low socioeconomic status causes changes in cortisol levels to either higher or lower than normal (Hernández-Martínez et al., 2019). The relevance of these results is that psychopathological processes can be related to alterations from normal levels of cortisol.

Young children face other developmental milestones, with tremendous growth within the first year. During the first few years, children learn to sit up, eat, walk, talk, discover likes and dislikes, assert themselves, and interact with others. These are activities and events that involve stress. Frequently, this is the normal experience of eustress, with prompt return to normal hormones and positive adaptations.

As children start school, and their social circle broadens, more such encounters and challenges are likely, as well as exposure to distressful circumstances. Again, however, if their environment is supportive, the child is likely to establish positive coping adaptations. Similar to the fetus or neonate, though, if the surroundings are negative or even abusive, maladaptive techniques for coping are apt to be developed. Maladaptive physical results from adversity, stress, or trauma in early childhood have also been explored for their contributions as ACEs (Smith & Pollack, 2020). Because infants and young children are in stages of substantial brain development, they are particularly affected by prolonged exposure to stress hormones. The effects of exposures to ACEs can result in remodeling of the brain, with a detrimental lifelong impact on learning and behaviors.

Puberty and adolescence are later developmental milestones, during which inherent stressors such as major growth spurts are common, with accompanying hormonal changes. During these stages, social development continues and expands, with more social events, such as birthday parties, school dances, sporting events, dating, and intimate friendships, each with potential for exposure to eustress and distress and for learning to develop positive coping skills. Reactions to stress tend to be more acute and prevalent in early phases of development, with most exposure to stressors and heightened reactions occurring prior to age 30 years. In young adulthood, people noted fewer stress reactions, and continued passage of time demonstrated a stabilization of stress (Almeida et al., 2023).

Early adulthood tends to involve new experiences, including advancing education through training, college, or university, all of which have inherent stress, as decisions are made and new social groups and independence are established. This is frequently also a time of intimacy and perhaps marriage and parenthood, further developmental stressors.

For some, middle and later adulthood is rather a period of status quo and stability or homeostasis, but with human experiences, stress is apparent even during normal days. So, whether adults are simply facing the challenge of slow traffic during a commute or a minor argument with a child, there are developmental and situational stressors with which to cope. Older adults often trade work stress for changes relative to health, wellness, attitudes, and advancing age. Losing physical strength, losing abilities, and ultimately death, are all likely stressors for older adults, and share some common threads with situational stress. However, reactivity to stress tends to have plateaued by older adulthood (Almeida et al., 2023).

### Situational Stress

Throughout a life span, there are countless circumstances and events that cause the stress response. Situational examples include a traumatic injury or accident, illness, losing a job and related financial burden, a divorce, or moving to a new area and home. Like all stressors, situational events begin the cascade of physiological responses that are the stress response, and the person adapts to the stress with positive or negative coping mechanisms.

As with developmental stress, responses to the situational stressor may range from very mild, with quick and positive resolution, to severe, with negative coping techniques leading to crisis. Unlike developmental stress, situations are typically not predictable. Where a person lands on such a continuum of responses (from very mild to very severe) is dependent on several factors. Such factors include internal skills, such as their own adaptation abilities, and their level of health and wellness. Also, availability of support and socioeconomic status influence abilities to cope. Discussion of these factors follows.

## Personal Factors Affecting Stress and Adaptation

From intrauterine development to birth, and throughout the life span, people encounter stressors, to which their bodies and minds respond, consciously and subconsciously. Some of the reactions to stress are purely physiological, like the innate actions of the SNS, including the fight-or-flight response. As a side effect of stress hormones, people also experience symptoms like anxiety. Some of the adaptive responses to anxiety may be subconscious too, but some are learned.

Unfortunately, some coping skills develop in maladaptive or negative ways. While the adaptations may help in the moment, maladaptive coping strategies lead to disruption of homeostasis in the long term, including psychopathological changes. The ability of a person to adapt depends to some extent on previous adaptations, dating back to fetal development. Subsequent exposures to stress over time contribute to the development of coping strategies. Depending on physical and environmental influences, the mechanisms for coping may be effective or ineffective and maladaptive. Effective coping skills contribute to short stressful episodes, often representative of eustress. Over time, and with repeated exposures, ineffective methods of coping result in chronic stress and related negative health impacts. Whether or not negative methods can be modified to improve results and minimize harmful psychophysiological outcomes depends on several factors. The upcoming paragraphs examine the ability to adapt, the influence of the current state of health, the impact of support systems, and the impact of socioeconomic status.

### LINK TO LEARNING

This video incorporates concepts from each of the upcoming topics, with its culmination in the final section. As you read about the [factors affecting stress \(https://openstax.org/r/77StressAdapt\)](https://openstax.org/r/77StressAdapt) and adaptation, think about these two young men, and how their different socioeconomic backgrounds affected stress and subsequently other aspects of their lives.

### Ability to Adapt

The ability of a person to adapt to stress depends on multiple factors. During fetal development, if the fetus is exposed to elevated levels of anxiety, worry about the birth, or negative feelings about the pregnancy, levels of cortisol and subsequent brain development can be undesirably affected (Hernández-Martínez et al. 2019; Smith & Pollack, 2020). Neonates and young children exposed to these stressful situations, as well as additional factors including neglect, maltreatment or abuse, financial woes, and parental mental illness, are at risk for abnormal cortisol levels and related psychopathology in the future.

Considering the negative effects of ACEs, an environment that is positive and supportive, with well-adjusted family and others who have adapted to stress themselves in affirmative ways, using constructive coping mechanisms, tends to foster development of similarly functional coping skills. Even simply removing the chronic stress response associated with ACEs can reduce development of maladaptive stress and coping responses and decrease chronic physical and psychological ailments occurring over time.

While many coping mechanisms, adaptive or maladaptive, are established in early life, they are used, modified, or reinforced throughout a lifetime. Some people are more adaptable, more able to “go with the flow” without feeling stressed and/or anxious, while others are negatively affected and feel heightened levels of anxiety with minor inconveniences. An ability to recognize and control emotions, especially those in response to stress, can also prove helpful. An attitude of gratitude and enjoyment improves stress (Wilson, 2023). Statements to reassure oneself can improve coping; such a statement might be, “This is a challenge, but I have overcome such challenges before and can do it again.” In the longer term, positive self-talk involving writing positive statements and practicing them to improve self-esteem and counter negative thoughts can foster coping (Wilson, 2023). When a stressful, negative situation presents, one repeats the positive statement(s).

Improved self-awareness is a key factor in establishing positive coping techniques and reducing stress-related threats to homeostasis (Cherry, 2022). The following are some methods for enhancing self-awareness:

- *Psychotherapy* helps identify defense mechanisms and determine improved adaptive strategies.

- *Relaxation*, meditation, deep breathing, mindfulness, physical activity, and setting goals, helps reduce anxiety and improves focus on positive actions.
- *Setting healthy boundaries* fosters positive relationships and commitments.
- *Reflection/journaling* helps reduce anxiety and enhances focus.

### Current Health State

The relationships of stress on health and of health on stress are intertwined or may be considered cyclical. This is because negative effects of stress, especially when persistent, accumulate over time and are identified as diseases and disorders. Diagnoses of health problems contribute to illness and therefore are themselves stressors. Stress impacts physiological changes through the actions of the SNS and the fight-or-flight response, resulting in release of cortisol and catecholamines. Immune responses, including inflammation and the potential for autoimmune implications, are also promoted by the renin-angiotensin-aldosterone system. Examples of diagnoses attributed to one or both of these stress pathways include HTN, HF, COPD, and DM.

Psychiatric disorders can also be affected by stress responses, and these may include depression, anxiety, bipolar disorder, and post-traumatic stress disorder (PTSD). These examples all decrease the ability to manage stressful circumstances, and measures used for coping may also be maladaptive, leading to worsening the situation rather than improving it. Additionally, PTSD symptoms may trigger the stress response and worsen anxiety; bipolar disorder, if not managed, results in volatile moods. Such ineffective adaptations easily swirl into the cycle of increasing stress and subsequent anxiety, with potential for crisis situations.

### Support System

A supportive environment and being surrounded by a community of support should not be underestimated in regard to positive coping strategies and dealing with stressors. Children are less likely to be adversely affected by ACEs if they have support and help to counter the results of negative experiences. While an entirely optimistic environment of course offers the most protection from ACEs, at least if there are some ways for the effects to be minimized and alternatives offered, outcomes can be improved.

Beyond the early developmental years, support systems remain very important positive means of coping with stressful situations and avoiding long-term negative effects. Talking to a friend or family member may also help provide support, calm anxious emotions, and avert crises. Assistance may also come from nursing and counseling or therapy sessions, offering simple support or professional guidance to recognize and manage stressors.

It is sometimes helpful to have another perspective, especially if overwhelmed by a particularly stressful circumstance. Someone from outside the experience may be able to identify a less gloomy perspective and find something positive or funny in it; humor can be a good stress reliever (Wilson, 2023). Informal group support may come in the form of friends, or people may seek formal support groups based on a common interest or need, like Alcoholics Anonymous or a group of patients recovering from cancer. Such alliances of people can help a stressed individual feel validated and emotionally strengthened. Religious or spiritual communities provide support, encouragement, and purpose for many, with customs and prayers proving to assist with positive adaptive skills.

### Socioeconomic Status

Socioeconomic status (SES) is societal standing based on factors such as occupation, education, and income. Other contributors to SES include availability of health care (ability to pay, e.g., insurance, group contributions, and access to providers), safe environments, and access to healthful activities and choices (e.g., nutritious foods, exercise, leisure activities). Subjective concepts, such as how a particular role is perceived (social class and/or status based on a position), are also part of SES. Sometimes, opportunities are based on perceptions of qualifications and abilities of those in a particular SES (American Psychological Association, 2024). Such opportunities can include the type of job a person is qualified for, the availability of employment, education and training, and pay.

The SES can be attributed to various psychopathologies (American Psychological Association, 2024). Previous topics within this chapter have alluded to factors that can be correlated to SES and their relationship to stress and adaptation. Examples have included stressors beginning with prenatal development, through early childhood (ACEs), and throughout the milestones and challenges of a life span. The SES, health and wellness, and the relationship to stress and adaptation may be best described as social determinants of health (SDOH), which group concepts mentioned earlier under the following categories/determinants (Healthy People 2030, n.d.):

- economic stability
- neighborhood and built environment
- education access and quality
- health care access and quality
- social and community context

## LINK TO LEARNING

Visit the Healthy People 2030 [Social Determinants of Health \(https://openstax.org/r/77HealthyPeople\)](https://openstax.org/r/77HealthyPeople) at the Office of Disease Prevention and Health Promotion website. Scroll down and explore the clickable buttons at the bottom. Consider ways you might use the research, the information about older adults, and the infographics in your interactions with patients.

Stressors can be found within all domains of the SDOH, including diagnoses impacting mental or physical health, adaptations and subsequent behaviors, financial worries, access to and preparation of nutritious food, transportation needs and access, and availability of affordable healthcare providers. Interactions between nurses and patients, including a thorough interview to identify applicable SDOH and any other influences from SES, can help identify stressors affecting individuals. Such assessment and care planning can assist with stress reduction, as well as establishing and fostering positive coping methods for people within their socioeconomic means.

## PATIENT CONVERSATIONS

### Help When There Is No Extra Money

**Scenario:** Mr. Alvarado is a 48-year-old married father of six children and the sole provider for the family. Mr. Alvarado comes to the free clinic and tells Reynaldo, the nurse, “I’m afraid my high blood pressure is back.” Reynaldo assesses Mr. Alvarado, and his blood pressure is 156/98. His pulse is 104, and Reynaldo notices some pedal edema.

**Nurse:** Mr. Alvarado, your blood pressure is indeed high today, it’s 156/98. Please tell me how you’ve been taking your medication.

**Patient:** [looks down and wrings his hands] Oh, Reynaldo, I’m so embarrassed. You know I was working at the meat packing plant. I lost that job four months ago. I haven’t been able to refill my blood pressure prescription because now I don’t have health insurance or money for extras like that.

**Scenario follow-up:** Mr. Alvarado was seen by the nurse practitioner. When he comes back to Reynaldo to check out, he has two prescriptions. One is for his blood pressure medicine, and the other is a food prescription.

**Nurse:** Mr. Alvarado, I see you have a new prescription for your blood pressure medicine. There are some pharmacies for you where you can get this blood pressure medicine at no cost.

**Patient:** I had no idea! There are pharmacies that help like that? This is good news, for sure!

**Nurse:** Since you haven’t taken this medicine in three months, let’s go review how you take it, and other things about it, okay?

**Patient:** Good idea. I’ve gotten used to not being on any medicines.

**Scenario follow-up:** Reynaldo explains the drug prescribed: how and when to take it, side and adverse effects, and reasons to call the clinic or go to urgent care, or the emergency department.

**Nurse:** The prescription is for three months. Please check your blood pressure at least twice a week—you can do that at the grocery store or pharmacy, or you can come here. Keep a diary of your measurements. Here is a little notebook for that. We want to see you in one month to recheck your blood pressure and review your diary of blood pressure entries.

**Patient:** Twice a week I check my pressure, and write it in this notebook?

**Nurse:** Exactly. And bring it with you when you come back in a month.

**Patient:** Okay.

**Nurse:** Now, let's talk about the food prescription program. Have you heard of it before?

**Patient:** No. I thought it was a joke when the nurse practitioner gave me a prescription and said it's for food!

**Nurse:** It's for real. Some grocery stores work with this program, and they will accept the prescription instead of requiring you to pay.

**Patient:** This will help so much! My whole family.

**Nurse:** It should. Let me also give you a list for other resources that might help your family. You can apply for Medicaid and the Supplemental Nutrition Assistance Program, which will also help you with groceries. And here is a list of dentists and eye doctors who charge less than many providers.

**Patient:** I have so much information, and so much help! I really didn't have any idea. My wife is going to be so happy too. Thank you!

---

## 34.4 Adaptation Theories and Models

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify different theories associated with stress and adaptation
- Analyze models of stress and adaptation to maintain homeostasis
- Describe adaptation techniques to maintain homeostasis

Stress is a necessity of life for humans, an integral part of growth and development, and a key to survival. Whether threats come in the traditional form of a bear to be fought or fled from, as an invisible invader that causes sepsis, or malignant thoughts and worries, the physiological responses to stress are the same. Stressors may even have positive results, like providing a nurse with the critical edge of vigilance while caring for a particularly acutely ill patient, or a public speaker's ability to impress an audience with charisma and fascination.

Some theories and models of stress and adaptation, as well as methods of adaptation, have implications for preparation of nurses for practice, as stress, adaptation, and homeostasis have major effects on health, wellness, illness, and equilibrium. A basic knowledge of homeostasis and the stress responses is important for nurses in all aspects and specialties of patient care.

### Theories Associated with Stress and Adaptation

Identification of stress as an issue facing all humans has been associated with Selye, and his stress-related research began in the early part of the twentieth century. Since that time, others have also investigated the stress phenomena, with additional data adding to that introduced by Selye. Evidence continues to be added as more research is conducted. In the upcoming section, three theories associated with stress and adaptation are explored: stress-response theory, GAS, and allostasis and **allostatic load** theories.

#### Stress-Response Theory

The **stress-response theory** reflects the identification of the body's nonspecific reaction to a need (threat or stressor) (Selye, 1956/1976). Selye's description of the approach to illness during his medical education was that it was diagnosis based. Each patient was approached and given a particular diagnosis, and treatment was suggested accordingly. As an early medical student, he made an association that although the patients had different infections, there were similarities. Ultimately, he determined the patients' physiological responses did share commonalities, and he identified this as the stress response (Selye, 1956/1976).

The stress-response theory involves the chemical (hormonal) actions and reactions upon recognition of a stressor by the limbic system. This reaction continues to the hypothalamus, which initiates the release of CRH, resulting in secretion of adrenocorticotrophic hormone (ACTH) from the anterior pituitary gland. The ACTH causes the adrenal

glands to release corticosteroids, most notably cortisol, and to activate the ANS, specifically the SNS. This causes release of fight-or-flight catecholamines: norepinephrine and epinephrine. Under normal circumstances, when the threat has been resolved, the effects of SNS stimulation are opposed by its counterpart, the parasympathetic nervous system (PSNS), and its rest-and-digest actions.

Selye's (1956/1976) research did not stop with merely identifying stress and its chemical actions and reactions. He continued to examine stress from various angles and with different experiments, through which he further specified the stress response as involving phases he branded as the GAS, which is discussed in the following paragraphs.

### General Adaptation Syndrome

The **general adaptation syndrome (GAS)** involves the concept that stress causes a three-stage syndrome of events resulting in either adaptation or exhaustion (potentially death) (Figure 34.7). The first stage is that of alarm, at which time the SNS is triggered. The activation of the SNS is likely apparent in signs of bronchodilation, tachycardia, tachypnea, elevated blood pressure and glucose, and pupillary dilation, as the body is prepared for facing the stressor. Such confrontation may involve physical or mental confrontation of the stressor, or a combination of both.

The second stage of the GAS is that of resistance. It is during this phase that effective adaptation allows the threat from the stressor to dissipate, and activation of the PSNS opposes the stimulating effects of the SNS. The chemicals released during the alarm phase and the SNS fade, and homeostasis is restored. If, however, ineffective coping by either conscious or subconscious means is apparent, the resistance stage can be extended, and maladaptive results become apparent. These maladaptive results may become apparent in physiological or psychophysiological behaviors and symptoms and in subsequent chronic diagnoses and disorders.

Unresolved adaptations to stress prevent a return to homeostasis and continuation to the third stage of the GAS: exhaustion. At this point, the hormones released during the alarm phase and their reactions have dwindled, and the organism does not have the resources to continue resisting the stressor. This stage can sometimes be prolonged by medical interventions, as healthcare providers order and nurses administer exogenous catecholamines and corticosteroids to critically ill patients. Patients whose compensation ability has been drained may be supported by intravenous medications, intubation, and ventilation, until such time as their own adaptive abilities are revived or reach a point of depletion that is irrecoverable.

**FIGURE 34.7** Selye's general adaptation syndrome theory consists of three phases with an associated time factor. modification of work from Psychology 2e. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Allostasis and Allostatic Load Theories

Allostasis is a concept related to homeostasis (Figure 34.8). The two are considered as nearly opposites in achieving and maintaining equilibrium. Homeostasis is the balance represented by normal vital signs, laboratory findings, and mental state. Stressors lead to instability, and the body naturally attempts to return to and maintain the state of homeostasis. The body's responses to stressors (e.g., bronchodilation, tachypnea, tachycardia, hyperglycemia) are necessary and life supporting, but the increased effect of these responses over time can be detrimental (Cherry,

2020; Guidi et al., 2021; Igboanugo & Mielke, 2023). The short-term response, with prompt return to normalcy after a challenge, is associated with homeostasis. Allostasis has been described as the ongoing changes within the body in response to stress. The greater the challenge, the more variability there is in the response. As previously established, allostatic load is the response to the collective capacity of events and related chronic stress.

**FIGURE 34.8** The diagram shows baseline as the solid blue line; the orange lines indicate the dynamic nature of equilibrium in (1) homeostasis and (2) allostasis. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Allostatic overload describes the situation when the threat or stress is more than the coping ability of an individual (Guidi et al., 2020; Igboanugo & Mielke, 2023). This may be seen as similar to a lack of effective coping during the resistance stage of the GAS, with an ultimate transition to the exhaustion phase if psychophysiological interventions are not taken or are unsuccessful. The following are examples of potential diagnoses ensuing from allostatic load (and overload):

- DM
- cancer
- HTN
- arteriosclerosis
- psychiatric/mental health disorders

### Models of Stress and Adaptation

While there are many models of stress and adaptation, two popular models of stress and adaptation are discussed here: Sister Callista Roy's adaptation model (RAM) and the psychophysiological stress model (PSM). Roy's (1984) original work is comprehensive, with a design that can be used as a foundation for nursing education programs and professional nursing practice. The PSM incorporates the complete processes involved in stress.

#### Roy's Adaptation Model

**Roy's adaptation model (RAM)** is a holistic approach to nursing as a combination of art and science, structured as a science, model, and practice discipline containing various elements. The model and elements note the inclusion of (1) the goal of nursing, (2) health, (3) environment, and (4) nursing activities (Gonzalo, 2024). The RAM provides a comprehensive foundation for all aspects of nursing and patient interactions, including psychophysiological concepts throughout the life span (Table 34.5). Nursing's goal is to foster adaptive behavior and alter ineffective behaviors to become effectively adaptive.

Concept	Definition
Adaptation level	The dynamic level of stimuli a person can react to with normal adaptation/coping
Adaptive responses	Reliable reactions toward goals of "survival, growth, reproduction, mastery"
Adaptive/effector modes	Coping methods manifesting in regulator and cognator actions; features four adaptive modes: physiological, self-concept, role function, interdependence
Cognator	Coping technique involving internal and external stimuli managed by emotions

**TABLE 34.5** Key Concepts of Roy Adaptation Model

Concept	Definition
Coping mechanisms	Physical and emotional methods of reacting to environmental alterations
Environment	Stimuli and situations that affect people/groups, and their development and actions
Health	Being and evolving to a state of wholeness
Ineffective responses	Reactions contrary to adaptation goals “survival, growth, reproduction, mastery”
Regulator	Automatic coping reaction to environmental change(s), e.g., neural and chemical responses
Stimulus	The source of an action or reaction
System	Closely related group forming a whole; includes “inputs, outputs, and control and feedback processes”

**TABLE 34.5** Key Concepts of Roy Adaptation Model

Integral to the RAM are the interactions of the person (an individual or a group) and the system. The system is composed of the inputs, outputs, control, and feedback (Gonzalo, 2024), which are compared to the functions of machinery (Figure 34.9). Scientifically, it is noted that the possibilities for adaptation are not infinite but are limited by the body’s resources and the person’s ability to cope. The strictly scientific approach to stress and adaptation is enhanced by the values of humanism, and the role of the person. The notion that the patient can be more than merely a reflexive participant in stress, and at least in some circumstances exert some control of stress, is a component of this model.

**FIGURE 34.9** This diagram shows the RAM, from input through output, and the associated feedback mechanism. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## UNFOLDING CASE STUDY

### Unfolding Case Study #5: Part 5

Refer to [Unfolding Case Study #5: Part 4](#) for a review of the patient data.

Provider's Orders	<p><b>1230:</b> Referral to dietitian for lifestyle changes related to diet to address elevated HbA<sub>1C</sub> and cholesterol levels. Provide patient with support group information for spouses of patients with cancer. Referral to psychiatry for history of depression and increased stress.</p>
-------------------	---

5. Take action: When implementing the provider's orders, how do these actions reflect concepts included in Roy's adaptation model?
6. Evaluate outcomes: After implementing the provider's orders, what findings should the nurse assess for that would indicate positive patient outcomes have been achieved?

### Psychophysiological Stress Model

The **psychophysiological stress model (PSM)** reflects the relationship between the mental and physical reactions and adaptations to stress. The adaptive component of the stress response may be where the relationship is most evident. Whether the body is responding to a physical or psychological threat, negative results tend to occur when the level of stress does not adequately dissipate, which typically happens during resistance or through adaptation. Effective coping leads to positive adaptation and minimizes poor outcomes. Maladaptive coping mechanisms, however, contribute to the signs, symptoms, and diagnoses of chronic disorders, including physical diagnoses like HTN, DM, HF, as well as mental health diagnoses like anxiety, depression, and PTSD. The stress response involves actions at the hypothalamus, pituitary gland, and adrenal glands, which cause physiological reactions. Hormones released activate the ANS, with particular signs of stimulation of the SNS. Effects from the SNS involve increased actions in the respiratory and cardiovascular systems and release of corticosteroids; nervousness and anxiety are also common consequences. Interestingly, anxiety may also be the original stressor starting the cascade of events. Considering that the limbic system of the brain is where stress is identified by the body, and that the hormones also act chemically as neurotransmitters, the relationship between the psychological and physical responses to stress are unmistakable. Sometimes these interactions occur in a rather cyclical fashion, either initiating or fostering the processes.

### Adaptation Techniques to Maintain Homeostasis

As the human body reacts to stress, various physical responses are apparent, reflecting, particularly, an activated SNS. The results include both psychological and physiological effects to maintain or return to homeostasis. The body is readied for fight or flight, if necessary. As Selye described, the resistance stage of the GAS is the period during which the body attempts to counteract the stress by adapting to its cause and effects. Coping mechanisms are established, starting with first encounters with stressors, and developing with continued exposures.

Strategies for coping and thereby adapting to threats can be effective or ineffective, and the consequences are similarly productive and stress reducing, or they are inefficient and ultimately lead to long-term changes. Such maladaptive alterations may be apparent in either mental or physical health disorders, and they may reflect minor to very serious stress-related problems. In the upcoming paragraphs, techniques for adaptation and maintenance of homeostasis will be investigated within the nursing process and the framework of the National Council of State Boards of Nursing Clinical Judgment Measurement Model (CJMM) in order to relate the processes to nursing care and clinical judgment.

### Identify Predisposing Risk Factors for Stress Reactions

Like the diagnoses induced by stress, there are many risk factors for development of stress and how it is handled by the body. As nurses plan their care of patients, an important piece can be to distinguish those risk factors that increase the patient's likelihood of being adversely affected by stress. Such risk factors begin early in life, with

stressors imposed during fetal development, based on maternal health status, mental health, and behaviors. Such early risk factors continue with ACEs and the effects of such adverse events on adaptation throughout the life span.

Despite negative experiences, there are some who are innately optimistic. There are also those who are pessimistic despite supportive environments and mostly pleasant experiences. Also, there are people who are predictably optimistic or pessimistic, based on incidents perceived as accordingly good or bad. Additionally, ascertaining whether a patient reaches high levels of anxiety, or a crisis point, easily can be a contributing risk factor for stress responses cascading out of control and away from balance. Therefore, a general outlook can be a predisposing risk factor of homeostatic maintenance.

During a nurse's interaction with a patient, helping the patient (or family) to determine what coping mechanisms have been successful in the past, as well as those that have been ineffective, may contribute as risk factors for inability to maintain homeostasis. After all, if an adaptive technique has not been helpful in the past, a patient's reliance on it is not likely to be fruitful with repeated use. Another piece of a patient's history that may be considered a stress risk factor is health and surgical history. Well-controlled diagnoses may still contribute to stress, either by worry about it or by the actual stressful event of an exacerbation. Similarly, while some surgeries offer definitive and complete resolution of a problem, sequelae or side effects may occur, involving subsequent stress and inflammatory responses. This adaptation technique toward maintenance of homeostasis is represented by the assessment phase of the nursing process. Within the CJMM, this is the phase Recognize Cues.

### Identify the Stressor

As the nurse considers a patient who is experiencing a stressful situation, it is important to identify the stressor. The assessment findings or cues from the previous risk factors step may prove helpful in narrowing down possible stressors to that which is currently causing psychophysiological stress responses. This adaptation technique reflects “analysis,” the second phase of the nursing process, or “analyze cues” from the CJMM.

At this point, the nurse investigates aspects of the patient's life that may shed light on specific stressors influencing the patient. This may include potential contributions from health history and current state, including current socioeconomic situations such as family and employment status (or lack thereof). Recent events that have already been identified as having produced stress, or that have caused issues in the past, are worthy of analysis and consideration. With the nurse and patient working together to analyze the possibilities, the stressor (or multiple stressors) is typically identifiable.

### Identify Personal Feelings Toward Stressor

For patients who are attempting to effectively cope with and adapt to stress, once a particular stressor has been identified, the next step toward hopeful success is to identify personal feelings relative to the stressor. Sometimes, stress responses are subconscious, as the body reacts to changes in homeostasis with automatic chemical reactions. Cases of this nature often reflect physical assaults to equilibrium, such as the vasoconstriction, aldosterone, and ADH release that are initiated to counter fluid volume deficit from blood loss or dehydration. These automatic reactions are often associated with acute stress circumstances, without the patient cognitively recognizing or responding.

An example of fluid volume deficit is an older adult patient who does not drink enough water. With this additional information in mind, the nurse can help identify contributions to the stressful incident. What is prohibiting adequate fluid intake? The nurse determines that the factors are forgetfulness and diminished thirst. And, because the patient has difficulty ambulating, it is too complicated to get up to fix a drink. As the nurse uncovers these issues, the patient can be collaborated with once again to determine what factors can be changed, and which among those the patient wants to change in order to minimize stress, maximize effective adaptation, and restore homeostasis.

## PATIENT CONVERSATIONS

---

### Diets of the Heart

**Patient:** [wipes her eyes and her runny nose] Nurse, I'm so worried about my heart!

**Nurse:** Tell me what worries you about it, Mr. Adams.

**Patient:** My heart's so bad. I just hate it!

**Nurse:** Ah. Yes, your heart failure has been getting a bit worse. I notice the doctor increased your lisinopril and your water pill today.

**Patient:** I know. I just want it to go away. My husband doesn't want to eat bland food, and I can't cook anymore, so he picks up stuff for us. He gets spicy food, and it does taste better.

**Nurse:** I wonder if you could find some foods that he just needs to heat up but are low in salt and fat and have flavor, if you'd eat them?

**Patient:** I guess it's worth a try. He's picky, but maybe.

**Nurse:** [shows a menu flier] Okay. Here are four companies that make meal kits suited for particular diets. Some of them are spicy. And I can give you a list of spices you can use, in case you want to add more. But if you want your heart failure to improve, or at least not get worse, you really need to not add salt, and limit fats.

**Patient:** If he'll use this, it'll make it easier for me, too.

**Nurse:** That's true. Let's follow up in three weeks, and you can tell me how you're both doing. We can think of more ideas then, if we need to. Why don't you bring Mr. Adams in with you then?

**Patient:** I'll see if he'll come. Maybe he'll like the food.

---

An ability and desire to change may reflect the same coping behaviors; sometimes, though, the fact that change is possible does not mean the patient wants to do so. This can pose a barrier to coping, leading to refusal to try or use of defense mechanisms. Maladaptive mechanisms unfortunately perpetuate negative results of stress and, ultimately, chronic stress-induced disorders. Nurses can assist patients through education about the following:

- pathophysiological processes
- prevention
- treatment compliance
- actions for effective coping:
  - regulating emotions
  - relaxing
  - novel approaches to stress and its relief
  - supportive relationships
  - professional therapy
  - positive self-talk and activities
  - participation in spiritual or religious actions (Peterson, 2021; Wilson, 2023).

Maintaining homeostasis continues with the analysis phase of the nursing process or the CJMM. During this step, collected data from the assessment or recognition phases are analyzed for possible interventions and actions by the nurse and patient. Subsequently, they will be arranged by priorities.

### Decide Action

At this point, the nurse has identified risk factors, applicable stressors, and the patient's feelings toward the stressors. With these pieces in place, the stressors can be prioritized, and actions can be considered and decided on. If there is but one stressor identified or noted to be of importance, prioritization is simple; frequently, however, patients have more than one issue going on at once, or the source of stress is complicated with multiple actions possible. Based on severity of symptoms, patient goals, and the patient's personal priorities, decisions need to be made about action(s) to plan and implement. To continue the previous exemplar about fluid volume deficit, the nurse previously considered possibilities for the patient's hypovolemia, including forgetfulness, diminished thirst, and ambulation challenges limiting access to fluids. With the patient's input, it is determined the most important action is to improve the availability of fluids. The patient feels that even without feeling thirsty, it will be easier to remember to drink if water is handy.

### Constructive

Some actions are constructive and will improve access to what the patient needs to effectively adapt to stress and

minimize its effects. Some are likely to prove destructive and are explored next. Ideally, constructive measures will either produce eustress or little to no stress, maintaining the homeostatic state.

Revisiting the example patient, constructive solutions include the following:

- having an assistive device (e.g., cane, walker) nearby for the patient to easily use to ambulate to the refrigerator or sink for water
- having water available in a cooler or insulated beverage container near the patient's bed or chair
- placing a bedside commode near the patient's bed or chair to prevent anxiety from having to ambulate to the toilet

### **Destructive**

Destructive actions are those that will produce distress for the patient and therefore foster negative coping strategies and maladaptive results. Some of these will be individual responses, as what may prove to be constructive for one patient may be destructive for another. A patient who is forgetful may need reminders for particular actions, so a reminder of some sort may be helpful. However, a phone call or an alarm may be startling and cause fear and agitation, so it may cause its own negative stress.

### **Evaluate Outcome**

Finally, in an effort to produce and foster adaptation techniques to maintain homeostasis, the evaluation process should be employed. At the point where actions were decided, patient goals and nursing goals were both considered in order to determine which action(s) to plan and act on. This period allows for the nurse to evaluate the outcomes of the previous actions; when the actions were implemented, were the established goals achieved? If so, then the cycle of the nursing process continues with assessment or recognition occurring again to determine the next important cues. If goals were not met, the process again begins, but with focus on what modifications may prove helpful for goal achievement and how to implement such changes.

## Summary

### 34.1 Stress and Adaptation

Stress involves a perceived threat and responses associated with the release of chemicals that stimulate the SNS. Resulting effects are those commonly recognized as the fight-or-flight response, which readies the body for action against challenges and dangers. In many circumstances, stress is necessary and life sustaining, or even lifesaving. Stress is integral in some aspects of growth and development, especially through adaptation. Adaptive, or coping, responses support the body's resistance to stress and ideally its resolution and return to a condition of homeostasis.

Resistance to stress involves adaptive responses, which when effective assist the body in its return to equilibrium, when the SNS effects diminish and homeostasis is restored. Unfortunately, coping does not always involve positive techniques, and maladaptive results may also occur, preventing or slowing the return to homeostasis. Sustained arousal responses, as seen by continued SNS stimulation, lead to chronic stress-induced illnesses and contribute to functional deterioration over time.

Stress and adaptation influence human development, health, and wellness throughout the life span. Responses to stress may be conscious or subconscious, as some reactions are strictly activated by neurobiological actions, and others may be controlled by the affected individual. Individuals who demonstrate higher levels of resilience and optimism typically experience fewer negative impacts from stress, with positive coping returning them to a level of homeostasis more promptly. Negative adaptive responses are more likely for those who lack resilience or have experienced adverse or traumatic events, as they have been hindered in developing effective coping skills and resilience.

Physiological and psychological aspects of homeostasis are maintained by various means. The stress response results in generalized, systemic effects, as well as localized effects, depending on the specific type of stressor. Classic examples of the LAS include reflex and inflammatory responses, while the GAS is exemplified by the fight-or-flight response associated with SNS stimulation affecting the entire body. Psychosocial homeostasis is affected by the close interaction of mind and body and by the development of effective coping mechanisms and adaptive abilities.

### 34.2 Effects of Stress on Health and Wellness

The effects of stress on health and wellness have been the topic of the previous sections. Using Maslow's hierarchy of needs as a guide, physiological, safety and security, love and belonging, self-esteem, and self-actualization needs have been described. The impact of stress on achievement and satisfaction of these basic and advanced needs has been analyzed and exemplified.

Because there are negative consequences of long-term stress, effects on the body in general, and the immune system specifically, have been explored. Unfortunately, many of the stress-related disorders are all too common, with nursing students beginning to become familiar with them during clinical experiences. Throughout professional practice, nurses are apt to encounter some of these diagnoses repeatedly. Additionally, poor health habits have been characterized, and some of the negative impacts such decisions and behaviors have on families have been shown.

When adaptive responses are ineffective, results can be critical. When such maladaptive coping is unable to keep up with the stress responses, crises are possible. In crisis situations, the patient loses psychological homeostasis and the ability to cope and adapt. Major, typically adventitious, events may manifest initially at the crisis level; maturational and situational events tend to begin at lower stress levels. If coping is insufficient, day-to-day stresses or unexpected incidents can cause an individual to spiral out of control and into a stage where they are not able to regulate the disequilibrium and restore homeostasis.

### 34.3 Factors Affecting Stress and Adaptation

Stress can be found in most any area of human life. Assuming normal growth and development, there are actual and potential stressors from prenatal development through old age and ultimately death. During any of these life span phases, developmental and situational stressors impact neurocognitive changes as neural pathways and responses are created and promoted.

Whether adaptations have positive or negative results depends on a variety of individual factors. How stress is received and perceived affects a person's ability to adapt. Additionally, state of health (essentially a continuum from wellness to illness, and ultimately critical illness and death) influences psychophysiological stress reactions. Outcomes tend to be better, demonstrating effective coping strategies and adaptive responses, when an individual is supported through stressful circumstances. A nurturing environment, support from family, friends, and the larger communities of employment, leisure, spiritual support, and perhaps formal mental health providers, tend to foster eustress and resilience.

Considerations within the topic of socioeconomic status may come to mind as simply financial, but there is more to it than money. While economic status is important, other issues, like healthcare access and availability of neighborhood and community systems, are also important under the socioeconomic umbrella. Again, these influences and systems reflect layers of support and the potential for stress. Such factors contribute, once again, to positive or negative stress responses and resultant impacts on health and wellness.

### 34.4 Adaptation Theories and Models

This final section of the chapter offers a high-level view of stress and adaptation through an exploration of theories and models. The stress-response theory and GAS are similar, with focus on the physiological response to a stressor or threat and resultant changes affecting psychobiological function. More recently, the concept of allostasis has been introduced, along with theories surrounding allostasis and allostatic load. This offers further information about physiological limits to chronic stress and how homeostasis is restored and maintained.

Two models of stress and adaptation, the RAM and the PSM, have been introduced. Roy's model is a detailed framework for nursing education and practice, applicable as a guide for curriculum and potentially as a textbook. Its comprehensive nature addresses stress and its physiological reactions and different applications for the holistic aspects of nursing. There is some correlation with Selye's stress and adaptation concepts but with expansion specific to nurses and patient care.

As the model's name indicates, the PSM's focus is on the connections between the psychological and physiological implications of stress and adaptation. There is an undeniable relationship between responses that are initiated by one system and have impacts on the other. As the PSM suggests, for example, anxiety can play a role as a stressor and lead to physiological responses, or it can be the result of a physiological threat, essentially a side effect of the stimulated SNS. Adaptations result, effectively or not, from either system as the original stimulus, and considering both aspects is important.

Coping strategies or adaptation techniques are the resistance mechanisms for restoring and fostering homeostasis. The process, from identification of risk factors, the stressor, and its impacts on the individual, through establishing priorities, producing solutions, implementing actions, and finally evaluation, has been studied.

## Key Terms

**adaptation** the ongoing changes within the body in response to stress

**allostasis** the ongoing changes within the body in response to stressors

**allostatic load** the collective burden of chronic stressful events.

**anxiety** an overwhelming feeling of apprehensiveness, nervousness, and worry about real or perceived events that have an uncertain outcome

**coping** an adaptive mechanism for managing stress

**crisis** an inability to cope with a stressful situation

**distress** negatively perceived stress, or stress that causes a negative response

**eustress** positively perceived stress, or stress that initiates a positive response

**general adaptation syndrome (GAS)** theory involving stress as the cause of a three-stage syndrome of events resulting in either adaptation or exhaustion

**homeostasis** the process by which the human body maintains balance by adjusting to internal and external stimuli

**maturational** events that happen in a person's life

**psychophysiological stress model (PSM)** the relationship between the mental and physical reactions and adaptations to stress

**Roy's adaptation model (RAM)** holistic approach to the art and science of nursing structured as a science, model,

and practice discipline containing various elements

**stress** the physiological response by the body to a stimulus, or stressor

**stress-response theory** the identification of the body's nonspecific reaction to a threat or stressor

**stressor** the stimulus or cause of the stress response

## Assessments

### Review Questions

1. Starting a final exam for which the student has not fully prepared will likely elicit which aspect of stress for the student?
  - a. allostatic load
  - b. distress
  - c. maladaptation
  - d. eustress
2. After being terminated from employment, a person stops for a drink and yells at the bartender. The nurse recognizes this behavior as representing what defense mechanism?
  - a. repression
  - b. projection
  - c. displacement
  - d. intellectualization
3. The nursing preceptor corrects the student when what chemical is described as a catecholamine?
  - a. dopamine
  - b. norepinephrine
  - c. epinephrine
  - d. cortisol
4. Allostatic overload describes which circumstance?
  - a. a level of physiological equilibrium
  - b. more stress than the person is able to cope with
  - c. stress that contributes to normal development
  - d. an incapacitating feeling of unease
5. A patient who is admitted to the hospital experiencing an exacerbation of chronic obstructive pulmonary disease is very anxious. The nurse is aware of which likely cause of the patient's anxiety?
  - a. extreme pain
  - b. elevated blood pressure
  - c. air hunger
  - d. gastrointestinal upset
6. Stress is initially recognized in which part of the brain?
  - a. limbic system
  - b. cerebellum
  - c. Wernicke area
  - d. brainstem
7. A 32-year-old patient who has been laid off from work has frequent episodes of anxiety, particularly in the evenings. This scenario shows that which of the patient's basic needs is not being met?
  - a. physiological needs
  - b. safety and security
  - c. self-esteem
  - d. self-actualization

8. A nursing student is caring for a patient who has been prescribed a glucocorticoid drug to treat inflammation. The student recognizes this type of drug has which additional result?
  - a. frequent hypotension
  - b. severe hives
  - c. reduced immune response
  - d. critical weight loss
  
9. A patient has not only lost their home, but the entire city has been demolished by a hurricane. Which type of crisis has the patient experienced?
  - a. maturational
  - b. situational
  - c. development
  - d. adventitious
  
10. An anxious patient has employed coping strategies that have worked to reduce anxiety in the past, but this time these are not effective. The patient is in which crisis phase?
  - a. crisis phase 1
  - b. crisis phase 2
  - c. crisis phase 3
  - d. crisis phase 4
  
11. Effective adaptation during the resistance phase of the general adaptation syndrome is anticipated to have what result?
  - a. homeostasis
  - b. alarm
  - c. exhaustion
  - d. allostatic overload
  
12. Exposure to maternal stressors affects which fetal hormone?
  - a. calcitonin
  - b. growth hormone
  - c. cortisol
  - d. oxytocin
  
13. Which patient typifies experiencing the developmental milestones of establishing intimacy and independence?
  - a. an 11-month-old, starting to walk
  - b. a 6-year-old, starting first grade
  - c. a 22-year-old, getting married
  - d. a 64-year-old, retiring
  
14. To counteract the negative effects of a dysfunctional and abusive family, the nurse will recommend a 12-year-old patient try what action?
  - a. participate in an after-school indoor soccer group
  - b. bring brochures for counseling home for the parents
  - c. stay outside with friends to avoid family arguments
  - d. dissociate from family to prevent conflicts
  
15. What is a frequent stressor faced by the older adult?
  - a. facing a promotion at work
  - b. having multiple health problems
  - c. searching for a new job
  - d. raising a defiant teenager

- 16.** A patient with a long history of bipolar disorder may have difficulty coping with stressful situations for what reason?
- the complexity of treating the disorder
  - a lack of financial resources
  - established maladaptive techniques
  - a natural tendency toward resilience
- 17.** What description characterizes the stress-response theory?
- a specific reaction to a threat
  - an adaptive response
  - nonspecific responses to a stressor
  - underdeveloped coping
- 18.** What theory related to stress and reactions to stress is represented by the following stages: acute, resistance, and exhaustion?
- allostasis and allostatic load theory
  - stress-response theory
  - psychophysiological stress model
  - general adaptation syndrome
- 19.** Roy's adaptation model includes which concept?
- the goal of nursing
  - resistance
  - specific diagnoses
  - alarm
- 20.** Which action would be constructive for a patient who is adapting to limited mobility after several falls?
- Encourage the patient's frequent independent walking.
  - Provide a raised seat for the toilet.
  - Restrict fluid intake.
  - Teach the patient use of a walker.
- 21.** During the resistance phase of the general adaptation syndrome, the action of the sympathetic nervous system is opposed by which system?
- immune system
  - vascular system
  - parasympathetic system
  - endocrine system

### Check Your Understanding Questions

- Adrenocorticotrophic hormone (ACTH) is released from the hypothalamus in times of stress. The ACTH causes release of cortisol, norepinephrine, and epinephrine from the adrenal glands. Describe four of the effects of the release of these hormones.
- A patient whose spouse has experienced a stroke with significant residual effects is at risk for effects related to stress and anxiety. Describe the type of crisis the spouse is at risk for if anxiety becomes overwhelming.
- Describe at least five negative effects stress can have on families.
- Select one of the social determinants of health and describe in approximately 100 words how it contributes to increased stress.
- Describe an example of how a nurse will identify which stressor is causing a patient's distress.

## Reflection Questions

1. Consider a patient who is an accountant and is extremely anxious a month prior to the income tax deadline. Describe positive coping behaviors and ways to introduce such behaviors to the patient.
2. Think about caring for a patient whose anxiety has been rising. The patient is experiencing severe stress and is extremely anxious. What are your concerns for the patient reaching the point of crisis?
3. Identify a stressor you have encountered since starting nursing school. Reflect on the following: (1) Was this developmental or situational? (2) How were you able to adapt? (3) Was your adaptation positive/effective or negative/ineffective?
4. Consider an action that exemplifies a destructive action relative to maintenance of homeostasis. Describe two things you as a nurse can do to assist your patient to identify constructive actions instead.
5. Describe what has happened physiologically when a patient has reached the exhaustion stage of the general adaptation syndrome.

## Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #5: Part 3](#). What psychosocial stressors is the patient experiencing?
2. Refer to [Unfolding Case Study #5: Part 4](#). Based on the Unfolding Case Study and Maslow's hierarchy of needs, how do you think the patient's stress is affecting his needs?
3. Refer to [Unfolding Case Study #5: Part 5](#). What are some examples of constructive actions that could be taken by the nurse?

## What Should the Nurse Do?

1. A patient who has a long-standing history of type 2 diabetes mellitus has been experiencing extreme episodes of anxiety with accompanying feelings of a racing heart, breathing fast, and high blood sugar. The patient asks the nurse why this is happening. What should the nurse do to explain the stress response?
2. A patient who is scheduled to undergo mental health testing is frequently asking to use the restroom to void. What should the nurse do in order to maximize the patient's performance on the test?
3. A nurse is caring for a patient with a long-standing history of hypertension. The patient is worried about this becoming worse, because a third prescription is now necessary for control. In talking to the patient, the nurse discovers the patient is not self-aware. What should the nurse recommend to help the patient foster self-awareness?

## Competency-Based Assessments

1. Describe how eustress is perceived as a positive response.
2. Create a maximum 300-word explanation for a patient as to how chronic stress affects immunity.
3. Create a three-minute video explaining concepts within socioeconomic status.
4. Review these concepts of Roy's adaptation model: adaptation level, adaptive responses, adaptive/effector modes, and health. Describe how they relate to nursing care of patients.

# CHAPTER 35

## Spirituality

**FIGURE 35.1** Spirituality can mean many different things to different people. However it's defined, its presence has the potential to improve a patient's health and well-being. (credit: modification of "Astro Spirituality" by Sujeet Singh/Wikimedia Commons, CC BY 4.0)

### CHAPTER OUTLINE

35.1 Dimensions of Spirituality

35.2 Applications of Spirituality to Health Care

**INTRODUCTION** If you were to ask 100 people what spirituality means, you would likely get 100 different answers. These diverse answers would likely reveal a person's innermost beliefs and values, as well as the meaning and purpose they derive from life and their relationships with the world around them. For many people, spirituality drives their decisions and provides comfort and resilience during difficult life experiences, including illness (Balboni et al., 2022). Consequently, understanding a patient's spiritual beliefs and needs—including recognizing how they may differ from one's own—is one of the most important parts of providing culturally aware, compassionate, and comprehensive nursing care. In this chapter, you will learn how to have open, respectful conversations with patients about their spiritual needs and identify the evidence-based practices that will help you meet those needs.

### 35.1 Dimensions of Spirituality

#### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Recognize key concepts of spirituality
- Identify the different practices of spirituality
- Explain how spirituality affects health and well-being

Many people believe in and feel connected to a power greater than themselves. This sense of connection helps give their lives meaning and purpose and provides solace and peace as they navigate life's challenges. One's **spirituality**

encompasses not only this connectedness but also the diverse practices that people follow in seeking **transcendence**, or experiences that move them beyond the physical or literal world. For some people, spiritual practices include belief in a particular deity or deities and worship in a religious institution such as a church, temple, mosque, or synagogue. Others may develop their spirituality through nature or art. An individual's sense of spirituality may evolve throughout their life as they have new experiences and cultivate new relationships.

Nurses play a pivotal role in helping people cope, and spirituality is often central to these efforts. Integrating a patient's spirituality with their care has been shown to lead to improvements in health and quality of life, as these beliefs influence how patients experience pain, respond to stress, and approach the challenges associated with serious illness and death (Balboni et al., 2022; Harvard T. H. Chan, 2022). To do this effectively, nurses must understand the key concepts and practices of spirituality.

## Concepts of Spirituality

One's sense of purpose or meaning in life, or one's **spiritual well-being**, depends on positive connections between one's self and the rest of the world, including other people, nature, art, and, for some, awareness of a higher power (American Nurses Association [ANA], 2015). When patients are confronted with an initial diagnosis of illness or a severe injury, they often struggle with the fundamental question, "Why is this happening to me?" This question is a manifestation of **spiritual distress**, or disruption to their core beliefs and values (Harrad et al., 2019). Nurses play a crucial role in alleviating patients' distress by responsively addressing their discomfort and advocating for their spiritual needs throughout the health care journey.

In its first provision, the American Nurses Association (ANA) Code of Ethics emphasizes nursing practice with compassion, respect for each person's inherent dignity, and the recognition of their unique attributes. According to this code, optimal nursing care seeks to enable patients to live with maximum well-being across physical, emotional, social, and religious or spiritual dimensions, reflecting their individual values. In the context of nursing, spirituality and spiritual values are closely intertwined with caring, as are key concepts such as faith, hope, and love.

## LINK TO LEARNING

The [ANA Code of Ethics for Nurses with Interpretive Statements \(https://openstax.org/r/77ANAEthics\)](https://openstax.org/r/77ANAEthics) is a useful guide for how to deliver quality, ethical care.

### Faith

An acceptance of certain religious doctrines is called **faith** and is often associated with specific religions such as Buddhism, Christianity, Hinduism, Islam, and Judaism. Although it may be viewed in monotheistic (belief in a single deity or god) tradition as adherence to specific doctrines, faith takes the form of an attitude of devotion facilitating a gateway to spiritual practice in some cultures and religions. In a broader sense, faith can refer to a relationship with a divine force—whatever an individual believes that to be.

Engaging in a faith-based and spiritual practice can be a valuable coping strategy for patients, addressing fundamental human needs such as identity, self-care, community, belonging, and connection. As nurses, advocating to meet patients' spiritual needs is one of the tasks of providing comprehensive, culturally aware care. Initiating conversations and creating a supportive space for discussions on faith and spirituality can play a pivotal role in promoting physical and psychological healing.

### Religion

People commonly associate faith with **religion**; however, they are distinct concepts. Religion is a unified system of beliefs, values, and practices that a person holds sacred or considers to be spiritually significant ([Figure 35.2](#)). It is possible to be spiritual without belonging to any religion, just as it is possible to belong to a religious community and perform all the required practices without deriving any spiritual meaning from them.

**FIGURE 35.2** These religious symbols represent some of the world’s most populous religions: (top row, from left) the word *Om* (Hinduism), the wheel of dharma (Buddhism), the Jain emblem (Jainism), the khanda (Sikhism); (bottom row, from left) the star of David (Judaism), the cross (Christianity), the crescent and star (Islam), and the taijitu (Taoism). (credit: modification of “Religious symbols collage” by “Howardcorn33”/Wikimedia Commons, CC BY 4.0)

Nurses should be familiar with the beliefs and practices of the religions present in their communities, particularly beliefs regarding health and well-being. For example, some religions prohibit the eating of certain foods or the utilization of specific medical interventions such as blood transfusions. Some religions celebrate holidays with different rules and expectations for behavior, such as fasting, prayer, or purification rituals. As much as possible, a nurse should tailor care to incorporate the religious needs of the patient and their family. Nurses should get clarification from patients and their families about their lived experiences of religion and spirituality—just because a patient identifies as a specific religion does not mean they follow it devotedly.

### Hope

The desire for a positive outcome is known as **hope**. Hope is a vital and influential aspect of spiritual practice in nursing and can guide patients through challenging moments. It is central to the healing process and emphasizes the efforts of the patient’s journey through recovery.

Cultivating hope is a skill that can be developed through practice and holding specific attitudes. Patience, the ability to endure delays and allow events to unfold naturally, is one such attitude. Courage, or confidence in the face of uncertainty, is another crucial element. Persistence, persevering regardless of obstacles, forms the third pillar. True hope is realized when we sincerely declare that all will be well and genuinely believe in that affirmation.

Hope is also a desire or goal for a particular event or outcome. For example, some people may view dying as “hopeless,” but a spiritual view can define hope as a “good death,” which is when a patient dies peacefully and according to their end-of-life preferences.

People in despair may try to find witnesses who can answer their questions and replace fearful voices with hopeful ones. At times, nurses may ask patients about their fears—in these moments, simply being a compassionate listener can be a powerful healing tool beyond practical nursing care. Quality connections shape the level of hope in a patient’s life, opening up a horizon of possibilities beyond the current situation.

### Love

The notion of **love**, a strong feeling of affection, may seem simple—after all, most of us use the word every day in a variety of contexts. But we clearly mean something different in each context: romantic love differs from parental love, which differs from the love someone has for a piece of music, a treasured possession, or delicious food. Nurses are not required to love their patients; a sense of professionalism or responsibility may be all the motivation they need to provide effective, quality care. However, contemplating the role of love in nursing can enhance nursing

practice in two significant ways. First, it prompts nurses to reflect on their values and beliefs. Second, it guides them in establishing meaningful interactions with patients. Love in nursing manifests through accountability, benevolence (being kind and well-intentioned), attentive concern, respect, and the recognition of others as human beings. These behaviors contribute to patients and nurses feeling valued, fostering self-esteem, and alleviating suffering.

## Practices of Spirituality

There are many ways that people can experience and express their spiritual beliefs, both as individuals and as part of a community. Practices such as praying or going to church are associated with particular religions. Others, such as communing with nature or practicing mindfulness, are more about feeling connected to oneself and the rest of the world.

Spiritual practices may involve **ritual**, a defined activity to commemorate or cope with something significant. Spirituality could also be a ceremony (a public, formal celebration or gathering to honor an important event). It is important for the nurse to be aware of the different spiritual practices that may matter to their patients so they can facilitate these activities as part of the healing process.

### Individual Practices

Although individual practices may be performed in a group setting (such as a yoga class or a prayer group), the focus is on the individual experience of spirituality. Many of these practices involve private contemplation or similar activities to increase compassion and empathy and quiet the mind (Delagran, n.d.). This section explains some common individual practices and their associated health benefits.

#### Mindfulness

The practice of being present in the moment and aware of one's thoughts, feelings, and environment is called **mindfulness**. This awareness is nonjudgmental: in a mindful state, we acknowledge negative experiences but do not fault ourselves for experiencing them. When practiced regularly, mindfulness helps us develop some control of our reactions, see the habitual patterns that lead to negative reactions and stress, and learn healthier patterns. Practicing mindfulness reminds us to pause, get a clearer picture of a situation, and respond more skillfully.

Consider your default state when studying for an exam in a difficult course or preparing for a clinical experience. What do you do? Do you tell yourself, "I am not good at this" or "I am going to look stupid"? Does this distract you from paying attention to studying or preparing? How might the experience be different if you had an open attitude with no concern or judgment about your performance? What if you directly experienced the process as it unfolded, including the challenges, anxieties, insights, and accomplishments, while acknowledging each thought or feeling and accepting it without needing to figure it out or explore it further? By simply observing thoughts and emotions instead of reacting to them, a person can develop a broader perspective and learn more effective responses (Schuman-Olivier et al., 2020).

#### Meditation

A mindfulness technique that involves focused attention—often on a particular word, phrase, or image—and deep breathing is known as **meditation**. Research suggests that regular meditation can contribute to reduced symptoms of depression, improved sleep quality, and enhanced mental clarity, making it a valuable tool for patients to manage stress, alleviate anxiety, and foster emotional resilience (American Psychological Association [APA], 2019). Some studies have also shown that meditation may help decrease the perception of pain and support pain management (Hilton et al., 2017).

In a healthcare setting, introducing meditation as part of patient care can be a simple yet powerful strategy. Nurses can educate patients about the practice, its positive effects on physical and mental health, and its potential to complement medical treatments. Offering guided meditation sessions or providing resources such as meditation apps can empower patients to incorporate this practice into their daily routines, promoting self-care and a sense of control over their well-being.

## REAL RN STORIES

---

### Focusing on the Moment

**Nurse:** Hillary, BSN

**Clinical setting:** Oncology unit

**Years in practice:** 16

**Facility location:** A hospital in rural New England

Even though I've been a nurse for well over a decade, I only transitioned into cancer care a few years ago. The career shift was actually for a personal reason—after my mom was diagnosed with breast cancer, I learned that our local healthcare system was really struggling to provide quality care to cancer patients and their families. I was determined to do my part to make things better, but I had no idea what I was in for. And I'll be honest, that first year, I wasn't sure I'd make it. But I had an amazing charge nurse, Kathy, who taught me so much about how to not just take care of my patients and their loved ones, but myself as well. One of the first “tricks” she taught me was meditation. And at first, I thought it was a little weird. Like one of those “new-age” things you go to a retreat to do. And besides that, I didn't see how I could possibly justify taking the time out of my shift to do it when I had patients who needed me. But Kathy was adamant about the self-care work that nurses have to do. Meditating was hard at first, because I couldn't get my brain to just shut up. But over time, it did start to get easier.

I'll never forget the first time I felt it really working for me. I had a patient with the same cancer my mom had, but a far worse prognosis. This patient, we'll call her Shanna, also didn't have any family support. The situation was stressful, not just because Shanna was in so much pain and so sad, but because watching her go through what my mom had gone through just brought up a lot of my own feelings again. I was getting distracted and making mistakes, which immediately alerted me that I needed to stop, reach out for help, and find strategies for coping—and in that order.

At first, it was just a few minutes when I was restocking supplies or waiting for the fountain to fill up my water bottle—just focusing on what I could hear, see, smell, and touch. I would focus so hard on being in the moment that it would force me out of the past, where my mom was the patient, and when I walked back into Shanna's room, I was present and there for her. Pretty soon, those little meditations just became a normal part of my shifts. Whenever I feel myself getting too caught up in my head, or someone else's, meditating brings me back to the present moment and the patient in front of me.

---

### Prayer

The practice of communicating with a higher power or divine entity is prayer. Unlike mindfulness and meditation, **prayer** is mainly used in the context of religion, though it is a deeply personal and culturally diverse practice. Encouraging prayer as part of the healing process for patients who are open to it can provide a source of comfort, solace, and connection during challenging times. Prayer can foster emotional resilience by offering patients a means to express their fears, hopes, and gratitude and helping them to navigate the complex emotions associated with illness. It is also a reminder of their faith and connection to a higher power, which can give patients a sense of hope and purpose.

For the nurse, supporting patients who want to incorporate prayer into their care plan demonstrates a commitment to holistic, patient-centered care (PCC). It honors the individuality of each patient and promotes an environment that respects and supports their diverse cultural and spiritual backgrounds. Prayer has been shown to have concrete benefits for patient health, linked to stress reduction and relaxation (Andrade & Radhakrishnan, 2009).

### Breathwork

Both healthcare providers and patients often face significant stress that affects their physical, mental, and spiritual well-being. One practical approach to interrupting the stress cycle and promoting relaxation is **breathwork**, a technique involving intentional, controlled breathing. Breathwork is a safe and easily accessible practice that can be utilized in any healthcare setting as well in one's daily routine. It has been proven to reduce anxiety and depression while improving sleep, making it a valuable tool for individuals seeking to enhance their well-being (Shaw-Metz, 2023). Both nurses and patients can prepare for moments of heightened stress by identifying their specific triggers

and stressors and incorporating breathwork into their self-care tool kit as a coping strategy.

### Nature

In many spiritual traditions, nature is a powerful source of symbolism and metaphor. The changing seasons, cycles of life, and relationships observed in nature can mirror spiritual concepts such as growth, transformation, and the interconnectedness of all living things. But the connection between the natural world and the self goes beyond metaphor. Sensory experiences in nature, such as the feel of the wind, the scent of flowers, or the sound of flowing water, can serve as conduits for spiritual experiences, promoting holistic well-being and reducing stress and anxiety (APA, 2020). As individuals relax in natural surroundings, they may find it easier to connect with their inner selves and explore spiritual aspects of their identity (Ryff, 2021).

Spending time in nature can also enhance spiritual healing by fostering a deep connection between individuals and something larger than themselves. In essence, nature provides a serene and nurturing backdrop for individuals to explore and deepen their spiritual connection. Whether providing awe-inspiring beauty or the comfort of everyday sensations, nature encourages a state of mindfulness and presence that is conducive to spiritual reflection, meditation, and inner peace (Yamada et al., 2020).

### Yoga

A practice rooted in ancient spiritual traditions, **yoga** combines physical postures, controlled breathing, and mindfulness techniques to harmonize the mind, body, and spirit (Figure 35.3). The physical aspects of yoga, including gentle stretches and postures, contribute to flexibility, balance, and improved circulation. Systematic yoga practice has been found to reduce inflammation and stress, decrease depression and anxiety, lower blood pressure, and increase feelings of well-being (Padmavathi et al., 2023; Yatham et al., 2023). Yoga can be a valuable tool for pain management and rehabilitation both for patients dealing with chronic conditions as well as those recovering from surgeries. Yoga has also been shown to improve sleep quality by promoting relaxation and reducing anxiety, which can help with physical healing (Woodyard, 2011). The practice also encourages emotional and spiritual healing by cultivating self-awareness and mindfulness and helping individuals be fully present in the moment.

**FIGURE 35.3** A yoga practice does not have to be advanced to offer mental and physical benefits. (credit: “Yoga” by Dave Rosenblum/ Flickr, CC BY 2.0)

By incorporating yoga into patient care, nurses contribute to a patient-centered approach to healing. Yoga’s holistic nature addresses physical ailments and the spiritual dimensions of well-being. The practice’s diverse origins provide an inclusive approach to spiritual healing that respects various cultural backgrounds. Nurses can educate patients on the accessibility and benefits of yoga, encouraging them to continue the practice independently as a valuable

tool for self-care beyond the healthcare setting.

### Journaling

Writing one's thoughts and documenting one's feelings in a journal or diary is called **journaling**. The practice can help people become more aware of their inner lives and feel more connected to experiences. Studies show that writing during difficult times may help a person find meaning in life's challenges and become more resilient in the face of obstacles (Sohal et al., 2022; Smyth et al., 2018). When journaling, it can be helpful to focus on three basic questions: What experiences give me energy? What experiences drain my energy? Did I experience anything today that made me feel alive and positively connected to my surroundings? Allow yourself to write freely without stopping to edit or worry about spelling and grammar.

### Social Support

Social support plays a crucial role in individual spirituality, offering avenues for connection, support, and growth within a community context. One essential practice of spirituality through social support is active participation in religious or spiritual communities. Some people find a spiritual community among their family and friends. Others join a spiritual group in the community, such as a church, synagogue, temple, mosque, meditation center, nature center, or yoga class. These communities provide a space for individuals to come together, share beliefs, engage in worship, and find support from others. Within these communities, individuals often form deep bonds, offering each other companionship, encouragement, and a sense of belonging.

Within social support systems, people may also seek guidance from spiritual mentors or leaders who can offer wisdom, advice, and spiritual insight, guiding individuals through challenges and helping them deepen their understanding of their faith or beliefs. Through mentorship relationships, individuals receive personalized support and encouragement tailored to their unique spiritual needs and aspirations.

Volunteering and serving others within the community are individual practices of spirituality. Serving alongside others fosters a sense of unity, purpose, and interconnectedness, deepening individuals' spiritual growth and fulfillment. Through acts of service, individuals express their spiritual values of compassion, kindness, and generosity while connecting with others and positively impacting the lives of those in need.

As a nurse, you may be called upon to help a patient connect with social support. There will also be times when you, as a human being, will need to lean on your social network for support. If you have a well-established support network, it will also help you help patients navigate the valuable connections with others that can bolster them spiritually in difficult times.

### Organizational Practices

Organized spiritual practices typically involve religion. Although the overall percentage has been trending downward, most Americans identify as belonging to a specific religion. However, the Census of American Religion, conducted annually by the Public Religion Research Institute (PRRI), underscores the complexity of these affiliations (Public Religion Research Institute, 2023). According to the 2022 survey:

- 26.8 percent of Americans identify as religiously unaffiliated, the largest individual category, which includes:
  - **atheist**, those who do not believe in the existence of any divine being, and
  - **agnostic**, those who believe that ultimate reality is unknowable, as well as,
  - people who are very spiritual but resist identifying with a specific religion.
- Of Christians in the United States, 27.6 percent identify as nonevangelical Protestant and 23.1 percent identify as Catholic. The survey further divides these totals into subcategories by race and ethnicity: 13.6 percent identify as evangelical Protestant, 1.5 percent identify as Mormon, and 1.1 percent identify as Jehovah's Witness.
- 1.9 percent of Americans identify as Jewish.
- Less than 1 percent of Americans identify as a member of any other specific religion, including Islam, Buddhism, and Hinduism.

Research by PRRI also reveals varying levels of certainty and nuance in the nature of belief in a god, illustrating that individuals hold distinct perspectives even within shared religious frameworks (Pew Research Center, 2023). PRRI findings emphasize the diversity within religious groups, as some unaffiliated individuals embrace specific religious beliefs, whereas some affiliated members report minimal importance of religion in their lives. Furthermore, the

survey indicates that the belief in absolute standards of right and wrong is influenced not only by religious beliefs but also by practical experiences, highlighting a nuanced and pragmatic approach to morality in the United States.

## LINK TO LEARNING

---

Learn more about the [2022 PRRI Census of American Religion: Religious Affiliation Updates and Trends \(https://openstax.org/r/77PRRICensus\)](https://openstax.org/r/77PRRICensus) that provides county-level religious affiliation data.

---

Every culture has atheists who do not believe in a divine being or entity and agnostics who hold that ultimate reality (such as a god) is unknowable. However, being a nonbeliever in a divine being does not mean the individual has no morality. A person who does not believe in a god can still be guided by a set of morals, ethics, and values, contribute to the world in positive ways, and have deeply meaningful relationships with others. At the same time, a person may believe in a god but do immoral, unethical, and harmful things. One's religious beliefs may influence their sense of moral judgment, but it is not synonymous with it.

To provide effective, patient-centered care, nurses must be knowledgeable about the various cultures in the communities they serve, and religion is a key component of culture. The following subsections provide a high-level overview of the religions that nurses in the United States are the most likely to encounter. However, it is essential to recognize that the categorization of religion is not without its limitations and complexities. Most religions have formal sects, informal movements or practices (sometimes at the local level), and intersect with cultural aspects related to the ethnicity, race, and national origin of members. These labels can be oversimplified and may not fully capture the diversity and complexity of religious beliefs and practices within specific cultural contexts, and can sometimes perpetuate stereotypes or essentialize cultural identities. Finally, media depictions and literature -- even when authentically written from the perspective of a member of the religion -- can lead to assumptions or stereotypes, because religions are not monolithic.

When a nurse encounters a patient whose belief system is unfamiliar, the situation presents an opportunity for cultural humility and respectful engagement. In such instances, it is imperative for the nurse to approach the situation with an open mind and a willingness to learn about the patient's unique traditions and practices. This begins with actively listening to the patient's perspective, asking questions to gain a deeper understanding, and demonstrating genuine curiosity and respect for their beliefs.

### Judaism

Judaism is the oldest monotheistic religion, with a history spanning nearly 4,000 years. Jewish law emphasizes righteous, just behavior in all aspects of life. The Jews were the first people to declare belief in a single, all-powerful deity, and for a time, they ruled two kingdoms in the Middle East, Israel and Judah. (The word *Jewish* is derived from the Kingdom of Judah.) They recorded their ideas, laws, stories, and poems in a collection of scriptures called the Tanakh. The first five books of the Tanakh are called the Torah, and they contain the most important rules and rituals that Jews are expected to follow, including the Ten Commandments ([Figure 35.4](#)). The three main branches of Judaism today—Orthodox, Conservative, and Reform—are characterized partly by how strictly they interpret the Torah (Vajda, 2024).

**FIGURE 35.4** The Torah is a sacred text that articulates the laws and rituals God expects Jews to follow. (credit: “Torah” by Lawrie Cate/Flickr, CC BY 2.0)

### Christianity

The history of Christianity begins approximately 2,000 years ago, with the birth of a Jewish man named Jesus. Jesus was a charismatic leader whose interpretations of scripture led some Jews to believe he was the Messiah, a legendary warrior-king prophesied to restore the Jewish kingdoms (The Editors of Encyclopedia Britannica, 2024). These beliefs threatened the Romans, who at the time ruled over much of the Middle East, and they killed Jesus through crucifixion (Figure 35.5). After Jesus’s death, some of his followers came to believe he was the son of God and eventually formed a new religion around this belief.

**FIGURE 35.5** The Romans crucified Jesus because they feared he would lead a revolt against their rule. Today, the crucifixion is one of the best-known symbols of Christianity. (credit: "Saint-Malo Stone Crucifix" by Nicolas Raymond/Flickr, CC BY 2.0)

The sacred text for Christians is the Bible, which includes the Old and New Testaments. The Old Testament contains many of the same books as the Jewish Tanakh, including the five that make up the Torah. The New Testament describes the life and teachings of Jesus and his early followers. Christians believe that through Jesus's death, their sins are forgiven. When they die, their spirits will live on with God.

Contemporary Christianity consists of several main branches. The two largest branches worldwide, Catholicism and Eastern Orthodox, developed out of the churches that took root in the western and eastern halves of the Roman Empire, respectively. Another branch, Protestantism, developed from criticisms of Catholicism and consists of many distinct denominations, including Anglican, Baptist, Lutheran, and Pentecostal. Each branch or denomination emphasizes different aspects of the Bible and may use slightly different versions of the text. The Church of Jesus Christ of Latter-Day Saints follows another sacred text, the Book of Mormon, in addition to the Bible. Members of the Church of Jesus Christ of Latter Day Saints typically abstain from alcohol, tobacco, and substances.

Jehovah's Witnesses are members of a Christian denomination that emphasizes the teachings of the Bible and the imminent establishment of God's Kingdom. They are known for their active evangelism (the practice of spreading or preaching the Christian gospel with the intent of converting individuals to the Christian faith), often going door-to-door to share their faith, and for their refusal to participate in activities that they believe are incompatible with their interpretation of Christianity, such as military service, voting in political elections, and celebrating holidays and birthdays. They adhere strictly to their interpretation of biblical teachings and maintain a strong sense of community and discipline within their congregations.

The Amish religion is another Christian denomination known for its simple living, plain dress, and reluctance to adopt many conveniences of modern technology. Originating from an Anabaptist movement in the sixteenth century, the Amish emphasize community, humility, and separation from the non-Amish world to maintain their religious values and way of life. They believe in adult baptism, pacifism (the belief that all forms of violence, including war, are unjustifiable and that disputes should be settled through peaceful means), and a literal interpretation of the Bible. The Amish are also known for their strong work ethic (which is often seen in their farming and craftsmanship) and their commitment to mutual aid within their communities. Worship services are typically held in homes and the church is governed by a set of rules called the Ordnung, which guides everyday behavior and ensures adherence to their religious principles.

## Islam

Islam is the third major monotheistic religion to originate in the Middle East. It is based on the teachings of Muhammad, an Arabian man who lived in the sixth and seventh centuries CE (Sinai & Watt, 2024). Muhammad had visions of an angel who declared there is only one God, Allah, and that a righteous life requires complete submission to Allah's will. Followers of Islam, called Muslims, believe that Jesus, Moses, and the other major figures from the Jewish and Christian Bibles were prophets whose visions and teachings are incomplete. Muhammad is the final prophet, and Islam represents the completion of Allah's will.

Muslims worship in buildings called mosques (Figure 35.6). Their sacred text, the Qur'an, is believed to be the literal word of Allah, which the angel recited to Muhammad during his visions. The two main branches of Islam, Sunni and Shia, originated in a disagreement over who should lead the faith following the death of Muhammad. In practical life, Muslims are guided by five "pillars" of their faith: the belief that Allah is the only God and Muhammad is his prophet; the participation in daily prayer; the obligation to give alms to those in need; the obligation for healthy adults to fast during the holy month of Ramadan; and, if possible, the making of at least one pilgrimage to the holy city of Mecca.

**FIGURE 35.6** Mosques are sacred spaces where Muslims worship. (credit: "Azadi Mosque (5730562789)" by David Stanley/Wikipedia, CC BY 2.0)

## Hinduism

Hinduism may be the oldest surviving religion on Earth, developing out of ancient traditions and ideas that originated in what is now India (Soniger & Narayanan, 2024). Hinduism encompasses an unusually diverse set of beliefs and practices, with different people in different times and places representing the nature of the divine and its relationship to human life in a variety of ways. Generally, Hindus believe in a universal, essential reality called Brahman, which may manifest in numerous specific entities, including the major deities Vishnu, Shiva, and Brahma (Figure 35.7).

**FIGURE 35.7** Hindu gods such as Shiva may appear in a wide variety of forms, which represent different aspects of their nature. (credit: “Shiva Statue Murdeshwara Temple” by “Nkodikal”/Wikipedia, CC BY 3.0)

Although there are Hindu temples, most Hindus observe religious rituals at home, and the rituals vary greatly among regions, villages, and individuals. The main sacred texts, collectively called the Vedas, were written in Sanskrit more than 3,000 years ago. They include poems and stories about various gods and heroes and articulate key principles such as dharma, a complex idea that includes a person’s moral duties in the world. Hindus also generally believe in **karma**, the notion that one’s future happiness is caused by present actions: actions performed with good intent lead to future happiness, whereas actions performed with bad intent lead to future unhappiness. Karma is often connected to **reincarnation**, the idea that a person’s soul or spirit is reborn into a new body.

### **Buddhism**

Another major religion that originated in the Indian subcontinent is Buddhism. According to legend, it was founded by Siddhartha Gautama, a Hindu prince who renounced his wealth and power and chose an itinerant, ascetic life after observing the poverty and suffering outside the palace (National Geographic, n.d.). However, he remained spiritually unfulfilled. At last, after meditating under a sacred fig, or bodhi, tree, he achieved a state of enlightenment called nirvana; the name *Buddha* means “enlightened one” (Figure 35.8).

**FIGURE 35.8** Through deep meditation, the Buddha escaped earthly suffering and achieved enlightenment. (credit: "Four Scenes from the Life of the Buddha - Enlightenment - Kushan dynasty, late 2nd to early 3rd century AD, Gandhara, schist - Freer Gallery of Art - DSC05124" by "Daderot"/Wikipedia, CC0)

Following the Buddha's teachings, Buddhists strive to lead a moral life by accepting the four Noble Truths: life is suffering, suffering arises from attachment to desires, suffering ceases when attachment to desires ceases, and freedom from suffering is possible by following the Middle Way. The concept of the Middle Way is central to Buddhist thinking; it encourages people to live in the present, practice acceptance of others, and avoid both extreme self-indulgence and extreme self-denial. Reflecting their common origin, Buddhists also share some beliefs with Hindus, such as karma and reincarnation.

### Sikhism

Sikhism is a monotheistic religion that began in the Punjab region of India in the fifteenth century (Fenech, 2014). The religion developed from the teachings of ten human gurus, each of whom is believed to have possessed the same soul, and their sacred text, the Guru Granth Sahib (Figure 35.9). These teachings proclaim the existence of one god, Waheguru, and emphasize equality for all and the importance of living a life of truth, honesty, and compassion.

Sikhism also strongly emphasizes community service; a fundamental concept of the religion is selfless service, or Seva (Sikh Missionary Society, n.d.). Another integral component is the Five Ks, which are symbols of devotion to the faith: Kesh (uncut hair), Kangha (a comb), Kara (a steel bracelet), Kachera (a cotton undergarment), and Kirpan (a sword) (The Sikh Coalition, 2018).

**FIGURE 35.9** This illustration from a nineteenth-century text depicts the founder of Sikhism, Guru Nanak, debating Hindu holy men. (credit: "Detail of 'Guru Nanak, the founder of the Sikh religion, in dispute with Hindu holymen' from Rani Jindan's book" by Unknown author/Wikimedia Commons, Public Domain)

### African Religions

African religions encompass a diverse array of spiritual traditions, beliefs, and practices that are indigenous to the African continent. These traditions vary widely across different ethnic groups and regions but share common themes such as reverence for ancestors, connection to the natural world, and rituals for healing and community cohesion. The grouping of African religions as a category acknowledges the continent's rich religious diversity while recognizing commonalities and shared cultural elements among various traditions. This approach allows for a broader exploration of spiritual practices within the African context, highlighting themes and dynamics unique to the continent's religious landscape.

Some common themes in African spirituality include belief in a specific god or supreme being and the existence of a spiritual world that is closely connected to the physical world (Chakale & Marumo, 2018). Many African religions also incorporate aspects of monotheistic Abrahamic religions, primarily Christianity and Islam, both of which are prominent throughout the country (Pew Research Center, 2010; Pew Charitable Trusts 2016; U.S. Department of State, 2022). African spirituality also emphasizes community, harmony with nature, and divine healing and medicine, which is reflected by the traditions and practices—many of which are passed down orally (such as through song) instead of in writing.

In some African religions, communal worship is often characterized by vibrant ceremonies that bring together members of the community to honor deities, ancestors, and spiritual forces. These ceremonies can vary widely depending on the specific religious tradition but often involve rituals such as drumming, dancing, chanting, and offerings. The importance of ancestors is also central to many African spiritual practices and is featured in many celebrations and festivals (van Beek, 2020). For example, in the Yoruba tribe's religion, ceremonies such as the "Egungun" festival are held to honor ancestors, whereas in Vodou, rituals such as the "lave tèt" involve purification and communion with spirits (Daniels, 2016). Some African religions worship different gods depending on region and culture:

- In some religions of the Yoruba culture, Olorun is considered the supreme deity, the creator of the universe, and the source of all life. Orishas, on the other hand, are deities that serve as intermediaries between Olorun and humanity and represent different aspects of nature, such as Oshun (goddess of rivers and love), Shango (god of thunder and lightning), and Ogun (god of iron and war) (Indiana University, 2024).
- Some religions in the Igbo culture, Amadioha is a deity associated with thunder and lightning. He is considered a powerful and fearsome god who punishes wrongdoers and protects the innocent. Amadioha is often invoked for justice, protection, and guidance in times of trouble (Kanu, 2021).
- Anansi is a trickster god in Akan mythology, primarily worshiped by the Ashanti people of Ghana. Anansi, depicted as a spider and known for his cunning and cleverness, is a symbol of wisdom, creativity, and resourcefulness (Britannica, n.d.).
- Nyame is the supreme god in Akan mythology, worshiped by some of the Akan people of Ghana and the Ivory Coast. Nyame, associated with the sun and considered the creator of the universe, is often invoked for blessings, protection, and guidance in daily life (Oxford Reference, 2024).
- In Vodun or Voodoo traditions, Osun is a deity associated with fertility, love, and healing. She is often depicted as a river goddess and worshiped by devotees seeking blessings in matters of love, childbirth, and prosperity (Britannica, n.d.).

### Indigenous American Spiritual Practices

Oral tradition through song and storytelling, honoring ancestors, and celebration of community are often key themes within Indigenous spirituality and central to the healing practices that are also part of the culture. The following are a few spiritual practices that nurses can familiarize themselves with related to American Indigenous communities (Smithsonian Institute, 2024; U.S. Forest Service, 2024; Centennial College, 2015):

- **Connection to the land:** Central to Indigenous American spiritual practices is a deep reverence for the land and the natural world. Many Indigenous traditions view Earth as a sacred and living entity, with spiritual beings inhabiting the land, waters, and skies. Spiritual practices often involve rituals and ceremonies conducted in natural settings, such as mountains, rivers, and forests, to honor and connect with the land and its spirits.
- **Ceremonial rituals:** Integral to some Indigenous American spiritual practices, ceremonial rituals serve as occasions for prayer, communion, and cultural expression. These rituals vary widely among Indigenous communities and may include sweat lodge ceremonies, vision quests, pipe ceremonies, sun dances, and powwows. Many traditions have rituals and ceremonies to mark important milestones and transitions in life, such as birth, puberty, marriage, and death. Seasonal ceremonies, such as harvest festivals and solstice celebrations, are common and serve to honor the changing seasons and give thanks for Earth's bounty.
- **Ancestral veneration:** Ancestor veneration includes traditions honoring and communing with the spirits of ancestors. Ancestors are guardians, guides, and sources of wisdom for the living, and rituals are performed to honor their memory and seek their blessings and guidance.
- **Visionary and shamanic practices:** Many Indigenous American spiritual traditions incorporate visionary and shamanic practices that involve altered states of consciousness, trance, and spiritual journeying. Medicine people, shamans, or healers play a central role in these practices, using rituals, chants, and herbal medicines to facilitate healing, divination, and communication with the spirit world.

### East Asian Spiritual Practices

East Asian religions also contribute to the religious diversity in the United States, especially for nurses working in areas with significant East Asian immigrant populations. The following are a few of the East Asian religions, philosophies, and traditions that a nurse may encounter in the course of their practice:

- **Confucianism:** Founded in China, Confucianism emphasizes social harmony, respect for elders and authority, and ethical conduct. Confucianism is not a religion in the traditional sense but a system of philosophical and moral teachings founded by Confucius. (Britannica, n.d.) The principles of Confucianism are an important part of many East Asian cultures and can influence how people view life, illness, and death. Confucianism emphasizes family, especially respecting elders.
- **Taoism (Daoism):** Another Chinese philosophical and religious tradition, Taoism (Daoism) focuses on striving for balance in life and living in harmony with nature (BBC, n.d.). Holistic healing practices paired with traditional medicine may be the preference of Taoist patients. In Taoism, there is an emphasis on health, longevity, and healing, which often includes the use of herbal medicine, acupuncture, and **qigong** (a traditional

- Chinese practice that integrates physical postures, breathing techniques, and focused intention).
- Shinto: Shinto, the indigenous religion of Japan, holds deep reverence for nature spirits and ancestors (kami) and balancing the physical and spiritual worlds. Shintoism emphasizes cleanliness and purification (Britannica, n.d.).
- Folk religions: Many folk religions throughout East Asia feature ancestor worship, animism, and deities specific to a region.

## The Impact of Spiritual Beliefs on Health and Well-Being

Spiritual care is associated with better health and well-being for everyone. Spirituality significantly contributes to a person's overall sense of wellness and quality of life. These impacts include the following:

- Meaning and purpose: Spirituality provides a framework through which individuals interpret their experiences and find a sense of direction in life.
- Connection and relationships: Spirituality nurtures connection with others. Positive relationships and a sense of community contribute to well-being.
- Inner peace and resilience: Spiritual beliefs and practices can provide individuals with inner peace, comfort, and resilience in the face of challenges, including illness.
- Quality of life: Studies suggest that individuals who report a strong sense of spirituality often experience a higher quality of life (Borges et al., 2021).
- Coping mechanism: Spirituality can serve as a coping mechanism during times of stress, illness, or loss. It provides individuals with a source of strength and support.

Spiritual resources can help nurses overcome the emotional toll of caring for seriously ill and dying patients and prevent compassion fatigue and burnout. Provision 5 of the ANA Code of Ethics states, “The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth” (ANA, 2015). A desire to help others in need is an important part of spirituality.

### LINK TO LEARNING

Michaela, a nursing student, is also a patient undergoing chemotherapy. In this video, she discusses how [her spiritual journey has helped](https://openstax.org/r/77spiritual) (https://openstax.org/r/77spiritual) in her recovery.

### Patient-Centered Care

Integrating a patient's spirituality into care aligns closely with the principles of patient-centered care (PCC), which prioritizes the individual's preferences, values, and unique needs. By recognizing and incorporating a patient's spiritual beliefs and practices into their care plan, nurses demonstrate a commitment to honoring the patient's holistic well-being and promoting a sense of connection and engagement (see [Chapter 6 Promoting Individualized Care](#) for more about patient-centered care).

Moreover, integrating spiritual participation into the care plan reflects a proactive approach to addressing the patient's holistic health needs beyond just the physical aspects of their condition. People who hold spiritual beliefs and participate in a community, such as religious service attendance, are associated with positive health outcomes, including greater longevity and reduced depression, suicide, and substance use (Chen et al., 2020). By recognizing the value of spiritual participation in promoting overall well-being, nurses demonstrate a commitment to providing comprehensive, patient-centered care that addresses the patient's spiritual, emotional, and social needs.

### Spiritual Healing

Nursing care has progressed significantly toward adopting a **holistic care model**, which views humans as biological, social, psychological, and spiritual beings and emphasizes the importance of considering all these dimensions in the care process. It is important to recognize how the spiritual dimension is integral to a patient's overall well-being and health (Forough Rafii, 2020). In times of crisis and illness, one's spirituality often becomes prominent and spiritual needs more evident. Patients frequently turn to spiritual coping strategies during the illness process, with spiritual healing and prayer being among the most widely utilized spiritual sources of comfort.

Spiritual healing is considered a form of alternative and complementary medicine and involves purposeful interventions by individuals to improve the conditions of others. Evidence suggests a rising global trend in the use of **spiritual healing**, with more than 64.1 percent of Americans incorporating prayer and spiritual healing (Forough Rafii, 2020). This process generally entails two components: the recipient, someone with a physical or mental illness, and the **healer**, an individual using faith and prayer to facilitate healing. Healers, performing nonmedical treatment either hands-on or from a distance, are involved in spiritual healing through prayer. For some patients with refractory diseases who have not found relief from conventional medical interventions, healing prayer has been explored as a possible therapeutic tool (Forough Rafii et al., 2020).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Balancing Spiritual Needs and Safety

The nurse is an advocate for patient safety, and there may be times when a patient’s spiritual beliefs could bring them harm. In these complex situations, the nurse will need the skills to navigate a compassionate conversation with the patient and their family and address the challenge that the balance of spiritual needs and safety presents.

Although some patients with refractory diseases (diseases or conditions that do not respond to standard treatments or therapies) may explore spiritual healing as an option when conventional medical interventions have failed to provide relief (Forough Rafii, 2020), it is important to be aware of risks and limitations—including for exploitation.

Patients who are afraid, ill, and in pain are often targeted by people who are touting “spiritual healing,” “miracles,” and “cures” only with the intention of monetary gain. Such scams are exploitative and harmful to patients and their families. Although the presentations of these scams may have similarities to the legitimate spiritual practices previously described, they are usually designed to appeal to patients with the ultimate goal of exploiting their need, desperation, fear, or hopelessness.

Healthcare providers, including nurses, must be aware of the potential risk and help patients access reputable resources and encourage them to be wary of any person, product, or service that makes promises or claims related to health and wellness—particularly when money is involved (National Consumers League, 2017).

There may also be less overt situations where spiritual healing offers a patient some relief or comfort, even if it’s more of a “placebo effect” than clinically measurable improvement. Although these situations may not harm a patient directly, they may become risky if patients are drawn away from the traditional medical care prescribed or recommended for them or if the practices interfere with evidence-based treatments (Cundiff-O’Sullivan et al., 2023).

Nurses should be prepared to discuss a patient’s spiritual healing preferences, and determine whether a patient is being placed at risk, and intervene, if necessary, to prevent harm.

---

Developing knowledge and skills related to patients’ spiritual care is essential for effective communication, trust, and empathy in nursing practice. Nurses not only address the varied spiritual needs of their patients but also meet those needs while also balancing their own beliefs—which may, at times, be at odds with those held by the patients they treat.

### Spiritual Practices

Just as the beliefs and values that define an individual’s spirituality vary, so will the activities that help them feel connected to their spiritual life. Spiritual practices that are commonly acknowledged and respected in the nursing profession include the following:

- **Prayer and meditation:** Many individuals find solace and connection through prayer or meditation. Nurses can support patients in their spiritual practice by providing a quiet and peaceful environment, respecting designated prayer times, and allowing patients the privacy to engage in their spiritual rituals.
- **Mindfulness and presence:** It can be spiritually enriching to practice mindfulness by being present in the moment and aware of one’s thoughts, feelings, and environment. Nurses can guide patients in simple mindfulness exercises, such as focused breathing or mindful walking, to promote a sense of calm and centeredness.

- Sacred rituals and ceremonies: A ritual is a defined practice that individuals or groups use to commemorate or cope with something, such as birth, death, healing, or another life transition. A ceremony is a public and formal celebration or gathering that honors or commemorates something. Nurses can support patients by respecting and facilitating their rituals and ceremonies, when possible, to ensure cultural sensitivity and inclusivity.
- Connection with nature: For some individuals, connecting with nature is a profound spiritual practice. Nurses can facilitate this by arranging access to natural settings, such as gardens or outdoor spaces for patients.
- Pastoral care and spiritual counseling: Many healthcare settings have **pastoral care services**, or spiritual counselors, (individuals who support patients in exploring and expressing their spiritual needs). Nurses can collaborate with these professionals to ensure patients receive spiritual guidance and counseling tailored to their beliefs.

Incorporating these practices into patient care demonstrates a commitment to addressing the spiritual dimension of health and well-being, and nurses should approach these discussions with sensitivity, respect, and a nonjudgmental attitude.

### Self Care Behaviors

Nurses are regularly exposed to human pain and suffering, which has physiological, psychological, and spiritual dimensions. Despite dedication to patient care, nurses often neglect their own physical, spiritual, and social needs, subconsciously overlooking their own needs as being a necessary aspect of professionalism. As nurses provide care involving death and dying, maintaining spiritual health is crucial for emotional and physical well-being. Studies indicate that some nurses may use religious beliefs to cope with patient deaths, emphasizing the importance of spirituality in healthcare settings (Greene, 2020). Nurses can also face moral distress and secondary traumatic stress, putting them at risk of burnout. Awareness of spiritual health is necessary for processing moral distress and preventing burnout ([Table 35.1](#)).

Pillar of Self-Care	What It Means	Examples
Physical	Take care of your body.	Moving your body (walk, dance, stretch), eating nutritious foods, getting enough quality sleep
Emotional	Manage your feelings.	Journaling, deep breathing, meditation, therapy
Mental	Keep your mind active.	Reading, learning, doing puzzles
Spiritual	Find meaning and connection.	Praying, meditating, spending time in nature
Environmental	Take care of your space.	Going outside, keeping your home clean
Social	Stay connected with others.	Spending time with loved ones, joining a club, volunteering
Recreational	Do things you enjoy.	Listening to music, playing a sport, doing something creative

**TABLE 35.1** Pillars of Self-Care

Spiritual health enhances self-awareness and self-care, acting as a shield against compassion fatigue, secondary trauma, and burnout (Ibrahim et al., 2020). Nurses can tend to spiritual health needs through conscious self-care planning, incorporating practices such as **remembrance and renewal (R & R)**—a practice that involves reflecting on the past while simultaneously revitalizing or rejuvenating oneself for the future—to process loss and grief through

reflection and strategies that promote growth.

## CULTURAL CONTEXT

---

### Cultural Perspectives on Self-Care

Cultural factors significantly influence self-care behaviors, shaping individuals' approaches to health and well-being. Cultural norms, beliefs, and practices play a pivotal role in determining the choices people make in caring for themselves. For instance, dietary habits can be deeply rooted in cultural traditions, influencing what individuals eat and how they view nutrition. Similarly, attitudes toward mental health, physical activity, and preventive healthcare measures are often shaped by cultural perspectives. The importance placed on communal and family support also varies across cultures, impacting the reliance on social networks for well-being. Additionally, cultural perceptions of health encompass physical and mental, emotional, and spiritual dimensions. Rituals and traditions further contribute to self-care, as practices related to food, exercise, spirituality, and holistic health are often intertwined with cultural identity. Recognizing and respecting these cultural nuances is essential for designing effective and inclusive self-care strategies that resonate with diverse populations.

---

### Source of Comfort

Meeting the spiritual needs of individuals involves recognizing the diverse ways they seek fulfillment, a dynamic process influenced by personal values and changing priorities. These methods often include spending meaningful time with loved ones, immersing oneself in nature, pursuing enjoyable hobbies, and engaging in religious practices such as prayer or attending services.

For patients with terminal illness, palliative care extends beyond the physical realm to encompass spiritual well-being. A diagnosis of a terminal illness often triggers shifts in spiritual needs, prompting individuals to address broken relationships, grapple with unresolved issues, and contemplate the deeper meanings of life and death. The holistic approach of palliative care acknowledges the interconnectedness of spiritual, physical, social, and emotional needs, ensuring comprehensive support for individuals and their families. Understanding the evolving nature of spiritual needs is crucial in promoting overall well-being for those navigating the complexities of terminal illnesses.

### Source of Conflict

When assessing sources of spiritual conflict or distress, nurses often are entrusted with information that may otherwise go undetected or recognized. Whether patients have acute, chronic, or terminal illnesses, they are often in situations that can cause spiritual distress. Asking questions about relationships, loss, fears, and conflict is important. Such information can reveal information including the following:

- Relationships: Feeling like they no longer have a role in their family, losing the ability to be a supportive person in the lives of loved ones, and experiencing loneliness.
- Loss of independence: Losing sense of personal identity, concerns about becoming a “burden” on loved ones.
- Fear of dying: Worry about what dying will be like, questioning what will happen after death.
- Loss of control: Struggling with a lack of control over physical and mental health, feeling like they no longer have agency in life, feeling like the future is out of their hands.
- Loss of purpose: Struggling to see the point of life, unable to find meaning in life.

It is important for nurses to include the patient's family and caregivers in the assessment, as they may also be experiencing spiritual distress as well. A patient's family needs to be included in the care plan to ensure a holistic approach to spiritual health and overall healing.

## PATIENT CONVERSATIONS

---

### Searching for Meaning

**Nurse:** Good morning, Mrs. Spiegel. How are you feeling today?

**Patient:** Oh, I'm still alive.

**Nurse:** You sure are! How is your pain?

**Patient:** Well, not much better than last night but . . . [tearfully] I feel such an ache in my chest and my throat. And I don't think it's from the treatment. Or the cancer. At least, not physically.

**Nurse:** It sounds like you're feeling a different kind of hurt—the emotional kind?

**Patient:** [nods, then starts to cry] Why did this happen to me?

**Nurse:** You aren't alone in asking that question. Is there any particular reason you're thinking about it this morning?

**Patient:** Oh, I don't know. I just lay awake all last night listening to these beeping machines and wishing I was home in my own bed, with my husband and my dog. I was trying to figure out where I went wrong—or what I did wrong.

**Nurse:** About the cancer, you mean?

**Patient:** Maybe it's silly but . . . [trails off and reaches for a tissue]

**Nurse:** It's not silly, it's how you feel. And it matters.

**Patient:** I never smoked or drank; I never did drugs. I ate right and exercised . . . sometimes. I always tried to be a good neighbor, a good wife, and a good mother. I volunteer, I donate money, I try to never say a bad word about anyone . . . now I wasn't perfect or a saint, not by a long shot. But I did all the things I thought I was supposed to do and I just don't understand why I'm getting punished.

**Nurse:** You feel like the cancer is a punishment?

**Patient:** Well, it sure feels like it.

**Nurse:** What you're feeling and thinking right now is very painful, but I want you to know that you're not alone. I have talked with patients, even in the same bed you're in, who have asked themselves the same question. And I don't have any answers, but I can listen and help you figure out what kind of support you'd like to have as you process this experience. It's a very personal journey, so what's helped someone else might not be what you need. But I'm here, and I'm ready and willing to help you figure it out.

**Patient:** Do people usually blame God?

**Nurse:** Not always. Do you blame God?

**Patient:** No, no. I guess I blame myself. I don't want to believe that God is anything but merciful.

**Nurse:** Is your spirituality an important part of your life?

**Patient:** I believe in God, yes. I haven't been to church since I got diagnosed though . . . just have felt so tired. I stopped praying because . . . well, I guess I don't know what to say.

**Nurse:** Well, let's talk more about what we can do to make sure you're feeling that connection and comfort.

**Scenario follow-up:** The nurse has opened the door for a compassionate, supportive conversation with the patient about their spiritual needs. The nurse actively listens and uses thoughtful, open-ended questions to guide the patient through their thoughts and help them better understand their needs. From this conversation, the nurse gathered the information needed to make a plan for incorporating spiritual needs into the patient's care.

---

## 35.2 Applications of Spirituality to Health Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify factors that affect a patient's spirituality
- Identify considerations for providing patient-centered care
- Recognize guidelines for providing competent nursing care

In exploring the intricacies of spirituality in health care, nursing professionals must understand the factors that

influence a patient's spiritual well-being. These factors extend beyond religious affiliations and include cultural background, personal experiences, and belief systems. By understanding these influences, nurses can better tailor their approach to spiritual care by laying the foundation for a holistic and patient-centered approach and fostering an environment that respects and acknowledges the unique aspects of each patient's spiritual journey. The purpose of spiritual care in nursing is to assess, diagnose, and respond to the spiritual needs of each individual patient. Nurses should be adept at conducting spiritual assessments, distinguishing between religious and spiritual needs, and identifying appropriate interventions.

### Factors Affecting Spirituality

Nurses must approach each patient with a sense of openness and respectful curiosity to understand how spiritual factors will affect overall health. Recognizing and understanding the role these factors play in a patient's daily life when they are well is necessary to develop care plans that treat the patient holistically (O'Brien, 2022).

- **Cultural background:** Cultural diversity plays an important role in shaping an individual's spiritual beliefs and practices. Patients from different cultural backgrounds may adhere to distinct religious traditions, rituals, and spiritual perspectives. Understanding and respecting cultural nuances is essential for delivering culturally competent care.
- **Religious affiliation:** An individual's religious beliefs—or lack thereof—influence their broader sense of spirituality. Patients may identify with specific religions, carrying their own practices, doctrines, and values. Conversely, some individuals may be nonreligious or identify as atheist, shaping their spiritual outlook in a secular context. Patients who identify as agnostic may have less well-defined spiritual beliefs than patients who follow a specific religion, but that does not necessarily mean spirituality can be left out of their care planning.
- **Personal experiences:** Life events, such as trauma, loss, or significant milestones, can influence spirituality. Positive or negative experiences may lead individuals to question or strengthen their spiritual beliefs. Nurses need to be sensitive to these life events and their potential impact on a patient's spiritual well-being.
- **Belief systems:** Beyond organized religion, individuals often have personal belief systems that shape their spirituality. This may include philosophical views, ethical and moral principles, or a sense of connection to nature. Understanding these belief systems helps nurses tailor spiritual care to better align with a patient's unique perspectives.
- **Health status and illness:** Health challenges and illness can evoke profound spiritual reflections. Patients facing serious health issues may seek solace, meaning, or hope through their spiritual beliefs. Conversely, illness may lead to questioning or reevaluation of one's spiritual framework.
- **Family and community influence:** Family upbringing and community environments contribute to an individual's spiritual foundation. Family traditions, religious practices, and community support systems all help shape spiritual perspectives. Considering these influences is essential for providing holistic care.
- **Interpersonal relationships:** The quality and nature of relationships, both within the family and broader social circles, can impact spirituality. Supportive relationships may strengthen one's faith or spiritual connection, whereas strained relationships could lead to spiritual distress.
- **End-of-life concerns:** Spirituality often becomes more pronounced during end-of-life decisions. Patients facing terminal illnesses may engage in spiritual reflections, seeking comfort, meaning, or reconciliation. Addressing these concerns with sensitivity is crucial in end-of-life care.

### Developmental Considerations

Patients of different ages and stages of life approach spirituality uniquely, influenced by various developmental considerations. Individuals may have distinct spiritual needs and expressions based on their life stage and personal development. For example, children and adolescents often form beliefs by absorbing those from family members and their communities. As they grow, their spirituality evolves as they question these beliefs more independently. Nurses can support their young patients' explorations by providing an open environment for them to express their own thoughts and feelings.

As patients age, more exploration solidifies their spiritual identity. Although some may distance themselves from their childhood beliefs and choose to forge a more personal connection to spirituality, others will build on the foundation laid in childhood. Most young adults, however, will experience some form of spiritual distress or confusion due to major life transitions such as entering the workforce or traumatic events. By mid-adulthood,

spiritual beliefs are typically integrated into overall worldviews. Patients may seek spiritual meaning in their relationships, work, and contributions to society. Spiritual beliefs may serve as coping mechanisms during midlife challenges, such as career changes, empty nesting, or emerging or worsening health concerns.

Older adults may engage in spiritual reflection, contemplating the meaning of life and legacy. Existential concerns and thoughts about mortality may become more prominent. During this stage in life, patients may find solace in cultural or religious traditions. Respecting and incorporating these traditions into care is essential for spiritual well-being at all stages of life.

### Life Events

Encountering stressful life events can challenge the spiritual and religious aspects of a patient's being, leading to spiritual distress. Distress can contribute to struggles such as spiritual disorientation, tension, and strain. Without proper guidance, the response to stressful events may contribute to negative outcomes such as increased distress and feelings of depression.

Traumatic life events can be devastating to an individual or the familial and community system as a whole. Interpersonal and intrapersonal struggles can cause separation within a family in addition to individual spiritual distress. Divine struggles, including spiritual discontent (feelings of discomfort or dissatisfaction with one's faith), reappraisal of God's powers (questioning a divine entity's power), and God's punishing reappraisal (believing that a negative circumstance in one's life is a punishment from a divine source) signify a disruption in beliefs about the order, predictability, and benevolence in the universe. Likewise, challenges to goals such as connection with a higher power and the associated experiences of intimacy and security are often tested and disrupted when the patient experiences adverse events in life.

### Family

Family and community dynamics profoundly affect an individual's spiritual foundation, influencing their beliefs, values, and practices. Familial upbringing, in particular, serves as a primary source for developing one's spiritual identity. Family traditions, religious practices, and the overall atmosphere within the household significantly contribute to shaping an individual's spiritual perspectives from an early age. Regular attendance at religious services, participation in family rituals, and exposure to specific cultural or religious practices create a framework for understanding the sacred and the transcendent.

Likewise, the community in which an individual is immersed also plays a crucial role in shaping spiritual beliefs. Communities often provide a broader context for shared practices, beliefs, and support systems. Local religious institutions, community gatherings, and cultural events further contribute to the multifaceted nature of spiritual development. The diverse array of experiences within a community can expose individuals to different spiritual traditions and perspectives, fostering an understanding and appreciation for a diverse range of belief systems.

Recognizing the profound influence of family and community on spiritual perspectives is vital for healthcare providers. To deliver holistic care, the nurse must understand the patient's background and the influences that have shaped their spirituality. Sensitivity to diverse cultural and religious practices within families and communities is crucial for providing culturally aware and patient-centered care (PCC). Nurses must also be attuned to the potential conflicts between individual and familial beliefs. Open communication with patients and their families can help uncover specific spiritual needs, preferences, or concerns that may impact the patient's well-being and recovery. By considering family and community influences on spirituality, nurses can foster a more inclusive and culturally competent approach to patient care, promoting physical health and addressing the emotional and spiritual dimensions of the individual, all within the context of their broader support networks.

### Ethnic Background

A foundational element for identity, meaning, and community among individuals is **ethnicity**. Ethnicity refers to the cultural, social, and ancestral characteristics that define a group of people sharing common historical roots, language, traditions, and often geographical origins. Understanding the intricate connections between ethnicity and these fundamental aspects is crucial for nurses. Although the foundational theory of ethnicity suggests that racial and ethnic differences are deeply ingrained in society and have historically delineated lines of intergroup conflict, the consensus recognizes that ethnicity undeniably provides people with essential elements of meaning, identity, and community (Pew Research, 2008). It is important for nurses to keep in mind that patients will often have complex feelings about their identities, and it is rarely binary (that is, where it's all positive or all negative).

For nurses, recognizing that ethnicity is more than just a demographic descriptor is key to understanding their patients from a whole-person perspective. Ethnicity encompasses shared cultural identity, language, and origin, forming the basis of a group with a collective heritage and sense of community. Like religion, ethnicity fulfills a crucial role in cohesion, acting as a powerful social glue.

Ethnicity and religion are deeply interconnected aspects of human identity, influencing individuals' beliefs, behaviors, and social interactions. At the core of this connection lies cultural heritage, as religious traditions are often passed down through generations within ethnic communities. For many individuals, ethnicity and religion are intertwined components of their cultural identity, shaping their sense of self and worldview. This connection is further reinforced by the role of religion as a unifying force within ethnic communities, providing a sense of belonging, shared values, and social cohesion. Moreover, ethnicity and religion influence individuals' social norms, practices, and behaviors in various aspects of life, including family dynamics, education, dietary habits, and healthcare decisions. Understanding the intertwined nature of ethnicity and religion is crucial for promoting cultural competence, fostering inclusive practices, and building bridges of understanding within diverse communities.

### Culture

The intersection of culture and spirituality is a complex aspect of human identity that significantly influences an individual's beliefs, rituals, and expressions of spirituality. Cultural background helps shape the lens through which individuals perceive and engage with the spiritual dimension of life. Patients from diverse cultural backgrounds bring religious traditions, customs, and spiritual perspectives that are deeply embedded in their heritage.

Religious traditions are often intertwined with cultural practices, creating a unique fusion that shapes an individual's spiritual identity. For example, certain cultural ceremonies, festivals, or rites of passage may have inherent spiritual or religious significance, providing a framework for understanding the sacred aspects of one's cultural environment. The dynamics of family structures, societal norms, and community expectations within a specific culture further influence how individuals conceptualize and express their spirituality.

Nurses must recognize and respect cultural nuances to deliver effective and patient-centered care. Understanding the diverse religious traditions and spiritual practices that patients may follow is necessary for promoting inclusivity and cultural competence. Sensitivity to cultural diversity ensures nurses can navigate conversations about spirituality with cultural humility, avoiding assumptions or stereotypes. Moreover, recognizing the influence of culture on spirituality contributes to a more holistic approach to health care. Culturally competent care extends beyond tolerance of cultural differences; it involves active efforts to incorporate cultural considerations into care plans, creating a space where diverse spiritual beliefs are valued and integrated into the overall healthcare experience.

### Formal Religion

Religious affiliation is often a cornerstone of spirituality in patient care. Patients may draw profound spiritual strength and meaning from their religious beliefs. Many religions provide comprehensive frameworks that include moral guidelines, rituals, and a sense of community. Nurses need to be attuned to and respectful of patients' diverse religious affiliations and be willing to learn about the unique practices, doctrines, and values associated with each faith tradition. A **congregation** (group of people who worship together) plays a vital role in providing spiritual support and essential social services. In nursing practice, being aware of the various services offered by congregations, such as counseling and assistance finding child care, schooling, and employment, is essential for planning care.

For patients who identify with a specific religion, nurses should strive to meaningfully integrate these beliefs into the care plan. This may involve facilitating access to religious leaders for spiritual guidance, arranging for religious rituals or sacraments, and respecting dietary restrictions or observances associated with their faith. The alignment of healthcare practices with religious beliefs contributes to a more patient-centered and culturally competent approach because it recognizes the integral role that religion plays in shaping an individual's spiritual identity.

### Considerations for Patient-Centered Spiritual Care

When providing spiritual care, the nurse must not impose their religious or spiritual beliefs on patients. There are several guidelines for therapeutically implementing nursing interventions to support patients' spirituality:

- Take cues from the patient: When bringing up spiritual health with patients, understand it may be a difficult

topic for them to discuss. Let them lead the conversation. Do not press further than they want to share.

- Be aware of nonverbal cues: Patients may be saying one thing, but their body language is saying something different. Gently point out the contradiction and seek clarification. For example, a patient may state that they do not blame God for their illness but begin to tear up as they say it. By responding, “I noticed you became tearful when you said that . . . what is causing these feelings to come up for you?” a door is opened for them to share more of their thoughts and feelings.
- Ask the patient how you can support them spiritually: Ask patients what they need to feel supported in their faith and try to accommodate their requests, if possible. For example, perhaps they would like to speak to their clergy, spend some quiet time in meditation or prayer without interruption, or go to the onsite chapel. Explain that spiritual health helps the healing process. Many agencies have chaplains onsite that offer patients a spiritual resource.
- Support patients within their faith tradition: Patients may feel they must “do as the nurse says” when under their care. With this power dynamic in mind, it is not appropriate for the nurse to persuade a patient toward a preferred religion or belief system. The role of the nurse is to respect and support the patient’s values and beliefs, not promote their own values and beliefs.
- Listen to a patient’s fears and concerns without adding your own stories: It is easy for the nurse to start adding personal examples from their own life. Although this may seem helpful or even empathetic, it is more often only distracting and shifts the focus away from the patient. The main event is the patient’s fears and concerns, not the nurse’s. Name and validate the emotions that are heard from the patient. Sometimes, patients don’t realize what they are feeling until it is kindly and tactfully pointed out to them.
- Pray with a patient if requested (or provide someone who will): Some nurses may feel reluctant to pray with patients when they are asked. They may feel underprepared, uncomfortable, or unsure if they are “allowed to.” Nurses are encouraged to pray with their patients to support their spiritual health, as long as the focus is on the patient’s preferences and beliefs, not the nurse’s. Having a short, simple prayer ready that is appropriate for any faith may help in this situation. If a nurse does not feel comfortable praying, the chaplain should be requested to participate in prayer with the patient.
- Share an encouraging thought or word: A scripture verse (based on patient preferences) or an inspirational poem may be helpful to share during difficult times. Having a few verses or thoughts readily available can be helpful during critical moments (Nourian, 2018).
- Use presence and touch: Sometimes, just the presence of a nurse is spiritually comforting for patients. Words are not always needed. It can be very comforting to know that someone will be sitting quietly next to them as they fall asleep or are in pain. Touch can also be a very powerful therapeutic tool to provide comfort (after asking permission of the patient) (Nourian, 2018).

## REAL RN STORIES

---

### Focusing on the Moment

**Nurse:** Maria, BSN

**Clinical setting:** Emergency department

**Years in practice:** 25

**Facility location:** A prestigious teaching hospital in a major city

Over the years, I’ve gotten a lot better at compartmentalizing my own spiritual beliefs so that I can focus on my patients, even when what they believe is completely at odds with what I do. But I still remember the first patient I had where I really struggled with respecting their beliefs in a crisis.

The patient was a young man, early 20s, who had been in a car accident. He was brought in by ambulance, and his wife, who was pregnant and about to deliver any day, had followed in her car. She was inconsolable, and we were having a hard time keeping her out of the trauma bay. The patient was actively seizing when EMS arrived, and his injuries were clearly severe. You couldn’t really make out what his face looked like between all the swelling and blood. His left arm was deformed from a fracture. The ER doctor was calling out orders as we tried to stabilize him, and from out in the hallway we heard his wife screaming, “Don’t give him any blood, don’t give him blood, please!”

Another nurse, who was my mentor at the time, came rushing in and just said, very calmly, “Patient is a Jehovah’s Witness.” The air in the room changed at that point. The frenzy sort of paused, and it was like everyone was trying to shift gears. I looked at her and she must have seen the confusion in my blank stare. She took me aside and quietly explained that due to his religious beliefs, the patient would not accept blood products. I remember just sort of blurting out, probably too loudly, loud enough that his wife in the hall probably heard me, “But he’s going to bleed out, he’s going to die.” And the nurse didn’t miss a beat, she just said, “We have to respect his beliefs. Accepting a blood transfusion can get someone excommunicated from the church. It’s a very big deal.”

I tried to wrap my head around what she was saying, but I just kept thinking about how young he was and his wife was about to have a baby. I felt angry, to be honest—confused and angry. The nurse picked up on this and told me to “go take a minute,” which I knew meant “get it together” but I wasn’t even sure where to start. I had a lot of questions but didn’t know how to ask them.

After that, I read as much as I could about Jehovah’s Witnesses, and then other religions and belief systems that were different from mine. I tried to make sure that I understood where people were coming from with their beliefs, and when I had patients who believed something different from me, I tried to think back to what I’d read. It’s hard to think about in the moment, but it’s gotten easier with time and experience. I find I can more easily put different beliefs in perspective and keep the patient at the center.

---

### Beliefs Regarding Healthcare Practices

The individualized nature of spiritual needs, combined with the complex dynamics between patients and healthcare professionals, places the responsibility on nurses and providers to seamlessly incorporate spiritual care into health care. Nurses should feel empowered to seek more information about spiritual practices, particularly those of the communities they serve. If a patient has a spiritual belief, value, or practice that conflicts with a treatment plan, the nurse should explain the rationale for the intervention or treatment. If the patient is not willing to complete the treatment as planned due to their spiritual or religious beliefs, the nurse should attempt to negotiate the treatment plan with the patient and/or healthcare provider. For example, a nurse can advocate for rescheduling a procedure after the Sabbath or modifying the dietary plan and medication administration times during Ramadan. Nurses should support patients' preferences when implementing interventions to support their spiritual well-being. The nurse should respect and listen to the patient’s expression of beliefs. Spiritual or religious practices should be accommodated if they are safe and feasible. The following list of healthcare considerations is not intended to be exhaustive—rather, it can offer some insights into situations a nurse may encounter. The nurse should identify resources in their community that may help them provide spiritually-aware and patient-centered care (PCC).

- Judaism
  - Jewish religious laws involve a complex set of restrictions that can affect medical decisions. Patients or family members may request to speak with a rabbi to determine the moral propriety of a particular decision. Exceptions are often made when an action is understood in terms of saving a life, such as emergency surgery or organ donation during the Sabbath. The value of saving a life is held in extremely high regard in Jewish tradition.
- Catholicism
  - Patients may have moral questions about treatment decisions, such as the withholding/withdrawing of life-sustaining treatment. A priest can offer guidance for patients in these situations.
- Jehovah’s Witness
  - A defining tenant is a strict prohibition against receiving blood (i.e., red blood cells, white blood cells, platelets, or plasma) by transfusion (even the transfusion of a patient’s own stored blood), in medication using blood products, or in food—even in life-threatening situations. It is very common for adults to carry a card at all times stating religiously based directives for treatment without blood. Some blood fractions (such as albumin, immunoglobulin, and hemophiliac preparations) are allowed, but patients are guided by their own conscience when making these healthcare decisions.
  - Organ donation and transplantation are allowed, but patients are guided by their own conscience.
- Amish
  - Although the Amish do not reject modern medicine outright, they often prefer natural and home remedies, turning to professional medical care when necessary.
  - Medical expenses are typically covered by the community, not insurance. The Amish practice mutual aid,

where the community helps with healthcare costs.

- Islam
  - Muslim patients may express strong concerns about modesty and may avoid eye contact as a function of modesty and oppose being treated by a provider of a different gender.
  - A Muslim female may need to completely cover her body and should always be given time and opportunity to do so before any person enters her room. Women may also request that a family member be present during an exam and may desire to remain clothed during an exam, if possible.
  - There should be no casual physical contact by nonfamily members of the opposite sex (such as shaking hands).
  - The act of washing may require running water, either from a tap or poured from a pitcher. As a result, Muslim patients typically do not feel truly cleaned by a sponge bath. Many Muslims wash with running water before and after meals, as well as before prayers.
  - Muslim patients may react to suffering with emotional reserve and hesitate to express the need for pain management. Some patients may refuse pain medication if they understand the experience of their pain to be spiritually enriching.
- Hinduism
  - Hindu patients may express strong, culturally based concerns about modesty, especially regarding treatment by someone of the opposite sex. Genital and urinary symptoms or conditions are often not discussed with someone of a different gender present.
  - The act of washing is generally conceived as requiring running water, either from a tap or poured from a pitcher. A patient may desire to wash their hands after meals.
  - For many Hindu patients, there is a cultural norm to use the right hand for “clean” tasks such as eating (often without utensils) and their left hand for “unclean” tasks such as toileting. Medical and nursing staff should consider this right-left significance before hindering a patient’s hand or arm movement. Discuss handed preferences with the patient.
  - Patients may wear jewelry or adornments that have strong cultural and religious meaning, and staff should not remove these items without discussing it with the patient or family.
- Buddhism
  - The importance of mindful awareness may affect patients’ or family members’ decisions about using pain medications, often out of worry that analgesics may cloud one’s awareness. Nonpharmacological pain management options are often more accepted.
  - Some Buddhists may express strong, culturally based concerns about modesty (e.g., regarding treatment by someone of the opposite sex).
- East Asian and Chinese religions
  - Many East Asians, particularly in Chinese cultures, use traditional Chinese medicine (TCM), which includes acupuncture, herbal medicine, tai chi, and qigong. TCM focuses on balancing the body's energy (qi) and maintaining harmony between yin and yang.
  - Health practices often incorporate a holistic approach that includes modern medical treatments and traditional methods, emphasizing prevention and overall well-being.

### **Vaccines**

Some patients may refuse vaccines, either for themselves or their children, due to their religious beliefs. Religious exemption may be cited by individuals of many denominations, though very few organized religions have specific prohibitions against vaccines. In some cases, people of a certain faith may believe their religion prohibits vaccines, when even their leaders indicate that no such prohibition exists; individual beliefs need to be respected, but this situation creates the need for strong community-based programs. Some smaller groups, such as Dutch Reformed Church and faith-healing denominations, do specifically object to immunizations. However, individuals within the faith may still accept vaccination.

It's also important for the nurse to be aware that patients of certain faiths may have concerns about vaccines due to the ingredients, as they would with medications that may contain ingredients that would be at odds with their dietary practices. However, many religious organizations—such as the Islamic Organization for Medical Sciences—have made statements to those of the faith about the use of certain ingredients in vaccines and take the stance that they are acceptable.

### Beliefs Regarding Death and Dying

Although the nurse will want to understand specific religious and spiritual beliefs about death, it's also important to remember that each patient will have their own ideas and feelings about what happens when they die, as well as what may come after. The nurse should also be aware that a patient's beliefs may change. A life-changing or life-threatening illness or injury can make people feel more drawn to believing in a higher power when they haven't before, particularly if they seek the comfort that worship seems to bring to others. But it may also "shake the faith" or instill doubt in a person who has been devout and may even lead to a spiritual crisis. The changes are not always profound; they may be subtle and gradual. Therefore, it's important for the nurse to monitor a patient's spiritual well-being as much as their physical and mental well-being. Nurses can and should tailor their approach to each patient, but the following are a few examples of situations they may encounter:

- Judaism
  - Questions about the withholding or withdrawing of life-sustaining therapy are deeply debated within Judaism. Some may be strongly opposed, whereas others may be more open to it. Family members often wish to consult with a rabbi about the specific circumstances and decisions regarding end-of-life care.
  - After a patient has died, Jewish tradition directs that burial happen quickly and that there be no autopsy (unless the autopsy is deemed necessary by a mandate from a medical examiner). The family may request that a member or representative constantly accompany the body in the hospital and even to the morgue (where the person may sit outside any restricted area yet remain relatively close to the body) to say prayers and read psalms.
  - Amputated limbs may be requested for burial. Details should be arranged through the patient's/family's funeral home.
- Catholicism, Eastern Orthodox, Lutheran, and some other Christian denominations
  - If a patient is near death, there may be an urgent request for a priest or minister to offer anointing of the sick (or last rites). Last rites are often associated with the Catholic denomination, but others perform similar rituals to support people who are sick or at the end of life. Even if the ritual has already been performed, there may still be a request for a priest to offer prayers and bless the patient.
- Jehovah's Witness
  - Tradition of Jehovah's Witness does not teach that people experience an immediate **afterlife** (what a person believes will happen after death; a place where the spirit goes after the death of the physical body) when they die. For example, the nurse would not hear a patient's family remark, "He's in a better place now."
- Amish
  - Amish funerals are typically modest and held in the home. They may not use elaborate caskets or grave markers. The community comes together to support the grieving family, providing meals and assistance.
- Islam
  - Muslim tradition generally discourages the withholding or withdrawing of life-sustaining therapy. However, because decisions involve the circumstances of the patient and the complexities of medical treatments, family members who are morally conflicted may wish to bring an experienced imam to their discussion with the healthcare team.
  - A family member may request to be present with a dying person so they can whisper a proclamation of faith in the patient's ear right before death.
  - After a death, the family may request to wash the patient and position the bed to face Mecca. The patient's head should rest on a pillow.
  - Burial is usually accomplished as soon as possible. Muslim families rarely allow for an autopsy unless there is an order by a medical examiner. Some Muslims may consider organ donation, but the subject is debated within Islamic circles.
  - There may be a request that amputated limbs be made available for burial. Details should be arranged through the patient's/family's funeral home.
- Hinduism
  - Hinduism teaches that death is a crucial "transition" with karmic implications.
  - There may be a strong desire for death to occur at home rather than in the hospital.
  - Family may wish to perform predeath rituals (e.g., tying a thread around the person's neck or wrist).
  - After death, family members may request to wash the patient's body (by family members of the same sex

- as the patient).
- The family may request constant attendance of the deceased's body. A family member or representative may wish to accompany the body to the morgue or at least remain as close to the body as possible (e.g., sitting outside a restricted area). (Ehman, 2012).
- Buddhism
  - In end-of-life care, Buddhists may be concerned about safeguarding awareness/consciousness. Clarification of the patient's wishes about the use of analgesics in the days and hours before death is strategically important for developing an ethical pain management plan.
  - As a patient approaches death, medical and nursing staff should minimize actions that might disturb concentration or meditation in preparation for dying. Near the time of death, a Buddhist patient's family may appear emotionally reserved and even keep their physical distance from the patient's bed. This can be a custom for the purpose of supporting the patient's desire to concentrate on the experience of dying without distraction.
  - After the patient has died, staff should try to keep the body as still as possible and avoid jostling during transport. Buddhism teaches that the body is not immediately devoid of the person's spirit after death, so there is continued concern about disturbing the body. The nurse should also be aware of how these beliefs may factor into discussion of organ donation.
  - Families may request that after a patient has died, the body be kept available to them for several hours for the purpose of religious rites. All requests should be negotiated carefully, maximizing the opportunity for accommodation in recognition of the religious significance (Ehman, 2012).

### Beliefs Regarding Pregnancy and Birth

Along with having unique perspectives on the end of life, patients also have their own beliefs about the beginning. Religious and spiritual beliefs and practices about pregnancy and childbirth vary, and the nurse should be knowledgeable about how different patients will view this time of life, as well as what concerns they may have about receiving care.

- Christianity
  - All requests for the sacrament of baptism should be relayed to a minister or priest. However, if an infant is likely to die before a priest can arrive, the infant may be baptized by any person with proper intent. The person would say, "[name of infant], I **baptize** you in the name of the Father, and of the Son, and of the Holy Spirit," then pour a small amount of water over the infant's head three times. Emergency baptisms must be reported to the local parish priest.
- Amish
  - Many Amish females prefer to give birth at home with the assistance of midwives. Hospital births are less common but accepted when necessary. Pregnancy and childbirth are community-centered, with significant support from family and neighbors.
- Islam
  - Immediately after the baby is born, the call to prayer (Adhan) is whispered into the baby's right ear, and the call to begin prayer (Iqamah) is whispered into the left (Al-Islam, 2013).
- Hinduism
  - Jatakarma is when the father chants mantras in the baby's ear to welcome them into the world (ISKCON Educational Services, 2018).
- East Asian and Chinese religions
  - In some East Asian and Chinese religions, there are various taboos during pregnancy, such as attending funerals, having negative thoughts, and moving heavy objects. It is believed that avoiding these practices protects the mother and baby from harm.
  - After giving birth, the new mother practices "zuo yuezi," or "sitting the month," a period of rest and recovery typically lasting about thirty to forty days. During this time, the mother is expected to stay indoors, avoid cold foods, and eat nutrient-rich, warm foods to replenish her energy.
  - The postpartum diet often includes foods believed to promote healing and recovery, such as chicken soup with ginger, eggs, and specially prepared herbal drinks.

## CULTURAL CONTEXT

---

### Cultural Diversity in Maternity Care: Navigating Unique Beliefs and Traditions

The practice of consuming placenta, known as placentophagy, has cultural roots in various societies. Although not a universal cultural norm, some communities have traditions or beliefs associated with the consumption of placenta. In some cultures, the placenta is considered a sacred or spiritually significant organ, and consuming it is believed to convey health benefits or symbolize a connection between the mother and child.

It's important to note that placentophagy is not a widespread or mainstream cultural practice, and opinions on its benefits vary. Some proponents argue that it provides nutritional benefits, helps with postpartum recovery, or has symbolic significance. Others may engage in placentophagy for religious or spiritual reasons (Farr et al., 2017; Stanley et al., 2019; Goeden, 2018).

It's crucial for healthcare providers to approach cultural practices, including those related to childbirth and postpartum traditions, with respect and understanding. Patient preferences and cultural beliefs should be taken into account when providing care, and healthcare professionals should be open to discussions about these practices to ensure holistic and culturally sensitive maternity care.

---

### Beliefs Regarding Diet

Dietary practices are central to many religious and spiritual groups. Although the nurse should know of and understand the dietary needs of all patients, they should also note those rooted in religious or cultural practices. The nurse must understand that just because a patient follows a particular religion does not mean they strictly follow all its practices, including those about diet. The nurse should not make assumptions but ask patients about their dietary needs and preferences to obtain information and demonstrate cultural sensitivity and respect.

- Judaism
  - Jewish patients often request a special **kosher diet** in accordance with religious laws that govern the preparation of certain foods (e.g., beef), the prohibition of certain foods (e.g., pork and gelatin), or the combination of some food (e.g., beef served with dairy products). However, not all Jewish patients keep kosher, so it is important for the nurse to be aware of their dietary practices. Prescribed nutrition therapy for patients must align with their cultural and spiritual traditions.
  - Hand washing before eating may also have a religious significance.
- Catholicism
  - Patients may request nonmeat meals, especially during the time of Lent (the forty days before Easter) (United States Conference of Catholic Bishops, 2024).
- Amish
  - Amish patients typically avoid processed foods and prefer homegrown and home-cooked foods, including meats, vegetables, grains, and dairy.
- Islam
  - Muslims may specifically request a diet in accordance with religious laws for halal food, though many Muslims choose a vegetarian diet as a simple way to avoid religious prohibitions against pork products or gelatin. Forbidden foods are referred to as haram.
  - Muslim dietary regulation can affect patients' use of medications, especially drugs that have pork origins or contain gelatin or alcohol. The dietary prohibition against alcohol has occasionally raised questions about Muslims' use of alcohol-based sanitizers in the hospital. Concerns should be addressed thoroughly and sensitively, and perhaps with the input of an imam (a person who leads prayers in a mosque).
  - During the thirty-day month of Ramadan, Muslims refrain from food and drink from dawn until sundown. Providers should consider whether it is medically appropriate for patients to fast while in the hospital. If so, they will need to look at the options for predawn meals, provide patients with dates and spring water in the late afternoon (a traditional way to break the daily fast), and delay dinner until after sunset (Ehman, 2012).
- Hinduism
  - Hindus are often strictly vegetarian and do not consume meat or animal by-products. For such patients,

even medications produced using animals would not be allowed. Some Hindus refrain from eating certain vegetables, such as onions or garlic.

- Fasting is a common practice in Hinduism, and patients may wish to discuss the possibility within the context of their medical/dietary care plan.
- Buddhism
  - Some Buddhists are strictly vegetarian and refuse to consume any meat or animal by-products. For such patients, even medications produced using animals would not be allowed.
- African religions
  - Some African religions have taboos against consuming certain types of meat, such as pork or shellfish, which may be seen as unclean or spiritually impure.
- Indigenous Americans
  - Preferred diets come from locally sourced and seasonal foods (rather than processed food) such as wild game, fish, fruits, vegetables, and grains that are harvested or gathered from the surrounding environments.
- East Asian and Chinese religions
  - Food is often seen in terms of its energetic properties (hot, cold, neutral) and its effects on the body. Balancing these properties is believed to promote health.
  - Some East Asian religions, such as Buddhism, promote vegetarianism to adhere to the principle of ahimsa (nonviolence). Taoism may advocate for specific dietary practices that align with natural and seasonal cycles.

### Beliefs Regarding Rituals or Holy Tenets

The unique and specific beliefs of each religion and spiritual culture come with their own set of practices or traditions that help people feel connected to them, as well as contribute to the broader sense of connectedness to the world. Patients may partake in some, but not all, of these practices and rituals, whereas others may strictly follow them. Meeting a patient's spiritual needs means understanding the practices that are important to them and finding ways to integrate them into care.

- Judaism
  - Some Jewish patients strictly observe the rule of not working on the Sabbath (from sundown on Friday until sundown on Saturday) or on religious holidays. If so, this religious injunction against work, including prohibitions against using certain tools or engaging in tasks that initiate electricity use, can prevent tasks such as writing, using a cell phone, flipping a light switch, pushing buttons to call a nurse, adjusting a motorized bed, or operating a patient-controlled analgesia (PCA) pump. The tearing of paper can be considered work, so roll toilet paper may need to be replaced with an opened box of individual sheets.
  - Medical procedures should not be scheduled during the Sabbath or religious holidays (unless they are lifesaving), nor should hospital discharges be planned during such times without the patient's consent. Although these restrictions on work are generally associated with Orthodox Judaism, they may be important for any Jewish patient.
  - Jewish holidays are usually highly significant for patients, especially Passover in the spring and Rosh Hashanah and Yom Kippur in the fall. These holidays may affect the scheduling of medical procedures and may involve dietary changes (related to a need for special food or a desire to fast). All Jewish holidays run from sundown to sundown.
  - It is common for male Jewish patients to wear a yarmulke or kippah (skull cap) during prayer, and some Jews may wish to keep them on at all times ([Figure 35.10](#)). Patients or family members may wear prayer shawls and use phylacteries (two small boxes containing scriptural verses and having leather straps worn on the forehead and forearm during prayer). There may be a request that at least 10 people (called a minyan) be allowed in the patient's room for prayer.
- Catholicism
  - Some patients may keep religious objects with them, such as a rosary (a loop of beads with a crucifix used for prayer), a scapula (a small cloth devotional pendant), or a religious medal. If patients request that an object remain with them during medical procedures, one option may be placing it in a sealed bag that can be kept on or near the patient. If an object is metal and the patient is having a radiological procedure or test (such as an MRI scan), explain why metal cannot be brought into the room for the exam and ask the

- patient or family if they can bring in a nonmetal substitute.
- Interruption of religious practices, such as regular attendance at Mass or special observance of special holy days, may be highly stressful to Catholic patients. It can be helpful to connect them with local clergy and/or a hospital chaplain.
  - Sacraments, the consecrated elements of the Eucharist (e.g., the bread or Host), and blessings by a Catholic priest can be viewed as highly important, especially before surgery or when there is a perceived risk of death.
  - Patients may request Holy Communion (Eucharist) prior to surgery. Although a Catholic priest or Eucharistic minister would typically offer only a tiny portion of a wafer, patients who are NPO (to have nothing by mouth) should have this request approved by the healthcare team as medically safe before proceeding.

**FIGURE 35.10** Yarmulkes or kippahs are often worn by Jewish men during worship. Some men keep them on at all times. (credit: “Casamento judeu1” by David Berkowitz/Wikipedia, CC BY 2.0)

## PATIENT CONVERSATIONS

### Reducing Anxiety with the Rosary

**Nurse:** Hello, Catherine. How are you feeling today?

**Patient:** Nervous. Well, terrified more like it. I didn’t sleep at all last night. I just kept thinking . . . what if I don’t wake up? Kind of ironic, wasn’t it? I was wide awake all night worrying that I wouldn’t wake up after they put me to sleep today.

**Nurse:** Being anxious is very normal, but we do want to help you feel more relaxed. Not just because feeling anxious is no fun, but because we want you to go into your surgery today feeling strong. So, what do you do when you feel worried? What makes you feel better?

**Patient:** Well, I used to call my mom but . . . well, she died right before I was diagnosed with cancer. In a way I’m glad she wasn’t here for it because I think it would have killed her to see me get so sick.

**Nurse:** I’m so sorry you haven’t had her by your side through all this. Do you have any way to feel connected to her? Maybe some photos or an old sweater of hers?

**Patient:** That’s great thinking. Can you get me that bag over there on the chair? I’m sure I packed it. . . .

**Nurse:** Sure, here you go.

**Patient:** Thanks. Yes, here it is—her rosary. I don’t even remember the prayers she used to say but . . . wow, I just

feel a little better even touching it. Just thinking about her.

**Nurse:** Sometimes, it's nice to have something physical to hold when we're feeling lost and adrift in all the anxiety and uncertainty.

**Patient:** Yeah, like an anchor.

**Nurse:** Exactly.

**Patient:** Can I hold on to it until they take me in?

**Nurse:** Of course.

**Patient:** Can I hand it to you to make sure it doesn't get lost? Can you make sure it gets put somewhere safe?

**Nurse:** Yes. And I'll put a note in your chart to make sure the nurse who is there when you wake up knows where to find it.

**Patient:** Thanks. That's right . . . when I wake up.

---

- Jehovah's Witness
  - Jehovah's Witnesses do not celebrate birthdays or Christian holidays (Ehman, 2012).
  - Contrary to popular misconceptions, faith healing is not a part of Jehovah's Witness tradition. Prayers are often said for comfort and endurance.
- Islam
  - Muslim prayers are conducted five times a day. Patients may desire to pray by kneeling and bending to the floor, but Islamic tradition recognizes circumstances when this is not medically advisable ([Figure 35.11](#)). If patients are disturbed by their inability to pray on the floor, advice should be encouraged from an imam.
- Buddhism
  - Buddhism places a strong emphasis on mindfulness, so patients may request peace and quiet for the purpose of meditation, especially during crises.
  - Patients or families may pray or chant out loud repetitiously. This is often performed quietly, and any noise concerns in a hospital can usually be negotiated easily. Families may sometimes wish to place a picture of the Buddha in the patient's room.

**FIGURE 35.11** Muslim prayers are done five times daily. When possible, patients may prefer to kneel on the floor for prayer. (credit: "Damascus, Umayyad Mosque, prayers" by Arian Zwegers/Flickr, CC BY 2.0)

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN: Patient-Centered Care

The nurse can demonstrate the competency of patient-centered care by ensuring that a patient's spiritual needs are part of their care plan. Reminders for the nurse include the following:

- Be open, receptive, and respectful as you listen to a patient describe their spiritual needs.
- Understand that a patient's beliefs may differ from, or even contradict, your own. Be aware of your own biases and questions. Avoid making assumptions or judgments.
- Through active listening, advocating for needs, and being respectful of a patient's belief, build and maintain a supportive rapport.
- As you plan for and accommodate a patient's spiritual needs through collaboration and resource gathering, be aware of how these needs may evolve over the course of a patient's illness or treatment. Be flexible and aware of how a patient's spiritual needs may change or intensify.
- Communicate effectively with other members of the patient's care team to ensure that the patient's needs are known, respected, and met.

### Guidelines for Providing Competent Nursing Care

Defining safe and competent nursing care is crucial to ensuring individual patients receive the needed care. Understanding the spiritual assessments and nursing diagnoses can help the nurse assist patients in maintaining their spirituality during their healthcare journey.

#### Spiritual Assessment

The nurse will often have a standardized spiritual assessment tool to complete when a patient is admitted. However, if a standardized assessment tool is not available, the FICA spiritual history tool can be used (Puchalski, 2021). The

FICA (which stands for faith/beliefs, importance/influence, community, and address in care) contains open-ended questions to ask patients about their personal spiritual beliefs and preferences in a way that is open and nonjudgmental ([Table 35.2](#)).

Components of FICA Model	Description	Application in Health Care	Sample Assessment Questions
Faith/beliefs	Explore the patient's faith or belief system. Ask about their spiritual practices and how they draw comfort from their faith.	Understanding the patient's core beliefs gives healthcare providers insights into coping mechanisms and sources of strength during illness.	Can you share with me your religious or spiritual background? How do your beliefs influence the way you cope with challenges, including health issues?
Importance/influence	Inquire about the importance of the patient's faith in their life and how it influences their healthcare decisions.	Recognizing the impact of spirituality on healthcare decisions enables tailored treatment plans that align with the patient's values and preferences.	How important is your faith or spirituality in your life? Can you share instances where your beliefs have influenced your healthcare decisions?
Community	Assess the patient's connection to a spiritual community or support system. Understand if they engage in communal worship or spiritual gatherings.	Recognizing the role of a community in a patient's life can guide healthcare providers in facilitating connections with spiritual leaders, support groups, or chaplaincy services.	Are you part of a religious or spiritual community? How does your community provide support during times of illness or stress?
Address in care	Discuss how the patient wishes to have their faith addressed in their health care. Inquire about specific spiritual practices or rituals they may want to incorporate into their care plan.	This provides a framework for integrating spiritual care into the overall treatment plan, respecting the patient's preferences and ensuring holistic well-being.	How would you like your faith to be included in your health care? Are there specific spiritual practices or rituals you would like us to consider in your care plan?

**TABLE 35.2 FICA Model** (Source: Dameron, 2005.)

The HOPE model is a framework also used in health care to assess and address patients' spiritual and existential needs ([Table 35.3](#)). The acronym HOPE represents key domains that healthcare providers can explore with patients. Compared to the FICA model, the HOPE model strives to encompass the entirety of patients' spiritual experiences, recognizing the interplay between individual beliefs, organized religious practices, and their impact on healthcare decisions.

Components of HOPE Model	Description	Application in Health Care	Sample Assessment Questions
H: Sources of hope, meaning, comfort, strength, peace, love, and connection	Explore the patient's sources of hope, meaning, and comfort. Inquire about what brings them strength, peace, and connection in their life.	Understanding the patient's sources of hope and meaning can guide healthcare providers in providing support and incorporating these aspects into the care plan.	What gives you hope and meaning in your life, especially during difficult times? How do you find comfort and strength in challenging situations?
O: Organized religion	Assess the patient's involvement in organized religion or religious practices. Inquire about their religious community and the role it plays in their life.	Recognizing the significance of organized religion in a patient's life can inform healthcare providers about potential sources of support and guidance.	Are you affiliated with a specific religious organization or community? How does your involvement in organized religion influence your approach to health and well-being?
P: Personal spirituality and practices	Explore the patient's personal spiritual beliefs and practices. Inquire about their spiritual rituals, meditation, prayer, or other practices.	Understanding the patient's personal spirituality provides insights into their coping mechanisms and strategies for maintaining well-being.	Can you describe your personal spiritual beliefs or philosophy of life? Do you engage in any spiritual practices or rituals that are meaningful to you?
E: Effects on medical care and end-of-life issues	Discuss how the patient's spirituality affects their approach to medical care and end-of-life issues. Inquire about their preferences for spiritual support during times of illness or nearing the end of life.	Understanding the impact of spirituality on medical care enables healthcare providers to tailor treatment plans and support patients' preferences for spiritual care.	How does your spirituality influence your decisions about medical care? Are there specific ways you would like your spiritual needs addressed as you navigate medical treatment or end-of-life issues?

**TABLE 35.3** HOPE Model (Source: Anandarajah & Hight, 2001.)

## LINK TO LEARNING

You can read more information about the [HOPE tool \(https://openstax.org/r/77HOPEtool\)](https://openstax.org/r/77HOPEtool) and how to use it.

### Objective Assessment

In addition to asking open-ended questions, nurses must observe patients for cues indicating difficulties in finding meaning, purpose, or hope in life. It is also important to determine if a patient has supportive relationships (Ackley et al., 2020).

Patients experiencing chronic or serious illness may make statements that suggest spiritual distress, and their words should cue the nurse that spiritual care is needed. Examples of these statements/concepts are (Puchalski et al., 2014):

- Lack of meaning: “I am not the person I used to be.”
- Loss of hope: “I have nothing left to hope for.”
- Mystery: “Why did this happen to me?”
- Isolation: “All my family and friends are gone.”
- Helplessness: “I have no control over my life anymore.”

### Nursing Diagnoses

To integrate spiritual care effectively, nurses must engage in self-reflection to better understand their own belief systems and spiritual perspectives. This awareness is fundamental for nurses to provide compassionate and patient-centered care (PCC). By utilizing assessment tools such as the FICA Spiritual History Tool and the HOPE Approach to Spiritual Assessment, nurses can gain insights into their patients' spiritual needs and tailor their care accordingly. Overcoming barriers to spiritual care requires commitment to the therapeutic relationship, effective communication skills, trust, empathy, self-awareness, and acknowledgment of diverse beliefs.

To surmount these challenges, nurses should view spiritual care as a structured process consisting of the following interconnected phases (Nissen et al., 2022):

1. identifying spiritual needs and resources ([Table 35.4](#))
2. understanding the patient's specific needs
3. developing an individualized spiritual care treatment plan in collaboration with relevant healthcare/spiritual care professionals
4. delivering spiritual care
5. evaluating the provided spiritual care

This process-oriented perspective emphasizes the dynamic and evolving nature of spiritual care, offering a framework that acknowledges the unique aspects of each local context, patient, and care provision.

NANDA I Diagnosis	Definition	Defining Characteristics
Readiness for enhanced spiritual well-being	A pattern of experiencing and integrating meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself, which can be strengthened	<p>Connections to self</p> <ul style="list-style-type: none"> <li>• Expresses desire to enhance coping</li> <li>• Expresses desire to enhance meaning in life</li> </ul> <p>Connections with others</p> <ul style="list-style-type: none"> <li>• Expresses desire to enhance forgiveness from others</li> <li>• Expresses desire to enhance interaction with significant other</li> <li>• Expresses desire to enhance interaction with spiritual leaders</li> <li>• Expresses desire to enhance service to others</li> </ul> <p>Connections with art, music, literature, and nature</p> <ul style="list-style-type: none"> <li>• Expresses desire to enhance creative energy</li> <li>• Expresses desire to enhance spiritual reading</li> <li>• Expresses desire to enhance time outdoors</li> </ul> <p>Connections with power greater than self</p> <ul style="list-style-type: none"> <li>• Expresses desire to enhance participation in religious activity</li> <li>• Expresses desire to enhance prayerfulness</li> </ul>
Impaired religiosity	Impaired ability to exercise reliance on beliefs and/or participate in rituals of a particular faith tradition	<ul style="list-style-type: none"> <li>• Desires to reconnect with previous belief pattern</li> <li>• Has difficulty adhering to prescribed religious beliefs and/or rituals</li> <li>• Distresses about separation from the faith community</li> </ul>
Spiritual distress	A state of suffering related to the impaired ability to experience meaning in life through connections with self, others, the world, or a superior being	<ul style="list-style-type: none"> <li>• Anxiety</li> <li>• Crying</li> <li>• Fatigue</li> <li>• Fear</li> <li>• Insomnia</li> <li>• Questioning identity</li> <li>• Questioning meaning of life</li> <li>• Questioning meaning of suffering</li> </ul>

**TABLE 35.4** Common NANDA I Nursing Diagnoses Related to Spiritual Health (Source: Herdman & Kamitsuru, 2018.)

### Readiness for Enhanced Spiritual Well-Being

A readiness for enhanced spiritual well-being can be defined as a pattern of experiencing and integrating meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater

than oneself, which can be strengthened. For example, many people experienced feelings of isolation as they sheltered at home during the COVID-19 pandemic; someone with a readiness for enhanced spiritual well-being would be encouraged to spend more time outdoors. In this situation, the nurse could encourage patients to visit local parks and walk outdoors while wearing a mask and maintaining social distancing.

### **Impaired Religiosity**

Impaired religiosity is when a patient has difficulty exercising their beliefs and/or participating in rituals of their particular faith tradition. Hospitalized patients may be unable to attend religious services as usual. In this situation, the nurse could help the patient overcome environmental barriers to practicing their religion by contacting the patient's pastor to arrange a visit or determine if services can be viewed online.

### **Spiritual Distress**

Spiritual distress is defined as a state of suffering related to the impaired ability to experience meaning in life through connections with self, others, the world, or a superior being. Events that place patient populations at risk for developing spiritual distress include the birth of a child, the death of a significant other, exposure to death, a significant life transition, severe illness or injury, exposure to natural disaster, racial conflict, or an unexpected life event (Herdman & Kamitsuru, 2018). Conditions that place a person at risk for developing spiritual distress include actively dying, chronic illness, illness, loss of a body part, loss of function of a body part, or a treatment regimen (Herdman & Kamitsuru, 2018). For example, a patient diagnosed with life-threatening medical diagnoses such as cancer may experience spiritual distress as they move through the typical stages of loss. In this case, the nurse would implement interventions to enhance coping.

### **Outcome Identification**

Goals and outcomes should be customized for each patient. When a patient has the nursing diagnosis of readiness for enhanced spiritual well-being, a sample goal statement might be, "The patient will demonstrate hope as evidenced by the following indicators: expressed expectation of a positive future, faith, optimism, belief in self, sense of meaning in life, belief in others, and inner peace" (Ackley et al., 2020). An example of a related outcome is, "The patient will express a sense of meaning and purpose in life by discharge" (Ackley et al., 2020).

When a patient has the nursing diagnosis of spiritual distress, a sample goal statement might be, "The patient will demonstrate improved spiritual health as evidenced by one of the following indicators: feelings of faith, hope, meaning, and purpose in life with connectedness with self and others to share thoughts, feelings, and beliefs" (Ackley et al., 2020). A sample outcome is, "The patient will express a purpose in life by discharge" (Ackley et al., 2020).

## Summary

### 35.1 Dimensions of Spirituality

Spirituality assumes a crucial role in the healthcare setting, with its profound influence on patients' well-being. Spirituality encompasses a connection beyond oneself and a pursuit of meaning, distinct from religion yet often intersecting with faith based on shared aspects such as hope, love, conflict, and healing. Faith is examined as an acceptance of religious doctrines or an attitude facilitating a gateway to spiritual practice. Religion, as a unified system of beliefs and practices, provides a contextual backdrop for patient care and recognizes the effect it has on physical illness and mental health. Hope emerges as a guiding force, assisting patients in navigating challenges, whereas love is depicted as a profound connection rooted in spirituality, influencing the meaning individuals find in life.

In the realm of health and well-being, spirituality extends beyond religious affiliations, involving an individual's pursuit of ultimate meaning, purpose, and connection in life. It profoundly influences a person's overall sense of wellness, quality of life, and coping mechanisms during challenging times. Patients explore dimensions of spirituality, seeking meaning, fostering connections with others or a higher power, and finding inner peace by way of individual spiritual practices or group practices. Nurses, as key facilitators of patient-centered care, play a pivotal role in recognizing and incorporating diverse spiritual beliefs into health care. This inclusive approach enhances patient engagement with the healthcare system and positively impacts overall well-being while providing patients with autonomy in their healthcare journey.

Encouraging spiritual practices such as prayer, meditation, mindfulness, sacred rituals, connection with nature, and pastoral care reflects a commitment to addressing the spiritual dimension of health. Nurses create a supportive environment for patients to engage in these practices, fostering a holistic approach that recognizes the interconnectedness of physiological, psychological, and spiritual well-being. Research underscores the prevalence of spiritual distress among patients facing serious illnesses, emphasizing the vital role of spiritual care in nursing.

### 35.2 Applications of Spirituality to Health Care

Beyond the dimensions of physical and mental health, each patient's spiritual well-being must also be considered by the nurse. Developing an understanding of what spirituality is in the broader sense, then looking at how it affects an individual's health, is key to providing competent, compassionate, and culturally aware nursing care. Although nurses do not need to be an expert on all religious and spiritual beliefs, they should strive to have an awareness of the differences between them so they can better address their patients' spiritual needs.

From a practical perspective, the nurse also needs to be aware of what spiritual, religious, and cultural beliefs and practices may be central to how their patients view the experience of receiving medical care, as well as affect their treatment decisions. The nurse must be aware of and care for their own spiritual well-being and know how to find support for themselves and their patients.

## Key Terms

**afterlife** what a person believes will happen after death; a place where the spirit goes after the death of the physical body

**agnostic** someone who believes that ultimate reality is unknowable

**atheist** someone who does not believe in any divine being or entity

**baptize** to initiate or adopt into the faith (particularly Christianity)

**breathwork** a technique involving intentional, controlled breathing to interrupt the stress cycle and promote relaxation

**congregation** a group of people who worship together

**ethnicity** the cultural, social, and ancestral characteristics that define a group of people sharing common historical roots, language, traditions, and often geographical origins

**faith** a belief in something without proof

**healer** an individual using faith and prayer to facilitate healing

**holistic care model** a framework that recognizes the interconnectedness of physiological, psychosocial, and spiritual well-being in patient care

**hope** the desire for a certain outcome and the belief that it will happen

**journaling** the act of writing one's thoughts and documenting one's feelings in a journal or diary

**karma** the notion that one's future happiness is caused by present actions; actions performed with good intent lead to future happiness, whereas actions performed with bad intent lead to future unhappiness

**kosher diet** a diet that adheres to Jewish dietary laws (kashrut), governing which foods are permissible based on specific religious guidelines such as the separation of meat and dairy products and prohibitions on certain animals and their products

**love** a strong feeling of affection

**meditation** a focused way of deeply thinking and reflecting that promotes awareness and acceptance

**mindfulness** the practice of being present in the moment and aware of one's thoughts, feelings, and environment

**pastoral care services (also, spiritual counselors)** individuals who offer support to patients in exploring and expressing their spiritual needs

**prayer** the practice of communicating with a higher power or divine entity

**qigong** a traditional Chinese practice that integrates physical postures, breathing techniques, and focused intention

**reincarnation** the idea that a person's soul or spirit is reborn into a new body

**religion** a unified system of beliefs, values, and practices that a person holds sacred or considers to be spiritually significant

**remembrance and renewal (R & R)** a practice that involves reflecting on the past while simultaneously revitalizing or rejuvenating oneself for the future

**ritual** a defined practice that individuals or groups use to commemorate or cope with something

**spiritual distress** a disruption to a person's belief or value system

**spiritual healing** a complementary form of medicine that embraces practices such as prayer to help a person focus on healing

**spiritual well-being** a person's sense of purpose or meaning in life

**spirituality** a profound feeling of connection to a greater power than oneself, as well as the practices used to explore this feeling

**transcendence** the experience of a reality beyond the physical or literal world

**yoga** a practice that combines physical postures, controlled breathing, and mindfulness techniques to harmonize the mind, body, and spirit

## Assessments

### Review Questions

1. What role do nurses play in spiritual care?
  - a. Nurses are involved in spiritual care at the patient's request.
  - b. Nurses facilitate spiritual healing primarily through prayer.
  - c. Nurses contribute to spiritual care through therapeutic techniques.
  - d. Nurses focus on physiological care and refer patients for spiritual care.
2. Which statement describes the relationship between religion and spirituality in nursing?
  - a. Religion and spirituality are not always mutually inclusive.
  - b. Religion and spirituality are mutually exclusive in nursing.
  - c. True spirituality encompasses both religious and spiritual dimensions.
  - d. Religion is not as important in nursing care as is spirituality.
3. What is the primary focus of spirituality in the context of health and well-being?
  - a. religious affiliations
  - b. ultimate meaning and purpose in life
  - c. physical well-being
  - d. community engagement
4. What practices are acknowledged and respected in the nursing profession to enhance patient outcomes in spiritual practices?

- a. adhering to recommended medical interventions as a primary source of healing
  - b. relying heavily on religious ceremonies for support in the healing process
  - c. respecting designated prayer times and facilitating spiritual rituals
  - d. promoting technological advancements for patient care that focus on holistic care
5. How might breathwork contribute to healthcare providers' well-being?
- a. recognizing stressors that led to anxiety and emotional difficulties
  - b. promoting ideas to address burnout and cognitive problems
  - c. serving as a technique to interrupt the stress cycle and promote relaxation
  - d. inducing holistic thought practices in patient-centered care
6. What is the significance of understanding cultural diversity in the context of spirituality and health?
- a. Resources can be identified to assist family members in care.
  - b. Individual spirituality can impact patient care plans.
  - c. Therapeutic modalities are impacted by spiritual practices.
  - d. Religious practices are a legal right of the patient.
7. How does age affect the spiritual development of patients?
- a. Spirituality remains constant throughout life.
  - b. Spiritual beliefs become more rigid in old age.
  - c. Spirituality evolves with age and life stages.
  - d. Spirituality develops primarily during midlife.
8. Why is cultural competence crucial for healthcare providers in relation to spirituality?
- a. Patient therapies are determined by spiritual practices.
  - b. A more inclusive and patient-centered approach can be implemented.
  - c. Cultural competence is correlated to religion and spirituality, impacting health outcomes.
  - d. Cultural competence is more aligned with religious practice than spirituality.
9. How can nurses *best* assist patients with their spiritual health?
- a. providing spiritual resources if patients do not have a spiritual preference
  - b. accommodating patient requests to support their faith and religious practices
  - c. recognizing personal values and beliefs so guidance can be provided for spiritual practices
  - d. discussing a patient's values and beliefs with family members and caregivers
10. When is it appropriate for a nurse to pray with a patient?
- a. during times when members of the clergy are present
  - b. when the nurse feels the patient needs prayer
  - c. following delivery of life-altering diagnosis
  - d. when the patient specifically requests it

### Check Your Understanding Questions

1. According to Provision 5 of the ANA Code of Ethics, what are the key responsibilities nurses owe to themselves?
2. How does journaling enhance spiritual well-being and promote healing?
3. How can encouraging a patient to engage in spiritual practices such as meditation or yoga impact overall health and recovery from illness?
4. Why is it important for nurses to take cues from patients when discussing spiritual health?
5. What should a nurse do if a patient has a spiritual belief that conflicts with their treatment plan?
6. What should the nurse do if a Jewish patient who keeps kosher is served a meal that contains pork?

## Reflection Questions

1. How can awareness and understanding of spirituality, as outlined in the content, contribute to a more holistic approach in health care, considering the diverse ways individuals express and practice their spiritual beliefs?
2. Reflect on how you would navigate a conversation about blood transfusions with a patient and their family who are Jehovah's Witnesses. How would you ensure that the patient and family are comfortable and feel heard during the conversation? What challenges might you encounter, and how would you overcome them?
3. In what ways can an individual's personal belief systems, beyond organized religion, shape their spirituality?

## What Should the Nurse Do?

1. What should the nurse do to create a supportive environment for patients interested in spiritual practices such as yoga?
2. What should the nurse do when they are caring for a patient who holds very different—even contradictory—spiritual beliefs from their own?
3. A patient expresses spiritual distress related to a life-threatening illness. How should the nurse address this distress and incorporate spiritual care into the patient's treatment plan?

## Competency-Based Assessments

1. Explain the concepts of spirituality, faith, religion, hope, and love.
2. Provide specific examples demonstrating how you would customize your interactions and offer support to patients with varied beliefs and values by applying the concepts of spirituality, faith, religion, hope, and love.
3. Explain each component of the FICA model used in a spiritual assessment. Provide at least three questions that could be asked for each component.
4. Select a religion and outline how you would tailor spiritual considerations to meet the specific religious needs of a patient from the selected faith, ensuring their cultural and spiritual beliefs are respected and integrated into their care plan.

## CHAPTER 36

# Grief, Loss, Death, and Dying

**FIGURE 36.1** Grief, loss, death, and dying are natural stages of life. Skills such as compassion, empathy, and advocacy will help the nurse provide competent, patient-centered care. (Credit: modification of “sad man” by “@VicTor”/Nappy, CC 1.0 Public Domain)

### CHAPTER OUTLINE

36.1 Concepts of Grief and Loss

36.2 Concepts of Death and Dying

36.3 Factors That Affect Grief, Loss, Death, and Dying

36.4 Legal and Ethical Considerations

---

**INTRODUCTION** Loss and grief are universal human experiences that can trigger deep emotions and feelings. Yet the experience of loss and the ensuing grief response varies significantly from person to person and is influenced by physical changes, cognitive changes, cultural norms, personal beliefs, and family values. Having a deep understanding of the pathophysiology of death and the related social-emotional effects on patients, families, and healthcare providers allows nurses to support individuals and families through this process effectively. Researchers have developed conceptualizations of grief that help nurses establish care plans for patients during any stage in the grieving process. With these tools, nurses can personalize care for individuals coping with loss and experiencing grief at any level.

Regardless of their specialty or level of experience, nurses inevitably face situations involving death and dying, whether it be from terminal illnesses, expected outcomes, or unforeseen events. Additionally, nurses frequently play a crucial role in supporting individuals dealing with acute or chronic grief. It is essential for nurses to possess emotional awareness and emotional intelligence when tending to patients undergoing the dying process, those expecting impending loss, and those going through the grieving process. Nurses must be equipped to navigate intricate discussions, remain composed, and effectively address emotions such as anger, guilt, sadness, and fear.

## 36.1 Concepts of Grief and Loss

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify concepts of grief
- Recognize concepts of loss
- Describe reactions to grief and loss

We often think of loss and grief in the context of the end of life. However, loss can be associated with many other life experiences, including divorce, estrangement, financial loss, job loss, medical diagnoses, and traumatic events. While the grief process is highly variable, individuals can experience grief in response to any of these life experiences, events, and losses.

Expressions of grief may present as physical symptoms, emotional responses, or changes in social interactions. While researchers have developed a comprehensive knowledge of grief patterns, everyone is unique and moves through grief stages at different rates and with various challenges. Nurses need to understand these differences to provide individualized care for patients who have experienced loss.

### Concepts of Grief

The emotional response to a loss, known as **grief**, is defined as the individualized and personalized feelings and responses that an individual makes to real, perceived, or anticipated loss. These feelings may include anger, frustration, loneliness, sadness, guilt, regret, and peace. Major concepts associated with grieving are loss, mourning, and bereavement. The actual or perceived absence of a possession, circumstance, or individual is called **loss**. The response to loss is grief, and the outward, personal expression of grief is mourning. After a patient dies, the family members and other survivors experience loss. However, the experience of grief may also be associated with the loss of health or with changes in relationships or roles.

### Mourning

The outward, social expression of loss is called **mourning**. Individuals outwardly express loss based on cultural norms, customs, and practices, including rituals and traditions. Some cultures may encourage the verbal expression of emotions: for example, by wailing or crying loudly. Other cultures are more stoic and promote a minimal reaction to loss. Culture also dictates how long one mourns a death and sometimes how a person in mourning is expected to behave. The outward expression of loss is also affected by an individual's personality, previous life experiences, and social support system.

After a death, mourning practices include funerals, wakes, and other rituals, often connected to spiritual beliefs. These practices are highly variable among cultures. Because nurses will encounter patients from a wide range of cultures, accepting individual mourning practices is essential. Mourning rituals may include the following:

- prayer
- meditation
- chanting (rhythmic and repetitive vocalization of words or sounds)
- singing
- wailing (prolonged, high-pitched, mournful cries)
- gathering of family
- presence of spiritual leaders
- fasting
- reading from a spiritual book
- applying herbs or oils
- covering or dressing the deceased's body

### LINK TO LEARNING

Learn more about [unique burial rituals \(https://openstax.org/r/77BurialRituals\)](https://openstax.org/r/77BurialRituals) worldwide, from sky burials to parades.

## Bereavement

Both the feelings of grief and the outward expression of mourning after a loved one has died are known as **bereavement**. A bereavement period is the time it takes for the mourner to process the loss, grieve, and mourn. There is no set bereavement period; everyone will adjust differently to the world without the presence of the deceased. Bereavement can take a physical and emotional toll on a person who has experienced loss.

Nurses can encourage a person who is bereaving to talk about the death and understand their feelings are normal. Individuals experiencing the bereavement process should allow for sufficient time for the expression of grief and, if possible, postpone significant decisions such as changing jobs or moving. If individuals connect with a specific religion or spiritual practice, leaning into these beliefs enhances coping during this difficult time. Individuals without a religious connection may still experience grief on a spiritual level; they can be encouraged to incorporate their individual beliefs on death and dying into healthy coping strategies. In all these instances, nurses offer individuals a sense of acceptance by encouraging them to express grief in their own way.

## REAL RN STORIES

---

### Too Much Crying

**Name:** Cadi, RN

**Clinical setting:** Ophthalmology clinic

**Years in practice:** 8

**Facility location:** Minnesota

I've worked in an ophthalmology clinic for five years; before that, I worked in an inpatient hospice unit. In our clinic, we see a lot of eye emergencies, people with vision loss, and retinopathy from diabetes. Even though we are always alert for underlying diseases contributing to eye disorders, sometimes the most straightforward explanations lead to recovery. I remember Mr. Gershen as a good example. He was a quiet, reserved 78-year-old male who visited our clinic for repeated eye irritation and infections. He had used many over-the-counter medications, including allergy drops and vasoconstricting drops. He had been to multiple urgent care clinics and received treatment for bacterial conjunctivitis. He explained that his symptoms would improve for a few days and then return.

Mr. Gershen was accompanied by his daughter, who was worried about these repeated infections. While taking Mr. Gershen's medical history, he did mention that he had lost his wife one year previously to breast cancer. He apologized for getting teary-eyed when he discussed his wife. The daughter stated that "he still cries a lot, and these infections just seem to make it worse." With further questioning, I discovered that Mr. Gershen experienced emotional crying for extended periods several times per week, sometimes daily. His daughter explained that he was not willing to take any medication for depression or see a grief counselor, and that he felt his grief process was "normal."

The ophthalmologist confirmed my suspicions that Mr. Gershen's recurrent eye irritation was related to his ongoing emotional episodes of crying. Tears caused by emotions contain compounds similar to basal tears. Basal tears are essential lubricating tears for your eyes and contain oil, mucous, water, and salt. In addition to lubrication, they help prevent infection. Emotional tears contain these same components but also contain stress hormones and chemicals that act as painkillers (Cleveland Clinic, 2022). Excessive crying may affect the quality of tears, particularly the amount of oil in the tears, which can lead to a sensation of irritation and visible redness. Without a complete medical history, the conjunctival inflammation could appear similar to an eye infection.

The ophthalmologist discussed the eye condition with Mr. Gershen and his daughter. He prescribed lubricating eye drops. He also discussed seeking grief support to help Mr. Gershen move through the grief process.

---

## Expression of Grief

Grief affects survivors physically, psychologically, socially, and spiritually. The grief process is not orderly and predictable. Emotional fluctuation is normal. There are times when the person experiencing the loss may feel in control and accepting, and there may be other times when the loss feels uncontrolled and unbearable. Normal grief reactions to a loss can consist of physical symptoms, intense emotions, cognitive changes, and outward behavioral changes. These reactions affect social interactions in a variety of ways.

## Physical

Individuals experience a range of physical symptoms during acute and long-term grief. Common physical symptoms associated with grief include the following:

- hollowness in the stomach
- tightness in the chest
- weakness
- heart palpitations
- dizziness
- sensitivity to noise
- shortness of breath
- muscle tension
- fatigue
- dry mouth
- eye irritation

These physical changes result from physiologic changes that occur within the body in response to stress hormones triggered by the grief response. Some of these physiological responses include the following:

- blood vessel constriction
- elevated blood pressure
- increased heart rate
- release of inflammatory chemicals
- increased platelet and fibrinogen activity

In addition to bodily sensations, individuals experiencing grief also report intermittent and sometimes chronic changes in their cognitive state. Some examples of cognitive symptoms include the following:

- depersonalization (feeling disconnected from one's own feelings and experiences)
- confusion
- forgetfulness
- trouble concentrating
- dreams of the deceased
- idealization of the deceased
- a sense of the presence of the deceased

By simply naming these common symptoms as part of the natural grieving process, nurses can help normalize the symptoms, thereby reducing an individual's sense of aloneness. Nurses caring for grieving individuals can help distinguish between expected symptoms of grieving and more serious underlying health issues. These symptoms may present as acute physical changes or emotional dysregulation, as previously noted. Much is known about managing physical symptoms associated with emotional dysregulation, and it can be applied to individuals experiencing grief. Nurses can encourage such activities as:

- healthy eating
- staying hydrated
- body movement
- massage
- deep breathing exercises
- maintaining healthy sleep patterns

## LIFE-STAGE CONTEXT

---

### Broken Heart Syndrome

Stress-induced cardiomyopathy, also known as Takotsubo cardiomyopathy (TC), is a heart condition often associated with increased stress (Ahmad et al., 2023). It is also recognized as “broken-heart syndrome” within the

healthcare community. While this disorder is uncommon, it presents most often in older women after an acute stress event such as:

- death of a spouse
- death of a relative
- traumatic accident
- diagnosis of medical illness
- extreme financial loss

The pathophysiology of TC is not fully understood, but it is thought to be associated with inflammatory chemicals, microvascular dysfunction, decreased estrogen levels, and coronary spasms, among others (Ahmad et al., 2023). Highly stressful events trigger reduced mobility in the left ventricle muscle fibers. This results in decreased ventricular systolic function, decreased overall cardiac output, and auscultatory systolic murmur. Symptoms are similar to acute coronary syndrome (ACS) or myocardial infarction (MI), including the following:

- chest pain
- shortness of breath
- tachycardia
- bradycardia
- arrhythmias
- systolic murmur

However, lab values suggesting cardiac damage may not show elevation consistent with the symptoms experienced. Because TC mimics other acute heart conditions, nurses should care for patients with TC in the same way as patients experiencing an MI (Ahmad et al., 2023). Patients are stabilized in a hospital setting; however, recovery as an outpatient is expected, with chest pain symptoms typically resolving after several weeks.

---

### Emotional

Physical and emotional symptoms associated with the grief response are closely linked. The physical symptoms of fatigue, chest tightness, breathlessness, or heart palpitations are related to common emotional symptoms such as anxiety, anger, and fear. Conversely, a person may develop anxiety related to physical symptoms associated with grief. Other emotional sensations commonly reported during the grief response include the following:

- numbness
- sadness
- shame
- loneliness
- relief
- yearning (a feeling of intense longing)
- guilt
- self-reproach (harsh self-criticism or disapproval)
- helplessness
- abandonment

Many strategies that are effective at reducing physical symptoms of grieving can also help alleviate emotional distress. In addition, speaking with a specially trained grief counselor can positively impact emotional dysregulation. As individuals progress through the grieving process, nurses can encourage them to do the following:

- Express creativity.
- Accept rapidly changing emotions.
- Practice patience with self and others.
- Incorporate frequent self-care activities.
- Express feelings in an emotionally safe environment.
- Maintain a consistent routine.
- Maintain connection with the deceased.
- Maintain connection with family and friends.
- Reach out to community through support groups.

## LINK TO LEARNING

Coping with grief is difficult, but nurses can promote simple tasks to help patients maximize their support during the different stages of grief. While formal counseling may benefit some, focusing on simple, day-to-day tasks such as getting proper sleep, hydration, and nutrition can also be highly effective. Check out this article on [ways to encourage and support patients through the grief process \(https://openstax.org/r/77GriefProcess\)](https://openstax.org/r/77GriefProcess) to learn more.

### Social

Individuals may have difficulty interacting with others during the initial stages of grief. People report having trouble maintaining conversation, making plans, and attending social gatherings, even with close family and friends. This social disruption can last indefinitely and is also associated with increased stress levels and many of the physical and emotional symptoms previously discussed. Individuals may struggle with tasks and interactions such as the following:

- work performance
- uncontrollable crying
- social withdrawal
- over-reactivity
- changed relationships
- avoidance of reminders of the deceased
- rage or anger

Anger is a volatile emotion common for those experiencing a loss, particularly an unexpected one. Anger may be held inward or directed outward toward others. Nurses should encourage individuals to verbalize their anger and offer compassionate listening without judgment as a way for people to work through their feelings of anger.

### Concepts of Loss

While loss is often thought of in the context of death and dying, many examples of loss are not associated with death. Some loss is perceived only by the individual experiencing it; other types of loss are readily visible to other individuals. This variation in types of loss may affect the grieving process. [Table 36.1](#) explains the various concepts of loss.

Concept	Explanation	Examples
Actual loss	Actual loss refers to the tangible, measurable loss of something that was once possessed or experienced.	The death of a loved one, loss of a job, loss of a limb in an accident
Perceived loss	Perceived loss is the subjective experience of loss, even if no tangible loss has occurred.	Feeling a sense of loss after a breakup or divorce, loss of a cherished dream or goal
Anticipatory loss	Anticipatory loss involves experiencing grief and mourning in anticipation of an impending loss.	Grieving the impending death of a terminally ill family member or pet

**TABLE 36.1** Concepts of Loss

Concept	Explanation	Examples
Maturational loss	Maturational loss refers to the loss experienced as a result of developmental milestones and life transitions.	Leaving home for college, retirement, becoming an empty-nester
Situational loss	Situational loss is the loss experienced due to specific circumstances or events.	Loss of a home due to a natural disaster, loss of financial stability after bankruptcy

**TABLE 36.1** Concepts of Loss

### Actual Loss

In addition to death, individuals may experience loss as the absence of an individual, a pet, a possession, a relationship, a job, a body part, or overall health. In **actual loss**, the absence is clearly noticed by others. This support reinforces the validity of the grief process and allows individuals the social and cultural space for grieving.

### Perceived Loss

A **perceived loss** is more complex in that the loss may not be evident to others. There is no observable loss, but the individual distinctly feels an absence. This may occur in a variety of situations, such as the following:

- disruption in identity
- changes in mental acuity
- change in housing stability
- loss of independence
- decreased mobility
- change in friendship dynamics
- disruption in spiritual beliefs
- loss of trust

## PATIENT CONVERSATIONS

### Perceived Loss

**Scenario:** Carlyn is a retired 75 year old who enjoys taking walking tours around the world and hiking with her children and grandchildren in national parks around the country. She also enjoys reading, trying new restaurants, and drawing. Over the last year, she has been struggling with pain in her right knee after a fall during a hike. Carlyn has been unable to complete any hikes over one mile long during the past year. Her daughter is concerned that Carlyn is depressed and convinces Carolyn to make an appointment with her primary care provider today. Jace, an RN, is taking Carlyn's history.

**Nurse:** What brings you in today, Carlyn?

**Patient:** My daughter thinks I am depressed. She is concerned because I haven't planned any trips and am just not interested in eating out anymore. She says I stay inside all the time, which is unlike me.

**Nurse:** Your daughter must be really worried about you. It sounds like you are feeling a lack of interest in your usual activities. Are you feeling down or depressed or having trouble sleeping?

**Patient:** I'm sleeping fine, but I am feeling down because of my knee.

**Nurse:** I know your knee has been painful over the last year. Do you think this pain is contributing to your decreased activity level?

**Patient:** Well, my pain has been better in the last few months, but that's because I have been taking it easy. I can't hike anymore, and all my travels in the past have been walking tours. I really miss that. I know it seems silly, but I really feel like I lost part of myself when I stopped being able to hike.

**Nurse:** Have you expressed these feelings before or talked about them with your family?

**Patient:** Not really; I don't think anyone can understand that being unable to walk and hike changes how I see the world. Sometimes, I feel overwhelmingly sad about this.

**Nurse:** Carlyn, I think you may be dealing with grief related to the loss of hiking. This type of loss is referred to as a perceived loss. It is sometimes complicated for others to understand perceived losses because they can't see or feel the loss themselves; however, grieving the loss of a vital part of your identity, such as hiking, is essential. I encourage you to let yourself feel the sadness as grief and seek a counselor or support group to help you with coping skills.

**Patient:** Thank you, Jace, for listening. And for helping me understand this is a normal feeling that others might not understand. I will talk with my family so we can come up with ways for me to cope with this grief.

### Anticipatory Loss

When an individual expects or foresees a loss or change it is known as **anticipatory loss**. This type of loss creates anxiety about a loss before it happens. Anticipatory loss is common and occurs in situations such as the following:

- chronic illness
- terminal illness
- cognitive changes such as dementia
- divorce
- expected changes in life stage

Anticipatory loss can cause a prolonged grieving process as well as create relationship tension if a person begins to withdraw prematurely from social connections. For example, a grandmother may feel anger, guilt, and sadness, anticipating the loss of being present as her grandchildren grow up. She may feel compelled to overextend herself physically and emotionally to spend time with them. A father may feel anxiety and anger associated with the anticipated loss of time with his children after a divorce. This may lead to conflict in creating a parenting plan with his ex-spouse. Nurses can engage with patients about anticipatory loss similarly to actual loss. Bringing in coping mechanisms will help in the present moment and also help prepare the individual for when the actual loss occurs.

### Maturation Loss

A **maturation loss** occurs at predictable intervals during an individual's life span. They are often tied to life stages ([Table 36.2](#)) (Child Care Resource Center, n.d.). Every individual will experience them differently. Maturation losses may lead to grief responses for some people; other people may simply experience them as a process of moving forward to a new stage of life.

Life Stage	Triggers for Maturation Loss
Early childhood	<ul style="list-style-type: none"> <li>• Change in attention or physical affection from caregivers</li> <li>• Separation from family for daycare or preschool</li> </ul>
Middle childhood	<ul style="list-style-type: none"> <li>• Adjustment to teacher-student relationship</li> <li>• Change in expectations associated with school or activities</li> <li>• Loss of time independence</li> </ul>

**TABLE 36.2** Maturation Losses

Life Stage	Triggers for Maturational Loss
Adolescence	<ul style="list-style-type: none"> <li>• Loss of physical contact with caregivers</li> <li>• Loss of simplicity of childhood</li> <li>• Change in identity from child to teen</li> <li>• Loss of pleasure in imaginative play</li> <li>• Change in the structure of childhood</li> <li>• Loss of protective status for parents</li> <li>• Loss of childhood identity</li> </ul>
Early adulthood	<ul style="list-style-type: none"> <li>• Moving out of childhood home</li> <li>• Adjustment to independent decision-making</li> <li>• Loss of independence if entering long-term relationship</li> </ul>
Childbearing	<ul style="list-style-type: none"> <li>• Loss of time freedom</li> <li>• Reduced energy</li> </ul>
Middle adulthood	<ul style="list-style-type: none"> <li>• Loss of energy level</li> <li>• Pressures of productivity</li> <li>• Changes in physical abilities</li> <li>• Loss of parents due to age/death</li> </ul>
Older adulthood	<ul style="list-style-type: none"> <li>• Loss of physical ability</li> <li>• Changes in health</li> <li>• Retirement</li> <li>• Change in routine</li> <li>• Change in productivity or meaning in life</li> </ul>

**TABLE 36.2** Maturational Losses

## LIFE-STAGE CONTEXT

### Grief in Children

Children understand and process death differently than adults. The grief process and symptoms in children vary based on the age of the child. Young children may be unable to verbalize their emotions and feelings, but support is crucial at any age.

Symptoms of grief in younger children include nervousness, uncontrollable rages, frequent sickness or accidents, rebellious behavior, hyperactivity, nightmares, depression, compulsive behavior, memories fading in and out, excessive anger, overdependence on the remaining parent, denial, and disguised anger. Children may not understand that death is permanent until they are in preschool or older. To help facilitate this understanding, it is important to use the word “death” and not euphemisms like “gone to sleep” or “gone away.”

Symptoms of grief in older children include difficulty concentrating, forgetfulness, decreased academic performance, insomnia or sleeping too much, compulsiveness, social withdrawal, antisocial behavior, resentment of authority, over-dependence, regression, resistance to discipline, suicidal thoughts or actions, nightmares, symbolic dreams, frequent sickness, accident proneness, overeating or undereating, truancy, experimentation with alcohol or drugs, depression, secretiveness, sexual promiscuity, and running away from home.

Play is the universal language of children, so nurses should use it therapeutically when possible. Reassuring children that their grief is “normal” can give them comfort. If necessary, refer children, parents, and families to grief

specialists.

---

### Situational Loss

A **situational loss** can encompass other types of loss but primarily describes losses associated with expected or unexpected life changes for an individual. These can include the following:

- loss of potential to have children
- loss of hope for achieving a dream
- loss of friends due to moving
- loss of body image
- loss of control
- loss of freedom
- loss of physical or emotional safety
- leaving childhood home
- going away to college
- moving to a new home
- graduating from school
- starting a new school

Situational losses may be sudden or anticipated. Situational grief is highly variable, with some individuals reacting with prolonged symptoms and others not having a grief response at all.

### Reactions to Grief and Loss

Reactions to loss and grief are often profoundly personal, but they are also affected by cultural and social expectations. Sometimes the reactions of others, including family, friends, and the wider community, can affect the grief process. Furthermore, a variety of cultural differences are associated with grieving.

Researchers have developed frameworks (e.g., Engel's Six Stages, Kübler-Ross's Five Stages) that are helpful for nurses in visualizing the stages of grief. Having a clear understanding of these stages allows nurses to support patients and families during the grief process. Based on these concepts, nurses will recognize specific emotional reactions as symptoms of grief and can help equip patients with appropriate coping strategies. Though the stages of grief provide a helpful framework, nurses must remember that each individual progresses through the experience of loss at their own pace. Setbacks and fluctuations through the stages are typical and even expected.

### Engel's Six Stages

American psychiatrist George Engel proposed his theory of grief in 1961. He wanted to answer the question, "Is grief a disease?" His answer compares the death of a loved one to a physical injury. The loss creates similar responses in the body as a physical wound, and the grief response is essentially a deviation from a normal state of health. The body requires a certain process to return to a state of normalcy or health. According to Engel, this process of grief consists of six stages (Registered Nursing, 2023):

- shock and disbelief
- developing awareness
- restitution
- resolving the loss
- idealization
- outcome

While the timeframe to proceed through these stages is not universal, Engel believed these stages occur sequentially. Initially, the person experiencing loss through death is in a state of disbelief, or shock, and refuses to accept the loss; some individuals report not feeling their loss as real. This is followed by an awareness of the finality of the death, after which they work through their own personal and cultural rituals in response to grief. As a sensation of resolution begins to occur, the individual may attend support meetings and open up with friends and family about the loss. Exhibiting a sense of idealizing the deceased person is also common. During the final stage, or outcome, Engel proposed that healing and maximum coping occurs, allowing the bereaved to adjust to life without the deceased.

### Kübler-Ross's Five Stages

A few years after Engel proposed his stages of grief, Swiss psychiatrist Elisabeth Kübler-Ross identified five main stages of grief: denial, anger, depression, bargaining, acceptance (Tyrell et al., 2023). Patients and families may experience these stages along a continuum, move randomly and repeatedly from stage to stage, or skip stages altogether. As [Figure 36.2](#) illustrates, there is no correct way to grieve, and an individual's needs and feelings must remain central to care planning.

**FIGURE 36.2** The Kübler-Ross grief cycle explains the normal grief process; however, it is common to fluctuate and move randomly through the stages, particularly in cases of complicated grief. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

#### Denial

When the grieving individual refuses to acknowledge the loss or pretends it isn't happening, **denial** occurs. The feeling of denial is self-protective, as the individual attempts to numb overwhelming emotions as they process the information. The denial process can help to offset the immediate shock of a loss. Denial is commonly experienced during traumatic or sudden loss or if other unexpected, life-changing events occur. For example, a patient who presents to the provider with a severe headache and receives a diagnosis of terminal brain cancer may experience feelings of denial.

#### Anger

In the grief process, **anger** often masks pain and sadness. The subject of anger can be quite variable: displeasure or hostility may be directed at the individual who was lost, internalized against the self, or projected toward others. Additionally, an individual may lash out at those uninvolved with the situation or have bursts of anger that seemingly have no apparent cause. Healthcare professionals should know that anger may often be directed at them as they provide information or care. Healthcare team members, family members, and others who become the target of anger must seek to recognize that it is not a personal attack but rather a manifestation of the challenging emotions that are a part of the grief process. The nurse can provide a supportive presence and allow the patient or family member time to vent their anger and frustration while maintaining boundaries. Rather than focusing on what to say or not to say, allowing a safe place for a patient or family member to verbalize their frustration, sorrow, and anger can offer great support.

#### Bargaining

During the grief process **bargaining** can occur as the bereaved attempts to regain control over the loss. When individuals enter the bargaining phase, they seek ways to change or negotiate the outcome, regardless of whether this is realistic or even possible. Some may try to "make a deal" with God or their higher power to take away their pain or change their reality; they may promise to live a better life or give more of themselves to religious practices if

only the circumstances were different. For example, a patient might say, “I promised God I would stop smoking if He would heal my wife’s lung cancer.”

### Depression

Prolonged sadness that affects an individual’s ability to perform everyday tasks is called **depression**. As part of the grief process, depression can manifest as intense sadness over the loss of a loved one or a similarly life-changing situation. It can cause a loss of interest in activities, people, or relationships that previously brought one satisfaction. It is not uncommon for individuals in the depression stage of grief to experience irritability, sleeplessness, significant fatigue, and loss of focus or energy. Simple tasks such as getting out of bed, showering, or preparing a meal can feel so overwhelming that individuals withdraw from activity. They may struggle to find meaning in their life or to identify their sense of personal worth or the value of their contributions. Depression can be associated with ineffective coping behaviors, and nurses should watch for signs of self-medicating with alcohol or drugs to mask or numb depressive feelings.

### Acceptance

The final stage of grief, **acceptance**, happens when the individual understands their loss and acknowledges their new reality. They begin to re-engage with others, find comfort in new routines, and even experience happiness with life activities again. The acceptance phase does not mean the absence of sadness or struggle; rather, it signifies the individual’s ability to cope with the grief experience.

## UNFOLDING CASE STUDY

### Unfolding Case Study #5: Part 6

Mr. Morales is at the oncology clinic, accompanying his wife who is undergoing treatment for aggressive breast cancer. The oncologist has just explained that Mrs. Morales has a type of cancer that is not responding effectively to treatment and hospice care is recommended at this time. Mr. Morales is visibly upset and states, “No. No. This can’t be happening. She’s young and healthy! This isn’t fair! You’re wrong! I want a second opinion right now. Get out and get someone in here that can give us a better answer!” Mrs. Morales begins to cry and says, “No. I refuse to believe it. I’ve been doing my treatments every day like I should. There’s no way this is true.”

1. Recognize cues: What cues are important for the nurse to recognize in this situation?
2. Analyze cues: Based on the Kübler-Ross grief cycle, which stage do Mr. and Mrs. Morales appear to be in?

### Tasks of Grieving

Other experts also describe the normal grieving process in terms of tasks that one must accomplish. These tasks include notification and shock, experiencing the loss, and reintegration.

- Notification and shock: This phase occurs when a person first learns of the loss and experiences feelings of numbness or shock. The person may isolate themselves from others while processing this information. The initial step for the individual is to accept the reality of the loss by evaluating and acknowledging it.
- Experiencing the loss: The second task involves experiencing the loss emotionally and cognitively. The person must work through the pain of separation and grief by reacting to and expressing it.
- Reintegration: The third task involves reorganizing and restructuring family systems and relationships by adjusting to the environment without the deceased. The person must form a new reality without the deceased and adapt to a new role, while also retaining memories of the deceased.

As a nurse, you can greatly assist patients and family members as they move through the grieving process by being willing and committed to spending time with them. Listen to their stories, be present, and witness their pain. Remember that you cannot fix everything, but taking time to assess their symptoms of grief helps you identify other resources for support.

### Complicated and Dysfunctional Grief

A disorder called **complicated grief** can occur after the death of a significant other. With this, the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment.

A specialized grief therapist may be necessary to address complicated grief.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Generate Solutions: Grief After Suicide

Nurses generate solutions by identifying actions or interventions to best address patient issues. Recognizing solutions to help patients cope with grief after the suicide (death caused by intentional harm to oneself) of a loved one is crucial. Suicide is often associated with complicated grief patterns that nurses must recognize to provide essential care. Nurses can watch for factors that can signal complicated grief that fails to follow normal expectations and leads to functional impairments. Complicated grief can present with the following:

- prolonged anxiety
- symptoms of post-traumatic stress disorder
- survivor guilt
- substance misuse
- prolonged sleep disorders
- nightmares
- lack of concentration
- inability to pursue everyday tasks

By identifying specific risk factors and common patterns of complicated grief, the nurse can create a safe environment for the patient to express themselves. With a nonjudgmental attitude, the nurse can help the patient seek support services, grief counseling, and mental health services as appropriate.

Complicated grief may become **dysfunctional grief** in which grief does not resolve as expected or an individual resorts to unhealthy coping strategies. This type of complicated grief is more common in response to traumatic deaths, violent deaths, unexpected deaths, death of romantic partners, and in parents experiencing the loss of a child. Dysfunctional grief may or may not follow the typical pattern of processing through the grief stages, but it frequently leads to secondary physical and emotional problems. [Table 36.3](#) displays types of dysfunctional grief, including chronic grief, delayed grief, exaggerated grief, and masked grief.

Type of Dysfunctional Grief	Clinical Example
Chronic grief	A 70-year-old man continues to sob on a regular basis and has difficulty taking care of himself three years after the death of his wife in a car accident.
Delayed grief	A 16-year-old girl insists on continuing all her activities, social engagements, and school projects after the death of her mother. For many months, she tells her friends and family that she is "fine." During her birthday celebration, she is overwhelmed with sadness and begins to exhibit normal grief reactions.
Exaggerated grief	An 8-year-old boy expresses grief in response to the death of his older brother by experiencing nightmares, extreme fear of illness, and misbehaving at school.
Masked grief	The son of a 70-year-old woman is concerned when his mother begins to experience new symptoms, such as heartburn and headaches, after the death of her husband.

**TABLE 36.3** Types of Dysfunctional Grief

To assist in treating complicated and dysfunctional grief, providers typically obtain a comprehensive grief assessment of the bereaved. A variety of standardized clinical tests can be used for this purpose, including the following:

- Pathological Grief Items Checklist
- Hamilton Rating Scale for Depression
- Inventory of Complicated Grief
- Hogan Grief Reaction Checklist
- Beck Depression Inventory
- Texas Inventory of Grief
- Social Adjustment Scale

## LINK TO LEARNING

Standardized and validated questionnaires such as the [Inventory of Complicated Grief \(https://openstax.org/r/77GriefInventory\)](https://openstax.org/r/77GriefInventory) can help nurses accurately evaluate grief and provide appropriate interventions based on the results.

## 36.2 Concepts of Death and Dying

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the concept of death
- Examine the effects of terminal illness
- Recognize the nurse's role in death and dying

Compassionate care during death and dying is a fundamental role of the nurse. Understanding the pathophysiological and outward physical changes that occur during the dying process allows nurses to create individualized care plans. Nursing interventions include care for the dying individual as well as family members coping with death, dying, and grief.

Unless death is immediate, as in violent or traumatic death, nurses can anticipate some of the physical changes that will occur. Nurses can educate patients and families about what to expect, anticipate symptoms, and provide individualized treatments focused on alleviating pain and discomfort. This highly responsive care is the basis for providing dignity and comfort for the dying.

### Concept of Death

The concept of **death** is commonly defined as the cessation of biological life functions, though specific conceptions of death may vary based on cultural and spiritual beliefs. How individuals think about death and dying can directly affect the process of death in an emotional as well as a physical sense. Individuals may experience emotions about death on a continuum from fear to peace, and these emotions may fluctuate within one individual over time.

As the body ceases to function, **physiological death** occurs, eventually rendering the individual unable to engage in necessary basic processes such as breathing and eating. When the individual begins to face their impending death and consequently regresses into the self, **psychological death** occurs. A daughter caring for her mother with terminal colon cancer may notice that after a period of expressing fear of dying, her mother becomes quiet and minimally responsive. She keeps her eyes closed and responds only to physical touch. When others, perhaps unable to effectively cope with the imminent loss and its implications, withdraw from the dying individual, this is known as **societal death**. For example, a granddaughter may make a final visit to her grandfather with terminal lung cancer several days before his actual death. She states that she is saying goodbye now because she does not want to see him suffering.

### Pathophysiology of Death

The pathophysiology of death explains the outwardly visible physical changes to the individual and the internal organ functions that deteriorate during the dying process. These changes may progress quickly or slowly. Many of these changes can be predicted and expected; however, not every individual experiences every symptom of dying. This is particularly true if the death is sudden rather than prolonged. The active dying process has three stages: early, middle, and late. Each stage has specific changes in behavior and physical changes in the body that influence the individual's appearance (Traditions Health, 2022). See [Table 36.4](#) for an overview of the pathophysiological

changes associated with each stage of death.

System	Stage of Death	Pathophysiology	Physical Changes
Cardiovascular	Early	<ul style="list-style-type: none"> <li>• Slight decrease in heart rate and blood pressure</li> <li>• Mild peripheral circulation changes</li> </ul>	<ul style="list-style-type: none"> <li>• Slightly cool, clammy skin</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>• More noticeable decrease in heart rate and blood pressure</li> <li>• Reduced cardiac output</li> <li>• Reduced perfusion</li> </ul>	<ul style="list-style-type: none"> <li>• Mottling of the skin</li> <li>• Cyanosis of extremities</li> </ul>
	Late	<ul style="list-style-type: none"> <li>• Significant decrease in heart rate and blood pressure</li> <li>• Peripheral circulation greatly diminished</li> <li>• Possible arrhythmias</li> </ul>	<ul style="list-style-type: none"> <li>• Pronounced cyanosis</li> <li>• Possible edema</li> </ul>
Respiratory	Early	<ul style="list-style-type: none"> <li>• Slight changes in breathing patterns</li> <li>• Occasional shortness of breath</li> </ul>	<ul style="list-style-type: none"> <li>• Mild dyspnea (shortness of breath)</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>• Irregular breathing patterns (e.g., Cheyne–Stokes respiration)</li> <li>• Weakening cough reflex</li> </ul>	<ul style="list-style-type: none"> <li>• Noticeable shortness of breath</li> <li>• Use of accessory muscles for breathing</li> </ul>
	Late	<ul style="list-style-type: none"> <li>• Markedly irregular and labored breathing</li> <li>• Significant decrease in respiratory rate</li> <li>• Accumulation of secretions in the airways (death rattle)</li> </ul>	<ul style="list-style-type: none"> <li>• Audible respiratory secretions</li> <li>• Severe dyspnea</li> </ul>
Neurological	Early	<ul style="list-style-type: none"> <li>• Mild confusion or disorientation</li> <li>• Decreased attention span</li> </ul>	<ul style="list-style-type: none"> <li>• Slightly decreased responsiveness</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>• Increased confusion and disorientation</li> <li>• Reduced response to stimuli</li> </ul>	<ul style="list-style-type: none"> <li>• Pronounced confusion</li> <li>• Agitation</li> </ul>

**TABLE 36.4** Changes Associated with Each Stage of Death

System	Stage of Death	Pathophysiology	Physical Changes
	Late	<ul style="list-style-type: none"> <li>Decreased consciousness</li> <li>Loss of motor and sensory functions</li> <li>Possible terminal agitation or delirium</li> </ul>	<ul style="list-style-type: none"> <li>Unresponsiveness</li> <li>Possible seizures</li> </ul>
Gastrointestinal	Early	<ul style="list-style-type: none"> <li>Decreased appetite</li> <li>Reduced bowel movements</li> </ul>	<ul style="list-style-type: none"> <li>Mild nausea</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>Significant decrease in appetite and intake</li> <li>Slowing of digestive processes</li> <li>Possible constipation or diarrhea</li> </ul>	<ul style="list-style-type: none"> <li>Noticeable weight loss</li> <li>Abdominal discomfort</li> </ul>
	Late	<ul style="list-style-type: none"> <li>Minimal or no intake</li> <li>Possible bowel incontinence</li> </ul>	<ul style="list-style-type: none"> <li>Severe weight loss</li> <li>Distended abdomen</li> </ul>
Urinary	Early	<ul style="list-style-type: none"> <li>Slight decrease in urine output</li> </ul>	<ul style="list-style-type: none"> <li>Slightly concentrated urine</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>More noticeable decrease in urine output</li> <li>Concentrated urine</li> </ul>	<ul style="list-style-type: none"> <li>Reduced urine output</li> </ul>
	Late	<ul style="list-style-type: none"> <li>Significant decrease or cessation of urine output</li> <li>Possible kidney failure</li> </ul>	<ul style="list-style-type: none"> <li>Anuria (no urine output)</li> <li>Edema</li> </ul>
Musculoskeletal	Early	<ul style="list-style-type: none"> <li>Mild weakness and fatigue</li> </ul>	<ul style="list-style-type: none"> <li>Slightly reduced muscle strength</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>Increased weakness and fatigue</li> <li>Difficulty swallowing (dysphagia)</li> </ul>	<ul style="list-style-type: none"> <li>Noticeable muscle atrophy</li> </ul>
	Late	<ul style="list-style-type: none"> <li>Loss of muscle tone</li> <li>Possible muscle twitching or jerking (myoclonus)</li> </ul>	<ul style="list-style-type: none"> <li>Severe muscle atrophy</li> <li>Involuntary muscle movements</li> </ul>
Integumentary	Early	<ul style="list-style-type: none"> <li>Cool, clammy skin</li> </ul>	<ul style="list-style-type: none"> <li>Slightly pale skin</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>Mottling of the skin</li> <li>Decreased skin elasticity</li> </ul>	<ul style="list-style-type: none"> <li>Pronounced mottling</li> <li>Skin breakdown</li> </ul>

**TABLE 36.4** Changes Associated with Each Stage of Death

System	Stage of Death	Pathophysiology	Physical Changes
	Late	<ul style="list-style-type: none"> <li>• Pronounced cyanosis</li> <li>• Pressure ulcers due to immobility</li> </ul>	<ul style="list-style-type: none"> <li>• Extensive skin breakdown</li> <li>• Pressure ulcers</li> </ul>
Immune	Early	<ul style="list-style-type: none"> <li>• Mild decrease in immune response</li> </ul>	<ul style="list-style-type: none"> <li>• Slightly increased susceptibility to infections</li> </ul>
	Middle	<ul style="list-style-type: none"> <li>• Increased susceptibility to infections</li> </ul>	<ul style="list-style-type: none"> <li>• Noticeable signs of infection (e.g., fever, inflammation)</li> </ul>
	Late	<ul style="list-style-type: none"> <li>• Compromised immune response</li> <li>• Decreased ability to heal</li> </ul>	<ul style="list-style-type: none"> <li>• Severe infections</li> <li>• Poor wound healing</li> </ul>

**TABLE 36.4** Changes Associated with Each Stage of Death

### Early Stage

During the early stage of dying, there may be few visible changes, depending on the underlying disease process. The human body begins to conserve energy in this early stage, resulting in a reduced appetite and a lack of interest in food. Patients may experience trouble swallowing, feeling full after consuming a small amount of food, and decreased pleasure sensation from food. For some individuals, chewing, swallowing, and digestion may become painful due to dry mouth, oral sores, dry throat, and bloating. This is the body's sign that fewer nutrients are needed. This stage is often difficult for family members and caregivers, since providing nourishment is essential to caregiving.

### Middle Stage

The middle stage of the dying process can last anywhere from a few hours to days. Nurses will notice predictable and expected physical changes that suggest a slowing of bodily functions. The physical changes noted during the middle stage of dying result from physiological changes, such as a reduction in peripheral circulation as blood flow is reserved for the functioning of primary internal organs. Changes to internal blood circulation result in findings such as low blood pressure, irregular breathing patterns, and bradycardia (slow heart rate). Visible changes include cool hands and feet, a sensation of being cold, and paling or darkening of the skin. Decreased circulation in the skin may result in **pallor**, an extremely pale hue of the skin, or **mottling**, a bluish-red, lace-like (reticular) coloration of the skin (Figure 36.3). Many of these circulatory effects also result in weakness and fatigue. Less blood to the brain may also affect cognition and verbal response, leaving some individuals unable to speak. The inability to communicate effectively often leads to social withdrawal. However, individuals can still experience touch, hearing, and emotions.

**FIGURE 36.3** Mottling appears as a bluish-red, lacelike (reticular) pattern in the skin in response to decreased peripheral circulation. (credit: modification of “Thromboembolic complication in essential thrombocythemia.” by National Library of Medicine, CC BY 2.0)

## LINK TO LEARNING

---

Learn techniques for [helping family members connect with loved ones at the end of life \(https://openstax.org/r/77DeathConnect\)](https://openstax.org/r/77DeathConnect) even if the patient is unresponsive.

---

### Late Stage

Depending on the cognitive and physical state before the initiation of the dying process, individuals may experience progressive failure of body organ systems. Because circulation is reduced to major organs, breathing muscles may be less effective and unable to clear secretions. This results in sporadic, shallow, or noisy breathing. Individuals may show respiratory changes such as labored breaths and periods of **apnea**, temporary pauses in breathing. Also, bowel or bladder incontinence may result due to a lack of muscle tone in the bowel or bladder. Patients may have little or no urine or stool output due to reduced metabolism and processing of nutrients. Skin changes progress to include widespread mottling. Continued circulatory changes include pronounced bradycardia and hypotension (low blood pressure). During this later stage, patients may become extremely restless, especially if the work of breathing is significantly impaired. Patients lose interest in food and may develop abdominal ascites as the liver is less effective in processing waste products.

## REAL RN STORIES

---

### Compassion During Impending Death

**Name:** Edela, RN

**Clinical setting:** Outpatient hospice

**Years in practice:** 20

**Facility location:** Various client homes in Chicago, Illinois

I've worked as a hospice RN for nearly 20 years. I have witnessed the spectrum of end-of-life situations. I started out working in an emergency department and saw the effects of traumatic deaths on family members. Most of the patients and families I care for now are experiencing death from an illness or disease with a somewhat anticipated death. However, this does not make the stage of impending death any easier. Each patient and family is different, but over the years I have developed some tips for supporting the family during this challenging stage.

One family stands out as an example. This family was moving toward the late stages of dying and into the stage of impending death with their 17-year-old son, who had osteosarcoma. The primary goal of his hospice treatment was pain control and comfort care. As he progressed into the stage of impending death, his mother became increasingly agitated by his unresponsiveness, irregular breathing patterns, and inability to eat or drink. She expressed concern that he was starving or suffocating and wondered if they should have considered other treatments to make him more comfortable.

While the patient was resting quietly during one of my visits, I spoke with his mother privately. I used visual handouts to explain the process of slowed digestion and irregular breathing. I explained to her the data that suggest that individuals can still hear and feel emotion late in the dying process. She cried and explained to me that she was not sure how to talk to her son when he could not respond. I encouraged her to continue to read aloud to him, as this was one of their long-time bonding activities. We agreed that I would request orders for medications to reduce the secretions associated with his breathing. I provided her with soft swabs to keep his lips moist, even though he could not drink. She expressed her gratitude for helping her better understand the process and maximize the quality of her time with her son.

Caring for the family is crucial during the stage of impending death, and individualizing care shows a high level of care and personalization that will set you apart as a caregiver.

---

### Physical Signs of Impending Death

Physical signs that signal impending death typically occur during the last hours before death. Sometimes, these are continuations of previous symptoms and may be more pronounced during this stage. Signs of impending death may

include terminal restlessness or terminal agitation. Individuals often have a fading of consciousness or even periods of unconsciousness. Sensory changes, including illusions, delusions, hallucinations, and death awareness, may occur (Hospice Foundation of America, 2023). Additional changes to breathing patterns are often a sign of impending death. **Cheyne-Stokes breathing** is a pattern of abnormal breathing characterized by progressively deeper and sometimes faster breathing, followed by a gradual decrease that results in a temporary stop in breathing (apnea), while **agonal breathing** refers to gasping or labored breaths that may be followed by periods of apnea lasting many seconds.

## UNFOLDING CASE STUDY

### Unfolding Case Study #5: Part 7

Refer back to [Unfolding Case Study #5: Part 6](#) for a review on the patient data.

After taking some time to think about options, Mr. and Mrs. Morales make the decision to pursue hospice care. They are currently waiting for the palliative care and hospice team to come discuss more specific information about what to expect.

Hospice Nursing Notes	<b>1400:</b> Completed intake assessment for Morales family. Agreed to start hospice nursing services in their home beginning tomorrow. DNR order in place. Mr. Morales expresses concern over what to expect in terms of the dying process. Discussed expectations at length with family. All questions and concerns addressed at this time.
-----------------------------	--

3. Prioritize hypotheses: What kind of information should the nurse anticipate Mr. Morales might want to know based on his questions about what to expect during the dying process?
4. Generate solutions: What specific information can the hospice nurse provide to Mr. and Mrs. Morales about what to expect during the dying process?

## Terminal Illness

Also referred to as life-limiting disease, **terminal illness** refers to a disease state for which no cure is known. As the name suggests, a terminal illness is expected to end with death; however, the classification of a terminal illness does not delineate any specific time frame for death to occur. In the age of new and rapidly advancing medical treatments, terminal illness may encompass diseases that are not expected to result in death in a short period. Depending on the disease state, life expectancy after diagnosis can vary widely between people diagnosed with the same terminal disease. A diagnosis does not imply terminality; instead, prognosis based on symptoms guides the classification of whether a disease state is terminal. Terminal illness definitions related to hospice care specify that the illness must reduce the life expectancy to less than six months (National Institute on Aging, 2021). Examples of diseases that may lead to terminal illness include the following:

- cancer
- dementia
- stroke
- multiple sclerosis
- Huntington disease
- muscular dystrophy
- HIV
- end-stage heart, lung, kidney, or liver disease

The type of terminal illness and prognosis affect how patients and families respond, how the treatment is provided, and how insurance companies cover costs.

## LIFE-STAGE CONTEXT

---

### Terminal Illness in Children

The diagnosis of terminal illness in children poses several challenges as compared with adults. Terminal illnesses in children tend to be:

- caused by rare diseases
- associated with specialized care
- associated with very short or very long duration of illness

While caring for the family is part of the nurse's role regardless of the age of the terminally ill patient, caring for families of children with terminal illnesses poses unique challenges. These challenges include factors associated with the following:

- travel to treatment centers
- costs of family travel
- family dynamics associated with siblings
- sibling visitation
- financial burden to the family depending on insurance status
- emotional burden on siblings
- high levels of fear and anticipatory grief

By anticipating these challenges, nurses can proactively provide families with options, care, and support resources. A team approach is crucial in helping these families. Nurses coordinate care and work directly with social workers, providers, specialists, home care providers, and palliative care providers to create the best care plan for the patient and family.

---

### Effects on Patient

The psychological effects of receiving a diagnosis of a terminal illness can be profound. While we know death is inevitable, being told that a specific disease is likely to deteriorate one's health and ultimately take one's life is life-altering. Individuals may experience psychological symptoms, including anxiety, anger, and fear, many of which are the same emotions experienced during a grief response. And like the grief response, people react in different ways to terminal diagnoses. By employing coping strategies similar to those used during actual loss or grief, nurses can help patients maintain the best quality of life for the duration of their illness.

### Effects on Family

Patients and family members often experience similar emotional reactions to terminal illness diagnoses. A significant change in life expectations and timeline is anticipated, and a sense of distress, panic, and grief may ensue. Terminal illness may change family dynamics as family roles change, treatment plans progress and change, and the dying individual experiences increased care needs at the end of life.

### The Nurse's Role

The nurse's role in caring for patients with terminal illnesses focuses on facilitating communication between patients, family members, healthcare providers, and ancillary care providers. Effective communication creates an atmosphere centered on maintaining quality of life and following patients' wishes. Nurses may work in palliative care, providing direct treatment to clients, or in hospice care, providing and coordinating comfort care at the end of life. Emotional support for families is crucial to nursing care at this stage. Education may involve teaching family members how to care for or assess patients, as well as what to expect and how to manage the expected physical and cognitive changes at the end of life. This information can be invaluable for easing the fear often experienced as a terminal illness progresses. It can also help to prevent **compassion fatigue**, the emotional toll experienced by individuals caring for others, and to identify caregivers who require a temporary break from their duties.

### Communication

Interpersonal communication techniques are crucial in grief, loss, death, and dying. Patients, family members, and other loved ones are in vulnerable emotional states and require patience, consideration, and a calm presence.

Nurses must respect different values and beliefs about death and offer clear and factual information to help family members cope with changes.

Helping caregivers and families understand how to communicate with the dying patient is also the nurse's role. They must explain the importance of continued verbal communication, even if the person is unresponsive. Studies based on brain responses to auditory stimuli show that the sense of hearing persists at the end of life (Blundon et al., 2020). While studies cannot measure how a dying person processes the information, researchers are certain that the sense of hearing is present. Loved ones should be encouraged to speak softly, sing, and continue to express themselves verbally with the dying individual. Other studies have explained the benefits of music for terminally ill patients. Music improves the emotional state and mental health of terminally ill individuals, even if physical symptoms are not changed (Gao et al., 2018).

### Emotional Support

Emotional support is necessary for the patient, caregivers, and family members. Each person will react differently to anticipated and actual death. Patients should freely express their wishes, desires, concerns, and fears. Support for caregivers includes **respite care**, which is temporary care for an individual to provide relief to their usual caregiver, and therapy to develop coping mechanisms for processing caregiver burnout. Caregiver burnout and compassion fatigue are similar concepts that explain the emotional toll experienced by individuals caring for others. Both caregiver burnout and compassion fatigue may result in emotional and physical symptoms, signaling a state of stress and extreme exhaustion. Nurses can anticipate possible caregiver fatigue and proactively prepare the caregiver and encourage use of available respite services before burnout occurs.

Emotional support for nurses caring for these patients and families is also crucial. Nurses often face intense emotional strain and can experience compassion fatigue and burnout. Resources available to them include counseling services, peer support groups, and stress management programs. Employers may offer employee assistance programs (EAPs) that provide confidential counseling and mental health resources. Additionally, regular debriefing sessions and access to professional development on self-care techniques can help nurses manage their emotional well-being.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Recognize Clues: Compassion Fatigue

Nurses must diligently recognize clues that can help guide their care actions. In palliative care, nurses may provide as much care for the family as the patient. Compassion fatigue often presents with subtle signs and symptoms that overlap with other reactions to loss and grief. Keeping an open line of communication with family members will alert nurses to symptoms such as the following:

- exhaustion
- irritability
- increased anxiety
- trouble concentrating

These clues alert the nurse that a caregiver requires respite care to continue providing high-quality care for their family member. It may be hard for the family member to acknowledge these feelings without feeling guilty for being unable to take on all the care. Nurses can assure caregivers that physical and emotional rest is critical for their health and the well-being of their loved ones.

### Palliative Care

An interdisciplinary approach to specialized medical and nursing care for people with severe and terminal illnesses is called **palliative care**. It focuses on providing relief from pain, physical stress, and mental stress at any stage of disease to improve the quality of life for both the person and their family. Providers who specialize in palliative care have had training tailored to helping patients and their family members cope with the reality of the impending death and make plans for what will happen after. End-of-life care may take on various forms depending on the length of the end-of-life period. However, palliative care actions generally focus on improving or maintaining the quality of life for individuals rather than providing curative medical treatment. Palliative care providers work in a team to provide

comprehensive care for patients with terminal illnesses. While care is individualized, palliative care teams often include the following:

- primary care providers
- nurses
- oncologists
- palliative care providers
- geriatricians
- pain management specialists
- physical therapists
- speech therapists
- occupational therapists
- social workers
- religious leaders
- medical specialists

Palliative care may occur in personal homes, long-term care facilities, or hospitals, and it occurs simultaneously with medical treatments that may improve or prolong prognosis. In the later stages of illness, palliative care may include **comfort care**. These interventions are meant to maintain an individual's physical and emotional comfort during the dying process. Comfort care in palliative care can also occur simultaneously with medical treatments.

### Hospice Care

According to the National Hospice and Palliative Care Organization (NHPCO, 2019), the mission of hospice and palliative care is to strive for patients to die pain-free and with dignity. A specific comfort care, **hospice care** is provided at the end of life for patients as well as their families. It involves caring for dying patients by helping them be as free from pain as possible, providing them with assistance to complete wills and other arrangements for their survivors, giving them social support through the psychological stages of loss, and helping family members cope with the dying process, grief, and bereavement. It focuses on five topics: communication, collaboration, compassionate caring, comfort, and cultural (spiritual) care.

Hospice care can be thought of as a type of palliative care, providing many services. However, there are distinct differences between the two ([Table 36.5](#)). Hospice care does not involve treatments aimed at curing the disease. The decision is typically made when curative treatments are no longer effective or when the burden of the treatment outweighs the benefits in terms of quality of life compared to the progression of the disease itself. As the dying process progresses, hospice care may involve routine, inpatient, and continuous care. Hospice-trained caregivers also provide respite care to allow family and other full-time caregivers rest time.

Feature	Hospice Care	Palliative Care
Definition	Comprehensive care for terminally ill patients focused on comfort and quality of life	Specialized medical care for people with serious illnesses focused on relieving symptoms and stress
Eligibility	Patients with a prognosis of six months or less to live	Patients at any stage of a serious illness, including those undergoing curative treatment
Goal	To provide comfort and support during the end-of-life process	To improve quality of life by managing symptoms and providing relief from pain and stress
Treatment focus	Symptom management without curative intent	Symptom management with the possibility of curative treatments

**TABLE 36.5** Differences Between Hospice and Palliative Care

Feature	Hospice Care	Palliative Care
Duration of care	Limited to the last six months of life	No time limit; provided based on patient need and illness progression
Insurance coverage	Often covered by Medicare, Medicaid, and most private insurance plans	Coverage varies; often included under standard medical benefits

**TABLE 36.5** Differences Between Hospice and Palliative Care

Because hospice care is a unique service paid for by insurance, patients must meet specific criteria to qualify for it. Hospice eligibility criteria include a terminal illness diagnosis and an associated life expectancy of six months or less (NHPCO, 2019). Hospice eligibility also requires that patients and healthcare providers limit their treatment goal to achieving, through palliative care and symptom relief, the best quality of life possible during the last days of life. Hospice symptom management is not paired with medical treatments, as in palliative care. Curative treatments are stopped for ineffectiveness as deemed appropriate by the healthcare provider.

Family members who have agreed to put their loved one on hospice may become anxious when the patient begins to experience death. They may believe that feeding or breathing tubes will sustain life and want to change their decision. Hospice workers try to inform the family of what to expect and reassure them that much of what they see is a normal part of the dying process.

#### Autonomy and Empowerment

Nursing interventions based on self-empowerment enable patients and families to identify and ultimately achieve their own care goals, thus producing a sense of control. Self-empowerment for terminally ill individuals has been associated with a perceived ability to better manage medical actions, changing life roles, and the psychological impacts of the illness (Wakefield et al., 2018).

Treatment plans that can incorporate a sense of control and autonomy into the dying individual's daily life are particularly effective at improving the patient's general attitude and decreasing levels of depression. Active coping (seeking information and working to solve problems) typically produces more positive outcomes than passive coping (characterized by avoidance and distraction). Although each situation is unique and depends partially on the individual's developmental stage, the consensus is that caregivers must foster a supportive environment and partnership with the dying individual, promoting independence, control, and self-respect.

## 36.3 Factors That Affect Grief, Loss, Death, and Dying

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine influencing factors affecting grief, loss, death, and dying
- Recognize psychological factors affecting grief, loss, death, and dying
- Analyze the types of death and how they affect grief, loss, death, and dying

The processes of death, dying, grief, and loss are highly personal experiences, but they also affect family, friends, and the wider community in a variety of ways. In addition to cultural or religious views on death, many factors affect how individuals, families, and communities respond to a death, care for a dying individual, and process the loss and grief after death. Many factors play a role, including the cause of death, the relationships and family dynamics that existed prior to death, and the ages of the affected individuals.

### Influencing Factors

As you have learned, the pathophysiological and physical progressions of death follow a predictable pattern regardless of cause of death or age. However, many other factors contribute to an individual's experience of death or the experience of loss through death. These factors relate to developmental stages, life stages, and family interactions. In addition, nurses may need to focus on cultural, socioeconomic, and psychological factors when providing care for individuals experiencing death or grief.

### Developmental Considerations

Developmental considerations for the nurse include the life stage of the dying individual as well as the social stage of the family. The treatment plans, terminal illness progression, family expectations, and grief response to loss will vary, and individuals will experience loss and grief differently, depending on these factors. Age considerations are most pronounced in children; however, the life stage and age of adults also play a role in grief response. Social considerations such as family stage and family cohesiveness affect grief both individually and collectively.

#### Age Considerations

Individuals' attitudes toward death and dying are linked to their cognitive ability to understand these processes. Infants and toddlers cannot understand death. They function in the present and are aware of loss, separation, and disruptions in their routines. They are also attuned to the emotions and behaviors of significant adults in their lives, so the death of a loved one may cause a young child to become anxious and irritable, cry, or change their sleeping and eating habits in response to the altered behavior of their caregivers.

A preschooler may approach death by asking when a deceased person is coming back; they might even search for the deceased person, thinking that death is temporary and reversible. They may experience brief but intense reactions, such as tantrums or other behaviors like frightening dreams and disrupted sleep, bedwetting, clinging, and thumb-sucking. Similarly, those in early childhood (ages 1–5) may regress to younger behaviors. They might also think that the person's death is their fault, based on their developmental belief in the power of their thoughts and "magical thinking." Their grief might be expressed through play rather than verbally (HealthyChildren.org, 2015).

Those in middle childhood (ages 6–11) begin to see death as final, irreversible, and universal. However, they may not believe that death could happen to them or their family—they may assume it happens only to the very old or sick, or they may view death as a punishment for bad behavior. They may engage in personification, seeing death as a human figure who carried their loved one away (HealthyChildren.org, 2015). Children at this developmental stage may try to keep a bond with the deceased by taking on that person's role or behaviors.

Preadolescents (ages 10–12) are better able to understand both biological and emotional processes of death. However, they may try to hide their feelings, seem indifferent, or have outbursts following the death of a friend or loved one.

Adolescents (ages 12–17) begin to apply logic to abstractions; they spend more time pondering the meaning of life and death and what comes after death (HealthyChildren.org, 2015). Their understanding of death becomes more complex as they move from a binary logical concept (alive or dead) to a more nuanced understanding—including the potential for life after death, for instance. This transition reflects a deeper comprehension of death that acknowledges its complexity and allows for broader interpretations beyond a simple binary classification. Adolescents are also tasked with integrating these beliefs into their identity development.

Young adults (ages 18–35) rely heavily on social support systems for coping strategies. They may have children and, therefore, view mortality and death in relation to the impact on their family. In addition, career plays a large role in the identities of young adults, who may have concerns about the impact of death and grief on their career and financial security.

Middle-aged adults (ages 36–64), when confronted with death and mortality, tend to reflect on life choices and may begin to take personal health considerations more seriously. Adults in this stage more often encounter the loss of parents, and the deaths of other friends and family members become more frequent.

Older adults (ages 65+) may struggle with frequent loss of friends and peers. In addition to grief associated with death, older adults may also struggle with grief related to the loss of function and physical decline. Spiritual reflection is common and may help older adults cope with these losses and the possibility of their own death.

#### Family Considerations

Family dynamics vary widely, and family members may have differing views on death, dying, grieving, and coping with loss. These views may be affected by the developmental stages of the various family members as well as the age of the dying person. Varying dynamics occur in the context of the loss of a child, parent, grandparent, or sibling. Other factors also play a role, such as whether the death is anticipated or sudden, as well as environmental factors associated with the death. For example, deaths occurring in peaceful and familiar surroundings, with supportive

family members and healthcare professionals present, may facilitate a more peaceful and dignified experience for both the dying individual and their loved ones. Conversely, deaths occurring in chaotic or traumatic environments, such as accidents or disasters, may exacerbate feelings of distress, confusion, and grief.

Coping after a family member's death will depend on family cohesiveness, communication patterns, and expression of emotions. Family roles may change in response to a terminal illness, a death, or the grief process. These changes may include home care patterns, work hours, financial responsibilities, and childcare (Table 36.6). Since many families rely on extended family for support, a loss may trigger a change in living situation, such as an elderly father moving in with his daughter after the death of his wife.

Family Considerations	Possible Family Changes
Cohesiveness of the family	<ul style="list-style-type: none"> <li>• Increased or decreased closeness</li> <li>• Increased or decreased spiritual connection</li> <li>• Varying grief responses</li> </ul>
Family structure and role changes	<ul style="list-style-type: none"> <li>• Changes in home care patterns</li> <li>• Increased or decreased work hours</li> <li>• Increased financial responsibility</li> <li>• Need for additional childcare</li> <li>• Need for respite care</li> </ul>
Communication patterns and expressiveness	<ul style="list-style-type: none"> <li>• Communication struggles based on expressiveness patterns</li> <li>• Increase or decrease in openly sharing emotions</li> </ul>
Support systems	<ul style="list-style-type: none"> <li>• Increased reliance on extended family</li> <li>• Reaching out to community resources</li> </ul>
Pre-existing family stressors/loss	<ul style="list-style-type: none"> <li>• Increases in financial strain</li> <li>• Trauma response related to multiple losses</li> <li>• Lack of support in estranged family members</li> </ul>

**TABLE 36.6** Family Considerations During and After Death

The death of a neonatal child can take the form of a miscarriage, stillbirth, neonatal death, or sudden infant death syndrome (SIDS), a term for deaths of children under the age of one which have no identifiable cause. Like people in every age group, children also die from accidents and illnesses. In most cases, parents find the grief almost unbearably devastating, and it tends to hold greater risk factors than any other loss. This loss also bears a lifelong process: one does not “get over” the death but instead must assimilate and live with it. Intervention and comforting support can make all the difference to the survival of a parent in this type of grief, but the risk factors are great and may include family breakup or suicide. Feelings of guilt, whether legitimate or not, are pervasive, and the dependent nature of the relationship disposes parents to a variety of problems as they seek to cope with this great loss. Grieving parents may also experience resentment toward others who experience successful pregnancies.

## PATIENT CONVERSATIONS

### SIDS: Sibling Grief

**Scenario:** Darcey is a 28-year-old mother. Her living children are Kaylee, age 6, and Darien, age 4. Darcey and her family recently experienced the death of their youngest child, Aiden, from SIDS four months ago. Aiden was 11 months old. Darcey is struggling with anxiety and depression. She is following up today with her primary care

provider after starting an antidepressant.

**Nurse:** How are your symptoms of anxiety and depression?

**Patient:** I've been able to get through the day and care for my other children, but I'm worried about my daughter and that I don't know how to help her cope with Aiden's death. She wants to talk about Aiden all the time, set up puppet shows like she used to for him, and draw pictures of him. I sometimes feel angry when she does these things. I know it is helpful for her, but sometimes I don't want to participate.

**Nurse:** Do you feel that the medication is helping?

**Patient:** I do feel the medication is helping, but I don't understand why I am having such strong reactions to my daughter's grief.

**Nurse:** Your feelings are normal during this time of grief. I can see that you know that your daughter's emotions and actions are also normal. Children often process grief through play.

**Patient:** I don't know what to do. How can I support my daughter without feeling even more guilty?

**Nurse:** Asking for help is the first step. We can provide you with a list of adult and child grief counselors. This may help your daughter work through her grief with therapeutic play while you work through your grief in the way that is most beneficial to you.

**Patient:** I didn't know grief therapy was available for children. I would feel relieved to know someone else could help her without feeling angry or sad about her actions. Thank you for helping me find the right resources.

---

For a child without support to manage the effects of the grief, the death of a parent may result in long-term psychological harm. This is more likely if the adult caregivers are struggling with their grief and are psychologically unavailable to the child. There is a critical role for the surviving parent or caregivers in helping children adapt to a parent's death. Studies have shown that losing a parent at a young age did not lead to negative outcomes only; there are some positive effects. Some children had increased maturity, better coping skills, and improved communication. Adolescents valued other people more than those who had not experienced such a close loss (Ellis et al., 2013).

When an adult child loses a parent in later adulthood, the experience may be considered "timely" or a normative life course event. This allows adult children to feel a permitted level of grief. However, research shows that the death of a parent in an adult's midlife is not a normative event by any measure but is a major life transition causing an evaluation of one's own life or mortality. Some adults may shut out friends and family in processing the loss of someone with whom they have had the longest relationship (American Cancer Society, 2023).

### Socioeconomic Considerations

Socioeconomic factors may play a role in access to care and financial resources available to individuals coping with death and grief. Access to care may be directly related to insurance coverage, transportation, and living situation. Quality of care may be dependent on physical location, finances, and ability to seek care in a timely manner. The impact of a terminal illness is significant, as it hinders not only the well-being of the affected individual but also the capacity of family members to maintain employment. This may put a further burden on already strained financial situations. Struggles with insurance companies to get coverage, particularly for new treatments, are common and add strain for caregivers and individuals experiencing the illness. Other economic considerations in death and dying may involve paying for the care of the body, funeral costs, and the resolution of estates or debts. The financial strain of medical bills following a death can further intensify the financial difficulties families face.

The Hospice Foundation of America notes that not all racial and ethnic groups feel the same way about hospice care. Certain groups may believe that medical treatment should be pursued on behalf of an ill relative as long as possible and that only God can decide when a person dies. Others may feel very uncomfortable discussing issues of death or being near the deceased family member's body. Not everyone holds the view that hospice care should always be used, and healthcare providers must be sensitive to the wishes and beliefs of those they serve. Similarly, the population of individuals using hospice services is not divided evenly by race. Approximately 76 percent of hospice patients are White, while 11 percent are Black, 8.5 percent are Hispanic, 2.5 percent are Asian/Pacific Islander, 0.5 percent are American Indian, and 1.5 percent are unknown or other (NHPCO, 2023).

### Cultural Considerations

Nurses must consider cultural factors when caring for individuals encountering death and grief. Cultural values influence how people experience death and whether they respond with particular rituals or mourning practices. Cultural awareness and an atmosphere of inclusiveness must guide nursing care. See [Chapter 35 Spirituality](#) to learn more about how several major religions view the concept of death. Individuals who do not identify with a specific religion also have views about death and expectations for care after death, which should be addressed with the same respect shown to individuals identifying as a particular religion.

### Psychological Factors

Dealing with death and dying and subsequent grief is a deep burden. Individuals may feel many negative emotions during these processes, including sadness, guilt, fear, and anxiety. These emotions can trigger a new onset of depression or the recurrence of clinical depression. This is particularly true in individuals with poor coping skills or those who are unable to process the death and move through the grieving process. Underlying mental health disorders affect the psychological stability of individuals experiencing grief. These individuals require sensitive support and straightforward discussions about their mental health and safety.

## LIFE-STAGE CONTEXT

---

### Grief in the Teen Years

Grief is a universal feeling after a loss; however, teens may require special interventions to help them process loss and grief. Teen reactions can be highly variable, even from day to day. Teens who connect with and trust their peers may succeed in peer counseling groups. These groups may involve sharing and talking, but other activities may also help teens. In the same way that younger children express grief through play, teens may find relief in guided activities such as the following:

- storytelling
- drawing
- creating art
- creating a book
- creating a memorial
- visiting a place that holds meaning with the deceased

Nurses must always be alert for signs of depression, withdrawal, violence, substance misuse, and suicidal ideation in grieving teens. If guided grief therapy or peer interactions are not enough, nurses should not hesitate to refer teens for specialized mental health care.

---

### Fear

Fear may be felt in both dying individuals and individuals fearing the loss of a loved one. Common fears involve their own mortality, their ability to care for themselves, and the potential for financial instability or loneliness. Individuals may not be able to see how they will “go on” after a death. Fear of the unknown is also common pertaining to death. Individuals experiencing the dying process may worry about what comes after death. Those experiencing the death of a loved one may worry about how their life will look and feel after this death.

People experiencing the dying process may fluctuate between periods of fear of dying, fear of pain, and feelings of peace at the end of their lives. Fear may be exacerbated by reactions from family, friends, or even religious leaders.

### Anxiety

An overwhelming feeling of apprehensiveness, nervousness, and worry about real or perceived events that have an uncertain outcome is known as anxiety. Anxiety and depression are closely linked; one may trigger or exacerbate the other, or they may occur simultaneously. Individuals who struggle with anxiety may find themselves ruminating and fixating on guilt. Individuals experiencing guilt or regret may have difficulty coming to terms with death. Nurses can encourage individuals to make amends and work through underlying guilt and regret to create a smooth psychological passage through death. Anxiety can be debilitating, particularly if the sensation of anxiety escalates into panic. Anxiety can trigger frightening physical symptoms that are often mistaken for other disorders, including

the following:

- chest pain
- trouble breathing
- heart palpitations
- nausea
- tingling face or lips

In chronic anxiety, stress hormones continue to be produced even after the stressful event has passed, creating ongoing physiological changes similar to the response shown in an acute fight-or-flight situation. According to the Mayo Clinic (2023), a chronic stress response leads to changes in mood, digestive alterations, increased blood sugar, and changes in the immune system. Chronic anxiety also causes adverse physical symptoms and problems with maintaining daily life functions, including the following:

- trouble sleeping
- focusing on wrongs from the past, or **rumination**
- unpredictable energy levels
- headaches
- muscle tension and pain
- high blood pressure
- weight gain
- trouble concentrating
- brain fog
- forgetfulness
- increased or decreased appetite
- digestive problems

### Guilt

Guilt is a common symptom associated with processing death and grief. After the loss of a loved one, particularly from a traumatic event, individuals may experience survivor's guilt: an overwhelming feeling that it is wrong for them to have survived when others did not. Guilt can also be associated with regrets that surface after a loss. These regrets may be related to unresolved conflicts, relationship tension, or simply unfinished plans. Moving forward is difficult after experiencing loss through death, and the timeline is different for each person. Some individuals may feel guilty for experiencing joy or starting a new relationship, but with support they typically can move past their guilt in a healthy way while maintaining important memories.

Guilt is closely linked with anxiety and often results in cyclic rumination, as the afflicted individual cannot stop thinking about past wrongs. The emotion can be crushing and lead to negative self-reflection and depression, which is best addressed with the help of a therapist.

### Types of Death

In the realm of death, the diversity of human experiences emerges in various types, each with its own distinct characteristics and implications. Types of death affect both the dying process as well as the grieving process. An individual's reaction to death often depends on whether they have time to anticipate the death or whether it is shocking. Either can trigger a cascade of emotions associated with death, loss, and the grieving process. This section aims to delve into the multifaceted nature of death, encompassing sudden and unexpected losses, tragic accidents, acts of violence, deliberate self-inflicted harm, the progression of terminal illnesses, anticipated deaths, and those resulting from medical conditions.

#### Sudden Death

Sudden deaths may occur from medical issues as well as from violence, whether accidental or intentional. They may occur in seemingly healthy individuals, such as with heart arrhythmias or brain aneurysms. They may also be linked with complications of a known disease. The most common cause of sudden death in the United States is cardiovascular disease (CDC, 2023c), which can lead to cardiac arrest or a heart attack. Other common medical causes of sudden death include pulmonary embolism, which is caused by a blood clot in the lungs; aortic rupture or dissection, which may be associated with a known or unknown aortic aneurysm; stroke; and sudden infant death

syndrome (SIDS).

### Accident

The incidence of accidental deaths varies by age group. These are also often considered preventable deaths. In infants younger than 1-year-old, mechanical suffocation is the leading cause of preventable death (CDC, 2023a). In young children, the most common cause of accidental death is drowning (NSC, 2021). For middle-aged adults, the most common cause is poisoning, which is thought to be associated with the opioid epidemic (NSC, 2021). Motor vehicle accidents (MVAs) cause the most deaths in young adults and older adults (NSC, 2021). Older adults also have the highest incidence of death from choking and falls, especially after the age of 70. Other causes of accidental death include sports-related injuries and exposure to fire or smoke. Many of these deaths are associated with a traumatic injury sustained from an accident.

Trauma for witnesses to an accidental death is an additional source of guilt, grief, and potential depression. Individuals surviving an accident where others have died may be unable to make sense of the situation and remain stuck in a cycle of blame and guilt.

### Homicide

The killing of one person by another person, **homicide**, can range from an individual death to mass casualties. It can result from various causes, from deliberate shootings or stabbings to random acts of violence without a specific target. Domestic violence also may result in homicide. Firearm homicides make up the majority of all homicides in the United States (NSC, 2021). The violence of homicide also has a ripple effect within the community where it happens. Homicide creates a sense of fear and shame. This may lead to complicated grief and even a sense of community grief, particularly in the wake of mass shootings.

### Suicide

Death caused by intentional harm to oneself is called **suicide**. When a parent loses their child through suicide, it is traumatic and sudden for all loved ones impacted by the death. Suicide leaves many unanswered questions and leaves most parents feeling hurt, angry, and deeply saddened by such a loss. Parents may feel they cannot openly discuss their grief and feel their emotions because of how their child died and how the people around them may perceive the situation. Parents, family members, and service providers have all confirmed the unique nature of suicide-related bereavement following the loss of a child (HealthyChildren.org, 2023). They report a wall of silence around them and how people interact with them. One of the best ways to grieve and move on from this type of loss is to find ways to keep that child as an active part of their lives. It might be private at first, but as parents move away from the silence, they can move into a more proactive healing time.

## LINK TO LEARNING

The [Suicide and Crisis Lifeline \(https://openstax.org/r/77SuicideLine\)](https://openstax.org/r/77SuicideLine) is a great resource for tips on helping to prevent suicide. Don't hesitate to extend a helping hand or helpful resource to someone you suspect might be at risk of suicide.

### Illness

Many types of acute illness may result in death. Deaths may occur from the progression of chronic disease states or from the rapid onset of an infectious disease. Even if death is anticipated, it may feel shocking when it finally occurs. The progression of death and symptoms depend on the specific pathophysiology of the disease process. Acute illnesses may be isolated to an individual or widespread, as in a pandemic. A population-wide illness may seem to affect individuals randomly, which may lead to fear and community grief.

### Anticipated Death

Anticipated deaths often take place within the context of chronic diseases and terminal illnesses. These illnesses and diseases may be associated with a slow decline in function, use of hospice services, and progressive changes. For caregivers and family members, anticipating a death can result in layered grief where the individual experiences the loss twice: first with the decline in function and knowledge of impending death, and then with the actual death.

## REAL RN STORIES

---

### Fear and Coping

**Name:** James, RN

**Clinical setting:** Cardiac rehab clinic

**Years in practice:** 15

**Facility location:** Arvada, Colorado

I've worked with many patients over the years struggling to adapt after a heart attack. I remember one individual whose fear drove him to work harder than anyone. Not only had he recently experienced a heart attack, but his wife was battling breast cancer. During his time in rehab, she took a turn for the worse with some spread of her cancer that had previously been stable. She began to experience more symptoms related to her metastatic process, and they decided to move forward with palliative care. My patient, Jerry, expressed extreme worry—not only about how he would care for his wife during their remaining time together, but also how he would care for himself when she died. He expressed fear that he would be unable to cook healthy meals, keep active, and receive the help he needed if she were not around. During his exercise sessions, we brainstormed ways he could enjoy his time with his wife without focusing on what life would be like without her. He qualified for some respite care when she began to require more assistance. He signed up for a healthy cooking class, was diligent with his cardiac exercises, and joined a walking group in his neighborhood.

When his wife passed away, Jerry had many healthy coping strategies already in place, including community, confidence in caring for himself, and improved health. While anticipatory grief can be limiting and cause extreme worry and anxiety, it can also be a motivator for improved wellness and an outlook of hope for the future.

---

### Medical Condition

Medical conditions are the most common cause of an anticipated death. Chronic illnesses and conditions may be lifelong disorders associated with various complications. These may include seizure disorders, genetic syndromes, cardiovascular malformations, cystic fibrosis, and autoimmune disorders. These may progress over time, or individuals may have a higher incidence of certain other diseases based on these underlying disorders. Other medical conditions may develop later in life and put people at higher risk for organ damage associated with diabetes, atherosclerosis, dementia, and other neuromuscular diseases.

## 36.4 Legal and Ethical Considerations

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe legal foundations of death and dying
- Explain ethical foundations of death and dying
- Identify nursing considerations for after death

Throughout the process of death and dying, nurses provide direct care for the patient and family. In addition to this hands-on care, nurses must also consider the legal and ethical aspects of death and dying. These aspects are a crucial guide to advance planning, making treatment decisions, and educating patients with respect to death. Nurses must recognize the role that cultural beliefs play in ethical and sometimes legal end-of-life care. In particular, cultural values guide decisions regarding advance planning. Depending on the clinical setting, nurses may be required to care for the bodies of individuals after death. Cultural rituals surrounding death vary widely; the best action for nurses is to keep open communication and maintain an atmosphere of respect regardless of any personal opinions they may have of patient and family wishes.

### Legal Foundations of Death and Dying

Legal considerations for nurses involve assisting patients in understanding, verbalizing, and documenting their wishes for care at the end of life. These legal documents are crucial whether a death is anticipated or sudden and whether a patient is old or young. Nurses are essential in providing education on advance planning and involving the family as appropriate.

## Advance Planning

While not all deaths are anticipated, the eventuality of death is a fact. Nurses play a significant role in advance planning for that fact. Advance care planning helps patients achieve autonomy and comfort in knowing their wishes will be fulfilled regardless of their ability to articulate them in a given moment. It also helps healthcare providers offer personalized care to each patient and reduces decision fatigue and family worry. However, while advance planning is helpful from a legal standpoint and for families making hard decisions, it is not a requirement in any state.

### Advance Directive

As individuals become more knowledgeable about medical procedures and practices, some want to ensure their wishes and desires with respect to death are known. This ensures that if the person ever becomes incapacitated, or unable to perform cognitive functions, or if they lose the ability to express themselves, their loved ones will know what they want. For this reason, a person might write an **advance directives** (also known as a **living will**), a written legal document that details specific interventions they want and do not want. For example, a person in the last stages of a terminal illness may not want to receive life-extending treatments. A living will can also name a **healthcare proxy**, a specific person appointed to make medical decisions if you cannot speak for yourself.

Encouraging patients to have advance directives is crucial at any age, but this potentially delicate conversation must be handled respectfully. People's desire for—or resistance to—living wills and advance directives is often influenced by their religion, culture, and upbringing.

## LINK TO LEARNING

---

Nurses have a unique role in facilitating education on advance planning with patients of all ages. Resources such as this [advance directive template \(https://openstax.org/r/77FiveWishes\)](https://openstax.org/r/77FiveWishes) can help nurses support patients as they express their wishes about end-of-life care.

---

### Physician Order for Life-Sustaining Treatment (POLST)

A **physician order for life-sustaining treatment (POLST)**, also called a portable medical order, is a personal directive for medical care (Tark et al., 2019). A POLST must be upheld anywhere the patient is, whether at home, in the community, in a hospital, or a doctor's office. POLST documents are reserved for individuals with terminal or progressive diseases and limited life expectancy. While any adult can create an advance directive that guides care in the event of accidents, emergencies, or unexpected health events, a POLST guides care during the last stages of life. Creating a POLST requires a detailed conversation with a trusted physician. The POLST can be created directly with a patient, but a healthcare proxy can also help create a POLST for individuals who cannot make these decisions for themselves. A POLST may include the following:

- Transportation wishes: Does the patient wish to be transported to a hospital for care in the event of emergency or a decline in health?
- Resuscitation wishes: Does the patient wish for full resuscitation or no resuscitation measures?
- Medical treatment wishes: Does the patient wish for medical treatments such as medications, fluids, or intubation in the event of an emergency or a decline in health?
- Disease-specific care: Does the patient wish for care related to specific diseases such as antibiotics for pneumonia or a urinary tract infection?

As a type of advance planning tool, POLSTs are optional; however, national standards are available for states to create standardized POLST recommendations and forms. Many states are creating standardized POLST forms for efficient and respectful end-of-life care.

## LINK TO LEARNING

The National POLST Coalition maintains this website with [information about POLSTs and advance planning \(https://openstax.org/r/77POLSTs\)](https://openstax.org/r/77POLSTs) in general, as well as sample forms.

---

### Do Not Resuscitate (DNR)

A **do not resuscitate (DNR)** order is a narrow directive for care provided in the event of cardiac arrest. DNR does not mean the patient does not want any treatment for their condition (Vranick, 2022). Instead, it states that if they stop breathing or their heart stops beating, medical personnel such as providers and nurses are *not* to take steps to revive or resuscitate the patient. Generally, these steps include cardiopulmonary resuscitation (CPR) and intubation. DNR orders are often included in a POLST. Some advance directives also include a separate **do not intubate (DNI)** order, stating that if a person stops breathing, medical personnel such as providers and nurses are *not* to place an intubation tube.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### DNR

Facility requirements vary regarding how to document DNR orders. However, they are always created during conversations between a provider and a patient or patient representative. Ideally, advance directives are in place before any life-threatening medical event; that way, even if the patient becomes incapacitated, an authorized representative can make the decision as to whether to create a DNR order. Nurses and other healthcare providers must know the status of their patients with regard to DNR. Examples of ways to create an environment of safety regarding DNR include the following:

- Create color-coded wristbands.
  - Make sure the DNR order is documented in the chart.
  - Be aware of the DNR status of all patients in your care.
- 

### Allow Natural Death (AND)

The term **allow natural death (AND)** is similar to DNR; however, the focus of this directive relies on allowing a natural unfolding of the dying process rather than withholding treatments. Some researchers have proposed that AND is a superior term in that it guides providers in creating an atmosphere of comfort and ease during death (Fan et al., 2018). The concept behind AND is providing comfort and dignity at the end of life and avoiding measures to prolong the dying process or sustain life.

### Comfort Measures Only

As you learned, comfort care is often a significant part of hospice and palliative care. It encompasses the following four areas:

- physical comfort
- mental and emotional comfort
- spiritual
- practical tasks

Comfort care only provides treatments that promote the comfort of the patient and family during the dying process. Comfort measures can be given whether or not a person has a DNR or AND order signed. Comfort care orders direct what treatments can and should be provided to maintain comfort during the last stages of life.

Comfort care measures provide pain control, relief from anxiety and agitation, support from spiritual leaders, and assistance with bodily functions and activities of daily living. [Table 36.7](#) lists comfort care interventions for common end-of-life situations (National Institute on Aging, 2022).

End-of-Life Situation	Nursing Intervention
Pain	<ul style="list-style-type: none"> <li>• Administer pain medication as directed.</li> <li>• Monitor for nonverbal cues of pain.</li> <li>• Administer preventive pain therapies if ordered.</li> <li>• Maintain comfortable positioning.</li> </ul>
Breathing problems	<ul style="list-style-type: none"> <li>• Raise the head of bed if tolerated.</li> <li>• Use medications to relieve breathlessness as directed.</li> <li>• Educate the family on expected changes in breathing patterns.</li> <li>• Administer medications to lessen secretions as directed.</li> </ul>
Skin irritation	<ul style="list-style-type: none"> <li>• Keep skin clean and dry.</li> <li>• Create a turning schedule to prevent pressure damage to the skin.</li> <li>• Apply lotions to relieve itching.</li> <li>• Keep lips moist with ointments.</li> <li>• Moisten the mouth with ice chips or swabs.</li> </ul>
Digestive problems	<ul style="list-style-type: none"> <li>• Offer small amounts of food if swallowing is not an issue.</li> <li>• Administer medications for nausea if indicated.</li> <li>• Allow eating and drinking to the patient's comfort.</li> <li>• Educate the family on the nutritional needs of the patient.</li> </ul>
Temperature sensitivity	<ul style="list-style-type: none"> <li>• Monitor for signs of heat or cold intolerance.</li> <li>• Provide warm blankets.</li> <li>• Use a fan if desired.</li> </ul>
Fatigue	<ul style="list-style-type: none"> <li>• Create resting spaces for people who are still ambulatory.</li> <li>• Create a restful atmosphere.</li> <li>• Have a commode near the bed.</li> </ul>
Emotional disturbance	<ul style="list-style-type: none"> <li>• Provide physical contact if the patient desires.</li> <li>• Play quiet music.</li> <li>• Use soft lights.</li> <li>• Communicate with the dying person.</li> <li>• Involve a spiritual leader if the patient desires.</li> </ul>

**TABLE 36.7** Comfort Care for End of Life

## UNFOLDING CASE STUDY

### Unfolding Case Study #5: Part 8

Refer back to [Unfolding Case Study #5: Part 7](#) for a review on the patient data. Mrs. Morales has been receiving hospice care for two months and is beginning to experience more severe fatigue and expresses her desire to “just get it over with already.” She has requested that her extended family come to see her and say their goodbyes. One of her friends is currently visiting and notices that Mrs. Morales has stopped breathing. The friend begins to panic and yells, “HELP! She’s not breathing! Someone start CPR now!”

5. Take action: What action should the hospice nurse take next?

6. Evaluate outcomes: After the patient's death, the nurse provides Mr. Morales with resources related to coping and support groups for grief. What findings would indicate that Mr. Morales is coping appropriately?

### Terminal Weaning

Removing or discontinuing life-sustaining treatments and procedures is referred to as **terminal weaning**, also known as **terminal extubation**. Most terminal weaning takes place in an intensive care unit (ICU) setting with the removal of ventilator tubes or other life-sustaining equipment. Terminal weaning occurs after a determination is made by providers that continued treatment will not improve or reverse the condition of the individual, and the intubation is only prolonging the dying process (Thellier et al., 2017). The patient's family ultimately makes the decision based on the provider's recommendations and facts about the prognosis for ongoing life. The time between terminal weaning and death is typically very short. Terminal weaning occurs in the presence of providers and nurses to ensure the patient's comfort level is maximized and the family has adequate support.

### Ethical Foundations of Death and Dying

Ethics in death and dying is a recurring topic in the medical community. It is also routinely addressed in legislation where national and state laws are set and often challenged based on varying ethical standards. As with any ethical conflict, considerations include autonomy (the right of independence), beneficence (to do good), nonmaleficence (to do no harm), and justice (fairness). Many of the preceding advance directives seek to ensure an ethical death in that quality of life is maximized and the decision made by others on behalf of a dying individual aligns with their values, beliefs, and cultural conditions. A nurse is ethically prohibited from administering medical aid in dying, but they must be informed and comfortable supporting patients and families in end-of-life situations.

### Euthanasia

Helping a person fulfill their wish to die, **euthanasia** can be categorized as active euthanasia or passive euthanasia. An **active euthanasia** involves deliberately taking actions to end the life of a person who is suffering from a terminal illness or unbearable pain, such as administering a lethal dose of medication to someone who wishes to die. In some cases, a dying individual who is in pain or constant discomfort will ask this of a friend or family member as a way to speed up what they have already accepted as being inevitable. This can have lasting psychological effects, such as anxiety, depression, post-traumatic stress disorder (PTSD), guilt, resentment, and emotional trauma, on the individual or individuals asked to help.

A **passive euthanasia** refers to the withholding or withdrawal of medical treatment or life-sustaining measures with the intention of allowing a patient to die naturally. This can involve discontinuing interventions like mechanical ventilation, artificial nutrition and hydration, or other forms of life support. Passive euthanasia allows the natural progression of the underlying medical condition to take its course, ultimately leading to the patient's death. It is typically carried out in accordance with the patient's expressed wishes, advance directives, or the decision of their legal representative. This is different from terminal weaning in that with terminal weaning, the intent is not death but rather removal of life-prolonging treatments. The distinction between active and passive euthanasia lies in the active nature of the intervention; in passive euthanasia, treatment is not actively administered to prolong life. Laws and ethical considerations regarding passive euthanasia vary across jurisdictions.

## PATIENT CONVERSATIONS

### Terminal Weaning vs. Euthanasia

**Scenario:** Elaine is a nurse caring for Roland in the ICU. Roland sustained a severe burn on his torso that required multiple grafting procedures. After he was moved to a rehab center, he developed pneumonia and was transferred to ICU for ventilator care. Marie is Roland's sister and only living relative. The provider has just explained to her that Roland's organ systems are failing, the ventilator is a life-sustaining treatment, and Roland is not expected to recover.

**Nurse:** Do you have questions about what the provider explained?

**Patient's sister:** I am an authorized representative for Roland, but I feel that removing the life support is euthanasia. Is that legal?

**Nurse:** Removing life-sustaining treatment in a setting such as the ICU is termed “terminal weaning.” Terminal means life-limiting, and weaning means removing the support that is prolonging life. Active euthanasia refers to providing treatment to end someone’s life per their wishes and passive euthanasia refers to withholding treatments with the intent to end life. Does Roland have an advance directive?

**Patient's sister:** Yes, but he did not specify whether he wanted ventilatory support. I just don’t know what to do.

**Nurse:** Is there a support person who could help you make the decision?

**Patient's sister:** Yes, I’d like to speak with the chaplain to discuss this before deciding.

**Nurse:** I will put in an order for the chaplain to visit you and help you process the information and make a decision.

---

### Voluntary Euthanasia

A **voluntary euthanasia** refers to helping someone fulfill their wish to die by acting in such a way as to help end that person’s life. The individual, who is usually experiencing a terminal illness or unbearable pain, makes a clear and voluntary request for assistance in hastening their death. This request may be expressed verbally, in writing, or through advance directive, and it reflects the person’s desire to have control over the circumstances of their death. An example of voluntary euthanasia would be a terminally ill cancer patient who, after exhausting all available treatment options and experiencing unmanageable pain and suffering, requests medical assistance to end their life peacefully and on their own terms. Another example could involve a person with a degenerative neurological condition, such as amyotrophic lateral sclerosis (ALS), who chooses to end their life before losing the ability to communicate or move independently. In both cases, the decision to pursue voluntary euthanasia is driven by the individual’s autonomy, dignity, and desire to avoid unnecessary suffering at the end of life.

### Assisted Death and Aid in Dying

Medical aid in dying, or **provider-assisted death**, occurs when a provider prescribes how a person can end their life but does not directly act in the process. Unlike euthanasia, it is regulated by a set of laws and backed by legal authority. Provider-assisted death is permitted in the District of Columbia and several states, including Oregon, Hawaii, Vermont, Montana, Maine, Colorado, New Mexico, California, and Washington. It is also legal in the Netherlands, Switzerland, and Belgium. In regions where it is legally permitted and regulated, a qualified healthcare provider may prescribe medication, usually a lethal dose of barbiturates or opiates, at the request of a mentally competent, terminally ill patient. The patient has the autonomy to self-administer the medication when they choose, with the goal of bringing about a peaceful and controlled death.

The terminology and legal status surrounding assisted death vary across different jurisdictions, and the ethical, moral, and legal considerations of this practice continue to be subjects of debate and discussion. In the United States, a growing number of the population support provider-assisted death. In 1997, a U.S. Supreme Court ruling upheld states’ right to determine their laws on provider-assisted suicide despite efforts to limit providers’ ability to prescribe medications for their patients requesting the means to end their lives. The position of the Supreme Court is that the debate concerning the morals and ethics surrounding the right to die should be continued. As more of the population enters late adulthood, the emphasis on giving patients an active voice in determining certain aspects of their death is likely.

### Palliative Sedation

The administration of pharmaceutical agents to reduce consciousness is known as **palliative sedation** (Cherny, 2024). These medications may be administered intravenously, subcutaneously, orally, or rectally. Palliative sedation is appropriate in the case of severe and intractable pain at the end of life, and it can be used in the ICU, inpatient hospice, inpatient general units, and at home, depending on the circumstance of each individual. Palliative sedation allows restfulness for the individual and reduces stress levels for the family (Cherny, 2024). Discomfort and pain in palliative care may result from the disease process itself or as a result of palliative treatments, procedures, or surgical interventions. However, palliative sedation is more than just administering pain relievers. Palliative sedation may also relieve emotional suffering, such as anxiety, and reduce physical discomfort, such as breathlessness or dyspnea. It can also alleviate symptoms of delirium and fatigue.

While both euthanasia and palliative sedation may use similar modalities, the distinction lies in the intention and the outcome. Palliative sedation intends to provide comfort and focuses on the ethical standards of beneficence and nonmaleficence. The outcome of palliative sedation is improved quality of life during the end-of-life period rather than inducing or hastening the process of death. In the case of palliative sedation, nurses may be carrying out orders to administer medication. Nurses need to assess their comfort level in providing care during this challenging time, as there is often a shift from delivering curative treatment to maintaining quality of life and providing dignity at the end of life.

## Nursing Considerations for After Death

Nurses may encounter death in a variety of settings, including inpatient units, emergency rooms, at-home hospice care, and the scene of a violent crime or accident. After-death care involves caring for the deceased individual's body, but generally the focus shifts to providing more intense care for the family.

### Postmortem Care

The care provided for an individual immediately after death is called **postmortem care**. At this time, the body will experience expected changes, including a drop in temperature, color changes to the skin, and **rigor mortis**, the stiffening of the muscles in the body. The skin will develop **passive euthanasia**, a pale to greyish color of the skin that occurs shortly after death, with some areas turning purplish due to blood pooling in lower body parts due to gravity.

The task of postmortem care falls to the nurse in a hospital setting and possibly in a long-term care facility or home setting. Nurses must provide gentle care to the body to prevent tissue damage and preserve dignity; modesty and privacy are also important. Nurses should remove all IV lines that fall under their scope of practice (e.g., some facilities will allow peripheral IVs to be removed but not tunneled or large-bore lines) and remove indwelling tubes, such as nasogastric or urinary catheters. It is important to note that if an autopsy is planned, no lines or tubes should be removed. Nurses should also remove or replace any soiled linens and clothing, close the eyes, and gently cleanse any soiled parts of the body before family viewing. Documenting a postmortem assessment is essential, particularly in inpatient settings and for individuals who will have an autopsy performed. The facility will dictate the type and extent of the exam.

Postmortem care should also provide time for the family to view the body and say goodbyes; a private space for this is ideal. Nurses have an important duty in creating a peaceful space for the family to view the body. By removing IV lines, tubing, ventilators, pumps, and other machines, nurses can help the family focus on emotional needs. Cleaning the room of visible stains and body fluids and applying clean linens will go far in creating a space for families to begin their healing. As much as possible, the patient's and their family's cultural beliefs and wishes should guide postmortem care.

## LINK TO LEARNING

This website will prepare you to [care for individuals after they die \(https://openstax.org/r/77CareAfterDie\)](https://openstax.org/r/77CareAfterDie) and includes information relevant to care of the surviving family.

### Organ Donation

The donation of organs or tissue that are removed from a person's body and used for treatment in another person's body or for research or other medical uses is known as **organ donation**. It is a personal decision that should be considered during advance planning. Anyone can volunteer to be an organ donor upon their death, though not everyone will qualify, and some illnesses, cancers, or bodily damage limit the viability of organs. However, organ donation networks will typically accept what is available and safe to use. According to HRSA (2024), common organs procured for organ donation include the following:

- heart
- kidney
- liver
- lungs

- pancreas
- intestines
- face
- hands

In some cases, other body parts may be procured, in whole or in part, for a variety of uses, including grafting skin, repairing veins and heart valves, restoring vision, and treating burns:

- corneas
- middle ear
- heart valves
- bone
- veins
- cartilage
- tendons
- ligaments
- stem cells
- bone marrow

Consent is required to begin the process of **procurement**, the harvesting of organs or tissues for donation. First-person consent is when an individual signs up as an organ donor prior to their death—typically when obtaining a driver’s license or completing an advance directive. If no first-person consent is available, family members are asked to decide. Time is crucial to keep the procured organs viable. Nurses may need to have open discussions with families to obtain their consent, particularly in the event of sudden or traumatic injuries in which the individual is otherwise healthy and many organs are viable. Given the circumstances of recent or impending death, nurses will need to take great care in approaching families about consideration for organ donation. This is a difficult conversation for both the nurses caring for the patient and the family. Nurses should keep in mind that they are not alone in the process and may rely on unit leadership, charge nurses, and trained representatives of organ donation procurement organizations to open the conversation with families about organ donation.

## LINK TO LEARNING

Visit this website on [resources for families considering organ donations \(https://openstax.org/r/770OrganDonation\)](https://openstax.org/r/770OrganDonation) for more information.

### Death Certificate

A **death certificate** is a legal document, signed by a provider, confirming the circumstances of a person’s death. Death certificates include the following:

- place of death
- time of death
- date of death
- primary cause of death
- secondary contributors to death
- patient name
- patient address
- name of parents
- parents’ birth and death information

A death certificate may also include information on the disposition of remains; a funeral director often fills out this section. Death certificates are usually prepared by a county medical examiner or coroner, though providers may also be certified to prepare them. Depending on the facility’s protocol, a nurse or provider can pronounce the time of death. Copies of death certificates can be ordered through the state where the death occurred.

### Autopsy

An **autopsy** is a medical procedure in which a deceased person's body is systematically examined to determine the cause of death and to gain additional insights into the person's health and medical history. Legal requirements for autopsy vary by state. Family members can request an autopsy if they have concerns about the cause of death.

Autopsies are typically performed after violent crimes, accidents, or for reasons of unknown cause of death.

Depending on state laws and circumstances surrounding the death, autopsies may be completed by the following:

- forensic pathologists
- medical examiners
- coroners
- qualified police officers

## Summary

### 36.1 Concepts of Grief and Loss

In all areas of care, nurses will encounter patients experiencing death, dying, loss, or grief. Understanding the concepts of loss and grief, particularly in relation to death and dying, prepares the nurse to support patients physically and emotionally. Grief is complicated, with no one-size-fits-all treatment plan. Many factors play a role in how people react to loss and experience grief. Grief, bereavement, and mourning are unique experiences for each individual and are affected by personal values and specific cultural beliefs. Nurses must maintain a nonjudgmental attitude in caring for grieving patients and consider cultural differences associated with bereavement and mourning.

Nurses must be prepared to address the physical, social, and emotional experiences of grief. Physical symptoms associated with grief, such as heart palpitations, dizziness, fatigue, and muscle tension, often overlap with emotional dysregulation, such as depression, anxiety, and anger. The social effects of grieving occur in response to these physical and emotional experiences and impact family and community relationships. Grief is triggered by loss, which may be actual, perceived, anticipatory, maturational, or situational. Regardless of the type of loss, nursing actions focus on the individual patient response. Although grief is highly variable, nurses can anticipate patterns and responses based on the stages of grief outlined by theorists such as George Engel and Elisabeth Kübler-Ross. Nurses knowledgeable about the variations in grief and other responses to loss are empowered to offer meaningful support to their patients.

### 36.2 Concepts of Death and Dying

Nurses must have a clear understanding of the dying process to provide appropriate interventions and education to patients and families faced with death and dying. Equipped with this knowledge, nurses can effectively create individualized care plans as patients begin to experience the stages of death. By anticipating individual and family needs during physical, psychological, and societal death, nurses promote quality end-of-life care.

Educating family members on expectations at the end of life can reduce stress and create a greater sense of peace as they say goodbye to their loved ones. Education should focus on explaining expected physiological changes associated with respiration, circulation, digestion, urination, and cognition. Nurses must include anticipatory guidance on how these changes will affect the visual appearance and responsiveness of the patient.

Supporting individuals and family members facing a terminal illness diagnosis is complex. Terminal illness progression is highly variable between individuals and disease states. Supporting individuals through terminal illness involves an interdisciplinary team approach to provide emotional, physical, and psychosocial care. Quality of life and dignity during death can be maximized through palliative care, comfort care, and hospice services.

### 36.3 Factors That Affect Grief, Loss, Death, and Dying

Responses to death and dying are highly individualized. However, there are commonalities in the factors that affect these responses. Type of death, timing, age, and maturation all affect how an individual perceives and processes death and moves through the grieving process. Family members experiencing a loss through death struggle with many emotional challenges, including fear, anxiety, and guilt, as well as a wide range of physical symptoms. After a death, family structure, financial situation, and dynamics may change. Socioeconomic factors such as financial stability, physical location, living arrangements, and transportation all impact an individual's ability to seek and access quality care. The type of death—whether sudden (such as an accident, homicide, suicide, or illness) or anticipated (such as a terminal illness)—influences the grieving process. Suicide is a particularly devastating type of death that may leave individuals feeling extreme guilt, shame, and depression. Nurses must be sensitive to cultural differences in the experience of grief and differences linked to the type and timing of death.

### 36.4 Legal and Ethical Considerations

Nurses must fully understand legal and ethical concepts surrounding death and dying, regardless of their practice setting. The complicated topics of euthanasia, provider-assisted death, and terminal weaning are a basis for understanding the legal and ethical aspects of death and dying in patients with terminal illnesses. Nurses will rely on state standards and federal regulations in regard to legal matters associated with provider aid in dying. Awareness of advance planning, POLST, and the concept of comfort measures at the end of life help nurses provide

individualized care that fulfills the wishes of each patient. Nurses provide hands-on care to dying patients and are an essential part of end-of-life family support. Nurses may be involved in comfort measures, terminal weaning, and care that allows natural death. Nurses must evaluate their thoughts and beliefs about death with dignity, comfort care, and advance directives. After-death care focuses on the dignity of the patient and the care of the family. Nurses can create a peaceful atmosphere for families to express their cultural responses to death in a safe environment. Organ donation consent, preparation for autopsy, and immediate postmortem care are all critical aspects of nursing care, particularly in the hospital setting. Understanding these issues empowers nurses to advocate for their patients even in their final days. Cultural awareness and compassion are essential in postmortem care.

## Key Terms

- acceptance** a grief stage marked by understanding the loss and acknowledging the new reality
- active euthanasia** the administering of a lethal dose of medication to someone who wishes to die
- actual loss** a loss clearly noticed by others
- advance directive (also, living will)** a written legal document that details specific interventions a person wants
- agonal breathing** gasping, labored breaths that may result in periods of apnea lasting many seconds
- allow natural death (AND)** a directive allowing a natural unfolding of the dying process rather than withholding treatments
- anger** a grief stage marked by an intense feeling of displeasure and hostility
- anticipatory loss** a loss that an individual expects or foresees
- apnea** temporary pauses in breathing
- autopsy** a medical procedure in which a deceased person's body is systematically examined to determine the cause of death and to gain additional insights into the person's health and medical history
- bargaining** a grief stage marked by attempts to “make a deal” that might change or renegotiate the undesired outcome
- bereavement** the feeling of grief and the outward expression of mourning
- Cheyne-Stokes breathing** a pattern of abnormal breathing characterized by progressively deeper and sometimes faster breathing, followed by a gradual decrease that results in a temporary stop in breathing (apnea)
- comfort care** interventions that promote the comfort of the patient and family during the dying process
- compassion fatigue** the emotional toll experienced by individuals caring for others
- complicated grief** a state of grief that is prolonged, delayed, or exaggerated in which individuals have trouble coping and progressing through the normal grief process
- death** the cessation of biological life functions
- death certificate** a legal document, signed by a provider, confirming the circumstances of a person's death
- denial** a grief stage marked by refusal to acknowledge a loss or insistence that it isn't happening
- depression** a grief stage marked by prolonged sadness that affects an individual's ability to perform everyday tasks
- do not intubate (DNI)** an order stating that if a person stops breathing, medical personnel such as providers and nurses are *not* to place an intubation tube
- do not resuscitate (DNR)** an order stating that if a person stops breathing or their heart stops beating, medical personnel such as providers and nurses are *not* to take steps to revive or resuscitate the patient
- dysfunctional grief** grief that does not resolve as expected or in which an individual resorts to unhealthy coping strategies
- euthanasia** the act of helping a person fulfill their wish to die
- grief** the emotional response to loss
- healthcare proxy** a specific person appointed to make medical decisions for you if you are unable to speak for yourself
- homicide** the killing of one person by another person
- hospice care** a specific type of comfort care provided at the end of life
- loss** a real or perceived absence of a possession, circumstance, or individual
- maturational losses** losses that occur at predictable intervals during an individual's life span
- mottling** a bluish-red, lace-like (reticular) coloration of the skin
- mourning** the outward, personal expression of grief

- organ donation** the donation of organs or tissue that are removed from a person's body and used for treatment in another person's body or for other medical uses
- palliative care** an interdisciplinary approach to specialized medical and nursing care for people with life-limiting illnesses
- palliative sedation** the administration of pharmaceutical agents to reduce consciousness
- pallor** an extremely pale hue of the skin
- pallor mortis** a pale to greyish color of the skin that occurs shortly after death
- passive euthanasia** the choice to withhold life-sustaining treatment with the intent to hasten death
- perceived loss** a loss that an individual distinctly feels as an absence, though it may not be apparent to others
- physician order for life-sustaining treatment (POLST) (also, portable medical order)** a personal directive for medical care
- physiological death** the state in which the body ceases to function, eventually rendering the individual unable to engage in necessary basic processes
- postmortem care** the care provided for an individual immediately after death
- procurement** the harvesting of organs or tissues for organ donation
- provider-assisted death** the act of a provider prescribing the means by which a person can end their own life
- psychological death** the state in which the individual begins to face their impending death and consequently regresses into the self
- respite care** temporary care for an individual to provide relief to their usual caregiver
- rigor mortis** the stiffening of the muscles in the body after death
- rumination** the act of focusing on wrongs from the past
- situational loss** a loss associated with expected or unexpected life changes for an individual
- societal death** the state in which others, perhaps unable to effectively cope with the imminent loss and its implications, withdraw from the dying individual
- suicide** death caused by intentional harm to oneself
- terminal illness** a disease state for which no cure is known; also referred to as a life-limiting disease
- terminal weaning (also, terminal extubation)** the removal or discontinuation of life-sustaining treatments, procedures, or devices such as a ventilator
- voluntary euthanasia** the act of helping someone fulfill their wish to die

## Assessments

### Review Questions

- What physiologic changes occur as a response to stress hormones triggered by a grief response?
  - noise sensitivity, fatigue, elevated blood pressure, dry mouth
  - weeping, dizziness, weakness, chest tightness
  - blood vessel constriction, elevated blood pressure, increased heart rate, inflammatory chemical release, increased platelet and fibrinogen activity
  - heart palpitations, eye irritation, hollowness in the stomach, muscle tension, crying
- What acute condition is associated with a heart murmur, chest pain, and shortness of breath in individuals who have experienced severe trauma, including the death of a loved one?
  - anxiety
  - pulmonary embolism
  - stress-induced cardiomyopathy
  - stroke
- What is considered “the universal language of children” and often incorporated into their process of grieving?
  - crying
  - laughing
  - play
  - denial
- The physical symptoms of decreased appetite, cool skin, and decreased cognition are all associated with

- what part of the dying process?
- social death
  - energy conservation
  - psychological death
  - lack of blood to the brain
5. What type of breathing pattern refers to gasping, labored, and intermittent breaths seen during the stage of impending death?
- terminal
  - life-limiting
  - agonal
  - restless
6. During a routine hospice care visit for a patient with stage 4 prostate cancer, the patient's sister expresses concern over finances, inability to keep up, extreme fatigue, and frustration with her brother's behaviors. What is the sister likely experiencing?
- anticipatory grief
  - respite care
  - compassion fatigue
  - terminal illness
7. Palliative care and hospice care provide many of the same services and nursing interventions; however, palliative care may also include which type of treatments that are not offered with hospice care?
- medical
  - comfort care
  - pain relief
  - respite
8. At what stage of child development might a nurse expect a recurrence of bedwetting, irregular sleep, tantrums, and magical thinking in response to a death?
- preschooler (3–5 years)
  - middle childhood (6–11 years)
  - preadolescent (11–12 years)
  - adolescent (12–17 years)
9. What socioeconomic and cultural factors can a nurse expect to encounter when caring for families experiencing an anticipated death?
- All socioeconomic groups access hospice care equally.
  - Funeral planning and costs are similar across socioeconomic groups.
  - Mostly White patients use hospice care.
  - Autopsies are performed regardless of cause of death.
10. After the death of his partner, Mr. Otto has an appointment with his primary care provider for a check-up. The nurse observes that Mr. Otto seems nervous, checks several times during the visit for his insurance card, reports trouble concentrating, and verbalizes that he does not know how he will “get by” without his partner managing the finances. What psychological factors are affecting Mr. Otto in his grief process?
- fear and guilt
  - guilt and sleep disturbance
  - anxiety and fear
  - sleep disturbance and anxiety
11. What is the most common cause of sudden death in the United States?
- SIDS

- b. accidents
  - c. homicide
  - d. cardiovascular events
- 12.** An advance directive is a legal document that serves what purpose?
- a. dictates the medical treatment plan at the end of an individual's life
  - b. explains an individual's wishes and desires for end-of-life care
  - c. directs providers on whether to extubate a patient
  - d. allows a healthcare proxy to override a patient's verbal wishes
- 13.** A POLST is a type of advance directive that serves whom?
- a. only individuals living in a long-term care facility
  - b. only individuals who independently create a POLST
  - c. any individual who creates a POLST with their physician
  - d. any individual with a terminal illness
- 14.** Where is a nurse most likely to encounter terminal weaning?
- a. an emergency room
  - b. a patient's home
  - c. a hospice facility
  - d. an intensive care unit
- 15.** What is the purpose of palliative sedation?
- a. to hasten the dying process
  - b. to maintain comfort and pain relief at the end of life
  - c. to allow family members time to say goodbye
  - d. to allow for curative treatment procedures
- 16.** What is true about organ donation?
- a. Only whole organs can be donated for use.
  - b. First-person consent is the only legal form of consent for organ donation.
  - c. Individuals of any age are potential organ and tissue donors.
  - d. Illnesses, cancer, and bodily damage do not affect organ donation.

### Check Your Understanding Questions

1. What is the fundamental relationship between the concepts of grief, mourning, and bereavement?
2. Why can a perceived loss create a challenge in the social aspect of grieving?
3. Describe three triggers associated with maturation loss during childhood.
4. What determines the terminality of a disease process?
5. What specific strategies can the nurse employ to help adolescents process grief?
6. How does care for family members after a sudden death differ from care after an anticipated death?
7. Explain the difference between active euthanasia, passive euthanasia, and provider-assisted death.

### Reflection Questions

1. How can nurses use Kübler-Ross's five stages of grief to develop patient-centered care for individuals during the grieving process?
2. How can nurses encourage self-empowerment and autonomy during the dying process?
3. Nurses may encounter individuals experiencing grief in many settings. Patients may not seek care specifically for grief. How can nurses coordinate care and support individuals during the grief process?

## Critical-Thinking Questions about Case Studies

1. Refer to [Unfolding Case Study #5: Part 6](#).  
What physical symptoms of grief should the nurse assess Mr. Morales for?
2. Refer to [Unfolding Case Study #5: Part 7](#).  
What information would the nurse provide to Mr. Morales about what to expect during the middle stage of death?
3. Refer to [Unfolding Case Study #5: Part 8](#).  
If the nurse listens to the patient's heart and determines that death has occurred, what postmortem care tasks should be performed?

## What Should the Nurse Do?

1. The nurse is caring for a 65-year-old patient who has recently entered hospice with a diagnosis of advanced muscular dystrophy. The patient states that his pain is terrible and that he needs more medication. The family members do not want the patient to be “too sedated.” What education can the nurse provide to meet the needs of both the patient and the family?
2. The nurse is caring for an 8-year-old patient with leukemia. The mother speaks to the nurse privately and begins crying as she expresses her guilt for not being available to her other children and her need to stay with her sick child. What next steps can the nurse take to help this mother?
3. A nurse is caring for a patient and family in an in-patient hospice unit. After the patient's death, the wife is reluctant to leave the bedside in order for the nurse to perform postmortem care. Her daughters are encouraging her to leave the room. How should the nurse respond?

Nurse Bree is working in a medical unit in a hospital. One of her patients is an 83-year-old patient with end-stage kidney failure; she receives dialysis regularly and has recently decided to pursue more comfort care options. Despite her end-stage disease, she has not completed any advance care planning. Bree feels she should address this topic with the patient and her daughter. Bree's other patient is a 24-year-old patient who was diagnosed with type 1 diabetes ten years ago. He has been hospitalized with diabetic ketoacidosis (DKA) multiple times since his diagnosis. Looking through his chart, she noticed he had a signed DNR order. Bree is shocked when she sees this order and initially feels compelled to discuss it with her colleagues and the patient's provider.

4. What factors likely affect Bree's reaction to the advance planning orders for these two patients?
5. As Bree cares for these patients, what support can she get in discussing the topic of advance planning with these patients? How can Bree care for these patients if she disagrees with their choices?
6. How should Bree explain the difference between comfort care and DNR to these patients?

## Competency-Based Assessments

1. Draw a diagram of a sample patient's progression through Kübler-Ross's five grief stages. Describe patient symptoms or responses at each stage. Draw a similar diagram of a patient experiencing a type of dysfunctional grief. Compare the two charts and reflect on places where the nurse will provide interventions.
2. A patient with terminal lung cancer is receiving palliative care and wishes to die in his home. Discuss how nurses can effectively collaborate with the patient's family and other caregivers. Explain nursing actions, team members and roles, and the overall goal of the interdisciplinary team.
3. Create a hypothetical dialogue between a nurse and a teen who has lost a friend to suicide. What coping strategies may the teen use, and how can the nurse support the teen?
4. Create a poster comparing DNR, comfort measures, and. Give examples of clinical circumstances in which these end-of-life orders may be in place.
5. Use the internet to create a table comparing arguments for and against provider-assisted death.

## CHAPTER 37

# Family Dynamics

**FIGURE 37.1** Healthy family dynamics influence individual health and wellness. (modification of “Ponggal Festival 2019 - Family Portrait” by John Ragai/Flickr, CC BY 2.0)

### CHAPTER OUTLINE

- 37.1 Family Concepts
- 37.2 Family Framework
- 37.3 Family Dynamics Influence on Health Outcomes
- 37.4 The Nurse’s Role in Caring for the Family Unit

**INTRODUCTION** Families play a central role in nearly every aspect of an individual’s life. Family units are important in all cultures throughout the world. Based on U.S. census data, the United States identifies more than 84 million families (Statista, 2023). U.S. families have increased by nearly 40 million over the last 60 years (Statista, 2023). Families significantly affect individual health over a person’s lifetime. Families have both passive and active influences on health outcomes. Passive influences include genetic disorders passed within families, unspoken family values that affect healthcare consumption and trust in the healthcare system, and interactions that promote or limit emotional well-being. Families also have an active role in health, directly influencing lifestyle choices, such as exercise, nutrition, substance use, social determinants of health, and socioeconomic status. Interactions among family members may result in a positive or negative impact on an individual’s health status. Families and family dynamics change over time in parallel with the life stage of adults, the growth of children, the creation of new family units, birth, death, and changing health patterns. With a longer average adult life span, individual roles within a family may change many times throughout an individual’s lifetime.

Nurses play a crucial role in the support of families and individuals within the family structure. From education regarding family dynamics and coping skills for managing acute or chronic health conditions to social considerations for managing dysfunctional family interactions and family interactions in the face of illness, nurses empower

individuals and families to create supportive and healthy connections.

## 37.1 Family Concepts

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify different perceptions of family
- Recognize different family assessment models
- Describe different theories of family function

Understanding the complexities of family perceptions helps nurses incorporate the family in an individual's care plan to meet the patient's needs best. In addition, nurses can care better for a family unit by understanding how each individual perceives the family as a whole and their specific role and value within the family. Family structures influence healthcare costs and social determinants of health, guide family assessments, and direct nursing interventions. By understanding family assessment models, nurses can properly evaluate families and family dynamics to provide personalized care. Nurses also need to understand the theories of family function to create a culture of acceptance and inclusion for all family types.

### Family Perceptions

Individuals perceive family differently depending on cultural values, social norms, age, and developmental stage. These perceptions can change over one's lifetime or fluctuate rapidly depending on family dynamics. Individuals identify with specific traits in their family structure but may also value and strive for traits of other families. These family perceptions may conflict with or align with the nurses' own family structure. Nurses create an environment of inclusion and respect by maintaining an awareness of family structures that differ from their own and acknowledging inherent values within different family structures. In this way, they provide unbiased, compassionate, and professional care.

Children begin understanding family structure from a very young age, and that understanding develops and changes as an individual progresses through developmental stages. The various concepts of family include the type of family, family members, gender roles, family values, internal family relations, and family relations outside the family core. Many cultural, social, and personal aspects affect how family is defined for each individual. These external factors affect how individuals see their own family.

A sense of family belonging may wax and wane over a lifetime, depending on internal and external factors, such as changes in the individual and how they see themselves fitting into the wider world and family changes related to life stage changes, deaths, marriages, divorce, and births. Perceptions of family and belonging depend largely on intra-family relations, particularly the parent-child relationship, which may include non-parent guardians. Some studies show that this feeling of belonging is more pronounced in individuals living in households with two biological parents (King & Boyd, 2016). This sense of well-being tied to the feeling of belonging within the family tends to lend a protective factor, particularly in adolescents who are experiencing emotional distress, violence, depression, suicide, and poor academic performance. A sense of family belonging creates more positive outcomes (King & Boyd, 2016). Additional factors that may lead to positive family perceptions include a higher parental education level, higher overall incomes, and positive sibling relationships. While some information points to similar effects in stepparent families, little research is available on adoptive families, single-parent families, or children living with non-relational guardians. Understanding the definition of family and the roles of individuals within the family gives nurses more insight into how the perception of family affects long-term individual outcomes.

### Definition of Family

Many variations exist in the definition of family. These include legal, cultural, social, and personal definitions of family. What constitutes a family is a prime area of debate for legal and health-related purposes. Family is often defined in terms of structure, with each family member filling a specific role (like father, mother, or child). On the other hand, family may be defined in terms of how members relate to one another. A **family** is a socially recognized group, usually joined by blood, marriage, cohabitation, or adoption, that forms an emotional connection and serves as an economic unit of society. Sociologists identify different types of families based on how one enters into them. A **family of orientation** refers to the family into which a person is born. A **family of procreation** describes one that is formed with the intention of bearing children. These distinctions have cultural significance related to issues of

lineage.

In a social or cultural context, families may also be defined as groups where participants view themselves as family members and act accordingly. In other words, families are groups in which people come together to form a strong primary group connection and maintain emotional ties to one another over a long period. Such families may include groups of close friends or teammates. Another perspective views families as groups that perform vital roles for society—internally (for the family itself) and externally (for society as a whole). Families provide for one another's physical, emotional, and social well-being. Parents care for and socialize children. Later in life, adult children often care for older adult parents.

The Health Resources and Services Administration (HRSA) defines family as “a group of two or more persons related by birth, marriage, or adoption who live together; all such related persons are considered as members of one family” (HRSA, 2023). This definition also considers older children who do not reside in the same home but are financially supported by the family. This definition does not consider foster children or non-related individuals functioning as part of the family unit while living in the same home. Other definitions suggest that a family is a kinship unit that remains present regardless of whether these individuals share a residence. In the current setting of communication ease, family relationships and communication can persist over long distances while influencing one another (Jabbari et al., 2023). Family structure and definition are complex and vary depending on whether social constructs, statistical analysis for census purposes, or individual beliefs and values related to the family are considered.

The government is less flexible in its definition of family. The U.S. Census Bureau defines a family as “a group of two people or more (one of whom is the householder) related by birth, marriage, or adoption and residing together” (U.S. Census Bureau, 2023). This definition of family does not capture the many other subtle ways people define family. While this structured definition can be used as a means to track family-related patterns over several years, it excludes individuals, such as cohabitating unmarried heterosexual and same-sex couples. Legality aside, health professionals would argue that the general concept of family is more diverse and less structured than in years past. Society has given more leeway to the design of a family, making room for what works for its members (Richardson et al., 2022).

### Relationship Between Families and Illness

The relationship between family and health has many facets. First, genetics and heredity significantly affect disease risk and overall health outcomes. Additionally, family dynamics and the environment have dramatic effects on individual health. This stems from the family's health practices, health literacy, and health choices, particularly during childhood. Family choices associated with health affect a child from the early years and often set the stage for health or disease later in life.

Heredity is a complex topic that is associated with a variety of health disorders. A disorder is considered **hereditary** if an individual can pass it naturally from parent to offspring through their genes. This makes hereditary disorders a subset of genetic disorders. A **genetic disorder** is caused by a change in a genetic DNA sequence or a mutation in a gene or multiple genes. Some, but not all, genetic disorders are heritable or can be passed from one generation to the next through their genes. These mutations can be caused by environmental factors or damage to DNA. Emerging research suggests that most diseases have some genetic component, meaning that there is some damage to a gene causing the disorder either before or after birth (NIH, Human Genome, 2018). Genetic and hereditary disorders encompass both rare disorders and common diseases.

A **familial disorder** is a disease that tends to present among individuals from the same family line. These may be genetic in origin or have a multifactorial cause. Familial disorders that are passed from one generation to the next through genetic material are called hereditary conditions. These gene mutations may cause a disease noted at birth or a risk for developing a disease later in life. Genetic disorders may also be affected by environmental factors. For example, an individual may have a genetic mutation predisposing them to high blood pressure. Still, they may or may not develop high blood pressure or hypertension if they maintain a healthy weight, consume a nutritious diet, and exercise regularly. In this way, environmental factors can also influence the expression of genetic predisposition for specific disorders. Familial diseases include the following:

- coronary artery disease
- hypertension
- heart disease

- arteriosclerosis
- congenital heart defects
- type I diabetes
- type II diabetes
- asthma
- lung cancer
- prostate cancer
- breast cancer
- colon cancer
- osteoporosis
- thyroid disorders
- autoimmune disorders
- arthritis
- Alzheimer disease
- autism spectrum disorders
- migraine headaches

Examples of hereditary chromosomal and genetic disorders include the following:

- down syndrome
- albinism
- ankylosing spondylitis
- cystic fibrosis
- Duchenne muscular dystrophy
- Ehler-Danlos syndrome
- Huntington disease
- Marfan syndrome
- sickle-cell anemia
- familial hypercholesterolemia
- hemochromatosis

## PATIENT CONVERSATIONS

---

### Breast Cancer Risk

**Scenario:** Raylee is a 25-year-old patient who has been a patient at the clinic for five years and has no specific concerns today. She is presenting for a general health exam.

**Nurse:** Let's review your medication and supplement list and update your family history.

**Patient:** I'm feeling healthy now, but I decided I should keep up with my routine exams because my mom was diagnosed with breast cancer last year. She keeps telling me I need to get tested, but I don't have any breast concerns like she did, and I take better care of myself, too.

**Nurse:** It sounds like your mom is concerned about your risk for breast cancer. When was your mom diagnosed with breast cancer?

**Patient:** She was 49 years old.

**Nurse:** Do you know if her oncologist recommended that you and your sister have genetic testing?

**Patient:** Yes, I think that's what she wants me to do, the BRCA test. I'm just not sure that's needed since I'm young and healthy, and I don't smoke or drink like my mom.

**Nurse:** You're right that maintaining a healthy lifestyle can help prevent cancers, but some cancers have a stronger genetic component. If your mom has told you that a BRCA test is indicated for you, this may mean she had a breast cancer type that is related to a genetic mutation that you may have inherited.

**Patient:** Does this mean I will get breast cancer?

**Nurse:** Not necessarily, but a test to see if you have this gene mutation can help you and your doctors understand your risk. I'd like to refer you to a genetic counselor. Is this okay?

**Patient:** Yes, I'd like to learn more about the test and decide if I want to get it done. Thank you.

## LINK TO LEARNING

Watch this [video on ankylosis spondylitis \(https://openstax.org/r/77AnkylosisSpon\)](https://openstax.org/r/77AnkylosisSpon) to learn more about this genetic rheumatological disorder that is often overlooked in young individuals.

While there are many ways in which family and family history affects individual members of the family, illness also affects families as a whole. In particular, chronic diseases and illness can have a significant impact on families and family dynamics. Health and disease affect financial resources, time resources, family member relationships, and roles. In addition, illnesses of one or more individuals can affect emotional coping strategies and the ability to engage in meaningful activities together. The illness of one family member may negatively affect the health of other family members by creating sleep disruptions, altered nutrition choices, increased anxiety/depression, caregiver fatigue, limited freedom, and emotional fatigue (Golics et al., 2013).

Family social dynamics, community interaction, and cultural perceptions of illness also affect health and risk for illness. These factors influence how an individual interacts within their community in relation to housing, education, physical exercise, nutritious dietary choices, and accessing medical care. The CDC (2023) reports that low family socioeconomic status, including income level, education level, and employment status, can increase risks for certain illnesses, such as cardiovascular disease.

Cultural perceptions of illness are often learned first within the family unit. This can affect trust or mistrust in the healthcare system, how and when individuals seek medical care, and adherence to recommended medical or nursing interventions. Cultural values guide family reactions to illness, perceptions of illness, coping strategies, response to the idea of medications, treatment adherence, and emphasis on health. Positive family interactions predict positive coping strategies and better outcomes, even in the face of chronic disease. Nurses have the opportunity and obligation to assess families for all of these characteristics so that they can provide care tailored to the patient and that patient's family.

## Family Assessment Models

Family assessment models help nurses understand family structure and dynamics in a general sense. By assessing individual families, nurses can better recognize the impact of acute or chronic illness on the family and each member. Several models exist to help nurses evaluate families and individuals within the family context, including the Calgary Family Assessment Model and Friedman's Family Assessment Model. These models allow nurses to gather information to make informed decisions when creating a care and treatment plan for families and individuals.

### Calgary Family Assessment Model

The Calgary Family Assessment Model (CFAM) and the Calgary Family Intervention Model (CFIM) were introduced in 1984 and 1994 by nurse researchers Maureen Leahey and Lorraine Wright. These practice models are widely known and used in nursing to understand families and create family-based interventions. The practice models were based on clinical practice, allowing for direct application to nurses working with patients. The founders of CFAM/CFIM acknowledge the many changes in family structure and assessment since these models were developed but are confident that the models are fluid and adaptable to contemporary circumstances affecting families (Leahey & Wright, 2016).

While the CFAM/CFIM is a theoretical framework, it directly affects nursing actions. The CFAM/CFIM focuses on identifying family strengths, weaknesses, ideals, and values. Using strategies, such as interviews, therapeutic communication, practice-based evidence, and reflection, nurses identify the strengths of each family. With this knowledge, nurses can work directly with families to co-create interventions that support their strengths (Leahey & Wright, 2016). By including the family in planning, the focus moves away from nurse-initiated interventions and

empowers the family in managing illness (Leahey & Wright, 2016). The CFAM/CFIM uses interview tools to evaluate a family's structural, developmental, and functional aspects. A portion of the CFAM that is particularly applicable to modern nursing practice is the 15-minute interview (Table 37.1). The researchers outline several essential elements, referred to as key ingredients (Wright & Leahey, n.d.). This interview technique maximizes information gathering within a time frame appropriate for busy nursing practice.

Key Ingredient	Definition	Nursing Action
Manners	Maintaining culturally appropriate social behavior, including respect, politeness, and courtesy	<ul style="list-style-type: none"> <li>• Introduce oneself.</li> <li>• Make eye contact.</li> <li>• Refer to the patient by name.</li> <li>• Acknowledge family members or other support persons.</li> <li>• Explain nurse role.</li> <li>• Explain procedures.</li> <li>• Keep time commitments.</li> </ul>
Therapeutic communication	Communication techniques that promote healthy discussion between the nurse and patient/family	<ul style="list-style-type: none"> <li>• Practice the art of listening.</li> <li>• Invite questions from patients.</li> <li>• Invite questions from family members.</li> <li>• Acknowledge patient/families' expertise in their own health.</li> <li>• Discuss treatment and follow-up with the patient and family.</li> </ul>
Family genograms and ecomaps	Diagrams illustrating patient and family demographics, behavior, interactions, and health history	<ul style="list-style-type: none"> <li>• Sketch a quick genogram during the initial interview.</li> <li>• Create a standard set of questions.</li> <li>• Ask about family members, health, and family roles.</li> </ul>
Therapeutic questions	Key questions that elicit answers helpful for providing nursing care	<ul style="list-style-type: none"> <li>• Ask what is most/least helpful to the patient.</li> <li>• Ask the patient what they need.</li> <li>• Ask the patient what their biggest challenge is.</li> <li>• Ask what questions the patient has.</li> </ul>
Commending family and individual strengths	Positively and verbally acknowledging individual and family strengths	<ul style="list-style-type: none"> <li>• Offer a compliment.</li> <li>• Acknowledge positive actions the patient has taken.</li> <li>• Verbalize positive actions observed.</li> <li>• Voice patient and family strengths.</li> </ul>

**TABLE 37.1** Key Ingredients for the 15-Minute Interview

Recent studies reflect the current use of the CFAM/CFIM in contemporary nursing practice across disciplines (Mileski et al., 2022; Zimansky et al., 2020). Nurses continue to use these frameworks to understand family strengths, experiences with illness, and coping strategies. The CFAM/CFIM may be beneficial for nurses in providing patient education. Understanding the family strengths allows nurses to tailor teaching methods, involve family members, and anticipate challenges that patients may experience in managing illness. Moreover, applying these

models allows nurses to practice effective communication, recognize and address specific barriers to communication, and promote intervention adherence in individual patients (Mileski et al., 2022). In particular, these strategies are effective during end-of-life care, psychiatric illness, and the highly emotional periods of the disease process (Mileski et al., 2022). Using the CFAM/CFIM during the assessment of patients and their families can empower the patients and families to embrace their strengths, lean on family coping mechanisms, and feel heard in their illness journey.

### Friedman's Family Assessment Model

The Friedman Family Assessment Model was created by Dr. Marilyn Friedman and published in 1981 (Texas Woman's University, 2023). Friedman's Family Assessment Model is based on the concept of treating the family in addition to the individual. Friedman created a family assessment tool based on sociology concepts and her clinical nursing experience (Texas Woman's University, 2023). The assessment tool is divided into six sections for evaluating a family ([Table 37.2](#)).

Assessment Category	Assessment Components
Identifying data	<ul style="list-style-type: none"> <li>• Name</li> <li>• Contact information</li> <li>• Family composition (genogram)</li> <li>• Cultural factors</li> <li>• Social class</li> <li>• Religion</li> </ul>
Family development stage	<ul style="list-style-type: none"> <li>• Developmental stage</li> <li>• Family history</li> <li>• Family of origin history</li> </ul>
Environmental factors	<ul style="list-style-type: none"> <li>• Home</li> <li>• Neighborhood</li> <li>• Geographic location</li> <li>• Community interactions</li> </ul>
Family structure	<ul style="list-style-type: none"> <li>• Communication patterns</li> <li>• Power structure</li> <li>• Role structure</li> <li>• Values</li> </ul>

**TABLE 37.2** Friedman's Family Assessment Tool Categories

Assessment Category	Assessment Components
Family functions	<ul style="list-style-type: none"> <li>• Connectedness</li> <li>• Response patterns</li> <li>• Child-rearing practices</li> <li>• Value of children</li> <li>• Health and illness beliefs</li> <li>• Perceived health</li> <li>• Dietary practices</li> <li>• Physical activity</li> <li>• Rest</li> <li>• Substance use</li> <li>• Illness prevention strategies</li> <li>• Perception of healthcare services</li> <li>• Use of CAM</li> </ul>
Family stress, coping, and adaptation	<ul style="list-style-type: none"> <li>• Stressors</li> <li>• Barriers to wellness</li> <li>• Reaction to stress</li> <li>• Coping strategies</li> <li>• Adaptation to illness or crisis</li> </ul>

**TABLE 37.2** Friedman's Family Assessment Tool Categories

The CFAM/CFIM and the Friedman Family Assessment Model offer similar perspectives on the importance of incorporating the family in the assessment of the individual. The CFAM/CFIM has a strong focus on communication between nurses and families. This model suggests that effective interactions with families allow the nurse to obtain information crucial in patient-centered care. The CFAM/CFIM 15-minute interview is a good choice for a nurse assessing the family of a patient being admitted to an in-patient hospice facility. This will allow the nurse to understand how best to help the family and patient navigate difficult physical and emotional changes. The Friedman Family Assessment Model guides the nurse in creating family-centered care to enhance the care of individual family members. This assessment model is a good choice for a nurse working with the family of an adolescent working toward discharge from an inpatient psychiatric health facility, for example. The nurse will understand the needs of the patient as well as the family members to maintain health and safety after discharge.

## Theories of Family Function

Healthcare providers, sociologists, social workers, and mental health professionals use many theories of family function. Because these theories explain the social interactions among family members and between families within a community, they provide context and are important in guiding nursing interventions. Several theories are relevant to nursing practice, including the family systems theory, Bowen family systems theory, and family communication patterns theory.

### Family Systems Theory

The family systems theory has proven to be very powerful in understanding the family. The family systems theory claims that the family is understood best by conceptualizing it as a complex, dynamic, and changing collection of parts, subsystems, and family members. Much like a mechanic would interface with the computer system of a broken-down car to diagnose which systems are broken (transmission, electric, fuel, etc.), a nurse would interact with family members and consider how and where the systems of the family are working and where they need repair or intervention. Nurses consider systems theory in integrating healthcare interventions for an individual with the care of the family. Nurses must also consider how family dysfunction affects illness and how illness contributes to the function or dysfunction of the family.

This theory also addresses the issue of **boundaries**—distinct emotional, psychological, or physical separateness between individuals, roles, and subsystems in the family. Boundaries are crucial to healthy family functioning. The

family systems theory addresses a variety of factors that affect the role family plays in the health of an individual. Consider a 75-year-old female with progressive Alzheimer disease who lives with her husband in an apartment attached to her daughter's home. Her dementia is worsening, and her daughter, son-in-law, husband, and grandchildren are facing significant challenges in her care (Table 37.3).

Family Interaction Considerations	Family Roles
Emotional responses	The patient's husband feels stressed and overwhelmed by his wife's dementia and responds with irritation. The daughter spends a great deal of emotional energy attempting to diffuse her father's sense of overwhelm.
Role expectations	Because the patient is no longer able to perform ADLs and IADLs independently, the daughter and adolescent granddaughters have taken on new roles in providing this care.
Boundaries	While the husband wishes for a continued level of privacy in his home, his wife's condition necessitates frequent visits from family member providing caregiving.
Loyalties	The daughter is overwhelmed by the idea of "putting mom in a nursing home." She feels this is a betrayal, even though the family is struggling to provide enough twenty-four-hour care.
Belief systems	The daughter strongly believes in taking personal responsibility in caring for her family, which is influencing her choice to keep her mom at home as long as possible.
Resilience patterns	Recently, the daughter has reached out to home health for assistance. She recognizes that even though she wants to provide the best care, the level of care needed is affecting her ability to maintain balance in caring for her children and keeping her work hours.
Communication techniques	The daughter struggles to communicate with her father who expresses his frustration with anger. She is using gentle redirection techniques when addressing challenging behaviors associated with her mom's dementia.

**TABLE 37.3** Family Systems Theory Example

### Bowen Family System Theory

The Bowen family systems theory, developed by psychiatrist Murray Bowen, MD, is a framework for understanding human behavior within a family construct. This theory describes the family through emotional connection and family interactions in terms of systems. Bowen's theory suggests that the interconnectedness of family members affects the way family members seek out attention, react to one another, and expect to be treated. Changes in one family member's function, emotional state, or health directly affect others. Nurses must consider these reciprocal reactions within a family when caring for individuals experiencing a health change or crisis.

The interconnectedness of families can promote positive coping strategies, including cohesiveness, cooperation, and emotional responsiveness (Bowen Center, n.d.). This same emotional attachment among family members may also contribute to negative responses to health crises or illnesses in family members, which may include the following (Bowen Center, n.d.):

- emotional overwhelm
- isolation
- unrealistic expectations
- poor decision making

Because emotional responses to family illness can be so intense, family members responding to an illness in another family member may experience physical symptoms, anxiety, substance abuse, and/or depression (Bowen

Center, n.d.). By understanding how the interconnectedness of family members affects emotional responses to illness and healthcare decision making, nurses can anticipate challenges and negative responses. Nurses can encourage appropriate coping strategies guided by specific family dynamics.

---

### Family Communication Patterns Theory

McLeod and Chaffee developed the family communication patterns theory in the early 1970s based on the concept of **co-orientation**, in which two or more people experience the same physical or emotional input and develop a corresponding perception or response (Koerner & Fitzpatrick, 2006; Hunsley et al., 2024). The theory postulates that each person develops their perception of an experience and evaluates how the other person perceives the situation. Additional terms important in understanding the communication patterns theory are as follows:

- **agreement:** in which the individuals have the same perception
- **accuracy:** in which a person's perception of the other person's evaluation accurately reflects the other person's actual perception
- **congruence:** in which an individual's perception and the other person's perception are similar

These concepts are essential for nurses caring for families so they can better understand interpersonal dynamics among family members. Perceiving harmony or incompatibility in accuracy, agreement, or congruence between family members' perceptions about health and illness helps the nurse guide the family toward appropriate interventions. The more accuracy and congruence between family members on a given topic, the more likely they are to perceive a shared reality (Hunsley et al., 2024; Koerner & Fitzpatrick, 2006). This increases their ability to interact positively with one another, provide support, and maintain coping skills.

Nurses can use these concepts to help family members navigate relationships and develop healthy communication patterns, even if their perceptions differ. The original researchers developed an instrument for assessing family communication patterns. In **conformity** communication patterns, family members are expected to conform to hierarchical family values. In **conversation** communication patterns, family members are encouraged to evaluate topics independently and discuss them with the family. The communication patterns lead to four common family types that exhibit specific communication patterns:

- pluralistic: high conversation, low conformity
- consensual: high conversation, high conformity
- protective: low conversation, high conformity
- laissez-faire: low conversation, low conformity

Consider the idea of spiritual family values. In a pluralistic family structure, the parents and children will have frequent open discussions about spiritual beliefs, and children are encouraged to make their own choices regarding these values. Conversely, in a family with a consensual structure, the family openly discusses spirituality, but the children are expected to conform to specific spiritual values. In a family with a protective structure, obedience to spiritual values is expected, without a significant amount of discussion on the topic. In a family with a laissez-faire structure, the family does not discuss individual values, and children develop their own value systems based on personal experiences. The family communications pattern theory can help the nurse understand how families interact so they can tailor communications and interventions most effectively.

## LIFE-STAGE CONTEXT

---

### Parenting Styles

Studies suggest that various parenting styles may affect outcomes for children. Commonly acknowledged parenting styles include the following:

- authoritarian
- authoritative
- permissive
- uninvolved

Each style has some positive and some negative attributes. Authoritarian parenting involves strict rules and punishment that often result in outward obedience. This strategy may also result in aggression or low self-esteem. Permissive parenting, while warm and nurturing, offers little structure, role-modeling, or guidance. This may lead to negative health habits, impulsive decision-making, and a lack of self-regulation. Uninvolved parenting is typically hands-off, offering minimal support, poor communication, and lack of discipline. While children raised under this parenting style may develop resilience, they also struggle with emotional connection, decision-making, and difficulty with interpersonal communication. Authoritative parenting offers a mix of nurturing relationships and appropriate boundaries, expectations, and communication. Overall, this strategy has the highest likelihood of positive long-term outcomes and the fewest negative outcomes.

Parenting styles are only one aspect affecting health habits, perceptions, and outcomes as children move into adulthood. Nurses working with families can consider these parenting styles when developing care plans. Focusing on parenting strengths while encouraging aspects of authoritative parenting may help families succeed in achieving a healthy lifestyle (Sanvictores & Mendez, 2022).

---

## 37.2 Family Framework

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the structure of family
- Understand the functions of family
- Recall the stages of the family life cycle

When assessing families, nurses must consider many aspects of family structure and how this affects disease prevalence, response to illness, and coping strategies. Important aspects of family structure include family composition, gender roles, birth order, and family member relationships. These interactions include immediate and extended family members in a traditional family structure. In unconventional family groups, individuals still function within the social construct of a family. Applying family systems theories, nurses may use genograms or ecomaps to help define and conceptualize individual families and their members. After all, understanding the family structure and associated tasks helps the nurse offer meaningful interventions to families.

### Family Structure

The internal and external makeup of families is known as **family structure**. These structures include the type and number of family members, living arrangements, and interactions. Legal or census definitions of family structures may not match cultural or social definitions of family. Definitions of the family may include individuals living within the same household, individuals related by blood or kinship, and individuals functioning financially as a family. Some groups of individuals function as a family regardless of living location or kinship. For nurses, the critical part of understanding family structure is accepting families as they perceive themselves. Respecting family units is crucial in providing comprehensive care to patients.

The internal and external structure of families directly affects the health of family members. Different family structures are associated with various long-term health outcomes, depending on the circumstances. Some evidence suggests that marriage combined with nonviolence and stability are associated with better outcomes in children (Bzostek & Berger, 2017). According to census records, 65 percent of children in the United States live with two married parents, 5 percent live with two cohabitating parents, 22 percent live only with their mothers, and 5 percent live only with their fathers (ChildStats, 2022).

### Internal Structure

Internal family structure relates to the relationships among family members, including gender roles and sibling order. Subsystems within families refer to the various interpersonal relationships, such as parent-parent, parent-child, sibling, and grandparent-child, and the interplay among these relationships.

## Family Composition

The design of a family structure, including relationships between members, known as **family composition**, is not static and is influenced by births, deaths, marriage, and divorce. Family composition is also influenced by life circumstances that may affect living arrangements. The family composition may consist of a nuclear, blended, or extended family, which may fluctuate over time. The family composition may influence health outcomes because of financial resources, living situations, emotional stability within the family, and coping strategies. Family composition evolves as children are born, grow up, and create new family structures outside their family of origin.

## REAL RN STORIES

---

### Sandwich Generation

**Nurse:** Alice, RN

**Clinical setting:** Public Health

**Years in practice:** 22

**Facility location:** Pennsylvania

I've been a public health nurse at the county health department for 18 years. I work with children, teens, adults, and families struggling with access to health care. I do a lot of home visits evaluating the needs of families with children with special needs. Most of these children have autism spectrum disorder (ASD). One of the most exciting cases I encountered was an extreme case of a married couple struggling in the sandwich generation—middle-aged adults caring for their own children as well as their aging parents. The family had four children, with the third child diagnosed with ASD. The father worked outside the home, and the mother performed all of the family and care duties within the home. The father's mother also lived in a small, attached apartment with the family. The grandmother developed mild cognitive impairment, which slowly progressed to more severe dementia. The mother was pulled in many directions caring for a young child with a disability as well as a cognitively impaired older adult family member. Finding resources for this family was challenging, particularly securing respite care to allow the mother to attend school events and functions with her other children.

Caring for a young family and an additional older family member also strained this family financially. We were able to set them up with some resources and care options to provide financial and stress relief. Many adults in midlife struggle with the burdens of being the sandwich generation. Our job as nurses is to help them navigate this difficult time and support them in their efforts to provide the best care for their families.

---

### Gender Roles

Gender role theory posits that males and females learn gender role behaviors and attitudes from the family and overall culture in which they grow up and that non-physical gender differences are a product of socialization. Social role theory proposes that social structure is the underlying force behind gender differences and that the division of labor between two sexes within a society motivates the differences in their respective behavior. Division of labor creates gender roles, which, in turn, leads to gender-specific social behavior.

Family is the most important agent of socialization because it is the center of a child's life. Socialization theory tells us that primary socialization—the process that occurs when a child learns the attitudes, values, and actions expected of individuals within a particular culture—is the most important phase of social development and lays the groundwork for all future socialization. Therefore, the family plays a pivotal role in the child's development, influencing the attitudes the child will adopt and the values the child will hold.

Socialization can be intentional or unintentional; the family may not be conscious of the messages it transmits, but these messages contribute to the child's socialization. Children learn continuously from the environment that adults create, including gender norms. For example, a child who grows up in a two-parent household, with a stay-at-home female parent and a male parent who works outside the home, might internalize these gender roles, regardless of whether the family is teaching them directly (see [Gender Role Expression](#) for more on gender roles). Gender roles within families are changing based on the changing structure of families in same-sex and other LGBTQIA+-parent families. These families show that gender stereotypes do not always apply, and gender roles within a family may be shared and dynamic over time.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Patient-Centered Care, Respecting Family Differences

**Definition:** Recognize the patient as the source of control and full partner in providing compassionate and coordinated care based on respect for the patient’s preferences, values, and needs.

**Knowledge:** Nurses must understand the multiple dimensions of patient-centered care. Involving the family, friends, and other members of the patient’s support network is crucial. The nurse must understand differences in cultural beliefs related to family and respect all family structure types.

**Skill:** During the family interview, nurses can identify patient preferences and understand their values and beliefs. This will help the nurse create an atmosphere of inclusion, respect, and sensitivity to family differences.

**Attitude:** Nurses can encourage patients to express their values and seek healthcare options aligning with them.

---

### Sibling Rank Order

The effect of sibling rank order in interpersonal family interactions varies between individuals and families. While some theories attempt to relate personality to birth order, this does not hold true for every person or in all families. Evidence does suggest that family factors, such as financial resources, social interactions, and the number of children, affect children differently based on their birth order and the circumstances within the family during their early years (Yan, 2023). Other factors affecting sibling order are parental values that change and adapt over time and interactions based on specific child personalities. Nurses can keep birth order in mind and consider factors that may affect an individual’s perceptions of health. Still, it must be viewed in the context of various other factors.

## REAL RN STORIES

---

### Sibling Rank Order After Death

**Nurse:** Gabe, RN

**Clinical setting:** Hospice

**Years in practice:** 10

**Facility location:** Florida

As a hospice RN, I interact regularly with families struggling with death, loss, and grief. I’ve encountered some families on multiple occasions. I cared for one large family during the final months of their youngest daughter, Erin’s, struggle with osteosarcoma. I cared for the family several years later during the grandfather’s battle with colon cancer. Most of the surviving children were young adults at that time. I remember the oldest son commenting on how the youngest surviving sister, Jessica, had taken on the role of “the baby of the family.”

During their interactions, the mother, father, and older siblings were seen doting on Jessica, making travel arrangements for her, and changing plans based on her preferences. There was palpable tension among some of the siblings during these instances. Some family members seemed to recognize the preferential treatment, while others, particularly the parents, did not. When the topic was approached in a conversation, the mother became tearful and the father defensive.

When I asked the oldest son about this dynamic, he said the family had never really gotten over Erin’s death. Some individual family members attended counseling independently, but no group counseling was pursued by the parents when the siblings were younger. He said, “This is just something else we have to deal with as part of her death.” Without bringing up this topic directly, I explained that the impending death of another family member would likely bring up past emotions related to Erin’s death. I encouraged family members to express their concerns with each other and make their individual needs known. I explained that discussing their grief coping strategies with one another may be beneficial for the whole family. In addition, I encouraged the family to seek counseling as a group to work through past and current grief.

---

## Subsystems

Family subsystems refer to interpersonal relationships within the family unit. These include the following:

- sibling relationships
- parental relationships
- parent-child relationships
- grandparent-parent relationships
- grandparent-child relationships

These relationships are guided by boundaries, communication techniques, shared experiences, and unspoken connections. Health subsystems within a family help buffer conflict between other members' relationships and increase individuals' abilities to cope and maintain resilience in the face of illness or adversity. These subsystems are primarily beneficial but can become toxic if dysfunctional interactions lead to **coalitions** or triangulation in which family members team up against another family member.

## Genograms

A **genogram** is a written or digital diagram showing relationships between family members. Genograms are useful in understanding kinship among family members. Genograms often indicate divorce and remarriage, as well as stepsibling relationships. More detailed genograms may note types of relationships, such as close and strained relationships. Using genograms in addition to understanding the basics of family structure will help the nurse in understanding each individual family.

## LINK TO LEARNING

## External Structure

The **external family structure** relates to how a family interacts with their community and extended family. In some families, day-to-day interactions include extended family members. In these families, multiple nuclear families may live near one another, and individual family members play important roles in the lives of others. Roles may differ in these families or may include different roles that fill childcare needs, emotional support, or financial needs. In interactions with the wider community, families support one another and seek out families with similar views and preferences. These family groups often enjoy meals together and care for each other as a family.

## Extended Family

The **extended family** is typically made up of at least three generations: grandparents, parents, and children. In families with traditional marriages or two-partner families, there are parallel generations on the mother's and father's sides. Extended families vary significantly based on culture. This variation can also affect the individual family members living within a household. In some cultures, the extended family includes cousins, aunts, uncles, great-grandparents, and any combination of these individuals. In addition, blended families will have a variety of extended family structures depending on relationship patterns. Nurses must keep these considerations in mind in promoting culturally competent care.

## External Systems

In addition to extended family, the external family structure encompasses how the family interacts within the community. This may include religious or spiritual connections, friend groups, neighborhoods, childcare connections, volunteer projects, and school/work interactions. These factors may affect individuals' health based on illness exposure, varying beliefs about health or health care, and shared interests. These community interactions also vary depending on logistics in providing care for children, individuals with disabilities, individuals with mental health disorders, or older adults.

## Ecomaps

An **ecomap** is a useful diagram that shows connections between families or family members and their social environment. Unlike genograms, which show primarily kinship relationships between family members, ecomaps can

focus on one or more individuals to help understand how this person interacts with their environment, including their family. An ecomap illustrates family dynamics and social support systems, such as church, therapists, counselors, friends, teachers, and co-workers. Social support systems may also include sports teams, hobby clubs, and spiritual influences other than church. Ecomaps can help nurses identify family strengths as well as gaps in resources or barriers to attaining quality health care. For example, in discharge planning, nurses can rely on an ecomap to help identify support resources for an older adult after a hip fracture, including close proximity to family members, supportive friends, church support, and community services, such as Meals on Wheels or library book delivery. An ecomap can also outline healthcare resources, such as primary care providers, social workers, financial representatives, medical specialists, and physical therapists. The nurse can rely on these members of the healthcare team to promote quality care for the individual. Ecomaps are dynamic tools and can be changed and adjusted as circumstances change for the family or individual (Figure 37.2).

**FIGURE 37.2** This sample ecomap displays a patient’s diverse support network. Ecomaps can help nurses identify family strengths and outline healthcare resources for patients. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## Functions of Family

The primary function of the family is to ensure the continuation of society, both biologically through procreation and socially through socialization. Given these functions, the nature of one’s role in the family changes over time. Beginning in early childhood, the family plays a pivotal role in socialization. Children learn where they fit within the social construct of their family and how their family fits within the wider social world. The parental role includes guiding and socializing children. In blended families, marriage sometimes alters legal parenthood and creates joint parental arrangements. Marriage also establishes a relationship between the extended families of the husband and wife. None of these functions are universal but depend on the culture in which the family is established.

### Environment

Family plays an important role in creating a home and community environment. Healthy interactions in the home lead to healthy long-term relationship patterns. All family relationships are reciprocal but not always equal in the ways they affect physical and emotional health. A healthy home is crucial for providing a sense of security during times of health crisis. A home environment that promotes health is free from abuse and neglect and promotes a

sense of physical and emotional safety for family members. All families have interpersonal struggles, but an overall atmosphere of respect and cooperation supports a healthy emotional environment. Families that promote shared interests, support differences, and encourage shared values among family members create a foundation for strong relationship patterns outside the family unit.

### Reproductive Function

The role of the family in reproductive function is multifaceted. The family unit is the classic unit of procreation. The creation and birth of children grow families and create additional layers of relationships with immediate and extended family. In addition, the social norms within the family regulate sexual reproduction based on the number of children, how the children are parented, and the value placed on children within the family.

### Socialization

The value of children and intergenerational relationships within the family is the basis of socialization within the community. Family is the first place individuals receive information about social norms, cultural values, and spiritual beliefs. The family has a role in social identity, social class, race, ethnicity, and religion. Some aspects of socialization are innate, while others are learned. Socialization can also be a source of conflict. For example, spiritual and cultural beliefs may be challenged as children grow and develop their own thoughts and beliefs.

### Economics

Families share financial resources in various ways. Financial resources are necessary to secure basic needs, create long-term security, and fund leisure activities. Families that struggle with low income and low socioeconomic status have higher rates of stress and mental health issues (Abrams, 2023). Increased stress levels are associated with a host of medical disease states, including cardiovascular disease and mental health disorders. Financial strain for families may relate to long-standing socioeconomic struggles and debt or unexpected events, such as job loss, injury, or national economic crises. Financial stability is also important during a health crisis, because funds may be needed for transportation, medical care, medications, or procedures. Mounting medical debt is a common issue for families in the United States. The Kaiser Family Foundation (KFF) reports that up to 41 percent of adults have some amount of debt from unexpected medical or dental expenses (2022). This debt can have long-lasting effects on family finances.

## Family Life Cycle Stages and Associated Tasks

The set of predictable steps and patterns families experience over time is referred to as the family life cycle. The family life cycle is used to explain the different processes that occur in families over time. Each stage has its own structure with different challenges, achievements, and accomplishments that transition the family from one stage to the next. For example, the problems and challenges that a family experiences as a married couple with no children are likely much different than those experienced as a married couple with teenagers. The success of a family can be measured by how it adapts to these challenges and transitions into each stage.

Early “stage” theories have been criticized for generalizing family life and not accounting for differences in gender, ethnicity, culture, and lifestyle. Less rigid models of the family life cycle account for changes in family development, such as the fact that in today’s society, childbearing does not always occur with marriage. It also reveals other shifts in the way family life is practiced. Society’s modern understanding of family rejects rigid “stage” theories and is more accepting of new, fluid models.

The family lifecycle can be categorized into five stages: independence, coupling, parenting, launching adult children, and the senior years. This concept of family stages is inclusive of a broader range of family types, such as those that do not move beyond the coupling stage, parenting that does not involve procreation but may include adoption or other circumstances of parenting, such as grandparents parenting grandchildren. In addition, this concept does not focus on marriage, which allows for the inclusion of many family types, including those that do not have a traditional marriage. Based on changing family patterns and boomerang kids (adult children who return to live in their parent’s home after having lived independently for a period of time), the senior years may not always be associated with an empty nest.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Patient-Centered Care for LGBTQIA+-Parent Families

**Definition:** Integrate understanding of patient and family values and describe how diverse social backgrounds function as sources of family values.

**Knowledge:** Nurses must consider values and preferences when caring for individuals from LGBTQIA+-parent families. Nurses must keep in mind the wide variety of ways that LGBTQIA+ families may be created, such as through adoption, insemination, or prior heterosexual relationships.

**Skill:** Nurses can encourage families to explain their family structure during the interview process and incorporate expressed values during care planning and implementation. Nurses must refrain from assuming family structure and preferences based on their own family values.

**Attitude:** By maintaining sensitivity for family diversity and the challenges LGBTQIA+ families may experience, nurses create an atmosphere of inclusivity. Nurses who take the time to understand different family structures empower the healthcare team to create high-quality patient-centered care plans.

### Independence

Most individuals progress through a stage during which they develop independence from their parents. This stage occurs traditionally during later adolescence and young adulthood but varies by culture. This stage often involves children leaving the home, finding new habits, and evaluating the gender and social roles in their family of origin. Making decisions about personal beliefs, spirituality, and values to carry through life is another task during this stage. This independence involves often becoming financially independent as well as emotionally and physically removed from parents. Young adults accomplish this task through relationship building with other adults outside the family circle, establishing work, career, or study commitments, and visualizing themselves as independent while still connected to family.

### Coupling

Coupling is the next logical stage and may occur simultaneously with independence. This involves relationships with others, defining one's sexuality, and finding shared goals with another individual. Often, the goal is creating a family, whether or not this involves having children.

### Parenting Through Adolescence

Parenting changes rapidly and drastically as children grow and develop. Parenting in the early years does have some similarities with parenting adolescents and young adults, such as setting boundaries, fostering relationships, and allowing independence; the magnitude and variations are distinct. Young children test boundaries and need clear limits while maintaining their sense of autonomy. For adolescents, parents must hold space for boundaries while allowing youth to test true independence in safe and healthy ways. Relationships are crucial during all stages of parenting but change over time. Parents who work hard to instill a strong foundation of social values in children at a young age reap the benefits of well-adjusted and emotionally healthy young adults. While this does not mean that children always make good choices, a foundation of strong relationships gives children an advantage in developing independence and healthy personal, professional, and social relationships.

## PATIENT CONVERSATIONS

### Health Care as Self-Care

**Scenario:** Sara is a 47-year-old female who works part-time as a substitute teacher. She and her husband have two teenage sons who participate in tennis, soccer, and ski racing. One son also participates in speech and debate while the other plays in the school orchestra. Sara presents to her PCP for evaluation of fatigue, weight gain, and hair loss.

**Nurse:** Hello, Sara. It's been a while since we saw you for a wellness exam. It looks like we already have your fasting blood test results to go over.

**Patient:** Yes, I finally decided to come in. I just can't seem to keep up with my sons and all of their activities. And when we have a day as a family, I'm always so tired that I just want to stay home.

**Nurse:** That must be frustrating. How long have you been feeling this way?

**Patient:** I think I've been feeling poorly for at least a year, but I've been so busy going to events and driving my kids around that I thought it was all stress-related. My husband finally told me that I had to make an appointment to find out why I felt so fatigued all the time.

**Nurse:** Your labs do show thyroid levels that deviate from the normal parameters. Many of your symptoms may be related to a thyroid issue. Your healthcare provider will discuss the results and possible treatment options with you.

**Patient:** So, it's not just life stress. I almost feel relieved that there is something physically wrong that can be fixed. I guess I need to keep better tabs on my own health so that I can enjoy time with my family.

---

### Launching Adult Children

Launching adult children can be an exciting time for families, particularly the youth embarking on the stage of independence. Parents may struggle with empty nest syndrome as children move out and begin independent lives. Some parents embrace this sense of renewed freedom; for a large portion of parents, however, this time is associated with psychosocial stress and a deep sense of grief. This relates to the physical act of children moving away from home and the emotional changes associated with role and relationship changes. This sense of loss and grief may stem from relationship and role factors as well as gender, cultural background, and current social climate within the country. While the concept of empty nest syndrome is commonly known, there are no set identified patterns of emotional or physical symptoms. Mothers tend to feel the effects of the empty nest more prominently, but this is dependent on the underlying relationship and connectedness with the youth. The risk of depression associated with launching children is increased if the parental role is associated with other prominent role changes, such as in the case of a co-occurring career change, an illness, a financial security change, or a move.

For children, this is a time of increasing independence, and success is largely based on their feelings of safety, security, love, and belonging. Young adults branch out if they have support from parents or other mentors and will attain high self-esteem and a sense of respect for themselves and their uniqueness. Safety and security are still held within the core family but become more the responsibility of the youth to maintain their health, find employment and financial security, and begin to think of a family.

### Senior Years

During their senior years, individuals focus on maintaining purpose and finding deeper meaning. They may have time to focus more on intergenerational relationships, such as with grandchildren. While they may experience new health risks and concerns, many may find joy in staying active and working to maintain the best health possible. Older adults still require love, belonging, and family security that may be found in children and their families. Depending on health status and cognition, older adults may need additional care in the home of their children or in facilities with assisted living or skilled nursing. The senior years may bring added grief due to the loss of peers to death, health concerns, loss of independence, and failing health. Intergenerational relationships play an important role in the well-being of older adults as they navigate many physical and financial changes associated with aging.

## 37.3 Family Dynamics Influence on Health Outcomes

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine healthy outcomes influenced by family dynamics
- Recognize unhealthy outcomes influenced by family dynamics
- Describe the effects of illness on family dynamics

Family dynamics play a major role in the health outcomes of all family members. Depending on the dynamics, individuals may experience positive or negative health outcomes. While family dynamics may be ingrained, often the dynamics between family members fluctuate and change based on factors such as the following:

- physical proximity
- financial crises

- medical conditions
- births
- deaths
- coping skills
- emotional connection
- interpersonal relationship skills

Healthy relationships among family members and healthy habits practiced by families lead to positive health outcomes. Overall health may be better, and acute illness recovery may improve. Even in chronic disease, healthy family relationships are associated with better outcomes and a better sense of overall well-being. Long-term negative family interactions are related to emotional distress and physical stress symptoms, which can increase the risk of a variety of health conditions. In addition, lifestyle factors and habits can also increase individual risk for certain types of cancers and gastrointestinal disorders (Salzmann et al., 2022). Most families and individuals have a combination of positive and negative family dynamics that affect their overall and long-term health. Nurses must consider these factors when creating care plans for individuals and families dealing with health crises.

### Positive Health Outcomes Influenced by Family Dynamics

Healthy interpersonal relationships between family members, particularly those who live together, result in many health benefits. These include better sleep, relationship resilience, lower stress levels, and positive health promotion habits. These factors promote physical and psychological health and improve resilience and coping in the face of acute or chronic health conditions that do develop. Individuals with a strong sense of well-being and family support can better manage the increased stress of an illness and overcome the struggles (Barnes et al., 2020). Positive health practices within a family strongly predict continued healthy practices generationally. For nurses, focusing on the family aspects that lead to healthy outcomes and concentrating on the whole family changes to meet health goals can improve health outcomes.

#### Effects on Sleep Health

Sleep habits and patterns are crucial for health. Sleep is among the first level of basic needs in Maslow's hierarchy of needs. Factors, such as nutrition, safety and security, physical environment, and emotional interactions play a role in the overall quality of sleep, which is directly related to individuals' health over time. Recent studies have found that positive family relationships and family member support are particularly important for adolescent sleep quality and duration. They experience better cognitive development, better performance in sports and school, and improved interpersonal relationships with non-family members (Maratia, 2023).

#### Effects on Interpersonal Relationships

The basis for interpersonal relationships begins with the family. Family relationships with low stress and a sense of security allow individuals to establish a norm for interpersonal relations. Positive family relationships promote wellness and the ability to be resilient in the face of adversity. Interpersonal conflicts arise within families, but healthy family dynamics allow individuals to resolve these conflicts in a safe and emotionally safe environment. This gives individuals a basis for resolving interpersonal conflict in the wider community and in other personal relationships.

#### Effects on Stress Level

Stress is affected by sleep, emotional responses, physical safety, and overall mental health. Positive family dynamics set a foundation of emotional security, which results in lower stress levels, the ability to achieve restorative sleep, and the development of coping strategies to manage varied levels of stress. Positive family dynamics minimize interpersonal stressors within these close relationships, creating more resilience when dealing with outside stressors.

### Negative Health Outcomes Influenced by Family Dynamics

Dysfunctional family dynamics have the opposite effect on the same health outcomes, leading to negative consequences and the development of health conditions. Additionally, ACEs play a role in poor resilience and coping, which can lead to negative health factors and disease. Unhealthy family dynamics can lead to health disorders such as the following:

- depression
- anxiety
- atherosclerosis
- cancer
- diabetes
- asthma
- ulcers
- addiction

For nurses, recognizing dysfunctional family patterns is the first step in helping families create better relationships and coping skills and decreasing the frequency of avoidable ACEs. Nurses can be alert for the following:

- signs of violence, abuse, or neglect (physical or emotional)
- substance use problems
- mental health disorders (diagnosed or undiagnosed)
- family structure instability (separation, incarceration)
- family financial insecurity (housing and food insecurity)

### Poor Sleep Quality

While sleep loss may result from specific sleep disorders, emotional stress associated with negative family dynamics can also significantly affect sleep. Poor sleep duration and quality are linked with a variety of negative health outcomes and disease conditions. Specifically, cumulative sleep loss is associated with health conditions, including hypertension, diabetes, obesity, depression, heart attack, and stroke.

Nurses can help promote better sleep for families by addressing the factors related to financial concerns, illnesses, and relationship strain, and connecting families with social workers. Nurses can address dysfunctional family patterns by promoting mental health care, encouraging socioemotional coping techniques, and referring families to trained counselors. In addition, nurses can offer all families tips for improving sleep, such as the following:

- limiting screen time, especially before bed
- providing security within the home
- providing a quiet sleep environment
- limiting consumption of digital violence
- providing healthy meals and limiting sugar and caffeine
- promoting sleep hygiene and sleep/wake routines

### Handling Stressors and Developing Coping Mechanisms

Family stressors are multifactorial. Some internal family factors, including adverse childhood experiences (ACEs), may trigger a stress response. External factors can increase the stress level for the family as a whole and subsequently for individual family members. Children exposed to high stress levels and ACEs during childhood develop many lasting consequences that can affect future relationships, job performance, learning ability, and social interactions throughout life. Family interactions affect stress levels on a continuum from high-level support to severe dysfunctional stress. Stress has emotional, physical, and psychological effects that can be long-lasting. External stressors, such as illness, sudden financial strain, job loss, and death can all change family dynamics.

In families with healthy coping and high support levels, individuals will better cope and experience fewer symptoms of stress ([Table 37.4](#)). In families with poor coping skills, the effects of stress can lead to physical and mental disorders. Stress may impair communication, leading to fighting, arguments, and fatigue. For children, this may create confusion about family relationships and a sense of insecurity. This can develop even in families with strong relationships and can be harmful in families with already high stress levels.

Nurses can help families cope with stress, particularly in dealing with illness, death, or family structure changes, by encouraging family members to do the following:

- Discuss their emotions.
- Set individual and family boundaries.
- Work together.
- Listen carefully for solutions.

- Focus on healthy habits.

Nurses' communication skills will be one of the best assets in managing families with high stress levels and poor coping skills. Nurses can model effective communication, including active listening and respect.

Positive Coping Skills	Negative Coping Skills
<ul style="list-style-type: none"> <li>• Talking</li> <li>• Seeking help from healthcare providers or counselors</li> <li>• Addressing shame response</li> <li>• Mindfulness</li> <li>• Confronting the issue</li> <li>• Physical exercise</li> <li>• Engaging in enjoyable activities</li> <li>• Discovering and avoid triggers</li> </ul>	<ul style="list-style-type: none"> <li>• Dysfunctional communication</li> <li>• Lack of communication</li> <li>• Isolation</li> <li>• Avoidance</li> <li>• Jumping to conclusions</li> <li>• Substance abuse</li> <li>• Relationship sabotage</li> <li>• Dopamine seeking (e.g., excessive gambling, videogaming, social media consumption, or risky behavior)</li> <li>• Excessive worrying</li> </ul>

**TABLE 37.4** Coping Skills

Nurses can focus on helping families find coping strategies that fit their family dynamics. Some families will prefer meaning-focused coping, which uncovers what a family problem means and how to address the associated feelings of distress (Algorani & Gupta, 2023). Some families will focus on the problem and finding a solution, while others will be drawn to minimizing negative emotions and creating a safe and positive environment (Algorani & Gupta, 2023). In addition, families and individuals may seek an external social support system to help cope with emotional stress. A combination of these strategies is also common and beneficial.

### Adverse Childhood Experiences

Some families struggle with high stress levels due to financial, socioeconomic, and interpersonal relationships. In more extreme cases, individuals experience **adverse childhood experiences (ACE)**, negative experiences in childhood that affect long-term physical and emotional health. Some ACEs are related to family social interactions, and others are external events shaping family member interactions. ACEs are common and have varying degrees of effect on individuals based on how the family responds to the events. ACEs include the following (Wang, 2021):

- parental death
- parental mental illness
- financial hardship
- food insecurity
- housing insecurity
- physical violence
- sexual violence
- emotional violence
- community violence

Because ACEs elicit high-level stress responses, they are associated with similar disease risk as the stress from other triggers. High-level ACEs and childhood trauma have the potential to be perceived intergenerationally. One of the most important parts of breaking this cycle is recognizing, acknowledging, and addressing the ACE and its long-lasting emotional effects. Nurses can focus on encouraging adults to address childhood ACEs through appropriate psychiatric evaluation, counseling, and interventions to break the cycle (Panisch et al., 2020).

### Increased Risk of Addiction

Addiction is also strongly associated with strained family dynamics. This is especially true for families in which addiction is prominent and many individuals struggle with addiction. Strong family connections can help individuals with addiction develop better coping skills. Relationships among family members affect an individual's ability to maintain abstinence and retain confidence in their ability to achieve and maintain abstinence while in recovery (Ram et al., 2016). Mental health disorders can increase the prevalence of substance use disorders. Mental health

disorders, such as anxiety and depression, when associated with ACE or dysfunctional family relationships, can lead to poor coping mechanisms, including substance misuse.

### Increased Risk for Aggression

Like addiction, aggression and violence can perpetuate intergenerationally within a family and often are correlated. Aggression may develop into physical violence or emotional violence, which is harmful to all family members involved. One study showed that repeated daily negative family interactions may be more strongly associated with long-term anxiety and depression than ACEs in which the individual was victimized (Morelli et al., 2023). This study also found that the dysregulation of one family member, whether a child or a parent, and the subsequent impaired communication and relational disruptions can affect all family members long-term. Aggression and violence risk is increased by intergenerational family violence and aggression, genetic risk, high stress levels, and harsh parenting styles. Conversely, adaptive family coping, including a sense of love and warmth, structure, and a shared experience, is associated with less aggression and violence.

### Effects on Cardiovascular Health

Individual family members tend to develop common habits, both positive and negative. Common health factors affected by family habits include cardiovascular and metabolic health. In addition, lifestyle factors and habits can also increase individual risk for certain types of cancers and gastrointestinal disorders (Salzmann et al., 2022).

Increased stress and dysfunctional family dynamics are associated with atherosclerosis and plaque build-up that is directly related to cardiovascular disease risk (Salzmann et al., 2022). Risks include coronary artery disease (CAD), stroke, and myocardial infarction (MI). ACEs are associated with negative family relationships and subsequently with cardiovascular disease in adulthood (AHA, 2024). One study suggests that over time negative family interactions during youth are associated with an increase in cardiovascular health risk as an adult (Chai & Almeida, 2023). Family habits that negatively affect cardiovascular health may include poor dietary and nutrition choices and lack of physical activity, while positive habits include engagement in joyful activity and shared hobbies. Nurses can address these issues at the family level by focusing interventions on improving diet, weight management, and increasing overall physical activity (Vedanthan et al., 2016).

Shared family health behaviors predict cardiovascular health and, specifically, hypertension (HTN) risk. Studies confirm that lifestyle factors, such as diet, exercise frequency, and sleep behaviors are associated with HTN risk (Gunn & Eberhardt, 2019). As discussed, family interaction and shared habits affect sleep habits and quality, which in turn affect the risk for HTN. Hypertension itself is a risk factor for progressive and severe cardiovascular disease states, including stroke, heart failure, and MI. In addition to family-behavior risk, HTN risk may also be inherited. This further increases the individual risk of developing HTN.

In caring for individuals with cardiovascular disease and HTN, nurses can focus on modifiable lifestyle changes and changes in shared family habits. Nurses can also recognize the presence of familial risk factors and discuss the importance of reducing these risks with healthy choices in sleep hygiene, dietary decisions, limiting nicotine and alcohol, and improving exercise frequency.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Hypertension

**Recognize clues:** The nurse is caring for a 57-year-old male in a primary care clinic. The patient is attempting to renew his commercial driver's license medical certificate. The nurse notes a blood pressure of 162/94 using an automatic cuff. The patient's BMI is 29.

**Analyze clues:** The nurse waits 10 minutes and rechecks the patient's blood pressure using a manual cuff. At this time, the blood pressure is 145/92. The nurse asks about family history and lifestyle factors and identifies the following risk factors:

- father had MI at age 60
- consumes of three to four alcoholic drinks per day
- smokes ¼ pack per day
- is "too busy" to exercise

**Generate solutions:** The nurse alerts the healthcare provider of the elevated blood pressure and gathers materials to reinforce the teaching about high blood pressure.

**Take action:** The nurse offers a discussion and handouts related to hypertension risk and lifestyle factors that influence this risk. The nurse also discusses findings with the healthcare provider so that medical interventions can be offered.

### Effects on Metabolic Health

As with HTN, the risk for obesity is strongly correlated with family dynamics, shared family behaviors, and family genetic history. The World Health Organization (WHO) classified obesity as a distinct disease state based on an increased body mass and excessive fat deposits (WHO, 2024). Obesity and overweight are widely prevalent worldwide, and the percentage of adults with a higher weight and obesity is shockingly high at 43 percent and 16 percent, respectively (WHO, 2024). Recent studies show that obesity remains on the rise, particularly in children and adolescents. Drivers of obesity within the body are complex and determined by endocrine system function. Many factors play a role in obesity, though, including psychological factors, genetics, psychosocial factors, and economic factors (Wang et al., 2022). Family sedentary lifestyles, financial hardship and poverty, and unhealthy food choices are directly related to the incidence of childhood obesity (Wang et al., 2022). Other factors that predict higher obesity rates are parental depression and authoritarian, permissive, and uninvolved parenting styles. Unmodifiable family factors that affect obesity risk include ethnicity and family history of metabolic disorders such as PCOS, thyroid disorders, and type 2 diabetes.

Obesity is a complex disorder that is associated with an increased risk for many other diseases, including cancers, cardiovascular disease, HTN, diabetes, digestive disorders, lung disease, depression, and anxiety (WHO, 2024). Many of these disease states have a reciprocal correlation with obesity, both resulting from and potentiating factors that increase obesity. Nurses can focus on various family-level interventions to help improve individual and family choices and behaviors to reduce these risks.

### Effects of Illness on Family Dynamics

Acute and chronic illness is hugely impactful on the lives of individuals and how they interact in the community and within their families. In families with positive and stable interpersonal interactions, illness can create a crisis that creates a disequilibrium in the family dynamics. For families that struggle with negative or dysfunctional baseline dynamics, illness can cause a complete breakdown in family functioning. Conversely, illness may unexpectedly create a sense of closeness and support for struggling families. The most important aspect of family dynamics in the face of illness is coping strategies and the strength of relationships. In addition, the type of illness, duration of illness, severity, financial stability, and cultural aspects will also determine the long-term family outcomes.

### Lifestyle Alterations

In responding to a new or ongoing illness, families must adapt by changing lifestyles and behaviors. This will depend on whether the disease is acute or chronic and whether it is stable or progressive. The family response also depends on whether the disease results in cognitive or physical impairments. Families will create changes based on the needs of the sick individual. Depending on illness, family changes may significantly improve the outcomes for the individual. For example, family-wide dietary and nutrition changes will substantially reduce obesity and cardiovascular risk. For individuals with chronic or progressive diseases, long-term changes in physical activity, tobacco use, alcohol use, and diet often improve physical symptoms.

### Role Modifications

In response to illness, particularly acute or progressive diseases, families often experience a change in roles. For example, in an older adult diagnosed with Alzheimer disease, moving into a child's home and experiencing more dependence changes the role of the parent to a more dependent role and the adult child to a caregiver role for the parent. This is sometimes referred to as role reversal. This can be a source of tension between family members, particularly as the older adult adapts to a change in independence and autonomy. Role modification also develops if a parent in a young family becomes ill; older children may need to take on caregiving roles for younger children.

In chronic illness, the parent or child may take on a sick role in which their social roles, such as work outside the home and family work, change. This affects the whole family and can lead to resentment if not openly addressed.

The family and individual can work together to address this sick role in a way that benefits all and improves the quality of life for the sick individual and the overall interactions and relationships between family members. Sibling roles also change during illness, but it is highly dependent on the type of illness. In long-term or progressive diseases, such as cancer, sibling relationships are affected by not only the outcome of the sibling's illness but also how parents and other family members react to the illness.

## CULTURAL CONTEXT

---

### Sick Role Behavior

Sick role behavior is a concept that explains the actions and expectations of individuals experiencing an illness or health crisis. This behavior influences the sick individual and their family. Illness role behavior is affected by ethnicity, culture, age, personality, social support, family dynamics, and type of illness. Depending on underlying family and societal values, these behaviors may be viewed as positive or negative. Changes in the expectations of the family and society of the sick person reinforce the sick role behaviors. Sick role behaviors may look like:

- health anxiety
- illness denial
- reduced expectations for the sick individual
- family tension related to focus on illness
- attention seeking by non-sick family members

Recognizing sick role behaviors is essential for the nurse in caring for the family. In particular, nurses must be alert for prolonged or disruptive behaviors that threaten the integrity of family relationships (Cosci & Guidi, 2021; APA, 2023).

---

### Socioeconomic Adjustments

Illness can present a high financial burden, especially if it is a progressive or chronic illness. Medical treatments and procedures pose a substantial economic burden. In addition, patients experiencing disease and family members providing care, particularly for children, may lose work hours, resulting in additional financial strain. Changes in the frequency of social interactions, work hours, and community support may change over the course of an illness. Families may struggle with coping, grief, and fear, all of which can affect the way families interact within their social network and can directly affect economic input into the family.

### Task and Function Changes

Family tasks and functions change depending on the lifecycle stage of the family at the time of illness, as well as which family member develops the illness. Caregiver tasks may increase depending on the type of illness. The function of the family may also change. In families with adult children, a sudden illness may create a resumption of direct parental caregiving activities. In families where a parent becomes ill, children may take on household duties, caregiving for the parent or younger siblings, and even begin working to help support the family financially. This may affect their ability to perform school functions, which can have long-term socioeconomic effects on the child and the family. Leisure time may also be affected, creating an environment of stress and fatigue that increases the risk for depression and anxiety.

## 37.4 The Nurse's Role in Caring for the Family Unit

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Describe actions involved in the nursing assessment of the family
- Understand different nursing interventions to promote family health
- Verbalize how the nurse collaborates with interprofessional teams

The nurse's role in caring for the family unit begins with a comprehensive family assessment, including therapeutic conversation techniques. An overview of family functioning also includes assessing individual roles within the family. Understanding the family values and behaviors allows the nurse to recognize specific needs and customize care plans for the family. Nurses will collaborate with other medical and social work professionals to create family care

plans.

## Nursing Assessment of the Family

The nursing assessment of the family involves direct assessment of an individual and their family members. This adds a further dimension to the nursing assessment by evaluating the individual through the lens of family interaction. This includes observing interactions between family members and between the family and other individuals, such as healthcare providers, friends, or community members. For nurses, keeping in mind the elements of therapeutic conversation will improve their ability to understand family dynamics. A detailed assessment of the individual and family helps the nurse uncover risk factors that may play a role in health and illness.

### Observation

Observation is an ongoing assessment tool that is paramount for nurses. In caring for families, nurses will be alert to positive interpersonal and negative interactions among family members. Nurses will use their observation skills to identify the most prominent support persons and identify cultural values within the family that can affect healthcare access, compliance, and recovery and outcomes. Nurses can observe individuals interacting in person and notice how patients discuss their families. In cases of family dysfunction, the nurse must remain alert for any signs of abuse, neglect, or emotional trauma. Nurses who care for families on multiple occasions or repeatedly over a long duration can develop relationships with patients, allowing them to notice subtle changes within the family that may give clues to illness.

### Therapeutic Communication

Therapeutic communication is crucial in all nurse-patient interactions (Table 37.5). In caring for families, nurses must maintain respect for family values and culture. Nurses can recognize verbal and nonverbal cues from family members. When families struggle with illness or health crises, keeping communication to the point may help them retain needed information and process it as a group. Families need time to discuss options, clarify plans, and create a shared experience around the health crisis. Nurses can use techniques in family discussions, such as beginning with broad topics and moving to more specific intervention and treatment discussions. Nurses should consider differing views and values within the family when discussing treatment options. The nurse should also consider the privacy of the patient. In most cases, the patient must request that a family member be present during an assessment or discussion about their health care. This includes telephone discussion and electronic communication methods. The nurse must be able to explain healthcare privacy rules to families clearly. This will vary depending on the age of the patient, child versus adult. This ensures that patients understand their privacy is respected and that family members understand their roles and rights with regard to family member health information.

Therapeutic Techniques	Definition	Example
Acceptance	Acceptance acknowledges a patient's emotions or message and affirms they have been heard. Patients who feel their nurses are listening to them and taking them seriously are more likely to be receptive to care.	Patient: "I hate taking all this medicine. It makes me feel numb." Nurse (making eye contact): "Yes, I understand."
Clarification	Clarification asks the family member to further define what they are communicating. It helps nurses ensure they understand what is actually being said and can help patients process their ideas more thoroughly.	Mother: "I feel useless to my child and my family." Nurse: "I'm not sure I understand what you mean by useless. Can you give an example of a time you felt useless?"

**TABLE 37.5** Therapeutic Communication Techniques for Families

Therapeutic Techniques	Definition	Example
Focusing	Focusing on a specific statement made by a patient that seems particularly important prompts them to discuss it further. Patients don't always have an objective perspective on their situation or past experiences, but as impartial observers, nurses can more easily pick out important topics on which to focus.	Patient: "I grew up with five brothers and sisters. We didn't have much money, so my mom was always working and never home. We had to fend for ourselves, and there was never any food in the house." Nurse: "It sounds as if you experienced some stressful conditions growing up."
Giving recognition	Giving recognition acknowledges and validates the family's positive health behaviors. Recognition acknowledges behavior and highlights it without giving an overt compliment.	Nurse: "It sounds like you've been enjoying your time exercising together."
Open-ended questions/ offering general leads	Therapeutic communication is most effective when patients direct the flow of conversation and decide what to talk about. Giving families a broad opening such as "What would you like to talk about?" is a good way to encourage clients to discuss what's on their mind.	Father: "I'm unsure of what to do next." Nurse: "Tell me more about your concerns."
Reflecting	Reflecting asks patients what they think they should do, encourages them to be accountable for their own actions, and helps them come up with solutions.	Daughter: "Do you think I should encourage my mom to accept this new dementia treatment?" Nurse: "What do you think the pros and cons are for the new treatment plan?"
Making observations	Observations about the appearance, demeanor, or behavior of patients can help draw attention to areas that might pose a problem for them.	Nurse: "You look tired today." Mother: "I haven't been getting much sleep lately because of how worried I am about my daughter's health."
Offering hope	Offering hope encourages a family to persevere and be resilient.	Nurse: "I remember you shared with me how well your family adapted when your niece was diagnosed with diabetes."

**TABLE 37.5** Therapeutic Communication Techniques for Families

### Identify Risk Factors

Nurses who focus on therapeutic communication and have excellent listening skills will find that they can identify patient and family risk factors in nearly every patient interaction. The things that patients say, their visible interactions with others, and their subtle nonverbal communication will give clues to risk factors. In addition, identifying important aspects of the family history is crucial. Creating a sense of rapport with patients allows nurses to obtain detailed information in a safe atmosphere.

Disease risk factors are present within the family history. The nurse asks questions that elicit information about the

health status, age, and, if applicable, cause of death and age at the time of death of blood relatives (parents, grandparents, siblings, children, nieces, nephews). Questions to ask include the following:

- Tell me about the health of your blood relatives. Do they have any chronic or acute diseases (e.g., cardiac, cancer, mental health issues)?
- Have any of your blood relatives died? If so, do you know the cause of death? And at what age did they die?

Nurses also want to assess the health status of non-blood relatives and individuals that clients have had close encounters with or live with; this can be an essential part of the assessment, particularly in terms of **communicable diseases**. Questions to ask include the following:

- Tell me about the health status of those you live with. Has anyone been sick recently? If so, do you know the cause? What symptoms have they had?
- Have you been around anyone else who was sick recently (e.g., at work, at school, or in a location that involved a close encounter, such as a plane or an office)?

### Nursing Interventions to Promote Family Health

Nurses must focus on individual patients and their families in providing care for families. Because many health habits, outcomes, risks, and diseases develop in the context of family habits and behavior, focusing on treating the whole family will improve outcomes for all. In addition, specific family interventions ensure that individuals with illness can recover within a supportive and healthful family environment. Researchers explain that health begins at home and that the family directly influences individuals' health (Hanson et al., 2019). Nursing care for the family can focus on primary prevention and risk assessment, disease education, medication and treatment management, connections with community, and healthcare resources. In these interactions with families, nurses can consider aspects including the following (Hanson et al., 2019):

- family engagement: relationship patterns that support individual well-being
- family responsibility: caretaking ability and advocacy for family members
- family stability: the resilience of the family structure in the face of health crisis
- family diversity: varying family values and roles that affect health outcomes

Nurses can apply these considerations to various areas that are important in providing family-based interventions for patients.

#### Education

Family-directed education may be focused on individual patient education that incorporates the family as a support system. In caring for families, nurses encounter situations where education for the whole family is important, such as in family planning, prenatal care, and well-child care. These educational opportunities may arise at dedicated visits but may also be incorporated into other patient interactions as appropriate. One primary goal of family education is reducing health risks and preventing disease. Risk reduction considers family genetic history, disease history, lifestyle, cultural beliefs, and values about health care. Nurses need to assess each family member's engagement and understand each family member's responsibility within the group. Having an idea of family stability will also guide education, as a high-risk family may require more focus on high-risk concerns. In contrast, a stable family may be focused more on preventative measures to improve and maintain health. Understanding family diversity also helps the nurse personalize the education plan, create interventions that are appropriate and culturally sensitive, and offer treatments that have a high likelihood of follow-through.

#### Screening for Risk

A significant part of nursing care of the family relates to developing a plan for determining family risk. This may include risk factors that run in the family, such as cancers, cardiovascular disease, and diabetes. Nurses must discuss health risks with individual family members and enlist the help of other family members as necessary in putting together a family ecomap or genogram that may uncover genetic risk factors. Nurses can encourage families to take responsibility for minimizing risks, particularly modifiable ones. This will often include behavior modifications to improve lifestyle, which may consist of parents taking responsibility to avoid tobacco use, limit alcohol use, exercise with their children, and provide and role-model healthy eating habits. Other screening for families includes prenatal screening, autism screening, and genetic testing in families in which certain cancer types are prevalent. Nurses must be aware of family cultural values and beliefs about health care when recommending

screening. Nurses can also be advocates for routine screening for depression and mental health disorders that are known to cause ripple effects through the family structure if not diagnosed and treated. A variety of screening tools are available to assess individuals for depression, for example. Nurses can also use family assessment tools to identify families at risk for addiction concerns, violence, economic strain, or abuse. Understanding these psychosocial risks within a family helps the nurse create a treatment plan that includes appropriate community resources.

### Pharmacological Management

While pharmacological management is primarily focused on individual care, it becomes the family's responsibility in situations where family members are also caregivers, such as with children. Other conditions in which a family member may be responsible for medication management include the following:

- developmental delays
- dementia
- debilitating mental health disorders
- physical disabilities

Nurses evaluate the need for family interventions regarding medication education, administration, and long-term management. Family stability and engagement are important in medication management because creating an appropriate medication regimen is crucial for adherence as well as the efficacy of medication therapy. The teach-back method is the gold standard for education about health-related treatments and medications. This is particularly important for medications administered through injection, such as insulin. This method can be adapted to include family members engaged in medication administration and assistance. Consulting family members is also an effective way to help determine the response and effectiveness of the medication, particularly in cases of mental health disorders and behavioral health disorders.

### Referrals to Community Resources

Nurses will find themselves frequently making referrals to various community resources for families. These resources may be directly related to a chronic or acute health conditions. In addition, community resources are available to help families obtain and maintain basic needs. These resources may include the following:

- housing assistance
- state Medicaid services
- nutrition services
- family planning clinics
- mental health support services
- autism support services
- home safety services
- educational services, such as HeadStart
- substance use support services
- youth homes
- disease-specific support groups
- WIC (Women, Infants, and Children)

## LIFE-STAGE CONTEXT

---

### Autism Screening

Autism spectrum disorder (ASD) is a prevalent and fast-growing bio-neurological developmental disability. It is most often diagnosed in childhood, although adolescent and adult diagnoses of less severe cases may occur. Nurses can be alert for specific risk factors that may indicate that screening for ASD is warranted. These risk factors include the following:

- genetic disorders
- sensory integration dysfunction
- sleep disorders

- autoimmune disorders
- speech delay
- anxiety disorders
- behavior concerns
- feeding problems

Nurses must focus on identifying risk factors and referring for screening. Screening is essential, as early diagnosis and intervention are the keys to limiting the impact of ASD on the individual and the family (National Autism Association, n.d.).

---

### Collaborate with Interprofessional Team

Nurses collaborate with professionals from many other specialties when caring for families. Depending on the type of needs of the family or individual within the family, the nurse may collaborate with the following:

- physical therapists
- occupational therapists
- speech therapists
- mental health professionals
- spiritual advisors

### Therapists

Family therapists and counselors will focus primarily on the health of the family as a whole and interactions among the family members. Nurses may refer patients and families to therapists to address long-standing issues and develop coping strategies for acute health crises. In addition, mental health concerns within the family, past trauma, death and grief, divorce, stress, sudden change, and other dysfunctional dynamics are triggers for therapy referral. Common types of counseling for families include the following (Cleveland Clinic, 2022):

- **functional family therapy:** focuses on behavior, communication, and parenting skills
- **relationship counseling:** focuses on communication and problem-solving for couples in a long-term or romantic relationship
- **strategic family therapy:** focuses on making structural and behavioral changes to improve the overall family environment
- **structural family therapy:** focuses on interpersonal relationships among family members
- **systemic family therapy:** focuses on family issues within the context of their wider system, such as cultural, religious, and socioeconomic status

Nurses must understand that families are dynamic, and therapy may be needed for a long or short duration depending on the individual family dynamics.

### Social Workers

Nurses and social workers share similar goals for family care and work hand-in-hand to create healthy environments for families. While nurses make referrals to medical specialists, ancillary specialists, and disease-specific specialists, social workers help address the many environmental constraints and burdens on a family. Nurses ensure that families in health crises can access social work services to help address these and other logistical concerns. Some social workers are trained in mental health counseling as well. They help families navigate complicated family and healthcare dynamics. They also apply their knowledge of family dynamics to create individualized care plans that address factors such as the following (Tadic et al., 2020):

- prevention and health promotion
- home visits
- lifestyle counselling
- financial advocacy
- housing assistance
- substance use recovery
- employment guidance
- interpersonal relationship

- communication counseling
- crisis intervention

## Summary

### 37.1 Family Concepts

Defining family is a complex and culturally sensitive topic. For legal and census purposes, families may be described as individuals living together or as related individuals with shared financial resources. For nurses, maintaining respect and consideration for how individuals define their families is the most critical aspect of caring for families. Nurses must understand the interactions among family members and how the family interacts with their environment and community. In particular, understanding the health beliefs of the family will contribute to better care planning. Considering family habits and lifestyle factors is as important in promoting family health as heredity, familial illness, and genetic factors.

Understanding family assessment tools is important in providing comprehensive care. These assessment tools help nurses apply family dynamics theories to identify strengths and weaknesses and provide guidance for families struggling with health crises. Applying the Calgary Family Assessment Model and the Friedman Family Assessment Model helps nurses understand family structure, interactions, and communication patterns. Understanding theories of family function, including systems theories, Bowen's theory, and communication theory, helps nurses effectively interact with families. Nurses can better identify family needs and develop the therapeutic relationship by understanding how family dynamics affect family-member interactions.

### 37.2 Family Framework

Understanding the various structures of families is important for nurses in creating inclusive and patient-centered care. This includes an understanding of the concept of family types, roles within the family, gender roles, and sibling birth order. Families are defined in many ways and differently throughout the life stage of the family. Family composition is dynamic and changes over the life cycle of the family. Nurses must consider the importance of families in socialization, relationship building, and emotional security. Nurses can understand family structures and relationships through genograms and ecomaps. Ecomaps help nurses to visualize how family members interact with each other as well as how families interact within their community.

The function of the family is multifaceted and includes factors such as economics, physical environment, reproduction, and socialization. The family life cycle is a set of stages that a family progresses through based on births, deaths, and family member age. The family life cycle progresses as the family members age and move through various life stages. The family life cycle stages include independence, coupling, parenting, launching, and the senior years. These life stages affect both individual and family health.

### 37.3 Family Dynamics Influence on Health Outcomes

Family dynamics can have positive and negative effects on health outcomes. Relationship patterns, coping skills, finances, and communication techniques affect how families experience wellness and illness. Positive family dynamics have a beneficial effect on sleep patterns, resilience, and health promotion. Healthy family habits reduce risk factors for disease. Conversely, dysfunctional family interactions negatively impact health outcomes and are correlated with specific health disorders. Negative family interactions increase the risk for cardiovascular disease, metabolic diseases, mental health disorders, and substance use disorders. Nurses must focus interventions on encouraging healthy habits, altering family habits contributing to disease states, and educating families about disease risk.

Acute and chronic illness is hugely impactful on the lives of individuals and how they interact in the community and within their families. The most important aspect of family dynamics in the face of illness is coping strategies and the strength of relationships.

### 37.4 The Nurse's Role in Caring for the Family Unit

To understand the family unit, nurses must perform a comprehensive assessment that involves observing family interactions, identifying individual roles, and recognizing communication patterns. By recognizing the role of the family in an individual's health care, nurses can effectively include the family to promote healing. Nurses use therapeutic communication techniques to elicit information and address the family's concerns. These communication techniques may include acceptance, recognition, open-ended questions, and hope.

Nurses use observation and interviews to identify risk factors guiding necessary interventions. Primary nursing interventions for families include education, risk screening, pharmacological management, and referrals to communication resources. Nurses also collaborate with other healthcare and ancillary specialties to care for families. This teamwork approach promotes a holistic view of the family and ensures that the family's health, social, and emotional needs are addressed.

## Key Terms

**accuracy** a person's perception of the other person's evaluation reflects the other person's actual perception  
**adverse childhood experiences (ACE)** negative experiences in childhood that affect long-term physical and emotional health

**agreement** the individuals have the same perception

**boundaries** distinct emotional, psychological, or physical separateness between individuals, roles, and subsystems in the family

**co-orientation** when two or more people experience the same physical or emotional input and develop a corresponding perception or response

**coalition** a situation in which family members team up against another family member

**conformity** communication patterns in which family members are expected to follow hierarchical family values

**congruence** an individual's perception and the other person's perception are similar

**conversation** communication patterns in which family members are encouraged to evaluate topics independently and discuss them with the family

**ecomap** a diagram that show connections between families or family members and their social environment

**extended family** a family group typically made up of at least three generations: grandparents, parents, and children

**external family structure** how a family interacts with their community and extended family

**familial disorder** disease that tends to present among individuals from the same family line

**family** socially recognized group, usually joined by blood, marriage, cohabitation, or adoption, that forms an emotional connection and serves as an economic unit of society

**family composition** the design of a family structure, including relationships between members

**family life cycle** the set of predictable steps and patterns families experience over time

**family of orientation** the family into which a person is born

**family of procreation** the family that is formed with the intention of bearing children

**family structure** the internal and external makeup of families

**functional family therapy** focuses on behavior, communication, and parenting skills

**genetic disorder** caused by a change in a genetic DNA sequence or a mutation in a gene or multiple genes

**genogram** written or digital diagram showing relationships between family members

**hereditary** when a disorder is passed naturally from parent to offspring through their genes

**relationship counseling** focuses on communication and problem-solving for couples in a long-term or romantic relationship

**strategic family therapy** focuses on making structural and behavioral changes to improve the overall family environment

**structural family therapy** focuses on interpersonal relationships among family members

**systemic family therapy** focuses on family issues within the context of their wider system, such as cultural, religious, and socioeconomic status

## Assessments

### Review Questions

1. What family-based factor contributes to emotional protection for adolescents?
  - a. two working parents
  - b. the presence of siblings
  - c. a sense of belonging
  - d. higher family income
2. What definition of family is used by the U.S. Census Bureau?

- a. a socially recognized group (usually joined by blood, marriage, cohabitation, or adoption)
  - b. a socially recognized group that serves as an economic unit of society
  - c. a group in which people come together to form a strong primary group connection
  - d. a group of two people or more (one of whom is the householder) related by birth, marriage, or adoption and residing together
3. In what way do family assessment models help nurses care for patients?
- a. Provide specific interview questions to ask all patients.
  - b. Guide nurses in understanding family structure and dynamics.
  - c. Help nurses classify families as functional or dysfunctional.
  - d. Teach nurses how to provide effective family counseling services.
4. According to the CFAM, what are the key ingredients in a 15-minute interview?
- a. manners, therapeutic communication, spiritual evaluation, risk assessment
  - b. therapeutic communication, spiritual evaluation, genograms, acknowledgment of strengths
  - c. spiritual evaluation, genograms, manners, risk assessment
  - d. genograms, therapeutic communication, manners, therapeutic questions
5. According to the family communication patterns theory, what is it called when two or more people experience the same physical or emotional input and develop a corresponding perception or response?
- a. accuracy
  - b. co-orientation
  - c. congruence
  - d. consensual
6. Which factors affect family composition?
- a. birth, death, career
  - b. birth, geographic location, divorce
  - c. birth, death, emotional dysfunction
  - d. birth, death, marriage, divorce
7. Genograms are useful for nurses to visualize which aspects of the family?
- a. future careers
  - b. relationships with spiritual advisors
  - c. interactions with healthcare providers
  - d. sibling birth order and relationships
8. What are two primary functions of the family?
- a. procreation and socialization
  - b. marriage and procreation
  - c. financial security and marriage
  - d. procreation and sibling relationships
9. A patient's family member asks how they will be billed for the medical services related to her sister's diabetes treatment. She mentions that they already have a lot of medical bills. The nurse knows that this family is among the \_\_\_\_\_ of families in the United States with medical debt.
- a. 25 percent
  - b. 72 percent
  - c. 53 percent
  - d. 41 percent
10. A nurse is caring for Janice Bell, a 47-year-old female recovering from appendectomy surgery. As she is getting ready for discharge, Janice expresses concern for how behind she feels going home; her daughter is

about to graduate from high school and go to college, her other three children are all in high school, and her father-in-law recently moved into their attached apartment. The nurse understands that Janice's family is experiencing what stages of the family life cycle.

- a. coupling, independence, senior years
  - b. independence, launching adult children, coupling
  - c. parenting, launching adult children, senior years
  - d. launching adult children, parenting, coupling
- 11.** A mother of a 4-week-old infant presents for her postpartum follow-up. The nurse knows that this patient may be experiencing negative health effects, such as fatigue and altered mood related to what?
- a. sleep loss related to infant awakening
  - b. poor coping techniques
  - c. high sugar intake
  - d. high caffeine intake
- 12.** In which ways can families improve outcomes for individuals with addiction?
- a. creating a sense of victimization
  - b. promoting supportive relationships and acceptance
  - c. requiring in-patient treatment
  - d. focusing only on physical health concerns
- 13.** What modifiable family-related factors contribute to diabetes risk?
- a. obesity
  - b. sedentary lifestyle
  - c. healthy diet
  - d. smoking
- 14.** During an initial patient assessment, the nurse notices that the patient does not make eye contact while talking. The nurse is using what assessment technique?
- a. therapeutic communication
  - b. observation
  - c. identifying risk factors
  - d. recognizing nonverbal cues
- 15.** During an interview, a patient states that she "feels useless ever since she was diagnosed with MS." The nurse responds, "I'm not sure I understand; can you give me an example of a time you felt useless?" What therapeutic communication technique is the nurse using?
- a. clarification
  - b. focusing
  - c. acceptance
  - d. reflecting
- 16.** In understanding nursing interventions related to at-home medication administration for an 85-year-old patient with dementia and their family, the nurse must consider what factor?
- a. family engagement
  - b. geographic location
  - c. genetic history
  - d. dietary choices
- 17.** A nurse is caring for the family of a 7-year-old child with leukemia. The mom has left her job to care for the child, and the father is taking on additional shifts to maintain their financial status. They will need to travel 500 miles multiple times over the next year for treatment. The nurse recognizes the need for a referral to what type of professional?

- a. physical therapist
- b. mental health professional
- c. social worker
- d. spiritual advisor

### Check Your Understanding Questions

1. Describe the difference between hereditary, genetic, and familial disorders. Provide an example of each.
2. Describe the concept of empty nest syndrome and how it affects individuals differently.
3. List risk factors for obesity based on whether they are modifiable or nonmodifiable.

### Reflection Questions

1. Consider a situation in which a family has recently experienced the birth of a child with Down syndrome. In what ways may this affect the family?
2. Explain the importance of using manners during a patient or family interview.
3. Discuss how the nurse would apply the Bowen family systems theory to a patient recovering from a head injury.
4. Explain the concept of social role theory.
5. Explain how nurses and social workers work together to create individualized care plans for patients and families.

### What Should the Nurse Do?

1. Ms. Kesterson is a 55-year-old female who is new to the clinic. She was recently diagnosed with type 2 diabetes two months ago before she moved to live with her sister. She arrives at her scheduled appointment with her sister. Her sister is very vocal during the visit and continually interrupts Ms. Kesterson. Using key ingredients from the CFAM 15-minute interview, what actions can the nurse take during the initial interview?
2. A nurse is assigned to discharge a patient after a heart attack. Just before discharge, the patient's son arrives with a to-go order of the patient's favorite cheeseburger and fries. How should the nurse address this issue?
3. A nurse is caring for Roger Chin, a 37-year-old male whose mother was recently diagnosed with early-onset dementia. Roger states that he and his mother struggle to communicate even on good days. His mother often seems angry and withdrawn when Roger cares for her. Roger reports feeling depressed and angry at times as well because he feels like he now must take on the caregiver role. The nurse recognizes that Roger and his mother are experiencing what effect on family dynamics related to the mother's illness?
  - a. lifestyle alteration
  - b. socioeconomic adjustment
  - c. role modification
  - d. crisis response
4. The nurse is caring for a patient with a recent hip pinning after a fall. The nurse discusses the home care plan with the patient and her daughter. The daughter mentions that she lives 50 miles away and will only visit on weekends. The nurse recognizes the need for which collaborative referrals?

### Competency-Based Assessments

1. Create a video illustrating the use of elements from the 15-minute interview's key ingredients.
2. Create an ecomap based on one of your family members or classmates.
3. Think about a friend or family member and write a list of positive and negative coping skills you have witnessed during times of stress.
4. Consider a family with a 10-year-old child recently diagnosed with type 1 diabetes. Develop an educational

pamphlet that describes a medication management plan that includes responsible family members.

## CHAPTER 38

# Growth and Development

**FIGURE 38.1** Care across the life span means serving patients at each age and stage of life. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### CHAPTER OUTLINE

38.1 Stages of Growth and Development

38.2 Specific Developmental Theories

38.3 Application to Care

**INTRODUCTION** Imagine you are a nurse working in a busy emergency department on a Thursday evening. There is a 6-month-old infant with a severe cough in Room 1, a 20-year-old with a leg laceration in Room 2, and a 65-year-old patient who fell and broke their arm in Room 3. As the nurse, you know each patient will need specific care—not only for their admitting diagnosis but for their specific age and stage of development as well. The 6-month-old will not be able to verbally communicate, and the caregivers may need additional support. The 20-year-old, though categorized as a young adult, may still have developmental traits more characteristic of the adolescent stage. The 65-year-old is likely to have additional medical concerns and a longer medical history to consider.

This chapter outlines the foundations of developmental stages as well as care considerations at each stage. Developmental theories are discussed to build the underpinnings of understanding for care and communication with patients as they grow and develop. Only by mastering this information can nurses provide appropriate, quality care to every patient they see.

## 38.1 Stages of Growth and Development

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify normal developmental changes from newborn to older adult
- Discuss different types of play and its importance in development

Though growth and development are often used interchangeably, they serve different purposes for the patient. The term **growth** refers to an increase in physical size. In the case of a patient, this includes the physical size of the whole body and of all corresponding body parts. The term **development**, on the other hand, is the process by which a person gains various skills and functions (Table 38.1). Most development occurs during the infancy and childhood periods (Figure 38.2); however, development can occur throughout the life span. The typical pattern of growth and functional motor development is **cephalocaudal**, meaning from head (cephalic region) to toe (caudal region). The cephalocaudal pattern reflects the idea that growth and development often follow a sequential order, with skills and abilities emerging in a top-down manner. While this pattern is a general trend, it's important to note that individuals may vary in their developmental trajectories, and some may demonstrate unique patterns or exceptions to this overall sequence.

Growth	Development
Height	Cognitive development
Weight	Psychosocial development
Head circumference	Personality
Skeletal growth	Communication
Bone density	Sexuality
Muscle mass	Motor

**TABLE 38.1** Growth versus Development

**FIGURE 38.2** Children experience rapid physical changes through infancy and early childhood. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Growth and Development over Time

Cognitive, psychosocial, personality, communication, sexuality, and motor function development can impact many aspects of nursing care. Thus, nurses working in any arena of health care must have a baseline understanding of how patients grow, develop, and mature over time (Centers for Disease Control and Prevention (CDC), 2022). The timeline of achievement for these milestones can be assessed in a multitude of ways. Formal tools, such as the Prescreening Developmental Questionnaire (PDQ-II) and the Denver II Developmental Screening Test (DDST-II), may be used to assess development of **fine motor skills** (precise movements of small muscle groups), **gross motor skills** (coordination of large muscle groups), personal-social skills, and language skills in young children. The PDQ-II is a prescreening tool used to determine if additional screening is needed with the DDST-II. Using the PDQ-II as a

prescreening tool assists healthcare providers in efficiently identifying children who require further assessment. In addition to such tools, nurses can determine where a patient stands developmentally through a health history, interview, or physical assessment.

## LINK TO LEARNING

Explore how to administer the [Denver II Developmental Screening Test \(https://openstax.org/r/77DenvIIDevTest\)](https://openstax.org/r/77DenvIIDevTest).

---

This section covers the highlights of growth and development for the following age groups: newborn, infant, toddler, preschool, school age, adolescent, young adult, adult, and older adult. Detailed information about these populations is covered in later chapters: [Chapter 39 Conception Through Adolescence](#), [Chapter 40 Young and Middle-Aged Adults](#), and [Chapter 41 Older Adults](#). For additional information regarding nutrition considerations for these populations, see [Chapter 21 Nutrition](#).

## LINK TO LEARNING

---

Watch this video overviewing [stages of developmental milestones \(https://openstax.org/r/77StgDevMilstns\)](https://openstax.org/r/77StgDevMilstns) for pediatric patients.

---

### Newborn (0–28 Days of Life)

The newborn (**neonatal**) stage, spanning from birth to 28 days of life, is characterized by rapid growth and development. On average, a newborn weighs about 7 lbs (3.4 kg) and measures 20 in (50 cm) in length, with a head circumference of 14 in (35 cm). Within the first seven days of life, newborns typically lose about 10 percent of their body weight due to the elimination of excess fluid and nutrients acquired from their mothers. As they begin feeding on breast milk or formula, they gradually regain fluid volume and exhibit an average weight gain of 1 oz (30 g) per day, typically reaching their birth weight again within ten to fourteen days.

### Infant (0–12 Months)

The **infancy** stage is the period from birth to 12 months of age. Weight, length, and head circumference all increase rapidly during this period. Infants may grow up to 1 in (2.5 cm) per month and gain 5 to 7 oz (142–198 g) per week for the first six months. Between 6 to 12 months, they can grow 3/8 in (1 cm) a month and gain 3 to 5 oz (85–142 g) a week. The average infant is expected to double their weight by about 5 months of age and triple their birth weight by about 12 months of age.

During the infancy stage, many vital organs undergo significant and integral changes. Externally, infants are also achieving great milestones. By the end of their first year, children typically will have begun interacting with other people and toys as well as babbling, sitting, crawling, standing, starting to walk, and saying a few words; teeth eruption will also have begun.

## PATIENT CONVERSATIONS

---

### Addressing Caregiver Concern

**Scenario:** Anne is the mother of Tatum, a 7-month-old child. She has one other child, who is now 4 years old and at home with her husband. Jeff is the nurse currently working in the pediatrician's office. Jeff just completed a head-to-toe assessment on Tatum.

**Nurse:** Tatum looks great and is a very happy baby. Did you have any questions or concerns about his growth and development?

**Patient's caregiver:** I have been a little concerned about him struggling to pick up his snacks with his fingers. He has been able to hold rattles and toys for a while now, but he still can't use his fingers to pick up bits of cereal, for example. I don't remember how old my other son was when he could easily pick up his snacks by himself. Should I

be concerned?

**Nurse:** I understand why you might have a concern regarding specific milestones. There are many gross and fine motor skills that develop during this first year of life. Babies are able to hold a toy or rattle placed in their hand around 1 month of age. This typically involves using their entire hand to grasp the object. Children develop a different grasp, called a pincer grasp, later. A pincer grasp involves using the thumb and index finger—that is, their forefinger or pointer finger—to pick up small objects. This skill usually develops around 9 months of age. It is what Tatum will use when he starts picking up his cereal. It is an important fine motor skill, as it sets the foundation for other skills such as holding a pencil, zipping a zipper, or buttoning a button. Though there are outlined ages for all milestones, it is important to remember that each child will develop on their own timeline. Your two children may reach their milestones at slightly different times.

**Patient’s caregiver:** All right, but when should I become concerned if Tatum continues to struggle?

**Nurse:** We can provide you with some resources for general milestone landmarks to take home with you. We also keep an eye out at all medical appointments to ensure Tatum is on track overall. If you’re still concerned at Tatum’s next appointment, we can discuss it further.

---

### Toddler (1–3 Years)

During the **toddler** stage—between 1 and 3 years of age—there are dramatic changes in cognitive, physical, emotional, motor, and language skills. Though their rate of growth and food intake slows, toddlers typically quadruple their birth weight during this period. Additionally, by 2 years of age, children are approximately one-half of their adult height. Toddlers are known for “toddling” around as they practice walking and finding their voice with short sentences and a growing vocabulary. They are also known for exploring their independence and pushing boundaries. Major gross motor milestones obtained during this stage include walking independently, climbing stairs, and standing on tiptoes. Many fine motor skills are also developed during this stage; they include using their index fingers to point, removing their socks or shoes, building towers of blocks at various stages, and undressing.

### Preschool (3–5 Years)

A **preschooler** is a child from 3 to 5 years of age. They increase their social activities and contacts during this stage—especially if placed in a more formal educational or care setting for at least part of their week. Motor skills improve as they learn from other children and mimic their behaviors, both negatively and positively. Dramatic play, utilizing their vast imagination, is key during this stage to foster growth and learning.

### Middle Childhood (6–11 Years)

The **middle childhood** is the period between 6 and 11 years of age. It is the bridge between preschool and adolescence, when children start to refine their previously accomplished motor skills. They also focus more on activities they enjoy and excel at, such as art, writing, physical games, theater, music, cooking, and science activities. Play becomes more formalized and rules become a large part of how these children operate. Though peers become more important during this stage, the family unit is still a crucial influence on development.

## LINK TO LEARNING

The Centers for Disease Control and Prevention (CDC) is an excellent resource for healthcare providers, as well as caregivers, to gather [reputable information about growth and development \(https://openstax.org/r/77GrowDevelInfo\)](https://openstax.org/r/77GrowDevelInfo) in children.

---

### Adolescent (12–17 Years)

The **adolescence** is the period from 12 to 17 years of age; it marks the end of childhood and the transition to adulthood. The onset of **puberty** begins a time of significant growth and developmental changes, as sex organs and sex characteristics develop and individuals become capable of reproduction. The average age for onset of puberty in people assigned female at birth is 11 years old; in people assigned male at birth, it is 12 years old. However, pending any additional complications, it is acceptable for children to begin puberty between 8 and 13 years of age. As adolescents become less reliant on caregivers for transportation and funding, peers become an increasingly important influence. Activities become more dangerous with access to motor vehicles and ancillary activities

stemming from independence.

## LINK TO LEARNING

As the largest professional association of pediatricians in the United States, the [American Academy of Pediatrics website \(https://openstax.org/r/77AmAcPeWebsite\)](https://openstax.org/r/77AmAcPeWebsite) is a credible source for parents and providers to learn more about growth, development, and care of pediatric patients.

### Young Adult (18–35 Years)

Adulthood ranges from 18 years of age until death, with various subsets of categories in between. A person who is 18 to 35 years of age is considered a **young adults**. These individuals typically spend a lot of time and energy figuring out who they are and what they want for the future. This path often includes a choice between higher education or moving directly into the workforce. Most decisions during this time frame set the stage for later years of adulthood.

### Adult (36–64 Years)

A person within the ages of 36 to 64 years is generally considered an **adult**. During their adult years, individuals continually make decisions regarding life partnerships, child rearing, and the maintenance of friendships. In addition, adults make career decisions, experience periods of work productivity, and manage life circumstances that have significant impacts on their future. During this stage of development, individuals typically seek to create or nurture things through such activities as volunteering, mentoring, or raising children.

### Older Adult (65 Years and Older)

A person who is 65 years and older is considered an older adult. Developmental stages in the older adult population range greatly from those who are still working and conducting their day-to-day lives, as they did in their adult stage, to those who are focusing on retirement or choosing a path for the remainder of their life. As we age, there may be more health concerns; comorbidities may develop as the body responds to physical aging and lifestyle changes. It is important to remember that age does not determine the level of health, activity, cognitive ability, or happiness of a person.

## Types of Play

In addition to understanding the changes patients face over their life span, nurses must be able to identify how patients encounter these changes and assist in this process. Generally, nurses can perform a head-to-toe assessment to assess their patient for the most needed information; however, when working with children, watching how they play can provide a significant amount of information about their developmental state. **Play** is considered the work of children. It is how children from a young age learn to conduct themselves in relation to objects and other people in the world. Play reinforces growth and development for a child regarding physical, emotional, social, cognitive, and moral development. Additionally, play can help children use and refine reasoning skills, enhance creativity, and work to form conclusions. As patients age, play looks different and serves a different purpose with each stage.

While the foundations of play are developed during childhood, play is still present in adults (American Academy of Pediatrics, 2022). Some adults consider competitive activities such as board games, trivia, or playing sports to be play. Others “play” by completing tasks such as writing a story or solving a puzzle or a math-based challenge. In adults, the intent and mental attitude toward an activity is important when determining play behaviors. For example, if an adult is completing a puzzle and feels content, challenged, and interested in the activity, it would be considered play. If the adult is completing a puzzle and is feeling angry, disengaged, or burdened, then it is not play. Adults can partake in all types of play present in childhood.

There are several observable types of play, which generally appear in a particular developmental order. They include solitary, parallel, associative, cooperative, and onlooker/observer play. Though play may look different at each stage, play helps children physically navigate the world, practice patience, cooperation, teamwork, critical thinking, and problem-solving. Play can help all people, no matter the age, reduce stress, boost creativity, build friendships, and build resilience.

### Solitary Play

The act of independent play is called **solitary play**, shown in [Figure 38.3](#). During this type of play, participants choose to play with an object that no one else is using at the time. This type of play is most common in infancy as children are learning how to navigate their world.

**FIGURE 38.3** The act of play is how children in early stages of development learn about the world. (credit: modification of work "baby playing" by Philippe Put/Flickr, CC BY 2.0)

### Parallel Play

When participants play side by side but not with one another, this is known as **parallel play**. Participants may use the same type of object for this play, but they do not have cooperative involvement with those around them. This type of play typically occurs in the toddler stage, but it can be seen in any age group. Two children in a preschool setting, for instance, may engage in parallel play when they are both playing with toy blocks near each other but not directly interacting with each other. While each child is absorbed in constructing their own structures, there is minimal communication or collaboration between them.

### Associative Play

During **associative play**, participants involve others around them to engage in the activity. Though the participants have a similar goal during the play period, this type of play lacks formal organization. There are no set rules or true structure, but there is involvement across participants. This type of play is most common in the preschool stage, but it can also be seen at the tail end of the toddler stage.

### Cooperative Play

Cooperative play has the most formal structure of all types of play. During **cooperative play**, participants establish rules—which may include restrictions on participation—and all participants are expected to follow those rules. Typically, one or more leaders are chosen. Team sports is one of the earliest forms of cooperative play, which is most common in middle childhood but can be seen starting in the late preschool stage.

### Onlooker/Observer Play

Those participating in **onlooker play** watch others perform a task or engage in some form of play. There is no effort put forth by the onlookers to engage in the activity. Onlooker play occurs most often in the toddler stage but can take place at any age.

## 38.2 Specific Developmental Theories

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Discuss the importance of theories of development for care across the life span
- Identify multiple theories of development used in health care

Theories of development help provide a framework for healthcare providers to understand how patients develop over their life span. These theories can help healthcare providers identify ways to help patients move through the

growth and development process by noting prevention and intervention techniques. Commonly accepted theories of development include Erik Erikson's theory of psychosocial development, Jean Piaget's theory of cognitive development, Lawrence Kohlberg's theory of moral development, and Sigmund Freud's theory of psychosexual development.

## Importance of Theories of Development

While growth and development are not linear, theories of development can help nurses care for and interact with patients based on their developmental needs. Additionally, these theories help healthcare providers predict possible future behaviors to guide education and anticipatory guidance for caregivers. Most importantly, when healthcare providers understand and appreciate theories of development, they have a common toolbox for assessing and interacting with patients through the life span.

## Theory of Psychosocial Development—Erik Erikson

Erik Erikson's **theory of psychosocial development** states that an individual's personality develops in a predetermined order through a series of stages. Erikson believed there are two outcomes at each stage: successful completion or unsuccessful completion. Successful completion leads to advancing to the next stage in a healthy and holistic manner. Unsuccessful completion of a stage can lead to unsuccessful completion of subsequent stages and an unhealthy self-attitude (Erikson, 1963). These stages can be reviewed in [Table 38.2](#).

Developmental Stage	Erikson's Developmental Stage	Age Range per Developmental Stage
Infant	Trust vs. mistrust	0–1.5 years
Toddler	Autonomy vs. shame and doubt	1.5–3 years
Preschool	Initiative vs. guilt	3–5 years
Middle childhood	Industry vs. inferiority	5–12 years
Adolescent	Identity vs. role confusion	12–18 years
Young adult	Intimacy vs. isolation	18–40 years
Adult	Generativity vs. stagnation	40–65 years
Older adult	Ego integrity vs. despair	65+ years

**TABLE 38.2** Erik Erikson's Theory of Psychosocial Development

### Trust vs. Mistrust

Trust vs. mistrust is the first stage in Erikson's theory of psychosocial development; it begins at birth and continues until about 18 months of age. During this stage, the child is learning about the world and the uncertainties within it. As they need support for all basic needs, they rely on their primary caregiver for safety and consistent care. If the child receives reliable and predictable care from their caregiver(s), they will feel safe and develop a sense of trust. This sense of trust will then carry on to other relationships, so that the child may feel secure even if they are in an intimidating or challenging situation. If children do not receive consistent care, however, they will develop a sense of mistrust and apprehension. This ultimately leads to a lack of confidence in the people and world around them as well as their possible influence on events in the world. Thus, the child may feel a lack of confidence in their ability to

influence events within the world and may approach the world with uneasiness.

## REAL RN STORIES

---

### Understanding Developmental Theories

**Name:** Naomi, RN

**Clinical setting:** Pediatric unit

**Years in practice:** 2.5

**Facility location:** Downtown acute care hospital, Ohio

I remember my first experience seeing firsthand how developmental theories can help you understand short- and long-term complications for patients. I was a relatively new nurse on a pediatric unit. We had a variety of patients, but this particular night a 6-month-old baby was diagnosed with nonorganic failure to thrive due to neglect and abuse. I remember this baby had a history of upward of twelve to eighteen hours without being fed, was not held or comforted by caregivers, and was physically and emotionally depleted based on age. I was trying to hold the child to provide comfort, but it only seemed to make the child more irritated. I was discouraged, wondering what I was doing wrong. The psychiatrist was making rounds and noticed my frustration while completing her own assessment of the child. She explained the child had unmet needs up to this point, demonstrating a failure to successfully move through Erikson's stage of trust versus mistrust. She informed me the child is not comforted as most children are because he had been left alone without comfort. She also explained to me how this lack of care might impact the child later in life, inhibiting him from successfully moving through different developmental phases outlined in Erikson's theory. She explained how this child would need to be monitored for years to come to ensure proper physical, mental, and emotional care. While it was difficult to hear, this helped me understand how developmental theories can help nurses and the rest of the healthcare team think about comprehensive and holistic care for their patients.

---

#### Autonomy vs. Shame and Doubt

The second stage of Erikson's theory is autonomy vs. shame and doubt. This phase occurs between 18 months and 3 years of age. A foundational keystone of this stage is the child developing a sense of control over physical skills as they gain a sense of independence. If independence is fostered, the child will become more confident and secure in their ability to make decisions and survive in the world. In contrast, if children are overly controlled or criticized, they will develop feelings of inadequacy. This may lead to a lack of self-esteem and an unhealthy dependence on others. It is important for caregivers to strike a balance between encouraging children to complete age-appropriate tasks by themselves—such as getting dressed and taking dishes to the sink—while providing constructive guidance that sets up children to succeed.

#### Initiative vs. Guilt

Initiative vs. guilt is the third stage, encompassing children between 3 and 5 years of age. During this stage, children assert themselves through social interactions and play activities. The foundation of this stage is the significant interactions that children have with one another. If they are given the opportunity to plan activities and make up games, children will feel secure in their ability to lead and harness a feeling of initiative. If this initiative is suppressed or criticized by caregivers, children will form a sense of guilt. This sense of guilt can inhibit creativity and cause the child to resist interacting with others. One way caregivers can support this stage is to validate the many questions that children tend to ask. If caregivers treat these inquiries as trivial or an annoyance, the child may develop a sense of guilt or embarrassment.

#### Industry vs. Inferiority

The fourth stage, industry vs. inferiority, encompasses children from 5 to 12 years of age. During this stage, peers play increasingly significant roles in a child's self-esteem. As tasks such as reading, writing, and mathematics become more prominent, children feel they need to gain approval by demonstrating these competencies. As they experience success, they develop a sense of pride and feel accepted and valued in society. If children are encouraged for their initiative during this stage, they will feel industrious and gain confidence to complete more difficult tasks. However, if children cannot develop the specific skills they feel that society values, they may develop a sense of inferiority.

### Identity vs. Role Confusion

The fifth stage of Erikson's theory, identity vs. role confusion, takes place between about 12 and 18 years of age. The foundation of this stage is an individual's search for a sense of personal identity, particularly in two realms: sexual and occupational. Individuals who successfully move through this stage are able to identify the transformations that occur during this time and work through these changes to ultimately feel comfortable and stand firm in their identity. This allows patients to accept themselves and others, even if there are major differences between them. Unsuccessful completion of this stage can lead to role confusion, meaning that the individual is not certain about their place in society. In an effort to avoid role confusion, patients may experiment with different lifestyles. It is important to note that if people in this process are pressured into a certain lifestyle, they may develop a sense of anger and rebellion, ultimately leading to unhappiness.

### Intimacy vs. Isolation

The sixth stage, intimacy vs. isolation, occurs between 18 and 40 years of age. Erikson believed people in this stage focus on forming intimate and loving relationships with other people; they explore relationships with the goal of making a long-term commitment to someone other than their family unit members. Successful completion of this stage leads to happy relationships centered around commitment and safety. Unsuccessful completion of this stage, driven by a fear of intimacy and commitment, can lead to loneliness and isolation.

### Generativity vs. Stagnation

The second-to-last stage in Erikson's theory is generativity vs. stagnation, which takes place between approximately 40 and 65 years of age. In this context, **generativity** is when an individual makes a mark on the world with something that will outlast their own life. Common examples include having mentees, raising children, making an impact at work, and being involved in community organizations. Individuals who experience generative success typically feel useful and accomplished. In contrast, failure to make a lasting mark can lead to stagnation, leaving the individual feeling unproductive and disconnected.

### Ego Integrity vs. Despair

The eighth and final stage in Erikson's theory is ego integrity vs. despair, which occurs from about 65 years of age until death. Patients in this stage spend time reflecting on their lives. Patients who find value in their experiences and accomplishments will successfully move through this stage and attain wisdom. They achieve a sense of completeness and integrity. Conversely, those who reflect back on their life and deem it unproductive or regret missed opportunities may end up with a sense of despair.

## Theory of Cognitive Development—Jean Piaget

Jean Piaget's **theory of cognitive development** claims that individuals pass through four stages from birth to adolescence, noting changes in the person's ability to use logic and scientific theory along the way. As shown in [Figure 38.4](#), these stages are sensorimotor thinking, preoperational thinking, concrete operational thinking, and formal operational thinking, sequentially. Piaget's theory assumes that every person experiences all four stages in the same order, that a cognitive transformation happens within each stage, and that each latter stage incorporates the previous stage (Malik & Marwaha, 2023).

## Piaget's Stages of Cognitive Development

**FIGURE 38.4** Jean Piaget's theory of cognitive development can be represented by a staircase that represents the cognitive growth gained while moving through each stage. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Sensorimotor Thinking (0–2 Years)

During this stage, children use their senses and physical actions—such as crawling, visual tracking, balancing, and coordinating their body in relation to their surroundings—to learn about the world and their place within it. The landmark achievement during this stage is **object permanence**, which is the understanding that an object still exists even after it is hidden or moved from sight. This corresponds to the knowledge that the world exists separately from the child themselves. Once this landmark has been accomplished, the child moves on to the next stage.

### Preoperational Thinking (2–6 years)

Thinking in this stage is influenced by how things appear versus how they really are. Children in this stage are able to mentally represent objects in multiple ways, though their thought processes remain incomplete and, at times, disorganized. A landmark of thinking during this stage is **dramatic play**, in which participants use their imagination to take on roles and characters as they interact with their surroundings. A common example is when children take on the role of a doctor and provide medical care to dolls or other people; they may use plastic sets of look-alike medical equipment, or they may imaginatively repurpose everyday objects. Though thinking during this stage tends to be illogical and lacking in reason, it is an important step on the way to higher levels of cognition.

### Concrete Operational Thinking (7–11 Years)

During this stage, children can solve problems more systematically than in previous stages, though their thinking remains focused on concrete objects and events rather than abstractions or hypotheticals. One major concept gained during this stage is **reversibility**, or the ability to understand a process and the steps of a process in any order. (Children in previous stages may be able to recite the steps of an experiment, for example, but only in the original order.) Another skill acquired during this stage is **decentering**, or the ability to investigate more than one problem at a time. This helps children to understand that others may have a different point of view. Children also acquire the concept of **conservation**: they understand that something may change its size or appearance without also changing its quantity. For example, children in the previous stage may understand that two cubes of clay that weigh the same contain the same amount of clay; however, children capable of concrete operational thinking understand that the two lumps remain equal even after one is reshaped into a pyramid.

### Formal Operational Thinking (12 Years and Older)

People who successfully pass through the fourth and final stage of Piaget's theory achieve the skill of hypothetical thinking, logical thought, deductive reasoning, and systemic planning. They are able to think logically and reasonably at more advanced levels about abstract objects and events in addition to tangible ones. Additionally, inferential reasoning is a key distinction of this stage. It is also understood with this theory that some people may never achieve or use formal operational thinking in their everyday lives. As an example, according to Piaget's theory, hypothetical thinking is necessary to scientific problem-solving. Many people do not deal with scientific problems or the scientific problem-solving process during the course of their lives; thus, it is understood that those people may never achieve or use formal operational thinking demonstrated through scientific problem-solving. Similarly, there is

a subset of people who use it only in certain areas in which they are most comfortable and familiar such as tasks at home, but not at work, or vice versa. Piaget believed that though adolescents who are able to achieve formal operational thinking may have more success in some facets of academia, it is not mandatory for students to achieve educational success.

## LINK TO LEARNING

Jean Piaget's [theory of cognitive development \(https://openstax.org/r/77CognDevTheory\)](https://openstax.org/r/77CognDevTheory) is further explained in this video.

### Theory of Moral Development—Lawrence Kohlberg

Lawrence Kohlberg's **theory of moral development** builds upon Piaget's theory of cognitive development. The foundational understanding of Kohlberg's theory is that moral reasoning develops in stages (Kohlberg, 1981). Specifically, it identifies six stages distributed across three levels ([Figure 38.5](#)).

**FIGURE 38.5** Kohlberg identified three levels of moral reasoning, each of which is associated with increasingly complex stages of moral development. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

#### Level 1: Pre-Conventional Morality (0–9 Years)

This level is considered the premoral level. Thinking is primarily egocentric, and behavior is driven by the desire to gain pleasure and avoid punishment or other types of pain. A hallmark of premoral thinking is that actions that lead to rewards must be good, while actions that lead to punishment must be bad.

##### Stage 1: Obedience and Punishment

In the first stage of Level 1 a child's response to a moral dilemma is that of obedience to rules and authority. In this stage, a child must follow the rules or they will be punished. The physical or tangible consequence of punishment is the driver of decision-making. Children believe if they are not being punished, they are good, and if they are punished, they must be bad or wrong.

##### Stage 2: Individual Interest

Progressing from the first stage, in this stage children comprehend that authority figures may have different views of what is "right and wrong," and that definitions may change depending on individual viewpoints. Thus, they realize the moral decisions they have learned may be influenced by personal needs while still considering the needs of others. This may guide children in this stage to believe it is okay to do something wrong if it will benefit them overall.

Children move away from thinking that punishment is the sign of what is “right and wrong,” while still knowing it is something to be avoided.

### Level 2: Conventional Morality (10–15 Years)

Moral reasoning at this level is based on one’s own interpretation and internalization of societal expectations. Individuals make decisions based on how they may impact interpersonal relationships in addition to their own self-interest. At this level, moral standards begin to be internalized.

#### Stage 3: Interpersonal

During this stage, the individual wants to gain and maintain the approval of those in their immediate group. Children want to be considered “good” or “nice,” and they equate these titles with having positive motives, showing mutual concern for others, and fostering friendly relationships based on loyalty, trust, and respect.

#### Stage 4: Authority

Within this fourth stage, individuals expand their decision-making process beyond their relationships with close acquaintances. Now, they also take societal norms and perspectives into consideration. The foundation of decision-making is no longer avoiding punishment or gaining rewards. Instead, individuals focus on doing their duty and maintaining social order.

### Level 3: Post-Conventional Morality (16+ Years)

In this third level, individuals define their own moral principles and value as they begin to create an image of how an ideal society could look. Balance is found between basic rights, societal expectations, and obligations. It is important to note that Kohlberg believed only 10 to 15 percent of people reach this stage of moral development.

#### Stage 5: Social Contract

Those within this stage still find value in and follow society’s law and norms, but they can also imagine possible changes to make society better. Individuals in this stage believe that subgroups can have different values, but everyone should be able to agree on foundational principles. Morality of this stage is the basis for the United States Constitution. The belief in this stage is that laws are flexible in order to accommodate new and changing circumstances.

#### Stage 6: Universal Ethics

The sixth and final stage of Kohlberg’s theory bases moral reasoning upon universal ethical considerations coupled with abstract thinking. A sense of justice is a guide within this stage, even if this conflicts with societal rules and laws; thus, there is an understanding that there are higher laws that go above and beyond laws that are imposed socially. Individuals in this phase believe all humans have value and thus are willing to accept the consequences of going against social norms if it is the “right” thing to do.

## Theory of Psychosexual Development—Sigmund Freud

Many people consider Sigmund Freud to have been one of the most influential minds of the twentieth century; however, he may also be one of the most controversial, and many people today discount his ideas. Freud had a background in neurology, which was the foundation for his theories of personality and human development. Freud believed that the human mind has three sections: the unconscious, the preconscious, and the conscious (Lantz & Ray, 2022). As shown in [Figure 38.6](#), these sections are often compared to the parts of an iceberg. According to Freud, the unconscious is like the part of an iceberg, well below the water’s surface, that cannot be seen; the preconscious is the part just at and directly below the water’s surface; and the conscious is the part of the iceberg, above the water, that can be seen.

**FIGURE 38.6** Sigmund Freud believed the mind is like an iceberg, with three sections: unconscious, preconscious, and conscious. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Freud also believed the mind has three fundamental structures: the **id**, the **ego**, and the **superego**. He claimed the **id** is the primitive or unconscious part of the mind, which seeks gratifications through physical needs; the **superego** is responsible for upholding social norms and making moral decisions; and the **ego** is the regulator between the **id** and the **superego**. From these beliefs, Freud established his psychosexual theory of development for children. His theory has five stages, each of which focuses on a different physical center of pleasure: oral, anal, phallic, latency, and genital.

Freud is often criticized by those in the medical community, who fault him for basing his theory of development solely on biological or physical determinants while ignoring social, cultural, and experiential factors. Furthermore, many believe this theory is not applicable to different cultures and communities.

#### Oral (Birth–1 Year)

During this stage, babies gain pleasure through their mouth: for example, by sucking, biting, and tasting. If needs are unmet during this phase, Freud believed a child's development could be hindered. For example, the child might compensate by developing oral fixation behaviors such as gum chewing, candy eating, smoking, and nail biting.

#### Anal (1–3 Years)

This phase happens as children typically begin the process of potty training and learn to control defecation. Therefore, the anal region is the focus of pleasure during this stage. Freud believed children who experience conflicts during this stage will develop either anal-retentive or anal-expulsive tendencies as they move into adulthood. An anal-retentive personality is one that compulsively sees order and tidiness. An anal-expulsive personality is generally messy and lacks self-control.

#### Phallic (3–6 Years)

Genital organs become the focus of pleasure during this stage. Children become aware of the presence or absence of a penis in individual bodies, and they may have internal conflict with either side of awareness as they demonstrate an increased interest in their genitals and the genitals of the opposite sex. Pending their desire to adopt the characteristics of the same-sex parent, this may lead to internal struggle if they are not able to achieve these full characteristics. Freud believed by the end of this stage, children resolve this conflict by identifying with a caregiver of the same sex in order to gain acceptance.

### Latency (6–12 Years)

During this stage, Freud believed that children repress their sexual focus and energy due to a dormant libido and channel it into other activities of development, such as hobbies, schoolwork, friendships, and social maturing, demonstrating an overall state of calmness. Children may focus their time on social or intellectual skills, such as hobbies, education, and friendship, versus a focus on romantic interests.

### Genital (Puberty and Beyond)

During this last and final stage, Freud believed the sexual urges of adolescents re-emerge and are directed toward another person. This leads to solicitation and pursuit of intimate relationships. After sexual experimentation, this stage is considered resolved when someone is capable of having a mature and emotionally safe adult sexual relationship. Unresolved conflicts during this stage can lead to emotional issues, sexual dysfunction, and inability to form and sustain healthy relationships.

## 38.3 Application to Care

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Demonstrate appropriate application of multiple theories of development
- Discuss aspects of well care specific to different populations across the life span
- Discuss aspects of vaccination administration and post-assessment

To care for patients across the life span, nurses must have a baseline understanding of growth and development at each stage of life. Newborns through older adults, and each stage in between, all have a subset of needs and concerns. For example, communication and the spectrum of growth and development pose challenges unique to the pediatric population, while chronic diseases and comorbidities that come with an extended life span create another subset of complications in older adult patients.

### Well Care across the Life Span

Well-visits and preventive care are crucial to the overall well-being of people on an individual and community level. Well-visits are more frequent in the younger years when developmental milestones are identified and reviewed. As will be discussed later in this section, a significant part of this preventive care is the process of immunization.

#### Well-Visit Schedule

While many patients find themselves visiting a healthcare provider only when they have an acute illness or problem, it is important for individuals to maintain regular well-visits with a focus on preventive care. Different from an appointment for a new issue, well-visits provide an opportunity for preventive care and screening to occur before issues arise. Well-visits allow communication between patient and provider and help the provider make a plan for the overall well-being of each patient.

## LIFE-STAGE CONTEXT

---

### Preventive Care

Due to the importance of preventive care, part of the Healthy People 2030 initiative from The U.S. Department of Health and Human Services Office of Disease Prevention and Health Promotion is a strong focus on preventive health (Office of Disease Prevention and Health Promotion, 2023). Their preventive care objectives for the general public include the following:

- increase the proportion of children who receive a developmental screening
- increase use of the oral healthcare system

Further objectives are identified by the following categories:

- adolescents
- cancer
- community

- diabetes
  - health care access and quality
  - health policy
  - heart disease and stroke
  - mental health and mental disorders
  - oral conditions
  - osteoporosis
  - pregnancy and childbirth
  - sensory or communication disorders
  - sexually transmitted infections (Office of Disease Prevention and Health Promotion, 2023)
- 

After 3 years of age, it is recommended for patients to have an annual well-visit. During these well-visits, multiple components should be reviewed, including vital signs and baseline laboratory tests; any medications the patient is taking should also be reviewed, and adjustments should be made as needed. Additionally, age- or health-related screenings such as mammograms, pap smears, colonoscopies, and vision screenings may either be ordered or referred out to a specialist for completion. Prior to age 3, there is a more frequent well-visit schedule for children:

- 1 week
- 1 month
- 2 months
- 4 months
- 6 months
- 9 months
- 12 months
- 15 months
- 18 months
- 24 months
- 30 months
- 3 years

This increased frequency for younger children is warranted due to the many physical, mental, and emotional changes during this time frame. After 3 years of age, a yearly well-visit is recommended pending any additional healthcare conditions.

## LINK TO LEARNING

---

The American Academy of Pediatrics provides [a schedule of well-visits \(https://openstax.org/r/77WellVisiSched\)](https://openstax.org/r/77WellVisiSched) that includes details for what should happen at each visit.

---

Early childhood is a crucial span of time to ensure proper growth and development. Well-visits are an optimal time for nurses and providers to deliver anticipatory guidance for caregivers. The anticipatory guidance involves proactively counseling caregivers regarding significant physical, psychological, emotional, and developmental changes their child will encounter in the future. This guidance is specifically tailored to the current age and stage of the patient as well as the stage they will encounter next. The nurse must also consider any communication barriers. Variations in language, cultural nuances, or varying levels of health literacy can act as barriers that may impact the comprehension of crucial information. Therefore, the nurse needs to approach anticipatory guidance with sensitivity, employing clear and simple language, utilizing visual aids when necessary, and ensuring caregivers fully grasp the information relevant to the child's physical, psychological, emotional, and developmental well-being.

## CULTURAL CONTEXT

---

### Communication Barriers

During their career, nurses are likely to encounter patients of all ages, stages, health levels, backgrounds, health literacy levels, and cultures. Though there are many factors to consider when interacting with and educating patients, one of the most foundational is language and communication. If there is a language or communication barrier between healthcare provider and patient or caregiver, everyone is likely to walk away from the care event confused and frustrated. Official translators must be used when there are any noted language barriers involving speaking, reading, or writing. Most healthcare systems have multiple forms of translators to ensure proper care of patients. This may be a physical person who is able to translate between languages, a phone call to a translator who can speak between languages, or a video call that allows the translator to view all participants while also translating. Depending on the size of the healthcare system and the urgency of a patient's needs, there is a time and place for each method, but one must be used if there is a discrepancy between languages. Nurses should not allow family members to translate even if able to understand and speak both languages, as it is impossible to ensure proper translation of all crucial information.

---

### Atraumatic Care

No matter the population with which the nurse is working, atraumatic care should be practiced. The **atraumatic care** is care that strives to eliminate as much trauma as possible from the experience for the patient. This is important to help minimize the psychological impact that can arise from healthcare interventions.

## LIFE-STAGE CONTEXT

---

### Providing Comfort and Demonstrating Atraumatic Care

Based on their developmental age and stage, patients may find different experiences traumatic, and nurses may need to take different actions accordingly. For example, while performing an adult physical assessment, the nurse can verbally direct individuals as necessary to complete the exam. Adult patients typically understand why they must assume certain positions and remain still while the nurse uses a variety of instruments to check vital signs. Completing a similar task on a child—especially a young child who cannot understand what is happening—often proves a more challenging task. Because infants are soothed when held during times of distress, nurses can allow caregivers to hold a child during most of the physical exam; in addition to providing the least traumatic experience possible for the patient, the nurse is more likely to gather accurate information from a calm, cooperative child. If no caregiver is available, the nurse can simulate this experience by holding or soothing the child before, during, or after completion of a care task.

Atraumatic care may look different for older children. For example, pediatric settings often have a playroom or other dedicated space in which no medical care is completed. This provides a safe place for patients to play, learn, and relax. Similarly, difficult or painful procedures may take place in a separate room from those in which routine examinations are conducted. This helps patients to relax during examinations, as they perceive the space as a safer, more healing environment. If steadying a patient or part of the patient is needed to complete a procedure safely, a trained medical professional should be the one to complete this safety hold. This leaves caregivers or loved ones available afterward to help provide comfort. Additionally, when support staff who are trained to properly stabilize and assist in a procedure, it limits the risk to providers and patients. Utilizing interdisciplinary team members, such as a child life specialist, can also be of benefit when providing care.

---

### Vaccination and Immunization

Though often used together, vaccination and immunization are not interchangeable terms. Vaccination is the act of presenting a vaccine to the body to elicit protection from a specific disease. **Immunization** is the method by which a person develops protection against a disease through vaccination. There are two main types of immunity, active and passive. Active immunity refers to immunity obtained from an individual's exposure to an antigen to which their own body then elicits an immune response to create antibodies. Vaccinations are an example of active immunity. On the

other hand, passive immunity refers to immunity that is obtained from antibodies created outside of the person and then introduced to the body. Breastfeeding is an example of passive immunity. Immunizations play a crucial role in creating **herd immunity**, which occurs when a significant portion of the population (the “herd”) becomes immune to a disease. When this happens, the disease can no longer spread within the population and may vanish completely.

## LINK TO LEARNING

The website for the CDC provides [specific definitions for vaccine, vaccination, immunity, and immunization \(https://openstax.org/r/77SpecDefsVacIm\)](https://openstax.org/r/77SpecDefsVacIm) to help provide clarity among these related terms.

The main function of the body’s immune system is to distinguish “self” from “non-self.” A toxin or foreign object the body determines to be a threat is called an antigen. Once the immune system identifies an antigen, it will elicit an immune response and work to eradicate it from the body, in the process creating antibodies. An antibody is a protective protein produced by the immune system to help fight invaders. By creating antibodies for a specific antigen, the immune system learns to recognize that antigen (or similar ones) moving forward and attack more efficiently. In essence, the immune system creates a blueprint for fighting off illness or disease more effectively if exposed in the future. This is how the process of immunization provides protection against specific diseases through vaccinations. A vaccination contains a weakened or inert form of a particular antigen—not enough to cause the disease itself, but sufficient to trigger the immune system to create antibodies, thus providing immunity for that disease.

There are multiple categories of vaccinations, with some more common than others. Categories of vaccinations currently used include inactivated, live-attenuated, messenger RNA (mRNA), toxoid viral vector, subunit, recombinant, polysaccharide, and conjugate vaccines (U.S. Department of Health and Human Services, 2022). Though obtaining vaccinations does require significant effort and time on the forefront, a fully immunized patient is protected from the physical, emotional, and financial risks of many dangerous infectious diseases.

## LINK TO LEARNING

The CDC provides a [schedule for childhood and adolescence vaccinations \(https://openstax.org/r/77ChildVacSched\)](https://openstax.org/r/77ChildVacSched), including a “catch-up” schedule for individuals who missed the recommended doses.

### Pre-Vaccination Care

For patients to obtain the best results from a vaccination, healthcare providers must understand appropriate pre- and post-care guidelines and be able to educate patients and caregivers regarding these topics. First and foremost, consent must be obtained prior to any vaccination administration. Patients who are considered adults or emancipated may sign this consent themselves. Those who are considered minors (not emancipated) or who have designated another person to make their healthcare decisions must have a guardian or caregiver sign consent.

## LINK TO LEARNING

The CDC provides a [recommended adult immunization schedule \(https://openstax.org/r/77AdultVacSched\)](https://openstax.org/r/77AdultVacSched) for those aged 19 years and older.

The provider must give patients and caregivers a vaccination information sheet (VIS) containing all pertinent information regarding the vaccine’s purpose as well as known side effects or adverse reactions the patient may have. The provider should also discuss allergies and contraindications with patients and caregivers and review the outlined vaccination schedule. Many children working their way through vaccinations may need a “catch-up” plan if they veer off schedule or need to adjust for other reasons. Patients who are acutely ill may not be in a stable condition to receive a vaccination, but those with a minor illness may still be able to obtain the vaccination. This should be discussed with the healthcare provider prior to administration.

## LINK TO LEARNING

The CDC maintains [current vaccination information sheets \(https://openstax.org/r/77CurrentVISs\)](https://openstax.org/r/77CurrentVISs) for all vaccines.

### Barriers to Vaccination

There are many reasons patients may choose not to receive vaccinations and why caregivers may choose not to have their children receive vaccinations. It is the nurse's role to provide factual information regarding this topic and help eliminate barriers when possible. Some possible barriers that nurses can help patients overcome include the following:

- challenges with access or proximity to facility
- anticipated side effects of vaccine
- misunderstanding of normal immune response and adverse reaction or contraindication
- belief that vaccination is unnecessary because they or their child is not at risk
- belief that natural immunity, acquired by contracting the disease, is better
- scheduling challenges
- cost
- personal preferences
- religious beliefs
- distrust of the healthcare system

The first step in helping patients and caregivers is understanding their specific concerns or barriers. Nurses should provide information, resources, and support no matter what choice the patient ultimately makes. Though healthcare providers may have different opinions from those of their patients and families, it is not appropriate to place judgement or decrease care levels because of these differences.

One large effort to eliminate the cost limitation for families is the Vaccines for Children (VFC) program, a federally funded program implemented in 1994 in response to the measles epidemic of 1989–1991. VFC vaccines are provided free to people with low incomes or no insurance through private physicians who have registered with the program. Additionally, the Affordable Care Act of 2010 classifies immunizations approved by the Advisory Committee on Immunization Practices (ACIP) as preventive services and mandates new health plans to cover them without charging a co-payment, deductible, or coinsurance (Centers for Disease Control and Prevention (CDC), 2022). Individual states also have a variety of resources to help provide free or discounted vaccinations. In an effort to combat the barrier of multiple trips to a medical facility for separate injections, the use of FDA-approved, manufacturer-produced combination vaccines is encouraged when appropriate.

### Vaccination Administration

Vaccinations are injected via intramuscular (IM), subcutaneous (SQ), or oral (PO) routes. Appropriate needle size and injection location are dictated by the type of vaccine and age and size of the patient (Immunize Action Coalition, 2020). For IM injections, the needle should be inserted at a 90-degree angle to the skin. Each muscle injected must have the capacity to hold the volume of the medication, an important factor in minimizing local reaction. The vastus lateralis (a thigh muscle) is the optimal location for children 12 months and younger due to its development and capacity. If the deltoid muscle is selected for children under 10 years of age, the needle size may need to be adjusted ([Figure 38.7](#) [Table 38.3](#)) lists other appropriate sites for IM injections.

**FIGURE 38.7** (a) The vastus lateralis is the preferred IM injection site for infants and toddlers aged 0 to 3 years. (b) The deltoid is the preferred IM injection site for those aged 3 and older. (attribution a and b: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Age	Injection Site	Needle Size
Newborn (0–28 days)	Anterolateral thigh muscle	5/8 inches (22–25 gauge)
Infant (1–12 months)	Anterolateral thigh muscle	1 inch (22–25 gauge)
Toddler (1–2 years)	Anterolateral thigh muscle Alternate: Deltoid muscle (upper arm) if muscle mass is adequate	1–1 ¼ inches (22–25 gauge) 5/8–1 inch (22–25 gauge)

**TABLE 38.3** Intramuscular (IM) Needle Injection Administration

Age	Injection Site	Needle Size
Children (3–10 years)	Deltoid muscle (upper arm) Alternate: Anterolateral thigh muscle	5/8–1 inch (22–25 gauge) 1–1 ¼ inches (22–25 gauge)
Children and adults (11 years and older)	Deltoid muscle (upper arm) Alternate: Anterolateral thigh muscle	5/8–1 inch (22–25 gauge) 1–1 ½ inches (22–25 gauge)

**TABLE 38.3 Intramuscular (IM) Needle Injection Administration**

Table 38.4 lists appropriate sites for SQ injections. For example, the most suitable SQ site in infants from birth to 12 months is the fatty tissue of the anterolateral thigh. The most suitable location for a SQ injection in those 12 months and older is the fatty tissue overlying the triceps. Needle insertion for SQ injections should be completed at a 45-degree angle.

Age	Injection Site	Needle Size
Birth to 12 months	Fatty tissue overlying the anterolateral thigh muscle	5/8 inches (23–25 gauge)
12 months and older	Fatty tissue overlying the triceps	5/8 inches (23–25 gauge)

**TABLE 38.4 Subcutaneous (SQ) Needle Injection Administration** Subcutaneous injection sites and needle size vary by age. Selecting the correct needle size and injection site can help ensure accurate administration and patients' comfort.

### Post-Vaccination Care

Following administration of a vaccine, providers should educate patients or caregivers about how to manage expected symptoms and side effects as well as when to seek additional care. When they return home, patients or caregivers should monitor for adverse reactions. It is normal for patients to have a low-grade fever, chills, body aches, pain or redness at the injection site, or fatigue following administration—these are all expected responses of the body to the triggered immune system as it creates antibodies to the introduced antigen. However, if patients have a high-grade fever, difficulty breathing, systemic rash, swelling or redness that proceeds down the extremity, or additional signs of allergy or severe reaction, they should reach out to a healthcare provider immediately for guidance.

### Documentation

Following administration of a vaccine, the provider will need to document several pieces of information:

- date of administration
- name of vaccine given
- manufacturer
- lot number
- expiration date
- site and route of administration
- name and title of who administered the vaccine
- notification of VIS given

### LINK TO LEARNING

The CDC maintains a web page with [facts about the Vaccination Information Sheets \(https://openstax.org/r/77FactsVISs\)](https://openstax.org/r/77FactsVISs) that must be given to patients prior to administration of a vaccine.

Documentation is important to help mitigate safety concerns for patients and expedite follow-up care as needed. Information about the site and route of administration is important when assessing for local site reaction. Information about the manufacturer, lot number, expiration date, and name of vaccination allow providers to follow up if there is a concern with a batch of vaccination or an identified adverse reaction. Additionally, it is important for patients and caregivers to maintain the recommended intervals for vaccinations, as detailed in the age-appropriate schedule. Having this information documented allows for tracking of vaccinations and helps healthcare providers develop an individualized plan for each patient.

The Vaccine Adverse Event Reporting Systems (VAERS) is the national vaccine safety surveillance program. National Institutes of Health. This program compiles reported information in order to create educational documents such as the VIS.

## Summary

### 38.1 Stages of Growth and Development

One of the first steps in providing care across the life span is understanding how a patient population grows and develops over that time frame. No matter the desired nursing specialty, to provide crucial care, nurses must understand the impact their care decisions may have on a patient—in both the short and long terms. Physical growth may be easier to assess, but this assessment must be coupled with all forms of development—cognitive, psychosocial, personality, communication, sexuality, and motor function—to fully understand a patient’s condition. From birth to end of life, patients are categorized into the following developmental stages: newborn (0–28 days), infant (0–12 months), toddler (1–3 years), preschool (3–5 years), middle childhood (6–11 years), adolescent (12–17 years), young adult (18–35 years), adult (36–64 years), and older adult (65 years and older).

Considered the “work” of children, play is a crucial component of development throughout the life span. Play can improve physical, social, cognitive, and emotional well-being. Types of play include solitary, associative, cooperative, and onlooker/observer play.

### 38.2 Specific Developmental Theories

Theories of development help provide a foundation for understanding how people grow and develop. Some of the most used and discussed theories in health care regarding development are Erik Erikson’s theory of psychosocial development, Jean Piaget’s theory of cognitive development, Lawrence Kohlberg’s theory of moral development, and Sigmund Freud’s theory of psychosexual development. Though Erikson’s theory was influenced by the work of Freud, he focused on psychosocial development rather than psychosexual development. Piaget’s theory focuses on cognitive development, which he claimed occurs in four sequential stages. Kohlberg’s theory, which builds upon Piaget’s theory, argues that moral development occurs in stages.

### 38.3 Application to Care

In order to provide the best care for patients across the life span, nurses must have a baseline understanding of growth and development and how this can impact all areas of care, such as a patient’s health status, developmental stage, family/caregiver support availability, resource availability, and desire for care. In addition to visits when patients are acutely ill, well-visits are an optimal opportunity for nurses to implement these aspects of care. Well-visits provide a designated time for providers and patients to review concerns, plan for the future, and screen for long-term complications. Well-visit intervals are more frequent with younger children to assess for milestones and monitor leaps in development.

A major aspect of providing quality and effective patient care through the life span is the administration of vaccinations and education regarding their purpose. As a key process of obtaining acquired active immunity, vaccinations help protect patients at the individual and whole population levels. A vaccine works by exposing the patient to foreign substances (antigens), triggering the patient’s immune system to produce antibodies and create a blueprint for more efficiently identifying and attacking that antigen in the future. Nurses must understand how to educate patients and caregivers regarding the benefits, risks, and anticipated outcomes of vaccinations. Additionally, nurses are also responsible for vaccination administration and patient evaluation.

## Key Terms

**adolescence** the life stage from 12 to 17 years

**adult** the life stage from 36 to 64 years

**anticipatory guidance** the process of proactively counseling caregivers regarding significant physical, psychological, emotional, and developmental changes their child will encounter in the future

**associative play** play in which participants involve and engage with others around them

**atraumatic care** care that strives to eliminate as much patient trauma as possible from the experience

**cephalocaudal** head-to-toe

**conservation** the understanding that something may change its size or appearance without also changing its quantity

**cooperative play** play in which all participants are expected to follow established rules

**decentering** the process of investigating more than one problem at a time

- development** the process by which a person gains various skills and functions
- dramatic play** play in which participants take on roles and characters and use their imagination to interact with their surroundings
- ego** the regulator between the id and the superego
- fine motor skills** precise movements of small muscle groups
- generativity** making a mark on the world with something that will outlast the life of the individual
- gross motor skills** coordination of large muscle groups
- growth** physical change in size
- herd immunity** a landmark reached when a significant portion of the population (the “herd”) becomes immune to a disease
- id** the primitive or unconscious part of the mind, which seeks gratification through physical needs
- immunization** the method by which a person develops protection against a disease through vaccination
- infancy** the life stage from 0 to 12 months
- middle childhood** the life stage from 6 to 11 years
- neonatal** the period of time from birth to 28 days
- object permanence** the understanding that an object still exists even after it is hidden or moved from sight
- onlooker play** the process of watching others perform a task or engage in play
- parallel play** play in which participants play side by side but not with one another
- play** considered the work of children; a crucial aspect in growth and development
- preschooler** the life stage from 3 to 5 years
- puberty** the stage of development during which physical and sexual maturity occurs and individuals become capable of reproduction
- reversibility** the ability to understand a process and the steps of a process in any order
- solitary play** an act of independent play
- superego** the part of the mind responsible for upholding social norms and making moral decisions
- theory of cognitive development** Jean Piaget’s theory that claims that individuals pass through four stages from birth to adolescence and notes changes in a person’s ability to use logic and scientific theory as they develop
- theory of moral development** Lawrence Kohlberg’s theory, building upon Piaget’s theory of cognitive development, that moral reasoning develops in stages
- theory of psychosocial development** Erik Erikson’s theory that personality develops through stages in a predetermined order, with two outcomes at each stage: successful completion or unsuccessful completion
- toddler** the life stage from 1 to 3 years
- vaccination** the act of presenting a vaccine to the body to elicit protection from a specific disease
- young adults** the life stage from 18 to 35 years

## Assessments

### Review Questions

1. Cephalocaudal development describes development in which direction?
  - a. distal to proximal
  - b. extremities to core
  - c. toe to head
  - d. head to toe
2. A nurse observes two toddlers at a playground. They are sitting in the same sandbox, but each is building their own sandcastle. The nurse knows these children are demonstrating which type of play?
  - a. solitary
  - b. parallel
  - c. associative
  - d. cooperative
3. What stage is a landmark for gaining independence and pushing boundaries?
  - a. infant

- b. toddler
  - c. preschool
  - d. middle childhood
4. The mother of a 12-year-old patient is discussing with the nurse how much her child likes to play on the baseball team at school. The nurse knows the mother is describing which type of play for this patient?
- a. parallel
  - b. solitary
  - c. associative
  - d. cooperative
5. What action would demonstrate to the nurse that an infant has mastered the landmark of understanding object permanence, according to Piaget's theory of cognitive development?
- a. laughing at themselves in a mirror
  - b. holding a shoe in each hand simultaneously
  - c. looking for a toy in their crib in the last place they saw it
  - d. throwing food from their tray to the floor
6. According to Erikson, what is the main conflict of the toddler period?
- a. autonomy versus shame
  - b. industry versus inferiority
  - c. initiative versus guilt
  - d. trust versus mistrust
7. Dramatic play is the landmark of which stage of Jean Piaget's theory of cognitive development?
- a. sensorimotor thinking
  - b. preoperational thinking
  - c. concrete operational thinking
  - d. formal operational thinking
8. What theory states that personality develops according to a predetermined order of stages, each of which has two outcomes: successful completion or unsuccessful completion?
- a. Erik Erikson's theory of psychosocial development
  - b. Jean Piaget's theory of cognitive development
  - c. Lawrence Kohlberg's theory of moral development
  - d. Sigmund Freud's theory of psychosexual development
9. The caregiver of a 9-month-old infant who received routine immunizations in their vastus lateralis the day before calls and asks to speak with the nurse. The parent is concerned and reports that the infant has a fever of 100.2°F and a small, red, slightly elevated area of skin at the injection site. How should the nurse respond?
- a. "This is an expected reaction to injections at the vastus lateralis. When your child is old enough to use other sites, they won't have these reactions."
  - b. "This is an expected reaction from the immunization process. The body's immune system has been activated."
  - c. "This is a concerning finding indicating an allergy. Bring your child in for evaluation."
  - d. "This is unrelated to the immunization. Bring your child in so we can determine the cause."
10. A caregiver comes to the pediatrician's office with her 2-year-old for a well-child visit. The caregiver reports that their child has missed the last two appointments due to scheduling issues. The nurse reviewing the chart realizes that the child is behind on several immunizations. What action should the nurse take regarding the immunizations?
- a. Ignore the issue because missing a few is not important.
  - b. Skip these doses and proceed to the next scheduled items.

- c. Recommend all vaccination series be restarted.
  - d. Refer to the CDC vaccination “catch up” schedule.
- 11.** A nurse cares for an 18-month-old patient who needs an intravenous line placed. What is an example of practicing atraumatic care in a hospital setting?
- a. performing the procedure in a designated treatment room
  - b. restraining the patient in the crib while performing the assessment
  - c. refraining from praising the child if they are crying
  - d. performing the procedure in the patient’s bed so they are more comfortable
- 12.** A nurse is caring for a 16-year-old patient. The patient asks the nurse how often they should have a well-visit. How should the nurse respond?
- a. every six months
  - b. every year
  - c. every year and a half
  - d. every two years

### Check Your Understanding Questions

1. Discuss the difference between growth and development. How should growth and development be used together as part of nursing practice?
2. Describe two examples of each of the following types of play: solitary, parallel, associative, cooperative, onlooker.
3. Summarize the foundational understandings of Erik Erikson’s theory of psychosocial development, including the eight stages.
4. List four theories of development used in nursing care.
5. What is atraumatic care? Why is it an important part of nursing practice?
6. The nurse is educating a mother regarding the well-visit interval for her newborn baby. The mother asks the nurse why the time interval is so short between birth and 3 years. How should the nurse best respond?

### Reflection Questions

1. As the nurse, you assess an 18-month-old child who does not demonstrate many of the milestones outlined for that age. You know you must discuss these deficits with the provider in order to complete additional assessment and testing. How should you convey this message in a supportive manner to the patient’s caregivers?
2. Which theory outlined in this chapter do you feel is most relevant to current nursing practice? Which theory do you feel is least relevant to current nursing practice? Why?
3. Discuss the importance of developmental theories. How can these theories help guide nursing care across the life span?
4. How would you, as the nurse, respond to a patient or caregiver who has a different opinion than yourself regarding the choice to vaccinate themselves or their children?

### What Should the Nurse Do?

1. The nurse receives a call from a caregiver who has given birth four days ago. The caregiver is concerned because she notices the baby seems lighter than at birth and has lost weight. The caregiver asks why this might be and what she should do. How should the nurse respond?
2. The mother of a 2-year-old child is expressing concern to the nurse, stating, “My child never plays with the other kids at the childcare center. He will sit next to them and play, but he won’t interact and play with them. He sometimes plays in the sandbox right next to another child but won’t build the same castle or play with

them.” What should the nurse do or say to the concerned mother?

3. The nurse is assessing developmental milestones on an 18-month-old patient. The nurse would like to assess the concept of object permanence. Outline how the nurse can assess for this milestone while in the hospital or clinic.
4. A nursing student is reviewing the process for during and after administration of a vaccination and asks the nurse why it is important to document each of these components. How should the nurse reply?
5. The caregiver of a 5-year-old patient is speaking with the nurse regarding the child’s vaccination appointment. The caregiver tells the nurse that they have not been able to maintain the originally outlined schedule but would like to get all the recommended vaccinations. What should the nurse do?

### Competency-Based Assessments

1. Create a brochure geared toward caregivers of young children highlighting the difference between growth and development. Discuss the importance of each concept and how they are intertwined in the assessment of children.
2. Create a chart comparing Erik Erikson’s theory of psychosocial development, Jean Piaget’s theory of cognitive development, Lawrence Kohlberg’s theory of moral development, and Sigmund Freud’s theory of psychosexual development.
3. Create a PowerPoint presentation outlining appropriate application of at least two developmental theories into nursing practice.
4. Use the internet to research common reasons why caregivers may choose not to allow vaccinations for their child. Write a script to determine how you would address these concerns with a caregiver.

## CHAPTER 39

# Conception Through Adolescence

**FIGURE 39.1** The largest transformation of human growth and development takes place from conception through adolescence. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### CHAPTER OUTLINE

- 39.1 Growth and Development Stages
- 39.2 Theories Related to Growth and Development
- 39.3 Health Risks for Each Stage
- 39.4 The Nurse's Role in Preventing Illness

**INTRODUCTION** Growth and development occur in a predictable sequence throughout our lives, but the most dramatic changes happen during childhood. Understanding growth and development is the foundation of pediatric nursing practice. Applying knowledge about pediatric growth and development to specific clinical scenarios allows nurses to address the cognitive, physical, and emotional needs of their patients.

## 39.1 Growth and Development Stages

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify growth and development of the conception and prenatal stage
- Recognize growth and development of the neonate stage
- Describe growth and development of the infant stage
- Recall growth and development of the toddler stage
- Understand growth and development of the preschool stage
- Analyze growth and development of the school-age stage
- Verbalize growth and development of the adolescent stage

The way in which children develop from conception through adolescence determines their personality, cognitive ability, psychosocial skills, and physiological response to illness. The sequential process through which children obtain new skills, cognitive ability, and emotional awareness is called development. The increases in height and

weight that happen as children mature are known as growth. Nurses need to understand this process to provide age-appropriate care to their patients. It is important to remember that development encompasses not only the physiological changes throughout childhood but also how emotions, psychological state, and social relationships change and adapt over time (Saddleback College, 2019).

## Conception and Prenatal Development

Human development begins at **conception**, which is the biological process of a sperm fertilizing an **ovum**, otherwise known as an egg (see [Figure 39.2](#)). The product of conception is referred to as a **zygote**, which is a fertilized ovum. Conception almost always occurs in a fallopian tube. A normally formed human zygote has forty-six chromosomes, twenty-three from the ovum, and twenty-three from the sperm. The development process that starts at conception and ends at birth is called **prenatal development**. Prenatal development has three subcategories: pre-embryonic, embryonic, and fetal (Lally & Valentine-French, 2019).

**FIGURE 39.2** Sperm and ovum fuse at the point of conception. (credit: "Sperm-egg.jpg" by Unknown/Wikimedia, Public Domain)

### Pre-Embryonic

The **pre-embryonic period** is also known as the germinal period. This pre-embryonic period occurs in the first two weeks after conception. In the early pre-embryonic period, days one to three after conception, the fertilized egg, or zygote, remains in the fallopian tube. By the third day, the zygote has replicated to be approximately sixteen cells. This mass of cells is called the **morula**, and it migrates from the fallopian tube to the uterus for implantation. In the uterus, the mass of cells continues to grow and forms a blastocyst and a trophoblast. The blastocyst is the cluster of cells that ultimately develops into the embryo; it is surrounded by the trophoblast, which is the group of cells that develops into the placenta. By the end of this period, the fertilized egg is implanted in the uterus (Lally & Valentine-French, 2019).

### Embryonic

The **embryonic period** is the period of development from approximately two weeks after conception to eight weeks after conception. During this stage, the blastocyst and trophoblast that developed in the pre-embryonic stage continue to specialize. The trophoblasts develop chorionic villi, or a network of blood vessels that penetrate the lining of the uterus. The blood vessels from the lining of the uterus dilate and grow around the chorionic villi, ultimately becoming the placenta.

The other cellular formation from the pre-embryonic phase, the blastocyst, develops into three cell layers: the ectoderm, the mesoderm, and the endoderm. These three layers develop into all the tissue and organ systems in the human body. The ectoderm becomes the outer layer of skin, hair, nails, and mucous membranes. The mesoderm becomes the deeper skin layers, cartilage, bones, muscles, cardiac structures, and kidneys. The endoderm becomes the lining of the trachea, pharynx, bronchi, and gastrointestinal (GI) and genitourinary (GU) tracts.

A key concept of embryonic development is that if there is a problem in a cell layer it will likely affect multiple organ systems. For example, both the cartilage, a key component of ear formation, and the kidneys develop from the mesoderm layer. It is common that children born with congenital kidney problems also have problems with their ears (Phelan & Rheault, 2018).

It is also important to remember that the risk of teratogenic exposure is highest during the embryonic developmental stage. A **teratogen** is any external force, like a medication, chemical, alcohol, drug, or maternal infection, that can cause fetal abnormalities. Since the basic structure of the human body is being developed in this stage, exposure to teratogen has the potential to cause permanent damage or even death (Lally & Valentine-French, 2019).

### Fetal

The **fetal period** describes prenatal development from week nine after conception to birth (see [Figure 39.3](#)). By week nine, all the organ systems and external structure of an infant are partially developed. From this point forward, the organ systems continue to mature and prepare the fetus for extrauterine life. There are several key developmental **milestones** of the fetal developmental stage. By sixteen weeks' gestation, the gender can be determined. At twenty-four weeks, fetal breathing movements start to occur. Around twenty-eight weeks, the fetus begins to develop surfactant, which is a hormone needed to keep the alveoli in the lungs open. Around thirty-two weeks, the fetus begins to demonstrate the sucking reflex, which is a survival reflex needed to feed. Forty weeks is considered full term (Lally & Valentine-French, 2019).

**FIGURE 39.3** During the fetal stage, the baby's brain develops, and the body adds size and weight until the fetus reaches full-term development. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Neonate Development: Birth to Twenty-Eight Days

The neonatal period refers to the first twenty-eight days after birth. This is an important developmental stage that establishes the feeding, bonding, and sleeping patterns of the infant. While these elements of development are extremely important, this is also a period of caution. Neonates are not born with a mature immune system and are at risk for serious infections. Also, previously undiagnosed congenital abnormalities are likely to be detected in this stage.

### Physical

Full-term newborns are born with reflexes that are protective in nature. For example, they have a rooting reflex and

a suck reflex. The rooting reflex is an innate response to stimulation of the face, mouth, or cheek. It helps babies find and latch onto a nipple to begin feeding. The suck reflex begins around thirty-two weeks' gestation and is an automatic response to suck and swallow in response to oral stimulation (Saddleback College, 2019).

A healthy newborn is expected to lose 7 to 10 percent of their birth weight in the first two to three days after birth. This is because newborns are born with excess fluid as a result of the birthing process, especially if the birthing person received intravenous fluid during labor (Miyoshi et al., 2020). They should regain their birth weight by the first two weeks. Once they regain their birth weight, newborns should gain an average of 1 oz (30 g) per day and grow 1 to 1.5 in. (2.5 to 4 cm) over the first twenty-eight days (Desiraju, 2018).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Procedure: Documenting Apgar Scores

The Apgar score is a standardized tool to report the status of a newborn immediately after birth. The scores are recorded at one and five minutes. The American Academy of Pediatrics defines a five-minute Apgar score of 7 to 10 as reassuring, 4 to 6 as moderately abnormal, and 0 to 3 as low.

Apgar Components	0	1	2
Color	Blue or pale	Acrocyanotic	Completely pink
Heart rate	Absent	<100 per minute	>100 per minute
Reflex irritability	No response	Grimace	Cry or active withdrawal
Muscle tone	Limp	Some flexion	Active motion
Respiration	Absent	Weak cry; hypoventilation	Good, crying

What is the nurse's responsibility in response to Apgar scores?

Apgar 7 to 10: Dry the infant, promote bonding with skin-to-skin contact, prevent heat loss.

Apgar 4 to 6: Stimulate, provide positive pressure ventilation via bag mask.

Apgar 0 to 3: Call a code, initiate CPR (Simon et al., 2023).

### Behavioral

The most important psychosocial milestone of the neonatal period is bonding with the caregiver and developing a sense of trust. It is important to educate parents about normal neonatal sleeping and feeding behavior so they can respond appropriately to their infant.

Neonates sleep for approximately twelve to sixteen hours per day. When they are not sleeping, they are most often feeding. It is common for a bottle-fed neonate to feed every two to three hours. Breastfed neonates may feed more frequently, every one and a half to two hours.

During these initial twenty-eight days, it is extremely important that parents learn to recognize cues from their infant. As parents respond when the infant is hungry, has a dirty diaper, or is uncomfortable, the neonate develops a sense of trust, which is an important element of psychosocial and personality development throughout childhood.

### Infant: One Month to One Year

The infant period of development is a time of rapid growth and development (Figure 39.4). With every passing month, infants acquire more skills, develop unique personality characteristics, and increase their height and weight. Knowing the normal pattern of growth and recognizing acquisition of key milestones is an important element of pediatric nursing. Applying this knowledge to a nursing assessment helps identify areas of concern so that the

healthcare team can intervene early.

**FIGURE 39.4** Rapid physical changes occur in infants over the course of their first year. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Physical

Rapid growth is the hallmark feature of infancy. By 6 months of age, infants are expected to double their birth weight, and they should triple their birth weight by 1 year. They should also be growing between  $\frac{1}{2}$  and 1 in. (1.3 and 2.5 cm) every month.

In addition to rapid changes in height and weight, infants' heads are also growing during this age range. At birth, an infant's head circumference, on average, is  $\frac{3}{4}$  in. (2 cm) greater than the chest circumference. The head continues to grow rapidly during the first four months and then starts to slow down. By approximately 6 months of age, the head circumference and the chest circumference are equal (Graber, 2023).

### Developmental Patterns

Infant development patterns revolve around acquisition of gross motor skills. There are two primary developmental patterns: **proximodistal** and cephalocaudal. In the proximodistal pattern, development occurs closer to the midline first and then in extremities. For example, infants have trunk control, which is midline, before they have control of their hands and feet, which are distal. In the cephalocaudal pattern, development begins first with the head and then extends downward toward the trunk. An example of cephalocaudal development is having head and neck control before having control of the trunk and extremities.

### Cognitive

Cognitive development in infancy is assessed by evaluating whether the infant is meeting developmental milestones. Developmental milestones are activities 75 percent or more of children can do by a certain age ([Table 39.1](#)) (Centers for Disease Control and Prevention, 2023).

Age in Months	Expected Developmental Milestones
2	Moves head side to side, tracks with eyes, makes verbal noises, has a social smile, holds head up when supine
4	Reaches for toys, rolls over, remembers faces, babbles
6	Sits with support, makes vowel sounds, responds to their name, looks in the mirror
9	Sits without support, crawls, stands, moves objects from hand to hand, develops object permanence
12	Takes independent steps, follows simple commands, says simple words, able to take toys in and out of a container

**TABLE 39.1** Milestones from Infancy to 1 Year (Source: CDC, 2024.)

### Psychosocial

The psychosocial development of an infant 1 month to 1 year focuses on recognition of caregivers and the initiation of play. By approximately 6 months of age, infants demonstrate **separation anxiety**, or fear of abandonment when

their primary caregiver leaves. This behavior is a normal part of development that children usually outgrow by age 3 years.

Throughout the first year, infants become more active with their play. Starting at 6 months, infants enjoy knocking over blocks, rolling a ball on the floor, and playing with other sensory toys. They learn to explore their environment through play and develop both their fine and gross motor skills. Providing a safe environment for infants to play is an important part of caring for them (Newton, 2022).

### Toddler: One to Three Years

The rapid changes in height and weight seen in the first year of life start to slow down in the toddler years. This developmental stage is more about acquiring new cognitive skills and less about changes in physical size. In a relatively short period of time, toddlers change from being completely dependent on their caregivers to gaining a sense of autonomy and being able to complete tasks like feeding themselves and dressing themselves (Saddleback College, 2019).

#### Physical

Although physical growth slows during the toddler years, toddlers noticeably change year by year in their physical size. By approximately age 2 years, toddlers have quadrupled their birth weight. Once this milestone is achieved, they continue to gain 4 to 6 lb (2 to 3 kg) per year and grow 2 to 3 in. (5 to 7.5 cm). This rate of growth continues to approximately age 3 years (Graber, 2023).

#### Cognitive

Toddlers are on the go. They love running, climbing, and testing out their new physical skills. Much of toddlers' cognitive development is demonstrated in their rapid achievement in gross motor skills. By the end of the toddler years, children should be able to throw a ball, kick a ball, and run without falling (Saddleback College, 2019).

In addition to rapid attainment of new gross motor skills, toddlers develop language skills and fine motor skills. By the end of the second year, children should be able to speak in two- to three-word sentences and have a 200-word vocabulary. They should also have the fine motor skills needed to scribble with a crayon or marker and be able to feed themselves with a spoon and fork (Byington & Kim, 2015).

#### Psychosocial

The primary psychosocial achievement during the toddler years is to transition from independent play to parallel play. Children learn how to socialize through play. During parallel play, children play near each other but not with each other. Although it appears that children engaged in parallel play are not paying attention to the other child, they are. They often mimic the other child and are learning to socialize (Figure 39.5). This type of play is a bridge to other more advanced play that develops throughout childhood (Newton, 2022).

**FIGURE 39.5** Children may engage in parallel play even when they are in close proximity, and may switch between playing together or separately at any time. (credit: US Army Southern European Task Force/Flickr, CC-BY 2.0)

## Preschool: Three to Five Years

The preschool developmental period is the bridge from the toddler years to the school-age years. Children in this age group learn new social skills that get them ready for school. For example, they learn to follow rules and play with other children in a group. While they continue to be very physically active, they have more self-control than toddlers and have a longer attention span.

### Physical

The rate of growth continues to slow during the preschool years. The average preschool-age child gains 5 lb (2 kg) per year and grows 3 in. (8 cm) per year. As their body proportions change, they become more coordinated with their movements. Their limbs grow longer, and their balance improves, making it easier for them to participate in active play. In addition to these changes, their abdominal muscles strengthen so their abdomen no longer looks distended, and they have a more slender physique (Graber, 2023).

### Cognitive

Cognitive development in the preschool years focuses on changes in how children think. Toddlers are very egocentric and view the world only from their perspective. Preschool-age children have a greater appreciation of others and are very creative. Their language skills are growing exponentially, and they love to tell stories. They also frequently have imaginary friends and like to play make believe.

By the end of this developmental stage, children should have the cognitive skills to learn new knowledge. Attending preschool helps them get ready. Children who attend preschool are likely able to write their name, cut with scissors, and draw shapes when they start school. They are also used to being in a group setting and can follow rules. All of this makes it easier for them to adapt to the school environment (Newton, 2022).

### Psychosocial

Psychosocial development in preschool children revolves around learning to function outside of the home, being away from their primary caregiver, and learning the rules of being in a group setting.

A common stress for parents of preschool-age children is separation anxiety. Children in this age group frequently have a hard time adjusting when they are left at preschool. It is important to teach parents that separation anxiety is a normal part of development and does not mean that their child is not ready for preschool (National Health Services UK, 2023).

## PATIENT CONVERSATIONS

---

### What If Your Child Cries When Dropped Off at Preschool?

**Scenario:** Nurse sees a 3-year-old patient and her mother at a community health center for a well child check.

**Nurse:** Hi! My name is Emily; I'm one of the pediatric nurses at the clinic. Do you mind verifying your child's name and date of birth?

**Mother:** Sure. My name is Jenny, and my daughter's name is Zoe. Her date of birth is January 2, 2020.

**Nurse:** Great! Is there anything in particular that you want to talk about today?

**Mother:** Zoe is really stressing me out right now. She cries and clings to me every time I leave her at day care. I feel like a bad mother for leaving her there.

**Nurse:** That must be really stressful for you! But don't worry, her behavior sounds normal for a 3-year-old. A lot of parents feel guilty when they leave their kids at preschool, but the truth is that preschool is great for this age group. It teaches them skills to get them ready for school. Does Zoe seem like she has fun when you come to pick her up in the afternoon?

**Mother:** Most of the time. She's starting to make friends at school, and she talks about them at home. Once she's there, she seems to do great. It's just the crying when I drop her off that breaks my heart.

**Nurse:** I understand. Moms hate to see their babies cry. It sounds like you're doing a great job. What Zoe is going

through is called separation anxiety. It is a normal developmental stage. The best thing for you to do when you drop her off is to remain calm and let her know what time you'll be back. She probably doesn't understand time yet. So it's best to let her know what time you'll be back in terms of her daily routine. Say something like, "I'll be back after lunch," or "I'll pick you up after nap time." Keep the goodbye brief. If you let her cling and cry for an extended period of time, she'll start to think having a fit is a good way to get attention.

**Mother:** Haha. Yeah, she's pretty smart, and she knows how to get her way. I'll try your technique and see if it gets better.

**Nurse:** It definitely should. It usually takes kids a couple of weeks to get used to the new routine. Before you know it, she'll be asking to go to preschool.

---

## School-Age: Six to Twelve Years

During the school-age period of development, children go through a significant amount of physiological and cognitive changes. From the early school years to the preteen years, they change from needing constant supervision to being largely independent. During this age bracket, they progressively develop more independence and establish patterns of behavior with regard to school, friends, and extracurricular activities. Children in this age group tend to have strong bonds with peers and like to participate in activities, hobbies, and sports (Saddleback College, 2019).

### Physical

Growth continues at a steady pace during the school-age years. On average, children grow 2.5 in. (6 cm) per year and gain 5 to 7 lb (2 to 3 kg) per year. By the end of the school-age period, children start to accumulate more fat in preparation for the growth spurt that occurs during adolescence. Another important physical change of this period is related to teeth. Around age 6 years, children start to lose their deciduous teeth. By age 12 to 13 years, all their adult teeth, except their wisdom teeth, should be in (Graber, 2023).

### Cognitive

As children mature through the school-age period, their ability to pay attention and concentrate increases. They move beyond learning through memorization to developing math skills, writing skills, and problem-solving skills. Their language evolves, and they can understand grammar rules, participate in creative writing activities, and use language in a more expressive way (Saddleback College, 2019).

### Psychosocial

Peer-to-peer relationships are the backbone of psychosocial development for school-age children (Tepordei et al., 2023). In this age group, children tend to have a best friend, and friendship groups start to form. Children like to spend time with their friends through activities like riding bicycles, skating, swimming, and participating in competitive sports (Figure 39.6). Although they are still very active, their fine motor skills have developed to the point that they can sit and work on projects. They frequently enjoy drawing, computer work, and hobbies like collecting things (Newton, 2022).

**FIGURE 39.6** Because they understand luck and fairness, children in middle and late childhood (6 to 11 years old) are able to follow rules for games. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

## Adolescent: Thirteen to Eighteen Years

Adolescence is the final development stage of childhood before adulthood. This stage is characterized by both cognitive and physical maturation. During this stage, adolescents develop cognitive abilities that are similar to adults, go through puberty, and reach or nearly reach their adult height.

### Physical

The primary physical change during adolescence is **puberty**, or the development process of becoming sexually mature. Puberty is a stepwise process that takes about five years. People assigned female at birth tend to enter puberty before people assigned male. The onset of puberty for females is usually between the ages of 8 and 13 years. Males tend to start puberty between the ages of 9 and 14 years (National Institutes of Health, 2021).

In addition to sexual maturation, all people go through a rapid growth spurt during adolescence. They tend to grow between 3 and 3.5 in. (7.5 and 9 cm) per year during their peak growth spurt. However, females tend to stop growing sooner. Most females reach their final, adult height two years after **menarche** (first menstrual period), while males tend to continue growing until age 20 years (Graber, 2023).

## REAL RN STORIES

---

### Sexually Active Teenager

**Nurse:** Ruth, BSN

**Clinical setting:** School-based clinic

**Years in practice:** 15

**Facility location:** High school in a large metropolitan area of Colorado

We serve students at a local high school. The clinic is staffed by a nurse practitioner and a registered nurse. There is also a social worker who rotates through multiple school-based health clinics. Students come in for sports physicals, sick visits, management of chronic illness, and reproductive healthcare services.

One day after school, Gina H., a 15-year-old sophomore, came into the clinic and requested a pregnancy test. Gina comes to the clinic often. She seems lonely and likes to talk with me and the other nurses. After checking Gina's vital signs, I obtained a urine sample for the pregnancy test and assigned Gina to an exam room to wait for the nurse practitioner.

Gina was not pregnant, but on further questioning, she admitted being sexually active with multiple boys. She was scared that she would get a sexually transmitted infection (STI) and was also paranoid she would get pregnant. She admitted that she was not using any form of birth control. The nurse practitioner screened Gina for STIs and requested that she return to the clinic for a counseling session with me and a social worker.

Gina came back the following week and met with me and the social worker. During the session, Gina admitted to problems at home. Her mother and father recently separated, and she did not get along with her mom's new boyfriend, who drank a lot and was sometimes verbally abusive. Since the boyfriend moved in with her mom, Gina had been spending more time with friends and meets up with guys at different parties.

After meeting with Gina, I filed a report with social services. I also discussed birth control options with her. As a 15-year-old in Colorado, she can consent for birth control without parental permission. After reviewing her options, Gina decided to use Depo-Provera, a long-acting birth control injection that lasts for three months. She also agreed to continue coming to the clinic weekly for counseling sessions.

Social services completed a home visit and determined that there was no evidence of abuse. However, a case file was created, and Gina was given appropriate phone numbers to call if she has problems at home. She continues to come to the clinic on a weekly basis to meet with me. Since starting therapy, her affect has improved, and she seems more interested in school.

---

### Cognitive

Cognitive maturation during adolescence focuses on two elements: abstract thinking and a sense of morality. By the end of adolescence, teenagers should have developed **abstract thinking**, or the ability to think through scenarios

with different possible outcomes and evaluate which outcome would be best. The same process is true with regard to a sense of right versus wrong. Prior to adolescence, children view ethical dilemmas based on the desire to follow rules or to avoid punishment. By the end of adolescence, they can analyze individual circumstances and make decisions based on a sense of ethical correctness (Figure 39.7) (Newton, 2022).

**FIGURE 39.7** Teenage thinking is characterized by the ability to reason logically and solve hypothetical problems such as how to design, plan, and build a structure. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

### Psychosocial

The primary psychosocial task of adolescence is establishing independence and an identity apart from the family of origin. Peer relationships are incredibly important in this age group (Figure 39.8). Adolescents dress like their friends, participate in the same activities as their friends, and are prone to give in to peer pressure. This can be a challenging time for parents. As adolescents try to assert their autonomy, they challenge the authority of their parents. This process is made even more tumultuous by the hormonal changes of puberty that can lead to emotional outbursts (Saddleback College, 2019).

**FIGURE 39.8** Peers are a primary influence on our development in adolescence. (credit: "130726-F-BZ180-001" by Staff Sgt. Luther Mitchell/U.S. Air Force, Public Domain)

## 39.2 Theories Related to Growth and Development

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain Freud’s theory in relation to growth and development
- Explain Erikson’s theory in relation to growth and development
- Explain Havighurst’s theory in relation to growth and development

Childhood development is both predictable and unique, meaning children progress through specific stages but also demonstrate unique psychosocial and personality characteristics throughout their childhood. The development theories help us understand how children develop and learn, and if their behavior and cognition fall within the normal range for children their age. There are three specific theories that are often discussed in pediatric development: Freud’s theory, Erikson’s theory, and Havighurst’s theory.

### Freud’s Theory

Freud described personality development through psychosexual stages. The stages are oral, anal, phallic, latent, and genital. According to Freud, *sexual* is a general term that refers to any pleasurable action, behavior, or thought. Based on children’s age, they progress through stages in which a specific part of their body experiences pleasure and tension. In each stage of development, there is a conflict between frustrated wishes and social norms. Ideally, children resolve each conflict and move on to the subsequent stage. Some children may linger in a stage because their needs are under met or over met. For example, according to Freud, both children who are underfed and overfed as infants may develop personality deficits (Lantz, 2022).

Another important aspect of Freud’s theory of personality development is the idea that personality is multidimensional. According to Freud, there are three parts of the human personality: the id, ego, and superego. The id represents our instincts and our impulses. The ego focuses on our reality. The superego focuses on morality. The three parts of the human psyche interact with each other to define our personality. These three elements of the human psyche develop in childhood throughout the stages of development (Table 39.2).

Stage	Age	Focus	Id, Ego, or Superego
I—Oral	0 to 1 year old	Gratification comes from the mouth, including biting and sucking activities.	Id is present at birth. Ego starts to develop.
II—Anal	1 to 3 years old	Anus is the primary interest. Toilet training is a primary developmental task.	Ego is the primary facet of this stage of personality development.
III—Phallic	3 to 6 years old	Genitals are the area of focus. Masturbation is common. Many children bond with the opposite-sex parent. This is referred to as the Oedipus complex.	Superego starts to develop.

**TABLE 39.2** Freud’s Development Stages (Source: Lantz & Ray, 2022.)

Stage	Age	Focus	Id, Ego, or Superego
IV—Latency	6 to 12 years old	Resolution of oedipal complex. Sexual drive channeled into socially appropriate behavior like schoolwork and playing sports.	Id is repressed as children want to conform to societal norms. Superego matures.
V—Genital	13 to 18 years old	Puberty and the capacity of true intimacy are the hallmarks of this stage.	Superego is fully formed; the three elements of the human psyche interact with each other.

**TABLE 39.2** Freud's Development Stages (Source: Lantz & Ray, 2022.)

## Erikson's Theory

Erikson's theory of psychosocial development is based on eight stages of development through which an individual passes from infancy to late adulthood ([Table 39.3](#)). In each stage, the individual should conquer a developmental milestone through resolution of a basic conflict. The theory is sequential, meaning the skills or psychosocial attributes obtained in earlier stages are needed for successful completion of later stages. Therefore, if the person does not master the milestone in each stage, it could result in repercussions later in life and/or an unhealthy personality (Orenstein, 2022).

Basic Conflict	Age Range	Important Skill	Outcome
Trust versus mistrust	Infancy 0 to 1.5 years	Feeding	Infants develop a sense of trust if caregivers respond to their needs. If not, they develop mistrust.
Autonomy versus shame and doubt	Toddler 1.5 to 3 years	Toilet training	Toddlers are egocentric and need to develop independence from their caregiver. Successful completion of this stage leads to a sense of autonomy, while failure leads to shame and doubt.
Initiative versus guilt	Preschool 3 to 5 years	Exploration	Children begin to assert control of their environment. Success in this stage is a sense of purpose and initiative to try new things. Children who experience excessive disapproval develop a sense of guilt.
Industry versus inferiority	School age 5 to 12 years	Social awareness	School-age children need to master the demands of school and friendships. Success leads to a sense of competence, while failure leads to feelings of inferiority.
Identity versus role confusion	Adolescent 12 to 18 years	Peer relationships	Teens need to develop their own identity that is unique from their family of origin. Successful completion of this stage leads to strong personal identity, while failure results in confusion and a weak sense of self.
Intimacy versus isolation	Young adult 18 to 40 years	Intimate relationships	Young adults need to build loving, reciprocal relationships. Success leads to strong relationships with friends and a partner or partners, while failure leads to isolation and loneliness.

**TABLE 39.3** Erikson's Stages of Development

Basic Conflict	Age Range	Important Skill	Outcome
Generativity versus stagnation	Adult 40 to 65 years	Professional life and parenthood	Middle-aged adults need to create something that will outlast them. This could be raising children or creating positive change. Success leads to a sense of accomplishment, while failure leads to withdrawal from society.
Ego integrity versus despair	Older adult 65 years+	Reflection on life	Older adults will look back at their life and have either a sense of fulfillment or a sense of regret and bitterness.

**TABLE 39.3** Erikson's Stages of Development

## LINK TO LEARNING

More information on [Freud's and Erickson's theories \(https://openstax.org/r/77erictheory\)](https://openstax.org/r/77erictheory) and their similarities and differences are presented in this video.

## Havighurst's Theory

Havighurst's theory of human development is based on the premise that individuals pass through a series of developmental stages from infancy through adulthood. In each stage, there are specific developmental tasks that must be completed ([Table 39.4](#)). A **developmental task** is a challenge the individual wants to solve that arises predictably at a certain period in life. Successful completion of these tasks leads to a person's happiness and increases the probability of completion of later tasks. Failure to complete tasks leads to societal disapproval and unhappiness (Jugert & Titzmann, 2020).

Stage	Age Range	Tasks to Be Completed
Infancy and early childhood	0 to 6 years old	<ul style="list-style-type: none"> <li>• Learn to walk</li> <li>• Learn to talk</li> <li>• Toilet train</li> <li>• Learn the foundation of reading</li> </ul>
Later childhood	6 to 13 years old	<ul style="list-style-type: none"> <li>• Acquire the skills necessary to play games</li> <li>• Learn to play with other children of the same age</li> <li>• Achieve personal independence</li> <li>• Recognize what society deems as masculine or feminine social roles</li> </ul>
Adolescence	13 to 18 years old	<ul style="list-style-type: none"> <li>• Accept physical changes of puberty</li> <li>• Prepare for having intimate relationships and starting a family</li> <li>• Plan for an economically viable career</li> <li>• Develop a personal ideology and a set of ethical values to guide behavior</li> </ul>

**TABLE 39.4** Havighurst's Developmental Stages and Tasks

Stage	Age Range	Tasks to Be Completed
Early adulthood	18 to 30 years old	<ul style="list-style-type: none"> <li>• Find a partner</li> <li>• Establish either a masculine or feminine role</li> <li>• Start a family</li> <li>• Take on civic responsibilities</li> </ul>
Middle age	30 to 60 years old	<ul style="list-style-type: none"> <li>• Achieve adult civic and social responsibilities</li> <li>• Assist adolescent children to become responsible adults</li> <li>• Develop adult hobbies or leisure activities</li> <li>• Accept physiological changes of aging</li> </ul>
Later maturity	60 years and older	<ul style="list-style-type: none"> <li>• Adjust to decrease in strength and loss of physical health</li> <li>• Adapt to retirement</li> <li>• Meet social and civic obligations</li> </ul>

**TABLE 39.4** Havighurst's Developmental Stages and Tasks

Havighurst recognized that humans do not develop in a vacuum and outlined specific factors that may affect an individual's development. These factors are societal influences, personal values, and physical maturation. By recognizing that development is affected by both environmental factors and personal characteristics, Havighurst's theory is applicable to a wider population base than other theories (Jurgert & Titzmann, 2020).

### 39.3 Health Risks for Each Stage

#### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify health risks of the conception and prenatal stage
- Recognize health risks of the neonate stage
- Describe health risks of the infant stage
- Recall health risks of the toddler stage
- Understand health risks of the preschool stage
- Analyze health risks of the school-age stage
- Verbalize health risks of the adolescent stage

Health risks vary depending on the stage of development. Nurses working in pediatrics or maternal-child health need to be knowledgeable about the specific health risks for each group. By having that baseline knowledge, nurses can anticipate what health needs are likely to occur and intervene early. Anticipatory guidance and early intervention are the basis of improving health outcomes and minimizing health risks.

#### Conception and Prenatal Health Risks

Women who would like to conceive need education, anticipatory guidance, and support before pregnancy, throughout the pregnancy, and after pregnancy. It is important to remember that there are specific health risks at every stage of this process. Nurses should be aware of the different health risks so that they can provide appropriate nursing care.

#### Infertility

The inability to conceive after twelve months of unprotected intercourse defines infertility. Across all socioeconomic groups, infertility is becoming more common. Infertility affects 10 to 15 percent of males and approximately 19 percent of females in the United States (Centers for Disease Control and Prevention [CDC], 2023c; Cleveland Clinic, 2024). The steady increase in infertility is related to several factors, including delayed childbearing, obesity, smoking, alcohol consumption, psychological stress, exposure to environmental toxins, and prevalence of STIs (CDC, 2023c).

Treatment for infertility depends on the underlying cause. Prior to beginning treatment, a baseline evaluation of a female's reproductive health is usually conducted to rule out common causes of infertility, like thyroid disorder, coagulation problems, and fibroids. Treatment for infertility can be broken down into three main categories: lifestyle modifications, medications, and advanced fertility treatments. Lifestyle modifications that have a beneficial impact on fertility include maintaining a healthy weight, eating a diet low in saturated fat, and exercising on a regular basis. Medications for fertility include drugs that induce ovulation or facilitate implantation of a zygote. Advanced fertility treatments, like in vitro fertilization (IVF) involves creating an embryo in a laboratory and then transferring the embryo into a female's uterus. Within the umbrella of advanced fertility treatments, infertile individuals have the option to use donated eggs or sperm to create healthy embryos. For some individuals, using donated genetic material is the only viable treatment for infertility.

### High-Risk Pregnancy

Any pregnancy in which there are increased health risks for the pregnant person, the developing fetus, or both is known as a **high-risk pregnancy**. Just as the incidence of infertility has increased in the United States, so has the risk of having a high-risk pregnancy. Approximately 50,000 people in the United States experience severe pregnancy complications, and the risk of complications is higher among the Black population (Hawkins & Baum, 2023).

There are several factors that contribute to the increased incidence of high-risk pregnancies. The first is delayed childbearing or advanced age of the pregnant person. People over the age of 35 years who are pregnant are considered at advanced age and are more likely to have complications compared to those under 35 years. Common complications for pregnancies in persons with advanced age include early pregnancy loss, a fetus with chromosomal abnormalities, and gestational diabetes.

Young age, being less than age 17 years, also contributes to an increased risk of having a high-risk pregnancy. People under the age of 17 years are more likely to have anemia, are less likely to receive prenatal care, and are more likely to have untreated STIs (Collier & Molina, 2019).

In addition to age, several other factors contribute to an increased risk of high-risk pregnancy, including the following (Cleveland Clinic, 2021):

- autoimmune disease
- diabetes
- fibroids
- high blood pressure
- HIV
- kidney disease
- unhealthy body mass index
- thyroid disease
- depression and other mental health disorders

## PATIENT CONVERSATIONS

---

### What if Your Patient Appears Scared about a Prenatal Diagnosis?

**Scenario:** Nurse enters the patient's exam room to provide prenatal education and finds the patient and her husband huddled in the corner whispering to each other. Both the patient and her husband appear to be upset and anxious.

**Nurse:** Hi, my name is Samantha. I'm going to be your primary nurse at the clinic. Do you mind verifying your name, date of birth, and the first day of your last menstrual period?

**Patient:** Hi, Samantha. I'm Beth, and this is my husband, Jerry. My last name is Gonzalez-Smith, and the first date of my last period was February 4.

**Nurse:** Great. Thanks, Beth. Okay, so if your last period started February 4, that would make you about five weeks pregnant. Congratulations!

**Patient:** Thanks. We came in right away because I've had a few miscarriages, and I'm so scared something will go wrong.

**Nurse:** I'm so sorry you've lost other pregnancies. Can you tell me more about that? How many miscarriages have you had? About how many weeks into the pregnancies do you miscarry?

**Patient:** I've had four miscarriages in the past three years. All the miscarriages were before I was nine weeks pregnant. It seems like I would take a home pregnancy test, get excited, and then a week or two later, start bleeding.

**Nurse:** That must be really tough for you and your husband. Have you had any genetic testing or had a prenatal workup to try and figure out a cause?

**Patient:** No, we haven't had health insurance, so I hated to go to the doctor and spend money if it wasn't an emergency. I would just stay home when I had a miscarriage. I didn't think I needed to go to the doctor because it felt like a heavy period. I just heard about your clinic that offers care for the uninsured.

**Nurse:** I see. I'm glad you found us. When we finish up today's appointment, I'll set you up with the clinical social worker to see if there is an insurance exchange program that you would qualify for. I'm not sure what the income requirements are, but the social worker can help with all of that. To start with, I'm going to give you some health history forms to fill out. Please fill them out as accurately as you can, and I'll be back in a few minutes to talk about the next steps.

**Patient:** Thanks.

**Nurse:** Okay, looking over your forms, it looks like you have a history of hypothyroidism. Are you currently taking your medication?

**Patient:** No, I stopped taking the medication about five years ago. I felt better, and it was annoying to have to go and get my labs checked.

**Nurse:** I understand. I'm not sure why you've had multiple miscarriages, but having untreated thyroid disease can lead to miscarriages. To start with, I'd like to get a full set of screening labs that include thyroid function, coagulation studies, and various infectious studies. Women have miscarriages for a lot of different reasons. I'm not saying thyroid disease caused your miscarriages; I'm just saying that is one possibility. We're going to work with you and get to the root cause of your fertility problems.

**Patient:** Okay. I really appreciate it. We've wanted a child for a few years now, and we've been so scared that it would never happen.

**Nurse:** It sounds like this has been a bumpy road for both of you. A lot of couples blame themselves for pregnancy problems. I want to make sure you both know this isn't your fault. There is almost always an identifiable medical cause that we can treat. I'm going to ask the nurse practitioner to sign the lab requisition forms so that you can get started on the blood work ASAP. Once the results are back, we'll have you come back to the clinic to discuss the next steps. In the meantime, if you have any unusual vaginal bleeding, vaginal discharge, fever, or any other symptoms you're concerned about, please call us. During clinic hours, there is a triage nurse, and after hours there is a phone service that can page the on-call provider. We're always available.

**Patient:** Thank you so much. I'm so glad we found this clinic.

---

### Prenatal Malnutrition

Women have increased nutritional needs before and during pregnancy and while breastfeeding. Maternal prepregnancy weight has a direct link to birth outcomes. Women with lower weight are more likely to give birth to low-birth-weight babies, and women with higher weight are more likely to give birth to large-for-gestational-age infants. Being of a higher weight also places women at risk for gestational diabetes.

During pregnancy and breastfeeding, women need to have access to diets high in fruits and vegetables, dairy, and protein. From the second trimester until women are done breastfeeding, they need approximately 300 extra calories per day to support their energy needs. In addition to increased calories, specific nutrients are vital during pregnancy. Prenatal diets with insufficient iodine, iron, folate, calcium, and zinc can lead to maternal anemia, preeclampsia,

hemorrhage, and maternal death. Inadequate maternal nutrition can also lead to low birth weight, developmental delays, and even stillbirth (United Nations International Children’s Emergency Fund [UNICEF], 2023).

## LINK TO LEARNING

Some [dietary guidelines to follow during pregnancy \(https://openstax.org/r/77dietpregnt\)](https://openstax.org/r/77dietpregnt) are provided by the American College of Obstetricians and Gynecologists.

## Neonate Health Risks

Neonatal patients face a unique set of health risks. They are one of the most at-risk populations because they are completely dependent on their caregivers, have an immature immunity system, and are physically immature, making them more prone to trauma. The categories of health risks that are specific to this age group are increased risk of infection, birth trauma, congenital malformations, and in utero exposure.

## LIFE-STAGE CONTEXT

### Risk for Infection in the Newborn Period

During the first twenty-eight days of a newborn’s life, the newborn is the most susceptible to infection. Neonatal sepsis refers to an infection in the bloodstream of an infant younger than 28 days old. Infants can contract an infection either from the birth process or via the transmission of pathogens from the environment. Neonatal sepsis presents differently than sepsis in other age groups. Common symptoms of neonatal sepsis include irritability, poor feeding, lethargy, and temperature instability, either hypothermia or hyperthermia (Singh et al., 2022). Neonates who are ill-appearing need a full septic workup, including blood, urine, and cerebral spinal fluid cultures. Broad-spectrum antibiotics should be started after cultures are obtained and then discontinued after forty-eight hours if all cultures are negative. If any culture is positive, antibiotics should be narrowed to treat the identified pathogen. To minimize the risk of newborn sepsis, parents should be advised to limit visitors for the first twenty-eight days. Also, they should avoid giving their newborn an antipyretic, like Tylenol, to prevent masking a fever. Any fever in a newborn must be reported to a healthcare provider for further evaluation (Fleiss et al., 2023).

### Birth Trauma

Birth trauma can be a result of maternal complications, fetal abnormalities, or external forces. The presentation of birth trauma in a newborn depends on the type and severity of injury sustained. The most common sites for birth trauma are the head, neck, and shoulders. Head trauma includes superficial lesions, extracranial and intracranial hemorrhage, and skull fractures. In severe cases, head trauma during birth can lead to permanent brain damage or cerebral palsy. Brachial plexus nerve injuries are the most common nerve birth trauma related to the neck and shoulders. They occur in 2.5 per 1,000 live births and are the result of stretching of the cervical nerve roots during the birth process (Dumpa & Kamity, 2023). These injuries are usually unilateral, and severity ranges from upper arm weakness to total arm paralysis. Most cases of brachial plexus nerve injuries can be treated with physical therapy. Rarely, infants have permanent nerve damage (Dumpa & Kamity, 2023).

### Congenital Malformations

Approximately 3 to 4 percent of infants born in the United States each year have a **congenital malformation**, otherwise known as a birth defect (Boston Children’s Hospital, 2023). A congenital malformation is any health problem or physical abnormality that is present at birth. The most common types of congenital malformations are heart defects, cleft lip/palate, Down syndrome, and spina bifida. Congenital heart defects encompass a wide range of problems that affect how blood flows through the heart and how blood exits the heart to both the body and the lungs. Cleft lip/palate is incomplete closure of the palate, or the roof of the mouth, and the upper lip. Down syndrome, also known as trisomy 21, is a chromosomal abnormality that causes intellectual developmental disorder and can be associated with problems in the gastrointestinal, cardiac, and endocrine systems. Spina bifida is when a section of the spinal column does not form normally, leaving a section of the spinal cord and the nerves exposed. Congenital malformations can be the result of a genetic defect or in utero exposure to a teratogen, or they can have

an unknown cause (Boston Children's Hospital, 2023).

### Exposure In Utero

Fetal exposure to medications, alcohol, illicit drugs, environmental toxins, and certain infections can all cause birth defects. The fetus is at greatest risk for congenital malformations secondary to uterine exposure during the first ten weeks of pregnancy. During this time frame, all the major organ systems and the basic physical structure of the fetus are developing. After ten weeks' gestation, the risk of in utero exposure to teratogens declines because the fetus is growing larger but not undergoing cellular differentiation. There are specific infections, known as the TORCH infections, that are associated with birth defects. Not all infections cause birth defects. However, the TORCH infections have a high probability of causing pregnancy complications. TORCH stands for toxoplasmosis, other (syphilis, hepatitis B), rubella, cytomegalovirus, and herpes simplex (Jaan & Rajnik, 2021).

### Infant Health Risks

Infancy can be a particularly stressful time for parents. Infants are unable to verbally communicate their needs, and parents often feel like their baby is always crying or needing something. The stress of new parenthood can be exacerbated if the infant has any health problems that demand more attention from the caregivers or parents. Specific health problems in this age group that require nursing attention are colic and failure to thrive (FTT). Infants are also at risk for child abuse, accidental injuries, and sudden infant death syndrome (SIDS). Nurses must be aware of all these health risks to provide parents with the appropriate education and support.

#### Colic

Colic is when a baby cries for a long period of time without an identifiable medical reason. It is most common in the first six weeks of life and usually goes away on its own within three to four months of life. Colic is common, affecting approximately one in four newborns.

Possible causes of colic include pain from gas, hunger, overfeeding, milk intolerance, and sensitivity to certain stimuli. Even though babies with colic look like they have abdominal pain, they eat well and gain weight normally. If parents can identify a trigger for colic, they should avoid that trigger. Otherwise, caring for an infant with colic revolves around trying to comfort the baby. Swaddling the baby in a blanket or holding the baby may help. Many parents use an infant carrier to hold their baby close to their body during colic episodes.

## REAL RN STORIES

---

### Frequent Use of RN Triage Line

**Nurse:** Kelly, RN

**Clinical setting:** Outpatient family practice clinic

**Years in practice:** 5

**Facility location:** Small town in Western Oregon

We primarily serve migrant farm workers and their families. This is a federally qualified health center that specializes in care for migrant farm workers, but other uninsured or underinsured members of the community also come here. We offer sliding-scale payments based on income and do not turn anyone away because of an inability to pay. I work in the nursing triage office of the clinic. We take phone calls from patients with questions and see patients in our triage office who walk into the clinic without an appointment.

One of the women who comes to the clinic, Maria Alba, has a 4-week-old infant. This is her first child, and she is very nervous. For the past week she has either called the clinic every day or come into the clinic without a scheduled appointment. She is very worried because her baby is crying a lot, and she does not know how to calm the baby down.

Based on the last interaction I had with her, I scheduled an appointment for her to see both the nurse practitioner and the social worker to see if we can provide her with the support that she needs. The nurse practitioner did a full examination and determined that the baby had no infectious problem or acute medical problem. She diagnosed the infant as having colic and tried to reassure Maria Alba that the baby was okay and was getting enough food and gaining weight well. The nurse practitioner offered advice on how to hold the baby in a way that might soothe her.

Because Maria Alba was exclusively breastfeeding her baby, the nurse practitioner recommended that she make changes to her diet to see if the baby would tolerate the breast milk better. Maria Alba agreed to remove all dairy from her diet and continue breastfeeding the baby on demand. We scheduled a follow-up weight check and nurse education session for Maria Alba and her baby in two days.

After the appointment with the nurse practitioner, Maria Alba met with the social worker to discuss what resources were available to her. The clinic has a new mom support group that meets once a week at lunchtime. The moms can bring their babies and meet other moms who have children who are approximately the same age. Lunch is provided by the clinic; a social worker and a nurse facilitate the meeting and support group. Maria Alba decided to join the support group.

At the end of the visit, Maria Alba verbalized understanding of infant distress warning signs and when she should call the clinic for guidance. She also agreed to try to return to the clinic in two days for another weight check and to meet with the nurse for education and reassurance.

---

### Failure to Thrive

An inadequate weight gain or sudden weight loss is called **failure to thrive (FTT)**. It is defined as a weight consistently below the fifth percentile for age and sex. Failure to thrive can be either organic, or caused by a medical condition, or nonorganic, or the result of an inability to obtain food (Raab, 2023). Examples of organic FTT include the following (Smith et al., 2023):

- food allergy
- malabsorption
- inborn errors of metabolism
- excessive calorie expenditure secondary to hyperthyroidism, congenital heart disease, chronic lung disease, and chronic immunodeficiency

Examples of nonorganic FTT include the following (Smith et al., 2023):

- incorrect formula preparation
- breastfeeding problems
- neglect
- eating a fad diet
- behavior problems affecting eating

The diagnosis of FTT is made after a thorough evaluation of the child's diet, home environment, and risk factors for illness affecting calorie use. Common information that is obtained is a five-day diet food journal, information about food allergies, or food restrictions that are placed on the child. A social work consult to evaluate the home environment and parent-child interactions may also be warranted. If it is determined that the FTT is organic, additional medical tests will be ordered to determine the specific cause of growth failure. Possible diagnostic tests include serum lead and zinc levels, complete blood count to look for anemia, stool-reducing substances to evaluate for malabsorption, and ova and parasite tests to evaluate for parasitic infections (Smith et al., 2023).

Many cases of FTT are multifactorial and are best managed with a multidisciplinary team of physicians, nurses, dietitians, child life specialists, pediatric feeding specialists, and social workers or mental health professionals. The overall goal of FTT management is to reverse the cause of slow growth and provide enough calories to allow for catch-up growth. The specific treatment will depend on the underlying cause. Nonorganic FTT requires extensive parent teaching about correct food preparation and close follow-up. A social services referral may be warranted. Organic FTT management depends on the underlying medical condition. Children with FTT may be hospitalized for several weeks to determine the cause of growth failure and reverse the trend prior to discharge (Smith et al., 2023).

### Accidental Injuries

Given the fact that infants do not walk, the mechanism of accidental injury in infants differs from older children and adults. Falls represent the greatest cause of accidental injury in this age group. Infants who accidentally fall should be evaluated by a healthcare provider. If there has been loss of consciousness, vomiting, or seizures, the infant will likely need a head computed tomography. Since subtle changes in consciousness in an infant may be hard to detect, it is important for parents to seek medical care if their infant has had an accidental fall or injury (Saltzman & Skube,

2021).

### Sudden Infant Death Syndrome

The sudden death of an infant that does not have an identifiable cause, even after a full investigation, is known as **sudden infant death syndrome (SIDS)**. In the United States, SIDS is the third leading cause of death in infants under 1 year of age (Kochanek et al., 2024). In most cases, the infant appears healthy before the event, which usually occurs during sleep. Risk factors for SIDS include premature or low birth weight, overheating during sleep, allowing the baby to sleep with loose blankets or on a soft surface, and having a family history of SIDS. The primary prevention technique for SIDS is to encourage safe sleep practices. Infants should be placed on their back to sleep on a firm mattress with one fitted sheet (Figure 39.9). To minimize the risk of suffocation, stuffed animals, pillows, and blankets should not be in the crib. With parent education and public awareness, the incidence of SIDS has declined from 130 deaths per 100,000 live births in 1990 to 38.4 deaths per 100,000 live births in 2020 (CDC, 2023b).

**FIGURE 39.9** Infants should be placed on their back on a firm mattress with one fitted sheet without stuffed animals, pillows, or blankets. (credit: “Safe sleep environment 2,” by NICHD/Flickr, Public Domain)

### Abuse or Neglect

Infants are fully dependent on their caregivers for survival, which makes them more susceptible to abuse and neglect than older children. Abuse and neglect in infancy can vary from accidental underfeeding to intentional physical abuse. Infants are at risk for **shaken baby syndrome**, a serious type of abuse that usually occurs when a parent or caregiver shakes a baby out of anger or frustration. Babies have weak neck muscles that are unable to fully support their large heads, allowing the head to move forward and backward quickly when shaken. This movement can cause serious brain injury, including subdural hematomas and subarachnoid hemorrhages. It can also cause other injuries like retinal hemorrhages, skull fractures, and fractures to other bones in the face (American Association of Neurological Surgeons, 2019).

### Toddler Health Risks

Toddlers have specific health risks related to their stage of growth and development. Toddlers are becoming more mobile, and their diet is changing, which places them at risk for accidental injuries and malnutrition. They are also at

increased risk for child abuse because children typically potty train during this age range. Potty training can be stressful for parents, and they may lash out and abuse their children (Chung et al., 2019).

### Accidental Injuries

The hallmark of the toddler years is exploration and rapid acceleration of gross motor skills. Children in this age group are on the go, which places them at increased risk for accidental injuries. According to the Centers for Disease Control and Prevention (CDC), the leading causes of accidental injuries in this age group are suffocation, drowning, poisoning, fires, and falls (CDC, 2021). Most accidental injuries are preventable. It is important to remind parents and caregivers about the importance of supervision in this age group. Although toddlers need to learn autonomy and independence, they still must be supervised at all times (CDC, 2021).

### Malnutrition

Malnutrition is a health condition that results from consuming food that contains either insufficient or too many carbohydrates, vitamins, proteins, and/or minerals. Toddlers are at-risk of malnutrition because their feeding patterns change as they become less dependent on caregivers to feed them. A common cause of malnutrition in toddlers is excess cow's milk consumption. During this age range, children should drink between 2 and 2.5 cups (473 to 592 mL) of milk per day. Consuming an excess of that amount can lead to iron deficiency anemia. Milk is not an iron-rich food source, and children who drink milk in excess often do not eat enough other iron-rich foods. Also, milk inhibits the absorption of iron, further lending to iron deficiency anemia. Because it is filling, drinking an excess of milk can also hinder establishing healthy eating patterns.

## LIFE-STAGE CONTEXT

---

### Iron Deficiency Anemia

Iron deficiency anemia adversely impacts childhood development because it is associated with learning and memory problems and fatigue. Prevention of iron deficiency anemia is a crucial element of primary health in this age group. Parents should be instructed on including iron-rich food in their child's diet and minimizing consumption of milk. If parents choose to follow a restrictive or a fad diet, the pros and cons of this should be discussed in detail (Sundararajan & Rabe, 2021). If a family meets the income requirements for assistance, a referral to the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) is a good resource. The WIC program provides nutritional education and food supplements for families with children under the age of 5 years (U.S. Department of Agriculture [USDA], 2023).

### Abuse or Neglect

Child abuse and neglect can happen in any age group and in families from all socioeconomic backgrounds. However, certain age groups and familial patterns place children at an increased risk of abuse or neglect. Family stresses, such as food insecurity, poverty, intimate partner violence, social isolation, parental mental health issues, or substance use disorder, are all factors that increase the likelihood of abuse and neglect (Pekarsky, 2022).

One of the developmental tasks of the toddler years that places this age group at particular risk of abuse is toilet training accidents. A common physical examination finding consistent with child abuse related to toilet training is an immersion burn. This refers to a burn of the buttocks and genital region. Parents and caregivers may immerse their child in hot water as punishment for soiling themselves and making themselves "dirty." A recent retrospective study of characteristics of abusive childhood burns found that burns to the buttocks or groin region are highly indicative of nonaccidental injury (Rosado et al., 2019).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

QSEN Competency: How to File a Report to Child Protective Services if There Is Concern for Child Abuse

Disclaimer: Always follow agency's policy for documenting and reporting suspected child abuse or neglect.

Steps	Description/Rationale
<p>Children may present with an isolated injury, like a broken arm, but on further review they have other injuries like bruises on other parts of their body. Always perform a complete assessment, even if the caregivers are insistent that just the injury needs to be addressed.</p>	<p>Children who experience abuse are frequently seen in the emergency department with injuries. Nurses need to be aware of the signs and symptoms of child abuse. One of the hallmarks of abuse is having injuries in various stages of healing, for example, various bruises of different colors.</p>
<p>Document all examination findings using a nonjudgmental tone.</p>	<p>Even if the nurse notices examination findings that are suspicious for abuse, they should not assume the child had been abused. Treating parents with respect builds rapport and trust. Use a respectful tone when talking with parents and when documenting in their child's medical chart. Once the patient has been evaluated and stabilized, the emergency room staff can move forward with filing a report with Child Protective Services (CPS).</p>
<p>File a report to CPS.</p>	<p>If a child comes into the emergency department with suspected child abuse, additional nursing staff will need to be assigned to the patient. The nurse who evaluates the patient needs to file a report with CPS. An additional nurse should be assigned to the patient to make sure the primary nurse has time to document the findings and file the report. Once the patient has been stabilized and the documentation is complete, the primary nurse should step away to contact CPS. Different states have different methods of filing a report. However, nurses are mandatory reporters in all fifty states.</p>

## Preschool Health Risks

Most children in the preschool age range are around other children their age in large groups. This grouping of children into groups could be preschool, Sunday school classes, and/or meeting with other children for playdates. As a result of this increased activity and being around other children, they have specific health risks, including accidental injuries and exposure to communicable disease. They are also becoming more autonomous in their eating habits, so they should have their food selection choices monitored to make sure they are eating a healthy, balanced diet.

### Accidental Injuries

Unintentional injuries are a leading cause of serious harm and even death among preschool-age children (CDC, 2020). Motor vehicle accidents are a leading cause of unintentional injury, causing approximately 4,600 deaths per year (CDC, 2020). Research has shown that many childhood injuries occur in or around the home, which highlights the importance of anticipatory guidance for parents about making the home environment safe (CDC, 2020). Other common accidental injuries in this age group include suffocation, drowning, poisoning, fire/burn injuries, falls, cuts and puncture wounds, foreign bodies in a body orifice, and swimming injuries (CDC, 2020).

### Risk for Obesity

In the United States, childhood obesity rates have tripled in the past decade. Historically, obesity in preschool-age children is rare. However, in the United States, approximately 15 percent of children aged 2 to 5 years have higher weight (Sanyaolu et al., 2019). A recent study indicates specific factors that place preschool-age children at greater risk for being of higher weight. The three factors identified were a high-calorie diet, increased screen time, and

decreased physical activity. The education level of parents was also a risk factor. Parents with a lower education level were more likely to have children with higher weight (Rosado et al., 2019).

### Exposure to Communicable Diseases

As children enter the preschool years, it is more likely that they will spend time with large groups of children, either by attending preschool or by being in play groups. Children in this age group are also notorious for getting sick all the time, in part because they are frequently in large groups of children where germs can spread easily and because their immune systems have not been exposed to many pathogens, so they do not have much innate immunity. Common health risks in this age group include viral illnesses like the common cold, head lice, gastroenteritis, and hepatitis A. Parents can help stop the spread of infections by keeping their children up to date on their immunizations, encouraging handwashing after going to the bathroom and before eating, and in general, focusing on hygiene.

### School-Aged Health Risks

As children start school, their level of independence from their parents changes rapidly. With each passing year, they are more responsible for feeding themselves, dressing themselves, and taking responsibility for their personal hygiene. There are specific health risks associated with this increased level of independence, such as poor food choices resulting in obesity and health conditions related to lack of personal hygiene. This is also a time in life when learning disabilities, if a child has one, are often diagnosed. Teachers and nurses need to be on the lookout for the specific health risks for school-age children so they can intervene and get the child the appropriate therapy or help.

### Learning Disabilities

Children who have a difficult time learning could have medical problems like hearing or vision deficits or have a more complex problem like a learning disability. If children are having a hard time paying attention or staying organized, and/or they are having problems with reading or math, they should be evaluated for learning disabilities and have their vision and hearing checked. The most common learning disability is dyslexia. People with dyslexia have trouble making the connection between letters and sounds and recognizing words. Other signs of dyslexia include the following:

- delay in being able to speak
- difficult time understanding what others are saying
- difficulty expressing thoughts or feelings
- problems remembering numbers in a sequence
- trouble telling left from right
- poor spelling and reading skills

In addition to dyslexia, school-age children can present with other learning disabilities, such as dysgraphia or dyscalculia. Dysgraphia is a learning disability that affects the individual's ability to write. Dyscalculia is a learning disability that affects the child's ability to understand numbers and math. Children suspected of having a learning disability need to be referred to a specialist. Early diagnosis and treatment can minimize the impact the learning disability has on the child's academic performance (National Institutes of Health, 2018).

## REAL RN STORIES

---

### Frequent Visits to the School Nurse

**Nurse:** Emily, RN

**Clinical setting:** Elementary school

**Years in practice:** 15

**Facility location:** Public school in a suburb of Portland, Oregon

Our school has a diverse patient population. Many of our students come from a lower socioeconomic background and speak English as a second language. I see a wide variety of complaints in the school nursing office, everything from acute infections to children who have a stomachache because they have not had enough to eat.

Last semester, I noticed that a second-grade student, Julia, came to the nurse's office two to three times per week

with the complaint of a headache. She always came at the same time of day, around 2 p.m., and after about thirty minutes said she felt better and would go back to class. I thought this pattern of behavior was odd and did some investigating. It turns out that 2 p.m. was reading hour in Julia's classroom. The students would be called on to read a portion of their reading textbook out loud to the rest of the class.

Once I learned Julia consistently came to the nursing office during reading hour, I spoke with her teacher. The teacher reported that Julia understands written instructions but frequently gets distracted in class and does not finish her schoolwork. The teacher and I decided to organize a meeting with the parents to discuss the possibility that Julia might have a learning disorder and need additional resources.

During the meeting, we discussed the observations the teacher and I had with regard to Julia's behavior at school. The parents reported that at home she gets upset when she has to do homework and frequently says that she hates school. Based on the discussion, we moved forward with a full learning ability workup. The workup will include testing Julia's hearing and vision. If both of those are normal, her parents agreed to meet with a learning disability specialist for further evaluation.

---

### Risk for Obesity

The incidence of obesity in school-age children has more than tripled since the 1970s. As of 2018 in the United States, one in five school-age children were of higher weight (CDC, 2022). There are multiple factors that contribute to the increase in obesity, including consumption of high-calorie foods, decreased activity level, short sleep duration, and experiencing trauma during childhood (CDC, 2022).

Having a comprehensive approach to obesity in the public school system may be an effective tool to decrease obesity rates. A comprehensive approach involves changing food items in the cafeteria, increasing physical activity during school hours, involving school nurses and after-school program professionals, and providing education to parents and caregivers.

### Poor Hygiene Practices

The process by which a person cares for their health by cleaning and caring for their body is called **hygiene**. Starting from birth, parents are responsible for their child's hygiene. However, as children mature, they must acquire independent hygiene habits. In some families, caregivers do not have adequate knowledge to instruct children in adequate hygiene practices. Common areas where school-age children lack hygiene practices include teeth brushing and oral care, bathing, and wearing clean clothes. Children who come to school with evidence of poor hygiene should be referred to the school nurse or a social worker to evaluate for possible neglect at home and/or provide the family with additional education and resources (Pérez Pico et al., 2022).

### Adolescent Health Risks

In the adolescent stage of development, teens are forming their personal identity that is unique from the family of origin. In this stage, peer groups are paramount to the adolescent's development. Adolescents tend to go along with the decisions of their peer group and focus on the opinions of their peers. During this stage, many adolescents experiment with drugs, alcohol, sex, learning to drive, and other risky behavior. Their bodies are also changing rapidly, which can lead to body image disturbances and eating disorders. All these life changes play into the specific health risks of the adolescent patient.

### Risk-Prone Behaviors

Risk-taking behavior tends to be low in childhood, starts to increase around puberty, and peaks in late adolescence. Psychosocial research proposes that risk-prone behavior reflects a gap between an adolescent's biological and social maturity. Adolescents frequently underestimate risks while simultaneously believing that there is a greater potential benefit to risky behavior. On the other hand, adults tend to make decisions based on education and experiences. Adolescents lack the necessary experience to use that logic. As a result, they are more likely to use drugs or alcohol, have unprotected sex, and pursue relationships with people with violent tendencies (CDC, 2024).

### Distress with Personal Identity

Identity formation is one of the principal tasks of adolescent development. During this age group, teens frequently try out different identities by making friends in different peer groups. A teen could be into playing soccer one year and obsessed with music the next. Adolescents tend to rely heavily on their peer group to help them form an

identity. If they are unable to find a close group of friends, identity formation can be difficult, which can lead to loneliness and a sense of despair (Lindekilde et al., 2018).

## PATIENT CONVERSATIONS

---

### What if Your Adolescent Patient Appears Anxious about Applying for College?

**Scenario:** Nurse walks into the exam room to talk to an 18-year-old patient who has come in for a sports physical prior to starting his senior year of high school. When the nurse asks open-ended questions about school and plans for the future, the teen gets anxious and looks at the floor. He acts like he doesn't want to discuss life after high school.

**Nurse:** Hi, my name is Rebecca. I'm one of the nurses at the clinic. I'm going to check your vital signs and ask a few questions before the doctor comes in to see you.

**Patient:** Hi, Rebecca. My name is Brandon.

**Nurse:** It's nice to meet you, Brandon. Can you confirm your full name and date of birth?

**Patient:** Sure, Brandon Harrison, January 14, 2006.

**Nurse:** Thanks. It looks like you play several sports: football, basketball, and tennis. Do you plan to continue sports in college next year?

**Patient:** Ummm, I'm not sure about next year.

**Nurse:** Okay. A lot of students like to get a fresh start after they finish high school. It's not unusual to want to try new things. Have you thought about what you'd like to do next year?

**Patient:** My dad wants me to go to his alma mater and major in business administration.

**Nurse:** I see. Business administration is a great major. It opens the door for a lot of different career options. Having said that, there are several different majors available to you. Have you thought of studying anything else?

**Patient:** I haven't thought about it. To be honest, I'm not sure I'm ready to go to college. [Looks anxious and stares at the floor.] Please don't tell my dad!

**Nurse:** Don't worry, Brandon. This conversation is confidential. I won't discuss anything that you tell me with your parents. If you're not sure about starting college next year, have you considered taking a gap year?

**Patient:** What's a gap year?

**Nurse:** It's when students take a break between high school and college. They might get an entry-level job in an industry they're interested in, volunteer, travel, or just work full time while they consider their options.

**Patient:** Interesting. I'd like that, but I don't think my parents would agree. They talked about college as if it's my destiny. I don't think they've considered the possibility that I might want to do something different.

**Nurse:** Well, maybe you should have a talk with them. College isn't for everyone, and if you take a break for a few months and decide you really want to go, you can apply at that time. Students tend to do better at their university studies if they're focused and driven to be there. If you want some tips on how to bring up this topic with your parents, let me know. I'm happy to help in any way I can.

**Patient:** Thanks. I'm going to think about what I want. Taking some time off might make sense. I'm not sure what I want to study in college. Maybe I'll get a job and save up some money while I explore my options.

---

### Risk for Self-Harm

The risk for self-harm is high in adolescents. Reported self-harm prevalence rates in this age group range from 17 to 60 percent (Brown & Plener, 2017). The high rate of self-harm in adolescents is likely multifactorial. Adolescents feel emotionally liable in response to the surging hormones of puberty. At the same time, they are struggling with an identity crisis as they attempt to form a personal identity that is unique from their family of origin. Known risk factors

for adolescent self-harm behavior include female gender, being an only child, poor school performance, harsh parenting styles, and poor mental health (Brown & Plener, 2017).

### Substance Use

Alcohol or drug use, also **substance use**, is common in U.S. adolescents. According to a recent government survey, 52 percent of twelfth graders reported using alcohol within the last twelve months (Miech et al., 2023). In addition, 41 percent report having the opportunity to use any illicit drugs (Miech et al., 2023). Tobacco use in any form (smoking, smokeless, and e-cigarettes) is an additional concern for substance use and abuse in this population. The ease of availability of alcohol and illicit drugs combined with the risk-taking behavior associated with the adolescent period makes substance use a significant problem. Teens who misuse either alcohol or illicit drugs are more likely to develop a substance use disorder later in life (Miech et al., 2023).

### Sexually Transmitted Infections

Although STIs affect people in all age groups, the burden is particularly high in adolescents. According to statistics from the CDC, nearly half of all STIs in the United States occur in individuals ages 15 to 24 years (CDC, 2024). The risk-taking behavior that is common among adolescents and young adults contributes to this high rate of infection. Many adolescents underestimate the risk of having unprotected sex and/or believe that they are invincible and unlikely to get an infection (CDC, 2024).

### Pregnancy

Teen pregnancy and childbearing are associated with economic hardship in both the short term and in the long term. One of the main indicators of this is high school graduation rates. High school graduation rates are significantly lower among teen moms. According to the CDC, only 50 percent of teen moms receive a high school diploma by age 22 years, whereas approximately 90 percent of other adolescent females graduate from high school (Youth.gov, n.d.). Teen fathers are also 25 percent less likely to graduate from high school (Youth.gov, n.d.). Teenage pregnancy is also associated with having more health problems, being incarcerated, and being unemployed (Youth.gov, n.d.). The good news is the rate of teenage pregnancy dropped by 78 percent between 1991 and 2021 (CDC, 2023a). The drop in pregnancy rates is believed to be associated with education and better access to birth control.

## 39.4 The Nurse's Role in Preventing Illness

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify nursing considerations for the conception and prenatal stage
- Recognize nursing considerations for the neonate stage
- Describe nursing considerations for the infant stage
- Recall nursing considerations for the toddler stage
- Understand nursing considerations for the preschool stage
- Analyze nursing considerations for the school-age stage
- Verbalize nursing considerations for the adolescent stage

Nursing considerations change throughout the life span. The specific considerations for each age group depend on the physical, cognitive, and emotional needs of patients during that point in their development. In addition to evaluating these factors, to provide the best nursing care, nurses need to consider the health risks associated with each group. By doing so, nurses are able to provide holistic, age-appropriate nursing care.

### Nursing Considerations for the Conception and Prenatal Stage

Regardless of whether women of childbearing age want to start a family or not, they need nursing support and education. Nurses play a crucial role in providing both birth control education and prenatal education. In many family planning and prenatal clinics, the nurses are the primary point of contact for patients receiving services. They triage phone calls from patients with questions or concerns, help manage patients' prescription medication, and make sure patients understand their plan of care.

#### Assist with Family Planning

Although a midlevel provider, physician assistant, nurse practitioner, or physician is required to write a prescription for contraception, registered nurses play a key role in instructing patients how to use contraception. Most outpatient

clinics that provide family planning services have nurses who provide one-on-one instruction on how contraception works, what to do if a dose of contraception is missed, and under what circumstances patients should use a backup contraception method. Nurses are also the ones who frequently provide education on different contraception options and manage the after-hours phone line for patients who have questions when the clinic is closed.

### Prenatal Education

Nursing prenatal education is aimed at helping expecting parents learn and implement healthy habits during pregnancy. The habits focus on the nutritional needs of the pregnant person and developing fetus, information on substances to avoid during pregnancy, and guidance on exercise and sleep requirements during pregnancy. The most important nutritional advice is to emphasize the importance of taking adequate folic acid throughout pregnancy. Pregnant persons also need to be reminded that alcohol, cigarettes, and illicit drugs will potentially harm the developing fetus. Most pregnant persons can continue their prepregnancy exercise routine, but a new exercise regimen should not be started during pregnancy. Pregnant persons should expect to be tired during pregnancy, particularly in the first trimester.

The nurse also educates expecting parents about pregnancy warning signs and when to seek medical attention during pregnancy. The pregnant person should be taught to seek medical attention for vaginal bleeding, persistent headaches, or unusual swelling in the hands or face. Vaginal bleeding is a sign of miscarriage, while persistent headaches and unusual swelling are associated with preeclampsia.

### Nursing Considerations for the Neonate Stage

Newborns and their parents need a lot of support and nursing care. In the neonatal stage, parents bond with the newborn through feeding and providing basic care. The feeding and bonding process can be stressful for both the neonate and the parents. Many new parents have difficulty breastfeeding or are stressed out by the responsibility of caring for a newborn. One of the primary roles of a nurse in this developmental stage is to facilitate bonding and ensure that the newborn is getting enough nutrition.

### Facilitate Bonding

When a caregiver and a baby feel a strong attachment to each other, this is known as **bonding**. Many parents feel love, joy, and a sense of protection for their baby. However, this bond does not happen instantly for all parents. For many parents, bonding is a process. It can take days, weeks, or longer to fully bond with a newborn. This is especially true if the newborn is admitted to the hospital after birth or is adopted. Parents need to be supported through this process and be reassured that they are not bad parents if bonding takes longer than expected.

## REAL RN STORIES

---

### Unexpected Newborn Intensive Care Unit Admission

**Nurse:** Ripal, RN

**Clinical setting:** Newborn intensive care unit (NICU)

**Years in practice:** 5

**Facility location:** Large teaching hospital in Colorado

We are the largest level 1 NICU in the state. We serve patients from all over the Rocky Mountain region. Our patient population comes from all socioeconomic backgrounds. Our hospital has contracts with Medicare and Medicaid and with multiple private insurance companies.

One night shift, a newborn was transferred via Flight for Life from a town in Western Colorado. The neonate was born with a severe congenital heart defect that was not diagnosed in utero. The parents were devastated by the diagnosis and completely unprepared for a NICU admission.

Upon assessment, the newborn was intubated, sedated, and had both arterial and venous umbilical lines in place through which he was receiving sedation, antibiotics, and a continuous prostaglandin E infusion. The infant was stabilized prior to transfer, but the plan was for him to remain intubated and sedated until he could have neonatal heart surgery within the next seventy-two hours. The parents were at the bedside in a complete state of shock. They were both crying and did not want to look at their infant son.

After talking with the parents, I learned that they had tried for several years to have a child and were so excited when they found out they were going to be parents. The mother had received prenatal care and could not believe that her child could have an undiagnosed congenital heart defect.

I provided emotional support for both parents and discussed ways that they could bond with their child while he was in the NICU. We discussed skin-to-skin contact, and I encouraged the mom to pump breast milk. We reviewed the breast milk storage and administration policy in our unit. With the help of our social worker, we developed a parent visitation schedule that worked with the newborn's nursing care so that the parents could be present at the bedside and have as much contact with their child as possible.

In addition to providing information on parent-child interactions while in the NICU, I encouraged the parents to take time for themselves. There is no right or wrong way to be a NICU parent. Some parents want to be at the bedside all the time, while others find the unit stressful and want to stay away. Regardless of where parents fall within the spectrum, the newborn-parent bond will happen. I reminded the parents that the NICU staff is here to take care of their baby and support them.

The parents were still teary eyed at the end of the admission but were able to focus on the steps that would take place over the next couple of days. Both parents chose to leave the hospital, spend the night at a nearby hotel, and return the next day to meet with the medical team. I advised them to get some rest and reassured them that we would call with any changes in their child's clinical status.

---

### Nutritional Support

One of the primary developmental tasks during the newborn period is to establish a feeding schedule. Not only does feeding provide a bonding opportunity, but it is also the sole source of nutrition for the infant. A preterm neonate needs 100 to 150 kcal/kg per day of nutrition, whereas a term neonate needs 100 to 120 kcal/kg per day (Patel & Rouster, 2023). If infants are breastfed, parents should be instructed that newborns feed approximately every two hours. Both breastfed infants and formula-fed newborns should have frequent weight checks to ensure that they are getting enough nutrition. Newborns should regain their birth weight by 2 weeks of age and then gain an average of 1.1 oz (30 g) per day (Desiraju, 2018).

Whether parents choose to breastfeed or bottle feed, nurses should provide guidance on best feeding practices. People who have given birth who breastfeed should be advised that breastfeeding can be a challenge. For many, it can take time for the milk to come in, and not all newborns learn to latch, suck, and swallow easily. The first three days after birth, the breast makes a thick, yellowish liquid called **colostrum**, a nutrient-dense liquid that also helps bolster the newborn's immune system. The person who gave birth may feel like their breasts are hard, full, and warm as the colostrum ends and the breast milk starts to come in. During this time, the person who gave birth may need to breastfeed more frequently. If parents have any concerns about breastfeeding, they should speak with a lactation consultant.

### LINK TO LEARNING

Review the [American Academy of Pediatrics policy statement on breastfeeding \(https://openstax.org/r/77AAPbreast\)](https://openstax.org/r/77AAPbreast) for more information on the benefits of breast milk.

If parents choose to bottle feed, they should receive instructions on selecting an infant formula, safely storing and preparing formula, and determining how much and how often the baby should feed. The U.S. Food and Drug Administration (FDA) regulates commercial formulas to ensure they meet the minimum nutritional requirements. Most infants tolerate standard milk-based formulas. Infants should not be switched to a specialty formula without speaking to their pediatrician. It is also not recommended that parents use homemade formula. Parents need to be advised to follow the instructions to prepare the formula and to avoid leaving the formula at room temperature for more than two hours. Formula can be safely stored in the refrigerator for up to twenty-four hours.

Newborns have small stomachs and feel full after 1 to 2 oz (28 to 57 g) of formula. Parents should start by offering 1 to 2 oz (28 to 57 g) every two to three hours. Most formula-fed infants feed eight to twelve times in a twenty-four-hour period. If the baby shows signs of hunger, offer them more formula. However, infants who have distended

abdomens or frequently spit up may be overfed. It is important that parents consistently feed their baby when they show signs of hunger but avoid overfeeding (CDC, 2023d).

### Health Promotion Screenings

There are several routine health promotion screenings for newborns. Newborns undergo a blood test to screen for genetic, endocrine, and metabolic disorders. Each state determines which disorders are included on their newborn screen. However, **phenylketonuria (PKU)**, a rare metabolic disorder that can cause intellectual disabilities but is highly treatable with diet modification, is tested for in all fifty states. Other routine newborn health screenings include hearing screens, vision screens, and congenital heart defect screens.

### Nursing Considerations for the Infant Stage

As infants grow and develop, their nutritional needs change. If possible, it is recommended that infants be exclusively breastfed for the first six months. However, for various reasons, many mothers are unable to exclusively breastfeed. In this case, formula is a viable alternative to breast milk. No parent should be made to feel guilty for not breastfeeding their child. It is also important to note that breastfed infants may require vitamin D and iron supplements. Most pediatricians recommend giving 400 IU of vitamin D daily to exclusively breastfed infants (CDC, 2023a). Full-term infants have approximately six months of iron stores from birth. If infants are predominately breastfed after six months, they may need iron supplements. Parents should discuss this with their pediatrician. Standard formulas are fortified with both vitamin D and iron, so formula-fed infants should not require nutritional supplements.

According to the American Academy of Pediatrics (AAP), solid food should not be introduced until infants are at least six months of age (AAP, 2021). The first food that parents should introduce is rice cereal because it has a low allergy profile. New foods should be introduced one week apart to make it easier to determine whether there is a food sensitivity or allergy. Sweet foods, like pureed fruit, should be used in moderation so that infants develop a taste for nonsweet food. Although infants can start to eat solid food at around six months, breast milk or formula should be their primary source of nutrition until age 1 year. At age 1 year, children can transition from breast milk or formula to cow's milk. Cow's milk should not be introduced before age 1 year because it does not provide balanced nutrition and may not be tolerated by the infant (CDC, 2023e).

### Vaccinations

Infants are at-risk for infections because their immune system is not mature. Giving recommended immunizations throughout infancy and childhood is the best way to protect infants from infection. Most infants receive their first hepatitis B immunization prior to leaving the hospital after birth. After that, multiple immunizations are scheduled at 2 months, 4 months, 6 months, and 12 months of age. Nurses should encourage parents to stay up to date on their child's vaccine schedule. Immunizing children against the most common diseases helps keep them healthy and safe (CDC, 2023b).

### LINK TO LEARNING

Some parents may be hesitant to vaccinate their children. Nurses need to be knowledgeable about [the risks and benefits of immunization to counter vaccine information \(https://openstax.org/r/77vaccineinfo\)](https://openstax.org/r/77vaccineinfo) and how to communicate with parents about vaccines.

### Nursing Considerations for the Toddler Stage

Parents of toddlers need a significant amount of anticipatory guidance to help them adapt to the toddler years. During the toddler stage, children are becoming more independent but still require constant supervision. Finding a balance between fostering autonomy and providing a safe and secure environment can be challenging for many parents. It is also important to remind parents of the importance of language development. During this stage, children should be exposed to language, through conversation, reading books, and playing games, to help them develop their language skills.

### Environmental Safety

The gross motor skills of toddlers develop rapidly, and toddlers are on the go. With the increase in their mobility

comes concerns with protecting them from harm. There are specific tasks that parents should do to protect their toddlers (Michigan Government, 2023):

- Place plug covers over electric outlets.
- Block stairs with a gate.
- Lock doors to hazardous areas like the garage or basement.
- Lock up medicines and household cleaners.
- Keep sharp objects in a safe place.
- Check toys for loose parts.

### Supervised Independence

One of the primary developmental goals of toddlers is to gain a sense of independence. As they mature, children become less dependent on their parents. Toddlers love doing things for themselves and are very egocentric. Parents need to let toddlers try new things and master new skills, but they still need constant supervision. Toddlers do not have the cognitive ability to think through what might happen. If they see something up high that they want, they will climb up to try to get it without any regard to the possibility of falling. Parents need to give toddlers the space to explore their environment while constantly keeping an eye on them so they do not get hurt.

### Language Development

During the first three years of life, the brain is still developing. During this time frame, children learn language easily. By age 2 years, children should have a fifty-word vocabulary and should use two-word sentences. As they continue to develop, their vocabulary grows, and they begin using plural words, saying things in the past tense, and adding inflection to questions. By age 3 years, their speech is usually understood well by their immediate family and caregivers. If parents are worried about a speech delay, they should speak to their pediatrician. Some children are slow talkers but catch up with their peers, while others may have a developmental delay or a hearing problem that makes it harder for them to learn to speak (NIH, 2022).

### Nursing Considerations for the Preschool Stage

The preschool developmental stage is the period when many children start to spend a significant amount of time outside of their home. Nursing considerations for this age group include getting them school-ready, fostering independence, and providing parents with anticipatory guidance about appropriate levels of supervision. As children gain independence, it is important to remember the importance of dietary choices. Providing children with multiple healthy food options will promote good nutrition and weight throughout their childhood.

### Healthy Eating Habits

Childhood obesity is a serious problem in the United States. Children with higher weight are more likely to become adults with higher weight and to struggle with chronic health conditions related to obesity. One of the best ways to prevent obesity is to establish healthy eating habits early in life. There are several techniques to help preschool children develop healthy habits to last a lifetime (Society of Behavioral Medicine, 2023):

- Stock the house with healthy food and teach by example. Children often develop the same eating habits as their parents.
- Encourage autonomy and healthy choices by offering two to three healthy food options each day.
- Focus on the health benefits of nutritious foods (e.g., “Eating veggies helps you grow big and strong”).
- No foods should be forbidden. Instead, encourage moderation, and set limits on unhealthy food.

### Promoting Early Learning

Attending preschool is a great way to get children ready to start school. Children who attend preschool learn how to function in a group setting, follow rules, and learn basic academic skills. There are also specific parenting techniques that engage preschool children and help them get the most out of their preschool experience. Nurses should teach parents to talk to their children about their school experiences. The parents should ask questions, such as “What did you do in school today?” or “What is your favorite part of class?” It is important to give children time to respond and to add new vocabulary to the conversation. Parents can also promote early learning by reading to their children at home and reinforcing concepts that they learn at school (American Speech-Language-Hearing Association, 2023).

### Environmental Safety

More than one-third of child injuries and deaths happen at home. Teaching parents how to make the home environment safe is crucial for keeping kids safe. Preschool children need less supervision than toddlers but should still be kept out of areas like the basement or the garage. Also, it is important to keep medicine out of the reach of children. Children in this age group should be supervised when playing around water or playing sports that could result in injury. Families that have swimming pools should use a pool fence with a gate that locks (National Safety Council, 2023).

### Nursing Considerations for the School-Age Stage

School-age children face a unique set of developmental tasks that require the attention of nurses. During the school-age years, children develop study habits, form friendships, and build a foundation for life skills that will serve them in adolescence and beyond. However, there are challenges in the school environment that can make it difficult for some students to accomplish these goals. Nurses need to be aware of self-esteem and bullying issues and be able to provide parents with anticipatory guidance regarding these topics.

#### Positive Self-Esteem

One's self-esteem, or the feeling of self-appreciation, is an important building block in childhood development. Children with high self-esteem are more likely to do well in school, participate in school activities, and be willing to try new things. Encouraging self-esteem in school-age children will help them adapt to changes in adolescence and later in adult life. The home environment contributes profoundly to their self-esteem. A specific step to develop positive self-esteem is to give positive reinforcement. Also, children should be encouraged to try different extracurricular activities to develop a sense of what they are good at and what they like.

#### Anticipatory Guidance

To build healthy parent-child relationships, parents need practical strategies to meet their children's developmental needs and address the stressors children face at school. Nurses play a crucial role in advising parents and providing concrete solutions to conflicts that could affect their family. In this age group, many children have access to smartphones and computers. Cyberbullying is becoming more prevalent, and schools and school nurses need effective strategies to educate parents about the risks children may face and ways to help protect children with parental controls and open conversation.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: What to Do if a Child Is Receiving Online Threats

Disclaimer: Always follow the school's policies.

Steps	Description/Rationale
Meet with the parents and the child.	The first step in addressing cyberbullying is to listen to the child who is being bullied without judgment. Gather information about how long the bullying has been going on, and save any documentation the child has with regards to the bullying.
Contact the school principal or administrator in charge of discipline.	The school administrator in charge of discipline should provide parents with the school policy on bullying. Based on the school policy, develop a plan of action.

Steps	Description/Rationale
Implement the plan to stop the bullying.	The school should provide specific details about the disciplinary action that will be taken and have a follow-up plan. If parents are unsatisfied with the school's response, they should consider contacting the school's superintendent.
Consider contacting law enforcement.	Physical threats of harm should be reported to the police immediately. Laws vary by state, but many states have cyberbullying or computer trespassing laws. When in doubt, contact the local police department.

### School Violence

School violence is violence that happens at school. It disrupts learning and has negative consequences for the students and the community at large. Examples of school violence include the following:

- bullying or cyberbullying
- fighting
- weapon use
- sexual violence
- gang violence

School violence is a serious social problem in the United States. According to the National Center for Education Statistics (NCES), approximately twenty students per 1,000 experience nonfatal school violence every year (NCES, 2023). There are specific steps schools can take to reduce school violence (National Associations of School Psychologists, 2023):

- Teach about the importance of resisting peer pressure.
- Encourage students to report potential school violence.
- Create an anonymous reporting system that students, teachers, and parents can use.

### Nursing Considerations for the Adolescent Stage

The adolescent years can be tumultuous for both parents and teenagers. Nurses play a crucial role in helping families navigate the process of finishing high school and forming an adult identity. Adolescents may need counseling to help manage the emotions and stress associated with high school. The best approach is to provide factual education and engage with adolescents using open-ended questions that allow them to express their feelings.

#### Support Learning Needs

Adolescence can be a challenging time for parents and teachers. In this age group, students are caught between two worlds—childhood and adulthood. They strive for independence yet yearn to be part of a clique. During this development time, it can be difficult to support adolescents' learning needs. The best approach is to focus on their desire to form bonds with peers. School lessons should be structured so that teens can work in groups. Also, teachers should try and form a connection with students. For adolescents who are homeschooled, encourage participation in peer activities in the community. For example, adolescents could participate in social organizations like the 4-H club or in community sports programs. Although adolescents are trying to establish their own identity, they still value the opinion of adults, even if they do not always act like they do. Having teachers and coaches demonstrate a genuine interest in adolescents' unique talents will go a long way in supporting their academic success (Association for Supervision and Curriculum Development, 2004).

#### Healthy Eating Habits

Encouraging healthy eating habits is important during adolescence. Most adolescents in the United States eat a diet that is low in fruits, vegetables, and calcium-rich foods and high in fat. Skipping meals is also a common concern, especially among teenage girls. Also, many teens experiment with fad diets or become vegetarians. Various factors impact the dietary choices that teens make. Peer group association and familial cultural norms are the two biggest factors. Addressing dietary concerns is best approached by having an open mind about the teen's choices and

providing education about what nutrients might be missing. Special screening and education should be tailored toward this population regarding eating disorders. Also, healthcare providers should screen adolescents for anemia or other potential dietary deficiencies that are identified through their history and physical (Daly et al., 2022).

### Behavioral Safety

Adolescents' interests in new experiences and their drive for independence are natural and help them mature. By pushing boundaries, teens learn to become self-reliant. However, pushing boundaries can lead to risk-taking behavior. Parents, teachers, and nurses need to help teens manage risks that threaten their behavioral safety. Although adolescents are maturing rapidly, they still need adult supervision. Parents should be aware of what their teens are doing and with whom. If the teen breaks the rules, there should be consequences. Also, parents should have high expectations for their teens, and they should openly discuss the importance of safety.

### Support Mental Health

The number of adolescents reporting mental health issues is increasing. According to the CDC, in 2021 42 percent of high school students felt persistently sad, and 22 percent seriously considered suicide (CDC, 2023d). Schools and school nurses play an important role in overcoming this crisis. Having support programs in place at school can help teens form connections with other students and teachers. Preventing social isolation is an important tool in supporting the mental health of teenagers (CDC, 2023d).

## PATIENT CONVERSATIONS

---

### What if Your Teenage Patient Appears Sad and Depressed?

**Scenario:** Nurse walks into the school nursing office and finds PW waiting to see her. PW is a sophomore in high school and recently transferred from a different school out of state. She frequently comes to the nurse's office with vague complaints about abdominal pain and requests permission to call her parents to take her home because she does not feel well enough to stay at school.

**Nurse:** Hi, PW. It's nice to see you again. Can I help you with something?

**Patient:** Hi, Nurse Sarah. I'm not feeling well. My stomach hurts, and I want to vomit. [After saying this, the patient looks away and wipes a tear from her eye.]

**Nurse:** I'm sorry you're not feeling well. Why don't you come into my office, and we can talk?

**Patient:** Okay, but what I really want is permission to go home.

**Nurse:** Well, I need to know a little bit more about what is going on before I call your parents. You seem sad. Is everything okay? Did something happen at school today?

**Patient:** No, nothing happened. I just hate this school. I don't have any friends here, and people aren't friendly. I feel like an outsider. I just want to go home and sleep on the couch.

**Nurse:** Changing schools can be really hard. When you started here, did the principal give you a student liaison?

**Patient:** What's a student liaison?

**Nurse:** It's the student who helps you figure out the ropes at school. They give you information about school clubs and activities and help you feel welcome at school. School liaisons sign up to be part of the program.

**Patient:** No, I've never heard about that program.

**Nurse:** Okay, I'm going to contact the principal and see if I can set it up for you. Now, let's talk about your stomachache. Do you have a fever? Any vomiting or diarrhea?

**Patient:** No fever, no vomiting or diarrhea. I just feel like I want to throw up.

**Nurse:** Okay. Let's sit here for a minute and talk about how things are going. I'd like you to drink some juice and eat a few crackers while you talk to me. If you're not feeling better when we're done talking, I'll call your parents.

---

## Summary

### 39.1 Growth and Development Stages

Growth and development start at conception and continue through adolescence. During conception and the prenatal stage, the genetic makeup and the basic physical structure of the child are determined. Immediately after birth, in the neonatal stage, the child learns to bond with their caregiver and develop a sense of trust. As they continue to develop through infancy, children experience rapid physical growth. When children enter the toddler years, their physical growth starts to slow down, and they rapidly develop gross motor and language skills. The toddler years are also characterized by the child's need for autonomy. As children enter the preschool years, they develop more fine motor skills and start to learn how to function in a group setting. During the school-age period, children tend to form strong friendships and enjoy being active. Their growth continues at a slow, steady pace. Once children enter adolescence, they go through a growth spurt and develop sexual characteristics. This final stage of child development is characterized by the child establishing a unique identity separate from their family.

### 39.2 Theories Related to Growth and Development

There are three theories of growth and development that are frequently discussed in pediatric nursing: Freud, Erikson, and Havighurst. Freud's theory is referred to as a psychosexual theory. It examines human development through the lens of sexual desire. According to Freud, *sexual* is a general term that refers to any pleasurable action or thought. Freud's theory is sequential, meaning children pass through a series of stages based on their age. If there is not appropriate resolution of the conflict in each stage, the individual could develop psychosocial problems later in life. Erikson's theory is similar to Freud's theory in that it is based on a series of stages that each child passes through, and there is a conflict that must be resolved in each stage. Not resolving each conflict could result in an unhealthy or maladaptive personality. Havighurst's theory of development is also sequential but does not have a conflict in each stage that needs to be resolved. In Havighurst's theory, there are specific tasks that need to be completed in each age group. Successful completion of these tasks leads to a healthy, happy individual.

### 39.3 Health Risks for Each Stage

Health risks are different for different population groups. Health risk for women of childbearing age who are considering having a family revolve around the ability to get pregnant, stay pregnant, and have a healthy pregnancy. A woman's general state of health impacts her fertility, but there are other genetic and physiological factors that must be addressed if she has had a hard time conceiving. Once a woman is pregnant, she needs lots of education about appropriate diet and self-care activities during pregnancy.

In terms of the health risks for children, they change as children progress through infancy and childhood. Newborns are at-risk for complications from exposure to toxins in utero, birth trauma, and congenital malformations. Infants are completely dependent on their caregiver and are at risk for child abuse and neglect that could result in FTT or accidental injuries. They are also at risk for SIDS. Parents must be educated on appropriate sleeping conditions to help prevent this.

As children enter the toddler years, they gain independence and mobility. This increase in mobility places them at risk for accidental trauma. Also, their quest for independence can be very frustrating for parents. The typical personality of a toddler combined with the milestones of this age group, like toilet training, make them at-risk of child abuse. Sometimes parents get frustrated and lash out at their toddler. This age group is also at risk for malnutrition. This is especially true when they transition from breast milk or formula to cow's milk at age 1 year. Parents need to be educated about providing a well-balanced diet and limiting consumption of milk.

When children enter preschool, their health risks continue to change. Most children in this age group are frequently in large groups with other children, which places them at risk for accidents and exposure to communicable diseases. As they enter school, they may be exposed to bullying or school violence. Also, previously undiagnosed learning disabilities could surface. Finally, the adolescent years bring a lot of changes that affect teens' health risks. This age group struggles with identity formation and frequently relies on their peer group for guidance and support. This can lead to risk-taking behavior, mental health issues, and problems adapting to a new adult role.

### 39.4 The Nurse's Role in Preventing Illness

Nursing considerations for the conception/prenatal stage, the neonate stage, and the infant stage focus on education related to family planning, pregnancy, and care of the neonate and infant. These stages are the foundation of development from infancy and beyond. Family planning education helps a person time when and if they have children. Prenatal education focuses on having a healthy pregnancy and minimizing the risk of congenital malformations and birth trauma. In the neonate and infant stages, parents need a considerable amount of support regarding bonding, feeding, and meeting the basic needs of the child.

The emphasis of nursing considerations changes as children enter the toddler years. Toddlers are quite a bit more independent than infants, but they still need constant supervision. The focus of nursing care is providing anticipatory guidance to help parents manage fostering independence while still constantly supervising their children. During this age group, parents should also be reminded about the importance of fostering language development.

Nursing considerations for preschool-age children focus on keeping them safe outside the home. During this age group, most children spend a significant part of their day with other children. Parents need guidance on promoting early learning and keeping children safe as they interact with others outside the home. Once children enter the school-age years, they are significantly more independent from their parents but still need guidance, especially if conflicts arise. Parents should have open conversations with their children about school violence and bullying. If children are being bullied, parents should involve the school administration to make it stop. This is also the time in life when children may be diagnosed with learning disabilities. Both nurses and parents should be aware of the signs of learning disabilities so that they can intervene early if there are concerns.

During the adolescent stage of development, nursing care focuses on helping teens develop a strong personal identity. This is a challenging time of development, and many teens experience anxiety and depression. Having an open mind and engaging teens may help them discuss their feelings. It may also be necessary to refer them to a therapist for help. This age group is also known to exhibit risk-taking behavior, especially if their peer group is engaged in risky behavior. Preparing parents for this possibility and providing them with resources may make this development period easier.

### Key Terms

- abstract thinking** the ability to think through scenarios with different possible outcomes and evaluate which outcome would be best
- bonding** when a caregiver and a baby feel a strong attachment to each other
- colostrum** a nutrient-dense liquid that also helps bolster the newborn's immune system
- conception** the biological process of a sperm fertilizing an egg
- congenital malformation** any health problem or physical abnormality that is present at birth, otherwise known as a birth defect
- developmental task** a challenge the individual wants to solve that arises predictably at a certain period in life
- embryonic period** the period of development from approximately two weeks after conception to eight weeks after conception
- failure to thrive (FTT)** inadequate weight gain or sudden weight loss
- fetal period** prenatal development from week nine after conception to birth
- high-risk pregnancy** any pregnancy in which there are increased health risks for the pregnant person, the developing fetus, or both
- menarche** first menstrual period
- milestones** activities 75 percent or more of children can do by a certain age
- morula** mass of cells that develops three days after conception
- ovum** an egg
- phenylketonuria (PKU)** a rare metabolic disorder that can cause intellectual disabilities but is highly treatable with diet modification
- pre-embryonic period** the period of fetal development that occurs in the first two weeks after conception
- prenatal development** the development period that starts with conception and ends with birth
- proximodistal** development occurs closer to the midline first and then in the extremities

**puberty** the stage of development during which physical and sexual maturity occurs and individuals become capable of reproduction

**separation anxiety** a child's fear of abandonment when their primary caregiver leaves

**shaken baby syndrome** a serious type of abuse that usually occurs when a parent or caregiver shakes a baby out of anger or frustration

**substance use** alcohol or drug use

**sudden infant death syndrome (SIDS)** the sudden death of an infant that does not have an identifiable cause, even after a full investigation

**teratogen** any external force, such as a medication, chemical, alcohol, drug, or maternal infection, that can cause fetal abnormalities

**zygote** the product of conception or a fertilized egg

## Assessments

### Review Questions

- During what stage of prenatal development is the developing child at greatest risk for birth defects due to a secondary teratogen exposure?
  - pre-embryonic
  - embryonic
  - fetal
  - pre-fetal
- The nurse is developing a care plan for a hospitalized toddler. What nursing intervention is appropriate?
  - Encourage the child to draw in a coloring book.
  - Allow the child to walk independently around the unit.
  - Encourage the child to feed himself finger food.
  - Give building blocks to play with.
- What comment from a parent would raise concern from the nurse about a school-age child's development?
  - Billy has a stamp collection that he likes to show off.
  - Billy is constantly changing his mind about which sport he wants to play.
  - Billy hates school and is having a hard time making friends.
  - Billy plays video games every day after school with friends that he met online.
- What type of play is typical in the toddler years?
  - solitary play
  - parallel play
  - group play
  - cooperative play
- What statement best describes typical development during the preschool years?
  - Preschool children are egocentric and only see things from their perspective.
  - Having imaginary friends is common during the preschool years.
  - Preschool children enjoy playing board games like checkers.
  - Playing on organized sports teams is common for preschool children.
- A 2-month-old infant has a caregiver who does not always respond to the infant's hunger cues, but the infant is fed enough to grow adequately. According to Erickson, what could be the result of this behavior late in life?
  - The infant will not suffer any long-term consequences.
  - The infant will not trust others later in life.
  - The infant will develop co-dependent relationships later in life.
  - The infant will become hypercompetitive and aggressive.
- According to Freud, what behavior is expected in a child aged 3 to 5 years?

- a. The child bonds with the opposite-sex parent.
  - b. Preoccupation with the anus is common.
  - c. Many children are anxious about trying new activities.
  - d. The child frequently has imaginary friends.
- 8.** According to Erickson's theory, what will happen if school-age children do not manage the demands of schoolwork and friendships?
- a. School-age children become lonely and withdrawn if they do not have friends.
  - b. Failure to keep up with peers results in a sense of inferiority.
  - c. Not balancing the demands of school causes angry outbursts.
  - d. School-age children who lag their classmates develop depression.
- 9.** What differentiates Havighurst's theory of development from Freud's and Erickson's theories?
- a. Development is unique to each individual and does not follow a predictable pattern of milestones.
  - b. Failure to complete a developmental task can be overcome if that task is completed later in life.
  - c. Individual factors like environment and personal characteristics influence development.
  - d. An individual's intelligence determines the likelihood of completing developmental tasks.
- 10.** According to Freud, what element of our personality is present at birth?
- a. id
  - b. superid
  - c. ego
  - d. superego
- 11.** At what time during fetal development is the unborn child at greatest risk for exposure to toxins in utero?
- a. during the first ten weeks of pregnancy
  - b. in the second trimester
  - c. between 10 and 15 weeks' gestation
  - d. in the final trimester, between 28 and 40 weeks' gestation
- 12.** What medical condition is screened for during the toddler years?
- a. iron deficiency anemia
  - b. hypertension
  - c. scoliosis
  - d. congenital heart defects
- 13.** Approximately what percentage of neonates are born with a congenital defect?
- a. 10 percent
  - b. 4 percent
  - c. 2 percent
  - d. 7 percent
- 14.** What parental advice would a nurse give to help prevent SIDS?
- a. Place infants on their abdomen to sleep.
  - b. Use a firm mattress with only a tightly fitted sheet.
  - c. Place the infant in the crib with a bottle of milk.
  - d. Sleep with the infant in your bed until they are able to roll over.
- 15.** What factor is a risk for obesity in school-age children?
- a. not getting enough sleep
  - b. living in a single parent home
  - c. experiencing food insecurity
  - d. attending an after-school program

- 16.** When providing prenatal education, what nutrition advice is the most important for the nurse to share with the patient?
- Consume at least 400 mcg of folic acid daily.
  - Focus on eating iron-rich foods like lean meat.
  - Avoid salty foods like potato chips and crackers.
  - Try to drink eight glasses of water per day.
- 17.** A nurse is obtaining informed consent from a mother for her child's newborn screen. What statement accurately describes what the newborn screen is?
- The newborn screen is a federally mandated health screen that is the same in all fifty states. It tests for genetic mutations that can affect newborns.
  - Each state has its own newborn screen based on the health conditions that are more prevalent in their state. It is a simple blood test that looks for genetic, endocrine, and metabolic disorders.
  - The newborn screen is recommended to parents who have a family history of genetic disorders. Individuals with no significant family history should not participate because there is a high rate of false positives.
  - The newborn screen provides a complete analysis of all genetic disorders. It is recommended that infants are screened regardless of familial history.
- 18.** What vaccine is given to infants prior to discharge from the hospital after birth?
- polio
  - varicella
  - pertussis
  - hepatitis B
- 19.** What speech pattern is expected in a 2-year-old?
- speaks using two-word sentences
  - has a 200-word vocabulary
  - correctly conjugates verbs
  - communicates by pointing and grunting
- 20.** What parenting strategy helps develop positive self-esteem in school-age children?
- Insist that the child participate in multiple after-school activities.
  - Provide positive reinforcement when the child tries new activities.
  - Encourage academic success by punishing the child if they do not get good grades in school.
  - Choose the child's school clothes for them so that they look stylish at school.

### Check Your Understanding Questions

- A newborn weighs 7 lb 4 oz (3.3 kg) at birth. What does the nurse anticipate the infant will weigh at their one-year well child check?
- Which reflexes does the nurse anticipate a full-term neonate will have at birth?
- Explain the Oedipus complex, and identify the stage of development during which this occurs.
- According to Havighurst's theory of development, what will happen if an adolescent does not complete all the tasks in the adolescent stage of development?
- Describe how nurses should educate parents about introducing solid food to their infant.
- Describe the process of language development during the toddler years.
- Outline steps parents should take to foster healthy eating habits in preschool-age children.

### Reflection Questions

- Describe in your own words the primary psychosocial task of adolescence.

2. Describe why infants are at risk for child abuse and neglect.
3. Explain why preschool-age children are at an increased risk for exposure to communicable diseases?

### What Should the Nurse Do?

1. AP is a 16-year-old female who presents to Planned Parenthood without her legal guardian and requests a prescription for birth control. She states that she is sexually active with multiple boys and does not consistently use a condom. Other than having unprotected sex, she denies other health problems. What do you think about providing birth control to a 16-year-old without her parents' consent? Is it legal to prescribe birth control to a minor? What other tests should this patient receive?
2. What should the nurse do if they notice that a 6-month-old infant does not respond to their name or make vowel sounds?
3. GD is a 16-year-old female student who recently broke up with her boyfriend. Since the breakup, she has stopped paying attention to her physical appearance and is neglecting her personal hygiene. In the past two months, she has missed class at least once per week and is no longer hanging out with her friends after school. What do you think about GD's mental health? Other than depression, what other health conditions is she at risk for?
4. PW is a 40-year-old female who would like to get pregnant. She has been having unprotected intercourse for six months and thus far has been unable to conceive. She is anxious and worried that she has passed her fertility prime and will never be able to conceive. Does PW's condition meet the criteria for infertility? What advice would you give her? What additional tests or diagnostic workup might be recommended for this patient?
5. What should the nurse do if a 6-year-old is having a hard time learning to read?
6. What should the nurse do if a school-age child is experiencing cyberbullying?

### Competency-Based Assessments

1. Develop a fifteen-minute presentation defining the nurse's role in assessing whether infants are meeting their developmental milestones during the first year.
2. Prepare a fifteen-minute presentation that compares and contrasts Freud's and Erickson's theories of development.
3. Use the Internet to research prenatal health risks. Discuss how specific ethnic groups face different prenatal health risks. Identify how nursing education can help improve prenatal health outcomes for at-risk ethnic groups.
4. Use the Internet to research the mental health crisis among adolescents in the United States. Discuss which factors are contributing to this crisis and which school-based interventions have been effective in supporting those with mental health issues.

## CHAPTER 40

# Young and Middle-Aged Adults

**FIGURE 40.1** The time period spanning from young to middle-aged adults is a crucial time for developing good health and wellness practices. (credit: modification of “Diverse people using phones” by Rawpixel Ltd/Wikimedia Commons, CC BY 2.0)

### CHAPTER OUTLINE

- 40.1 Growth and Development Stages
- 40.2 Theories Related to Growth and Development
- 40.3 Health Risks for Young and Middle-Aged Adults
- 40.4 The Nurse’s Role in Preventing Illness

**INTRODUCTION** During adulthood, individuals pass through several stages of development, including early adulthood, middle adulthood, and older adulthood. Individuals in early adulthood are often referred to as young adults. During middle adulthood, also known as midlife, individuals are referred to as middle-aged adults. Individuals in early and middle adulthood make up most of the U.S. population (Statista, 2022). While age ranges for each category vary depending on beliefs and family constructs within cultural groups, combined early and middle adulthood typically ranges from approximately age 18 to 64 years (Committee on Improving the Health, Safety, and Well-Being of Young Adults, 2015). Young adulthood is typically considered as persons 18 to 35 years of age. For example, social norms and legal constructs such as the ability to seek health care independently often classify individuals as adults at age 18 years. Chronological age defines adulthood in some families and cultures. In others, the transition to adulthood is marked by marriage or a religious or spiritual ritual.

During these developmental stages, individuals progress through many physical, emotional, family, personal, and social changes. While significant change is expected during this forty-plus-year time frame, specific changes are not universally experienced. Each individual will progress in unique ways (Lachman et al., 2015). By identifying patterns in physical change and behavior during early and middle adulthood, nurses can tailor education, treatment options, and healthcare prevention strategies to maximize their benefit to the individual. The experience of early and middle

adulthood is guided by developmental changes, lifestyle choices, social circumstances, and disease.

A range of developmental theories encompass the changes experienced during early and middle adulthood. These theories relate to psychological transitions, identity development, social constructs, and physical changes. Understanding these theories prepares nurses to support adults during expected and unexpected changes in health.

Nurses encounter young and middle-aged adults in various settings, including college health centers, family planning clinics, obstetrics-gynecology clinics, fertility clinics, primary care offices, chronic disease specialty clinics, work-based clinics, mental health facilities, and hospitals. Providing individualized care requires nurses to understand the variety and complexity of the health issues that emerge during the adult life stage. However, health risks in early and middle-aged adults are not universal—rather, they are affected by an individual’s lifestyle, age, and genetics. Since these risks affect long-term health, nurses should look for opportunities to discuss them, offer education, and promote change.

A nurse’s role in preventing illness is crucial during the early and middle adult years, as this is when risk reduction will have the greatest effect on producing positive long-term health outcomes. Nurses are essential in promoting wellness for all patients, regardless of an individual’s underlying or hereditary risk for chronic disease. Nurses can empower individuals to develop healthy habits to carry them through life.

## 40.1 Growth and Development Stages

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify growth and development patterns for the young adult stage
- Recognize growth and development patterns for the middle-aged adult stage

Individuals experience physical, physiological, psychological, and psychosocial changes during early and middle adulthood. Physical changes during this time are more subtle than the visible changes of growth during adolescence and are directly related to lifestyle choices such as physical activity level, nutrition choices, and substance use (Lawrence et al., 2017; Zheng et al., 2017). Physiological changes are also subtle and may even go unnoticed in early adulthood, though they become more pronounced as aging progresses during the later stages of middle adulthood. Physical changes refer to alterations in the body’s structure or appearance, such as body shape, skin texture, or muscle mass, while physiological changes involve modifications in bodily functions or processes, such as metabolism, kidney function, and blood pressure.

Many physiological and physical challenges in early adulthood can be addressed with prompt lifestyle changes and treatment of acute illnesses. During middle adulthood, these changes may manifest as a decline in health. For example, unhealthy dietary practices and reduced physical activity beginning in early adulthood can contribute to weight gain and lipid metabolism changes that may result in a progression to atherosclerosis, glucose intolerance, and hypertension as the individual ages. Nurses can encourage patients to maintain healthy lifestyle practices in young adulthood to reduce health risks as they move into middle adulthood.

Any change in physical or physiological health, whether acute or chronic, may affect psychological well-being and social interactions. In addition, challenges associated with developing an identity, starting or maintaining a family structure, and sustaining a work-life balance can alter interpersonal (interactions between individuals involving communication, relationships, and social dynamics), intrapersonal (processes and experiences within an individual, such as thoughts, emotions, and self-awareness), and social interactions. The many changes individuals experience during early and middle adulthood are easier to navigate when personal health, resiliency, and prevention are prioritized.

### Young Adult Stage

During the young adult stage, ages 18 to 35 years, individuals experience stabilization in **physical growth**, particularly changes in height and weight. While young adults may continue to increase muscle mass and bone strength, this stage is often considered the peak in physical development. In healthy young adults, many organ systems are at peak function. These physical attributes allow young adults to perform at maximum ability and are directly tied to their physiological development. Physical development of early adulthood is affected by **physiological change**, or bodily functions happening at a cellular level. Young adults experience significant brain

development, which continues up to age 30 years (Hochberg & Konner, 2020). This ongoing brain development in early young adulthood significantly affects the psychological and social development of the individual. Changes relating to the mind and emotions are called a **psychological change**. A **psychosocial factor** is related to interpersonal interactions, such as relationships, work communication, and cooperation in living situations. The ability of young adults to develop an awareness of psychosocial interactions and strategies for maintaining appropriate social interactions is both challenging and rewarding.

### Physiological Development

Physiological and physical development changes continue throughout young adulthood. Body size and physical appearance are consistent with an adult stage, and growth velocity slows and stabilizes. In healthy young adults, organ systems are functioning at the highest capacity. Young adults can maximize energy output and have significant physical endurance. The following are some physiological processes that are at their peak in early adulthood:

- lung function
- cardiac function
- agility
- flexibility
- vision
- hearing
- reproduction

Health in young adulthood can vary significantly from one individual to another. Peak ability and physiological performance depend on underlying chronic health disorders, genetic factors, and lifestyle choices. The body is highly adaptable and may compensate to a certain degree for poor lifestyle choices during this stage. However, there is an epidemic of obesity and inactivity spanning the adolescent and young adult population. Lifestyle choices, such as unhealthy eating habits, lack of exercise, or substance use disorders, can have significant negative short- and long-term effects on health (Zheng et al., 2017). While young adults may have a certain level of resilience, chronic poor lifestyle choices can increase the risk of developing various health issues later in life, such as obesity, cardiovascular disease, and diabetes. It is important for individuals to prioritize healthy behaviors and habits from a young age to promote long-term health and well-being. While individuals may still experience their personal best health during their early adulthood, they may be in comparatively poor health due to the presence of chronic diseases such as obesity, type 2 diabetes, and depression. These increasingly prevalent disorders are often interrelated and associated with a sedentary lifestyle (Lawrence et al., 2017; Zheng et al., 2017).

In the later part of young adulthood, organ systems start a slow, gradual decline. By the mid to late 30s, young adults start noticing signs of aging. These signs may include a decline in immune function, sensory response time, agility in movement, and ability to recover quickly from physical exertion. For example, running or other physical exercise may cause individuals to feel winded longer after stopping an activity. While many physical changes occur and some physical decline is expected with age, individuals of all abilities can experience the benefits of maintaining physical activity throughout their life span. Finding joyful body movement that fits one's abilities, preferences, and lifestyle shows a commitment to maintaining health.

A concise report on a study evaluating [diabetes and obesity rates in young adults \(https://openstax.org/r/77DiabetsObesty\)](https://openstax.org/r/77DiabetsObesty) is presented by NPR.

### Psychological Development

During the stage of emerging adulthood, very young adults work through a process of emerging as adults. Significant brain development continues throughout this stage of adulthood, which occurs immediately after adolescence and typically lasts until around the age of 25 years (Wood et al., 2017). Young adults experience significant behavioral and social maturation during this time, during which they are expected to perform as adults. Brain maturation continues through early adulthood and includes increases in brain white matter and development and integration of the frontal and prefrontal cortex of the brain. Behavior changes associated with these brain developments include

the following (Hochberg & Konner, 2020):

- decreased aggression
- impulse control
- role changes

Many of these psychological changes occur in response to the development of the frontal cortex, which controls **executive functioning**—the ability to develop plans, focus attention, perform from working memory, maintain self-awareness, initiate and execute complicated tasks, control impulses, and manage emotions. As individuals progress through young adulthood, they typically experience significant improvement in executive functions that are based on both life experiences and the completion of brain development. Individuals may notice improved parenting skills, ability to function in a work environment, and coping skills to manage life stressors.

Young adults are highly capable of learning new and complex ideas and tasks. As the white matter in the brain develops, communication improves within and between brain regions. Therefore, young adults have a high capacity for integrating new information, generating new ideas, and synthesizing information (Harvard University, n.d.).

## REAL RN STORIES

---

### Screen Addiction

**Name:** Karen, RN

**Clinical setting:** University health clinic

**Years in practice:** 13

**Facility location:** Oregon

I've spent the last fifteen years of my nursing career working with students at a university health clinic. I have definitely noticed a significant shift in medical concerns in this age group during that time. While I care for students of all ages, most of my students are very young adults, usually 26 years old or younger. There has been a significant increase in depression, anxiety, sleep-related issues, and addiction. While each case is unique, screen addiction is a common thread linking many of these health concerns. When a patient in my care is experiencing any combination of these health challenges, I always bring up the difficult topic of screen use and addiction. I remember one patient in particular, Jason, a 24-year-old studying civil engineering. He had persistent struggles with insomnia, trouble concentrating in class, escalating anxiety related to tests, and spiraling depression related to these other stressors. He told me that he had to quit his intramural soccer team because he didn't have enough time to attend the games. During our discussion about his insomnia, I inquired about his screen use. Initially, he brushed off the question, stating he only used screens for studying, "fun," and communicating with friends. We discussed sleep hygiene habits, including limiting or stopping screen use within one to two hours before bed. After his second visit, with no improvement in sleep despite adhering to most of the habits except screen use, I asked him to keep a screen use diary. When he returned to the clinic, he was shocked by his screen use, telling me he didn't realize he was using some screen or device for up to twelve hours per day. He did not know the connection between screen use and dopamine production in the brain or that true addiction can occur. He'd try to limit his use but always found himself back at the computer or scrolling on his phone. At this point, we discussed the effects of excessive screen use on sleep quality, including the following:

- hyperarousal
- disruption in circadian rhythm
- altered sleep patterns
- trouble concentrating

After we created a plan to curb his screen use, he significantly improved his sleep duration and quality. He also reported back with considerable improvement in a variety of areas that he hadn't realized were connected to his screen use, including the following:

- resolution of neck pain
- reduction in headache frequency

- improved interactions with his roommate
- less anxiety about upcoming tests
- sense of relief when his automatic downtime engaged
- improved outlook on his success in college

Jason had success overcoming screen addiction, partially due to his motivation to finish college but also because he sought to understand the cause of his health challenges and sought professional help.

---

Young adult brain development is affected by stress, life chaos, physical or emotional threats, and unpredictable environments. In addition, habits like food choices, screen use, and substance use influence brain neurotransmitters, including dopamine. For example, in some cases, video gaming can positively affect reaction time and cognitive plasticity—the ability of the brain to adapt to new experiences. However, recent studies have shown that due to dopamine production and release during gaming, playing for more than three hours per day can increase the risk for attention problems, depression, and attention deficit hyperactivity disorder (ADHD) symptoms. These results apply to children and emerging adults whose prefrontal cortex is still developing (National Institutes of Health [NIH], 2022). Screen use of any type has been shown to affect sleep onset, duration, and quality of REM sleep, which is essential for activating memory and storing information. Variable reward systems are unpredictable psychological rewards that provide a dopamine surge in the brain and encourage individuals to pursue additional gratification (Haynes, 2018). Variable rewards are associated with social media and gaming and may challenge some young adults who lack the self-control needed to limit their screen use (Harvard University, n.d.).

### Psychosocial Development

Young adults begin the transition to adulthood at approximately age 18 years. Following are some of the many social cues that mark the progression to adulthood:

- obtaining a driver's license
- becoming eligible to vote
- going to college
- joining the military
- reaching the legal drinking age

Cultural cues that indicate a progression toward or into adulthood vary widely among cultures or families but may include the following:

- buying a car
- moving out of their parents' home
- dating
- getting married
- having children
- buying a house

## CULTURAL CONTEXT

---

### Multigenerational Households

In the last fifty years, the number of people living in a **multigenerational household** with three or more generations living together in one home has increased significantly. The Pew Research Center indicates the number of multigenerational households in the United States increased fourfold since 1971. Up to 18 percent of individuals live in a multigenerational household, and the U.S. Census Bureau data indicate that 7 percent of family homes are multigenerational. Most individuals living in multigenerational households are Asian, Black, and Hispanic American. In some cultures, multigenerational living is a common standard. Still, multigenerational living is becoming increasingly prevalent in the United States. Recent trends show a significant increase in non-Hispanic White Americans living in multigenerational households. Reasons for multigenerational living across cultures include caregiving for older adults, caregiving for young children, financial stability, and convenience. While multigenerational living can be stressful, in most individuals' experience, the benefits outweigh the negatives (Vohn

et al., 2022).

These social and cultural guideposts are not universally experienced, and individuals who do not attain them can still progress through early adulthood. Since the timeline associated with reaching adulthood is highly individual, it has been proposed that there is a new stage of development between adolescence and early adulthood called “emerging adulthood.” During this time, young people do not yet identify with adulthood. Therefore, they may wait longer to join the workforce, move out on their own, get married, and/or have children. However, by the end of early adulthood, most individuals will have accomplished the core developmental tasks of becoming more autonomous, taking care of themselves and others, committing to relationships and jobs/careers, getting married, raising families, and integrating into their chosen communities. Healthy lifestyle habits such as adequate nutrition, exercise, positive social interaction, and moderating digital and social media use during young adulthood affect health during the next stage.

## LINK TO LEARNING

Understanding the [link between the neurotransmitter serotonin, the gastrointestinal tract, and dietary choices](https://openstax.org/r/77Serotonin) (<https://openstax.org/r/77Serotonin>) is crucial for explaining the rationale for healthy eating to patients.

## Middle-Aged Adult Stage

Around the time individuals reach their 40s, they enter middle adulthood, which extends to the mid-60s. Social and cultural overlap occurs between the end of young and early middle adulthood and is primarily based on lifestyle choices and social demands. For example, physical fitness in young adulthood may translate to a healthier physical body in middle adulthood. In addition, challenges experienced in middle adulthood depend on an individual’s ability or choices regarding having children, work, money, and the consequences of their social decisions in young adulthood. During this time, middle-aged adults confront challenges related to common physical, psychological, and psychosocial changes. While these unique challenges are described in many developmental theories, the experience of middle adulthood is highly individual.

### Physiological Development

During middle adulthood, individuals continue to notice signs of aging, although these may be more subtle or more pronounced depending on individual characteristics and life choices ([Table 40.1](#)). Expected changes occur in various organ systems, including the following:

- musculoskeletal
- cardiovascular
- integumentary
- gastrointestinal
- urinary
- sensory
- dental
- reproductive

Organ System	Physiological Change	Physical Sign or Symptom
Cardiovascular	<ul style="list-style-type: none"> <li>• Reduction in blood vessel elasticity</li> <li>• Elevated cholesterol</li> <li>• Reduction in cardiac output</li> <li>• Reduction in exercise endurance</li> </ul>	<ul style="list-style-type: none"> <li>• Elevated blood pressure</li> <li>• Vessel plaques begin to form</li> <li>• Reduction in exercise tolerance depending on fitness</li> </ul>
Respiratory	<ul style="list-style-type: none"> <li>• Mild decline in lung compliance</li> </ul>	<ul style="list-style-type: none"> <li>• Decline from peak stamina</li> </ul>

**TABLE 40.1** Physiological Changes in Adulthood

Organ System	Physiological Change	Physical Sign or Symptom
Musculoskeletal	<ul style="list-style-type: none"> <li>• Sarcopenia begins to develop</li> <li>• Early signs of osteoporosis</li> <li>• Decreased proprioception—perception of movement and position of body parts</li> </ul>	<ul style="list-style-type: none"> <li>• Reduction in muscle mass</li> <li>• Reduction in strength, dependent on physical fitness</li> <li>• Reduction in joint mobility</li> <li>• Joint pain</li> <li>• Reduced flexibility</li> </ul>

**TABLE 40.1** Physiological Changes in Adulthood

Organ System	Physiological Change	Physical Sign or Symptom
Sensory	<ul style="list-style-type: none"> <li>• Eardrum damage worsens</li> <li>• Eardrum thickens</li> <li>• Decreased lens flexibility</li> </ul>	<ul style="list-style-type: none"> <li>• Reduced hearing</li> <li>• Tinnitus (ringing in the ears)</li> <li>• Presbycusis</li> <li>• Slow reaction to changing light</li> <li>• Presbyopia</li> <li>• Trouble with night driving</li> </ul>
Reproductive	<ul style="list-style-type: none"> <li>• Reduction in estrogen and progesterone (persons assigned female at birth)</li> <li>• Reduction in testosterone (persons assigned male at birth)</li> </ul>	<ul style="list-style-type: none"> <li>• Vaginal and breast atrophy</li> <li>• Vaginal dryness and irritation</li> <li>• Erectile dysfunction</li> <li>• Hot flashes (persons assigned female at birth)</li> <li>• Depression and irritability (persons assigned female at birth)</li> <li>• Thinning of vaginal tissue (persons assigned female at birth)</li> <li>• Erectile dysfunction (persons assigned male at birth)</li> </ul>

**TABLE 40.1** Physiological Changes in Adulthood

### Musculoskeletal

One of the primary musculoskeletal physiological changes that occurs during middle adulthood, regardless of health status, is the loss of muscle mass. In **sarcopenia**, loss of skeletal muscle mass progresses throughout aging but begins showing pronounced effects during middle adulthood. Some studies show that people aged 75 years may have up to 30 to 60 percent fewer nerve endings in their leg muscles than they did in their early 20s. In 2018, the U.S. Centers for Disease Control and Prevention (CDC) assigned sarcopenia its own discrete medical code. Sarcopenia can be associated with various other physical changes, including a loss in overall muscle strength and a decrease in endurance and flexibility. These changes put individuals at risk for musculoskeletal injuries, including muscle, connective tissue, and bone injuries.

Sarcopenia and associated **osteosarcopenia**, the decline of muscle and bone tissue, pose significant physical change during middle adulthood. These changes are associated with alteration in mobility and strength and a higher risk for certain diseases. Human beings reach peak bone mass around 30 years of age (Mayo Clinic, 2022). In **osteoporosis**, a patient experiences a loss of bone mass. Osteoporosis is often associated with persons assigned female at birth (AFAB) because bone mass can deteriorate more quickly in persons AFAB during middle age due to estrogen loss in menopause. After menopause, persons AFAB can lose 5 to 10 percent bone mass annually. However, beginning in their 60s, persons assigned male at birth (AMAB) and persons AFAB lose bone mass at roughly the same rate. The CDC reports that 4.2 percent of persons AMAB and more than 18.8 percent of persons AFAB older than 50 years of age have osteoporosis (2022). Attention to lifestyle factors affecting bone health during this stage of life may bring pronounced health benefits for all, now and later.

### Integumentary

The integumentary system changes throughout a person's life span; changes include decreased subcutaneous tissue thickness, hair graying, and reduced skin elasticity. Manifestations of skin cancer from earlier sun damage will also present during this time. Middle-aged adults may also notice some of the following changes:

- dry skin
- skin tags
- dark spots

- wrinkles
- delayed wound healing

### Cardiovascular

An individual's underlying health influences the cardiovascular changes they may experience during middle adulthood. Some common cardiovascular changes during this stage include increased blood pressure due to blood vessels losing elasticity, decreased cardiac output, plaque buildup in the arteries, and thickening of the heart muscle. Many chronic diseases that affect the heart and vascular system, such as coronary artery disease and heart failure, begin to manifest in middle-aged adults. The presence of chronic diseases such as diabetes, high blood pressure, and obesity accelerate the aging process of the cardiovascular system through chronic organ stress and damage caused by vascular impairment. These negative physiological changes typically start in middle adulthood and progress to older adulthood unless significant lifestyle changes or treatment plans are implemented. This highlights the importance of managing weight, engaging in physical movement, and eating a nutritious diet. For example, focusing on lifestyle changes such as limited alcohol intake, daily physical activity, and treatment of high blood pressure with medications can reduce the long-term impacts of high blood pressure on cardiovascular and kidney health.

### Gastrointestinal

Gastrointestinal (GI) changes in middle adulthood are primarily associated with the early stages of muscle loss, including the musculature of the intestinal tract and colon. These changes can contribute to slow digestive transit times, resulting in constipation. Stomach acid changes may also occur. In some individuals, slackening of the **esophageal sphincter**, the musculature closure between the esophagus and stomach, may contribute to **acid reflux**, in which gastric acid moves up the esophagus and causes mucosal irritation. The disorder **achlorhydria**, in which the stomach produces insufficient acid, may also occur. There also may be a change in the microflora in the GI tract that can affect carbohydrate metabolism, fat storage, vitamin uptake, serotonin pathways, and immunity (Olvera-Rosales et al., 2021). Therefore, this microflora environment plays a critical role in the development of disease and response to illness.

### Urinary

Urinary physiology may also change during middle adulthood. Persons AMAB may begin to notice symptoms of prostate enlargement, such as urinary frequency, urinary urgency, incontinence, weak urinary stream, and urinary retention. Persons AFAB may start to notice signs of weakening pelvic floor muscles, which manifests in the urinary system as urinary frequency, incontinence, pelvic pain, and difficulty initiating urine stream. Both persons AMAB and persons AFAB may start to experience the early signs of loss of elasticity of the urinary bladder, including urinary frequency and stress incontinence.

### Sensory

Sensory changes also begin to arise during middle adulthood, including hearing loss. Hearing changes can be influenced by genetics as well as be caused by long-term and repeated exposure to high-decibel sounds from machinery, music, or other environmental noise. The CDC (2022) reports that exposure to noise at 70 dB or higher can cause permanent ear damage and subsequent hearing damage. Hearing loss becomes more pronounced as an individual ages, and **presbycusis**, or age-related hearing loss, is a common condition. Presbycusis typically begins around age 60 to 70 years. The condition affects the ability to hear high-frequency sounds and can significantly impact communication and quality of life (Sherman, 2024).

## LINK TO LEARNING

Understanding what [noises cause hearing loss \(https://openstax.org/r/77HearingLoss\)](https://openstax.org/r/77HearingLoss) helps nurses encourage patients to protect their ears and prevent hearing damage.

Visual changes associated with aging may emerge during the middle adult stage. In particular, reduced eye flexibility can cause trouble adjusting to light at night and create a glare. The rigidity also affects the eyes' ability to adjust focus on close-up objects. The condition **presbyopia**, the loss of ability to focus on close-up objects, can progress throughout middle age and stabilize in older adulthood as other eye changes arise.

## Dental

Dental changes in middle adulthood include receding gums, cavities, and wear on teeth, which can lead to subsequent cracking and the need for dental work. Changing oral secretions leading to dry mouth can also negatively affect dental health. Lifelong dental hygiene practices also affect the long-term health of teeth and gums. Periodontal disease and poor oral health can lead to an overall inflammatory response in the body and a cascade of inflammatory markers, which increase the risk for other diseases (Luo et al., 2022).

## Reproductive

The cessation of the menstrual cycle for at least twelve months is known as **menopause**. It is a period of transition during which the ovaries stop releasing eggs, and the level of estrogen and progesterone production decreases. Menopause typically occurs during middle adulthood, though some individuals experience abnormal early menopause in young adulthood. After menopause, menstruation ceases. Menopause primarily ends an individual's natural ability to conceive a child, but the hormonal changes also affect other organ systems (Figure 40.2). Changes during menopause and **perimenopause**, the stage preceding menopause, can include direct physical changes to organs and tissue, such as vaginal dryness and atrophy associated with estrogen reduction, lower libido, and hot flashes.

**FIGURE 40.2** Persons assigned female at birth may experience a wide range of symptoms during menopause. (credit: modification of “Symptoms of menopause (vector)” by Mikael Häggström/Wikipedia, CC0 1.0 Public Domain)

Menopause is not seen as universally distressing (Brown et al., 2021). Changes in hormone levels are associated with hot flashes and sweats in some people; however, the intensity, duration, and frequency of these symptoms vary. Other symptoms like depression, irritability, and weight gain are not necessarily caused by menopause (Brown et al., 2021). The incidence of depression and mood swings is not greater among menopausal people than nonmenopausal people.

## PATIENT CONVERSATIONS

### Hormone Replacement in Menopause

**Scenario:** Jenell is a 50-year-old eighth-grade teacher who spends her free time traveling with her husband and two teenage sons, hiking and skiing with her dog, and studying history. She sees her primary care provider yearly for a wellness checkup. She has made an appointment with her provider to discuss unexpected weight gain and other menopausal changes. Anna works as a nurse in the primary care medical office, where Jenell is a patient. While Anna takes her vital signs, Jenell states, “I’m in menopause, so I guess it’s time to start hormones.” Anna remembers that only a small percentage of persons AFAB experiencing natural menopause take hormone replacement therapy.

**Nurse:** Are you still having a menstrual cycle? What symptoms are you experiencing with menopause?

**Patient:** My last period was fourteen months ago. I have noticed some weight gain, even though I’m pretty active. I have some irritability and feel down a lot. I have had a few hot flashes, but nothing really bothersome, not like what my friends tell me about. Another big concern is painful intercourse. I know some friends who are taking herbal supplements, but I thought it was just best to get on a hormone replacement.

**Nurse:** There are many ways to cope with menopausal changes, including hormone replacement therapy. Some people take a supplement for a short time, others only use topical hormone treatments, and some use no hormones at all. It all depends on your symptoms.

**Patient:** I want to hear my options. I’d rather not take a hormone if I don’t need to.

**Nurse:** I’ll let your provider know your symptoms, and you can discuss the options. For example, they might suggest medication that affects serotonin to help with emotional symptoms and hot flashes as well as a vaginal cream to improve vaginal lubrication and skin elasticity.

A reduction in testosterone production in males is called **andropause**. While the reduced hormone production does not affect their overall ability to reproduce, it may cause changes in libido, body hair, loss of muscle mass, and breast enlargement. Adult persons AMAB can experience erectile dysfunction at any age and for a variety of reasons, but it is more common as they age, due to factors such as stress, lack of physical activity, obesity, and chronic underlying health issues.

### Psychological Development

Physiological changes may affect psychological health at all life stages, and vice versa. The psychological developments in middle adulthood relate to prior life circumstances, including childhood experiences and life choices made during young adulthood.

Middle-aged adults may experience significant daily stress related to family disputes, work overload, raising children, and caregiving for aging parents. Exacerbations of depression symptoms may be triggered by specific stressors, including death, divorce, job changes, or unemployment. Psychological well-being is also associated with lifestyle choices.

In the later part of middle adulthood, individuals may begin to experience mild cognitive impairment and memory loss. Hormones that affect sleep may worsen cognition and mental health management. Depression and anxiety early in life may be exacerbated during the middle-life stage due to increasing life and social stressors and worries about finances, health, and family (Brown et al., 2021). Middle-aged adults continue accumulating **crystallized intelligence**, the ability to draw and extrapolate from previously learned experiences (Perera, 2024). However, **fluid intelligence**, the ability to reason, transform, or generate new information, may decrease during middle age (Perera, 2024). The effects of knowledge, experience, and increased ability to regulate emotions can compensate for these losses.

Brain science is evolving and will provide new insights about cognition in midlife, such as the brain’s capacity to renew, or at least replenish, itself (Mayo Clinic, 2024). The capacity to renew brain connectivity through new connections is called **neurogenesis**, while the capacity to replenish or strengthen existing connections is called

**neuroplasticity.** Disease states such as depression, high blood pressure, and sleep apnea; alcohol; as well as medication interventions such as opioids, benzodiazepines, antihistamines, and proton pump inhibitors may affect cognitive outcomes (Mayo Clinic, 2024).

Working memory, or the ability to simultaneously store and use information, becomes less efficient with age (Craik & Bialystok, 2006). The ability to process information quickly also decreases with age. The slowing of processing speed may explain age-related variations in the performance of different cognitive tasks (Salthouse, 2004). Some researchers have argued that **inhibitory functioning**, or the ability to focus on certain information while suppressing attention to less pertinent information, declines with age and may explain why performance on cognitive tasks tends to vary by age (Hasher & Zacks, 1988).

### Psychosocial Development

Middle adulthood typically involves establishing one's career and contributing to others' development through activities like volunteering, mentoring, and raising children (Infurna et al., 2020). During this stage, middle-aged adults may begin contributing to the next generation, often through caring for others. Often, they also engage in meaningful and productive work that contributes positively to society (Infurna et al., 2020). During this time, adults also experience a range of interpersonal challenges, such as the following:

- coping with the death of parents and associated grief
- supporting children as they move on into their own lives
- adjusting to home life without children (often referred to as the “empty nest”)
- supporting adult children who return to live at home (known as “boomerang children” in the United States)
- becoming grandparents
- preparing for late adulthood
- acting as caregivers for aging parents or spouses
- experiencing workplace satisfaction/dissatisfaction

Some psychosocial theorists believe that the early years of middle adulthood are a time for reappraisal or, perhaps, the reaffirmation of goals, commitments, and previous choices. It can be a time for taking stock and recalibrating what is important in a person's life. This new perspective on time brings a sense of urgency to life. A person focuses more on the present than the future or the past. They may grow impatient with being in the “waiting room of life,” postponing doing things they have always wanted to do. A previous focus on the future gives way to an emphasis on the present. Neugarten (1968) notes that in midlife, people no longer think of their lives in terms of how long they have lived. Rather, life is thought of in terms of how many years are left. If an adult is unsatisfied at midlife, there is often a heightened motivation to make changes “before it's too late.”

### LINK TO LEARNING

Middle-aged adults may experience “empty nest syndrome” when their children grow up and leave home for the first time. In this video, suggestions for encouraging [healthy coping with empty nest syndrome](https://openstax.org/r/77EmptyNest) (<https://openstax.org/r/77EmptyNest>) are presented.

## 40.2 Theories Related to Growth and Development

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine Erikson's theory in relation to young and middle-aged adults
- Explain Levinson's theory in relation to young and middle-aged adults
- Examine Vaillant's theory in relation to young and middle-aged adults
- Explain Neugarten's theory in relation to young and middle-aged adults
- Examine Kegan's theory in relation to young and middle-aged adults

Many theories exist to explain the lifelong process of human development. These developmental theories explain the progression of human needs, physical abilities, and psychosocial dynamics throughout an individual's life span. Changing social and cultural norms affect the application of these theories in nursing practice. In theories describing

young and middle adulthood, nurses must recognize that the current developmental stage is affected by both previous and later stages. The way individuals experience life stages is not universal. The theories form a framework for understanding the range of social and physical developments across the life span. Development does not stop at a certain age; it is a continuous lifelong process.

There are many individual and group differences in patterns of development, with the influences of gender, cohort/generation, race, ethnicity, culture, socioeconomic status, education level, and time in history all influencing these patterns. Life span developmental theories give nurses a comprehensive perspective of individual developmental journeys. Nurses with a strong understanding of the psychosocial theories of aging have a unique ability to individualize care for patients in various clinical settings. They can see commonalities and differences stemming from their patients' diverse geographic and cultural backgrounds and incorporate these to enhance care.

## Erikson's Developmental Theory

Erik Erikson was one of the first formal life-stage theorists. In his work published in 1963, **Erikson's psychosocial development theory** explained social aspects of human development from infancy through adulthood, including personality development through the life span. He described the idea that an individual's sense of self is affected by how they interact with others. Erikson believed that humans are motivated by a need to achieve competence during the eight stages of development. Competence at any stage is achieved by resolving a specific developmental task or conflict, which leads to a healthy personality. Conversely, failure to master the developmental tasks in each stage may produce an internal sense of inadequacy.

According to Erikson (1963), individuals progress through a predictable series of developmental stages, as summarized in [Table 38.2](#). People in early adulthood are concerned with intimacy versus isolation. After developing a sense of self in adolescence, individuals are ready to share their lives with others. A strong sense of self and a positive self-concept are essential for developing healthy intimate relationships and avoiding feelings of loneliness and emotional isolation.

During middle adulthood, the social task is generativity versus stagnation. Generativity involves finding one's life's work and contributing to the development of others through productive activities. For some, this may include volunteering, mentoring, or raising children; for others, it may include making career choices or addressing societal needs. For example, someone who feels called to help marginalized or at-risk populations may pursue a career in social work. An individual may identify a societal need or problem and start their own business to address this need. Those who do not master this task may experience stagnation, having little connection with others and little interest in productivity and self-improvement.

Understanding Erikson's theory is key to developing a patient-centered nursing practice. The complex dynamics of human personality development through the life span directly affect health and wellness at each stage. For nurses, understanding the highly variable aspects of human development allows them to create individualized care plans regardless of the age or stage of the individual. Typically, progression through Erikson's developmental stages happens in a predictable sequence; however, individuals may revisit earlier tasks or work through multiple tasks simultaneously depending on their specific life circumstances. This is particularly true for the adult population, as it spans a wide range of ages. For example, a young adult living away from home of origin for the first time may struggle with identity versus role confusion while working to develop interpersonal relationships through the task of intimacy versus isolation. For young adult and middle-aged adult populations, nurses may incorporate stage-specific interventions, such as the following:

- encouraging physical activity based on specific hobbies and passions
- connecting individuals with in-person social support groups
- encouraging learning new activities or career changes as desired
- educating individuals on healthy eating for long-term disease prevention
- providing referrals for behavioral health support services for individuals and families
- showing respect for a wide variety of family structures

## Levinson's Theory of Adult Development

Life span development theories have evolved over the years. In the 1970s and 1980s, psychologist Daniel Levinson suggested his theory on adult development. While he began with a study evaluating primarily males, he later

expanded his research and theory to include females. Like Erikson, **Levinson's theory of adult development** suggests that adults work through tasks as they progress through developmental stages. However, unlike Erikson's psychological theory, Levinson believed that life structure changes occurred due to changes in an individual's physiology, psychology, and societal roles (Agronin, 2014). He believed that transitions between these five stages include significant disturbance, which leads individuals to modify, build, or change their internal character or external life structure over several years. Levinson further breaks down the young and middle adult years into transition periods ([Figure 40.3](#)).

**FIGURE 40.3** Levinson's model shows the alternation between transition and stabilization in adult development. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

In explaining these transitions ([Table 40.2](#)), Levinson focused on the concept of life structure. Life structure is how individuals interact with their social and cultural environment as well as how they see themselves within this structure throughout their lives. Levinson's theory is based on the idea that individuals move through periods of stability and transition during each stage of life.

Transition Period	Age Range	Tasks	Examples
Early adult transition	Ages 17 to 22 years	Young adults alter their life structure by making choices and creating goals.	<ul style="list-style-type: none"> <li>• Move out of their parent's home</li> <li>• Support themselves financially</li> <li>• Become independent in decision-making</li> <li>• Question social norms present in their family of origin</li> <li>• Question family values</li> <li>• Identify core personal values</li> <li>• Create a desired social network</li> <li>• Develop plans to pursue dreams</li> </ul>
Age 30 transition	Ages 28 to 33 years	Adults experience a time of reflection on early adulthood and planning for the future.	<ul style="list-style-type: none"> <li>• Consider creating a family</li> <li>• Address past failures and create a plan for success</li> <li>• Settle down in family life or career</li> <li>• Envision a new identity that reflects their values in this stage</li> </ul>

**TABLE 40.2** Levinson's Adult Transition Periods

Transition Period	Age Range	Tasks	Examples
Midlife transition	Ages 40 to 45 years	The tasks in this stage are deep reflection and often alteration in life structure based on these reflections.	<ul style="list-style-type: none"> <li>• Adjustments in family structure</li> <li>• Reassessment of career aspirations</li> <li>• Desire to set new personal goals</li> <li>• New sense of direction</li> <li>• Intense desire for change</li> <li>• Relationship crises</li> </ul>
Late adult transition	Ages 60 to 65 years	Adults in this stage may reflect on successes and failures, make peace with prior life experiences, and create a vision for the future.	<ul style="list-style-type: none"> <li>• Experience acceptance of life stage</li> <li>• Create goals for maintaining connection with others</li> <li>• Prioritize relationships and unfulfilled goals</li> </ul>

**TABLE 40.2** Levinson's Adult Transition Periods

For nurses, Levinson's theory gives insight into the many struggles experienced by young and middle-aged adults. Nurses can express compassion for individuals struggling in these stages by acknowledging the universality of change during this developmental period. Nurses can also encourage individuals to seek stability through internal reflection and maintaining healthy psychological and physical practices to maximize their well-being. Normalizing behavioral health services to help individuals through these transitions is also a crucial responsibility of nurses.

### Vaillant's Theory of Adult Development

Another psychosocial theorist, George Vaillant, built on the established theories of Erikson and Levinson. Vaillant analyzed research data to support his theory about adult development. His theory begins with adolescence and intersects with and adds elements to Erikson's theory. **Vaillant's theory of adult development** is based on educational and physical health measures, proposing that higher education levels directly affect self-care and health monitoring over the adult life stage. Additionally, he proposed that these factors directly influence overall health and success in the aging process (Nolan & Kadavil, 2003). Vaillant's theory is often conceptualized as an expanding set of concentric circles as adults move to complete sequential tasks of development ([Figure 40.4](#)). He included six stages, two of which are additions to Erikson's theory:

- identity
- intimacy
- career consolidation
- generativity
- keeper of meaning
- integrity

**FIGURE 40.4** Vaillant's theory suggests concentric growth in the completion of developmental tasks. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

Vaillant's additions to Erikson's theory include career consolidation (which falls just after the development of intimacy and before generativity) and becoming keeper of the meaning (which comes after generativity and before achieving integrity).

Vaillant's idea of career consolidation is essential in understanding young and middle-age development. Career consolidation involves the task of finding contentment and satisfaction in career aspirations. Vaillant used commitment, compensation, contentment, and competence to describe the goals in the career consolidation stage. This stage allows individuals to internalize lifetime learning and offer specific contributions to society and the next generation. Career consolidation is an individual's sense of well-being in their role and transitioning from a mentee to a mentor (Malone et al., 2016).

In caring for young and middle-aged adults, nurses should remember the importance of developing a sense of contentment and competence during these life stages. The application of Vaillant's theory in nursing care can be twofold.

Nurses can support individuals in their journey to maintain health in middle adulthood. Individual health can be considered an offshoot of career consolidation with a focus on commitment to both mental and physical health. This includes compensation as a response to unexpected changes and the ability to grow physically and mentally from these changes. It also includes contentment in life choices or continual work toward better life choices, competence in evaluating one's health, and deciding on changes and implementing them.

Nurses may also apply Vaillant's career consolidation theory to nursing practice in ways that improve their own and others' health. Nurses applying Vaillant's career consolidation theory will have continued and renewed commitment to promoting health in the populations they serve. They receive compensation for the intangible rewards of helping others. They show a sense of contentment in encouraging the newest generation of nurses and a sense of integrity in serving this population by offering education and mentorship. Their competence and expertise empower them based on their clinical experience, and they can adapt and expand their nursing knowledge from this strong base.

### Neugarten's Theory of Adult Development

Contrary to the developmental theories proposed by Erikson, Levinson, and Vaillant, Bernice Neugarten, an American theorist, introduced a distinctive perspective in the 1960s centered on the concept of a "social clock." **Neugarten's theory of adult development** defines the "social clock" theory as a culturally determined timeline prescribing when individuals should achieve certain milestones and life events, such as marriage, parenthood, career advancement, and retirement. Neugarten's theory emphasizes how individuals' adherence to, or deviation from, these societal expectations can shape their developmental trajectory and psychological well-being. She suggested that individuals may experience stress or satisfaction depending on how closely their personal life timelines align with societal norms (Ferraro, 2014).

These age norms, as manifested through outward behaviors like dress, actions, family dynamics, and lifestyle choices, are subject to change based on cultural values and beliefs. The notion of the "social clock" encompasses diverse cultural values associated with gender, social class, spirituality, occupation, and ethnicity that shape individuals' life choices and behaviors. Neugarten viewed these norms as subtle forms of social control, influencing

individuals' major life decisions in accordance with societal expectations.

Questions remain around the effects of adhering to these cultural age norms on individuals' overall happiness and contentment throughout their lives. While these norms may evolve across generations, they remain entrenched in distinguishing between older and younger adults. Neugarten proposed that cultural age norms contribute to age grading within society, wherein individuals are categorized and judged based on their age, often resulting in the assignment of specific roles and responsibilities associated with particular age groups.

Neugarten raised critical inquiries regarding the appropriateness of these entrenched social norms, exploring strategies to challenge their influence and assessing their long-term impact on individual well-being, especially when one's life trajectory diverges from the conventional social clock. By questioning the rigidity of these norms, she sought to understand how they shape individuals' choices, opportunities, and sense of self over time. Neugarten explored strategies for challenging the influence of these norms, recognizing the importance of empowering individuals to navigate their own life paths rather than conforming to predetermined societal expectations. She also examined the long-term impact of adhering to or deviating from these norms on individual well-being. She was particularly interested in understanding how diverging from the conventional social clock might affect individuals' psychological adjustment, social relationships, and overall life satisfaction. By questioning whether strict adherence to age-appropriate behaviors might inadvertently limit individual development, Neugarten highlighted the potential for these norms to function as a form of social control, constraining individuals' autonomy and inhibiting their ability to pursue authentic and fulfilling lives.

### Kegan's Constructive Developmental Theory

A contemporary theorist on adult cognitive development is Robert Kegan, a former Harvard psychologist. In 1982 and 1994, he developed the constructive developmental theory (CDT). While previous theories focused on action and responses to age-related stages and social norms, the CDT theory focuses on adult thought processes. **Kegan's constructive developmental theory** explains that individuals change their thought processes over time as their cognitive development progresses. The tiered structure of the CDT theory implies that individuals progress through various levels of cognitive development, with each stage representing a greater understanding of oneself and others. This advancement involves the capacity to reflect on one's thoughts and behaviors objectively, gaining insight into personal motivations and social dynamics.

Kegan's CDT focuses on the importance of adult thought processes in daily life, family life, work interactions, learning environments, and spiritual awareness. Higher cognitive thinking allows individuals to interact constructively by understanding themselves and others in a broader sense. The stages of Kegan's CDT assume that individuals progressively mature in their cognitive processes over time and derive meaning from experiences that also affect how they understand their lives and interactions with others ([Table 40.3](#)). Kegan used two critical definitions when explaining his theory. He explained that rather than adding new insight or learned tasks, adults progress through a **transformation** in which they change their thinking and understanding of the world around them. He also described a subject–object shift in which individuals move from simply understanding their character traits and interactions with the world (subject) to acquiring the ability to reflect on their traits and interactions and engage with themselves and others (object).

Kegan's Orders of the Mind Stages	Examples Related to Nursing Care
Impulsive mind—early childhood	<ul style="list-style-type: none"> <li>• Understanding the fantastical and impulsive thinking of children</li> <li>• Focusing on safety and incorporating flexible thinking in planning nursing actions</li> </ul>
Imperial mind—adolescence	<ul style="list-style-type: none"> <li>• Focusing on supporting decision-making</li> <li>• Encouraging learning through asking questions and obtaining information</li> <li>• Explaining health promotion in terms of how actions directly affect the patient</li> </ul>
Socialized mind—adulthood	<ul style="list-style-type: none"> <li>• Involving family and significant others in decision-making</li> <li>• Allowing individuals to interpret and make decisions based on spiritual values</li> <li>• Maintaining flexibility and respect for varied values and beliefs</li> <li>• Supporting patients through internal struggles related to treatment options</li> </ul>
Self-authoring mind—adulthood	<ul style="list-style-type: none"> <li>• Empowering patients to be key players in their own care and treatment</li> <li>• Providing guided support rather than specific task-oriented treatment plans</li> <li>• Helping patients verbalize wishes to help family members understand treatment choices</li> </ul>
Self-transforming mind—adulthood	<ul style="list-style-type: none"> <li>• Empowering individuals to seek acceptance of changes and transformations</li> </ul>

**TABLE 40.3** Stages of Kegan's Constructive Developmental Theory

## 40.3 Health Risks for Young and Middle-Aged Adults

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify physiological health risks for young and middle-aged adults
- Recognize psychological health risks of young and middle-aged adults
- Explain psychosocial health risks of young and middle-aged adults

Health risks for young adults and middle-aged adults exist on a continuum. While some health risks are age related, all are influenced by long-term lifestyle choices, genetics, and social circumstances. Nurses must remember the physiological, psychological, and psychosocial differences between young and middle-aged adults, as this age spread significantly affects baseline health and health outcomes. Many health outcomes are related to individual circumstances. Disease prevention and health promotion can be maximized by understanding the wide variation in health risks for adults aged 18 to 65 years. The following are high-risk areas for young adults:

- nutrition
- safety
- healthy habits
- health maintenance
- mental health

For middle-aged adults, nurses can focus on high-risk areas, including the following:

- mobility
- cognition
- psychosocial factors
- mental health

Individualized care is crucial, as health and wellness depend on age, chronic disease, lifestyle choices, and genetics. The range of ages in this category challenges nurses to assess individuals based on the different factors that affect the health and wellness journey and make the experience unique.

## Physiological Health Risks

Young and middle-aged adults experience the possibility of many **physiological health risks** that affect normal biological function. Common risks that develop in these age groups are those associated with metabolic syndrome, a constellation of disorders including high blood pressure, high blood sugar, increasing abdominal obesity, and high cholesterol levels. These conditions significantly increase the individual's risk of developing diseases such as type 2 diabetes, heart disease, and stroke. Because these conditions and disorders are interrelated, nursing interventions can be tailored to address multiple concerns simultaneously. As adults move through young adulthood into middle adulthood, their risk for various types of cancer also increases.

### Malnutrition and Obesity

Adults of all ages are at risk for nutritional concerns, including obesity and malnutrition. In younger adults with poor nutritional habits, the body will counter with effective compensation. However, nutrient deficiencies can develop if individuals maintain a persistently poor diet or enter adulthood with poor nutrition and nutritional habits that began in childhood. Imbalances in nutrient intake can be referred to as malnutrition and encompasses deficiencies and excesses (World Health Organization [WHO], 2024). Malnutrition may occur from inadequate food choices or restrictive dieting, regardless of whether an individual appears underweight. This can include eating disorders such as bulimia and anorexia nervosa as well as other forms of disordered eating, such as bingeing, fasting, or restricting, that can affect nutrient absorption. Disordered eating can trigger micronutrient deficiencies in vitamin D, calcium, iron, and other important vitamins and minerals. Nutrient imbalances can contribute to or trigger chronic health disorders, such as obesity, diabetes, bone thinning, cardiovascular disease, and certain cancers (WHO, 2024).

To maintain health, the body must use essential nutrients from food and fluids for growth, energy, and bodily processes. Essential nutrients are those necessary for bodily functions. They must come from dietary intake because the body cannot synthesize or make them internally. Essential nutrients include vitamins, minerals, amino acids, and fatty acids. Adults require various protein sources, carbohydrates, and fats to maintain balanced nutrient intake.

Health risks develop when an individual's intake does not provide adequate nutrients and calories or their diet does not provide essential nutrients. Obesity is the most common type of malnutrition in the United States. The CDC defines **obesity** as a disorder in which an individual's weight is greater than the healthy maximum for their age and height (2022a).

By understanding the complex nature of the development of obesity and the metabolic shifts caused by obesity, nurses can provide focused care for patients. Factors that may increase the risk for obesity in otherwise healthy individuals include the following:

- overeating patterns
- poor food choices
- low physical activity
- sedentary lifestyle
- altered sleep routines
- poor sleep quality
- genetics
- low socioeconomic status

There are many health consequences of poor nutrition and obesity. Poor nutrition can lead to hair thinning, kidney failure, liver strain, and gastrointestinal disorders. Severe eating disorders can damage vital organs such as the heart, liver, and gastrointestinal tract (National Institute of Mental Health [NIMH], 2021). Obesity is by far the most

widespread nutritional disorder in the United States, with the CDC reporting a prevalence of 41.9 percent in 2017. Between 2000 and 2017, the obesity prevalence increased by 11 percent nationwide. Obesity is the strongest risk factor and predictor of other metabolic disorders, including heart disease, stroke, and type 2 diabetes (National Institute of Diabetes and Digestive and Kidney Diseases [NIDDK], 2023). Increased mortality risk associated with obesity is due primarily to the many diseases that develop secondary to obesity, including metabolic disorders, liver disease, sleep apnea, and kidney disease, as well as those already mentioned (NIDDK, 2023).

### Type 2 Diabetes

A disease defined by impaired glucose metabolism is **type 2 diabetes mellitus**. Type 2 diabetes is becoming increasingly prevalent in the adult U.S. population and is directly related to the prevalence of obesity in the nation. The CDC estimates that 38.4 million people have diabetes, whether they have been diagnosed or not. Up to a third of the adult U.S. population has **prediabetes**, a chronic abnormal elevation in blood sugar levels that is not elevated enough to be considered diabetes (NIDDK, 2024).

Prediabetes serves as the most potent indicator for the development of type 2 diabetes, yet its progression is not inevitable. Without substantial lifestyle adjustments, individuals diagnosed with prediabetes often transition to type 2 diabetes, although the timing varies from person to person. While type 2 diabetes involves chronically elevated blood sugar levels, it is not always permanent. Embracing a healthy lifestyle composed of regular physical activity, a well-balanced diet, weight management, and stress reduction can frequently enhance blood sugar management and potentially decrease or eliminate the necessity for medication in individuals with type 2 diabetes.

The development of diabetes puts individuals at risk for other health concerns that stem from damage to the vascular system. These risks include damage to tiny capillaries that supply organs and nerves. A complication associated with diabetes is **end-organ damage** caused by damage to vascular organ systems. End-organ damage can lead to or compound other metabolic disorders, significantly raising the risk of mortality in these individuals.

The most common end-organ damage and complications associated with diabetes include the following:

- kidney disease
- peripheral nerve damage
- retinal damage
- heart disease

### High Cholesterol

High cholesterol is another component of metabolic syndrome often seen in individuals with diabetes and high blood pressure. Elevated blood lipid levels are highly prevalent in the adult population, with the CDC (2024b) reporting that up to 10 percent of adults have a total cholesterol greater than or equal to 240 mg/dL. Some elevated cholesterol is hereditary, but the single most significant factor affecting cholesterol levels for most people is lifestyle. Lack of physical exercise and high consumption of saturated fat increase total cholesterol. Lifestyle choices, including a high-sugar diet, also increase **triglycerides**, the most common lipids circulating in the body derived from food intake. As excess sugar is processed by the liver, it is turned into triglycerides that circulate in the bloodstream. All increased lipids put individuals at risk for vascular damage and heart disease. Specifically, fatty deposits, or **plaques**, develop on the inside of blood vessels. This deposition can happen throughout the body, particularly in the heart vasculature. These deposits slow the flow of blood and limit the oxygenation of heart tissue. The plaques can also break off and travel to distant smaller vessels, completely blocking blood flow. If blood flow is lacking to parts of the brain or heart, it can result in a heart attack or stroke.

### Hypertension

Hypertension (HTN) is another vascular risk factor associated with metabolic syndrome. A consistently elevated blood pressure is hypertension. Due to vascular muscle contraction, impaired fluid balance, or other chemical reactions, the blood vessels are less flexible and more rigid. This increases the diastolic blood pressure, the baseline pressure within the vessels. Consequently, the heart must exert more force to pump blood and oxygen to the body's organs. The **systolic blood pressure** is the pressure within the blood vessels when the heart contracts and moves blood peripherally. Untreated hypertension puts constant extra strain on the heart muscle, which can lead to a variety of other problems, such as kidney disease, vision loss, aortic aneurysm, peripheral artery disease, and congestive heart failure. Like diabetes, HTN is associated with end-organ damage, and the vascular pressure within the small vessels feeding organs damages the vessels. End-organ damage can be seen in the eyes, kidney, heart,

brain, and larger vessels in the chest. Heart enlargement can develop from persistently elevated and untreated HTN. People with HTN are at higher risk for stroke and heart attack.

### Cancers

According to the National Cancer Institute, cancer risk steadily increases with age (Figure 40.5). Historically, cancer rates among young adults have been lower than for middle-aged and older adults. However, recent trends in cancer rates between 2010 and 2019 show a significant increase in cancers in younger adults (Koh et al., 2023; Zhao et al., 2023). Studies show that these “early-onset” cancers, particularly breast and gastrointestinal cancers, are becoming more prevalent (Koh et al., 2023). The median age for several common cancers, including breast cancer, lung cancer, and prostate cancer, is between 60 and 70 years old (National Cancer Institute, 2021). Although it is much more common to be diagnosed with cancer in later middle adulthood, cancer is still a risk for adults of all ages.

### LINK TO LEARNING

Colon cancer is a common and often treatable cancer that typically arises during middle adulthood. New guidelines for [colorectal cancer screening \(https://openstax.org/r/77ColonCancer\)](https://openstax.org/r/77ColonCancer) were put out in 2021 by the U.S. Preventive Services Task Force (USPSTF). The new recommendations changed from initial screening at age 50 years to age 45 years.

Several known risk factors predispose individuals to certain types of cancer ([Table 40.4](#)).

Risk Factors	Cancer Type
<ul style="list-style-type: none"> <li>• Older age</li> </ul>	<ul style="list-style-type: none"> <li>• Lung</li> <li>• Breast</li> <li>• Prostate</li> </ul>
<ul style="list-style-type: none"> <li>• Heavy alcohol use</li> </ul>	<ul style="list-style-type: none"> <li>• Mouth</li> <li>• Throat</li> <li>• Esophagus</li> <li>• Larynx</li> <li>• Liver</li> <li>• Breast</li> </ul>
<p>Environmental exposures:</p> <ul style="list-style-type: none"> <li>• Work environment</li> <li>• Mining</li> <li>• Air pollution</li> <li>• Water pollution</li> <li>• Foods</li> </ul>	<ul style="list-style-type: none"> <li>• Lung</li> <li>• Various other</li> </ul>
<p>Chronic inflammation:</p> <ul style="list-style-type: none"> <li>• Obesity</li> <li>• Chronic dental infections</li> <li>• Crohn disease</li> <li>• Ulcerative colitis</li> </ul>	<ul style="list-style-type: none"> <li>• Colorectal</li> <li>• Gallbladder</li> <li>• Breast</li> <li>• Liver</li> <li>• Prostate</li> </ul>
<p>Dietary:</p> <ul style="list-style-type: none"> <li>• Deficiencies</li> <li>• Excess sugar</li> <li>• Food additives</li> </ul>	<ul style="list-style-type: none"> <li>• Endometrial</li> <li>• Breast</li> <li>• Kidney</li> <li>• Prostate</li> </ul>
<ul style="list-style-type: none"> <li>• Estrogen dysfunction</li> <li>• Genetic mutations</li> </ul>	<ul style="list-style-type: none"> <li>• Breast</li> <li>• Uterine</li> <li>• Ovarian</li> </ul>
<ul style="list-style-type: none"> <li>• Immunosuppression after organ transplant</li> <li>• HIV infection</li> </ul>	<ul style="list-style-type: none"> <li>• Non-Hodgkin lymphomas</li> <li>• Lung</li> <li>• Kidney</li> <li>• Liver</li> </ul>
<ul style="list-style-type: none"> <li>• Obesity</li> </ul>	<ul style="list-style-type: none"> <li>• Breast</li> <li>• Colorectal</li> <li>• Endometrial</li> <li>• Esophagus</li> <li>• Kidney</li> <li>• Pancreas</li> <li>• Gallbladder</li> </ul>

**TABLE 40.4 Cancer Risk** (Adapted from the National Cancer Institute, 2021.)

Risk Factors	Cancer Type
<ul style="list-style-type: none"> <li>• Radon</li> <li>• Nuclear test or development sites</li> <li>• Excess CT scanning</li> </ul>	<ul style="list-style-type: none"> <li>• Lung</li> <li>• Leukemias</li> <li>• Others</li> </ul>
<ul style="list-style-type: none"> <li>• UV damage</li> </ul>	<ul style="list-style-type: none"> <li>• Skin cancer</li> </ul>
<ul style="list-style-type: none"> <li>• Tobacco</li> </ul>	<ul style="list-style-type: none"> <li>• Lung</li> <li>• Larynx</li> <li>• Mouth</li> <li>• Esophagus</li> <li>• Throat</li> <li>• Bladder</li> <li>• Kidney</li> <li>• Liver</li> <li>• Stomach</li> <li>• Pancreas</li> <li>• Colon</li> <li>• Rectum</li> <li>• Cervix</li> <li>• Acute myeloid leukemia</li> </ul>

**TABLE 40.4 Cancer Risk** (Adapted from the National Cancer Institute, 2021.)

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Recognize Clues: Lung Cancer Risk

When patients seek care for health screenings, nurses must be alert for their specific disease risk factors. Many individuals do not know the recommended guidelines for routine health screenings and rely on nurses and other healthcare providers to recommend screening tests at the appropriate times. In reviewing health history, a patient may inform the nurse that they “quit smoking a while ago.” The nurse will recognize this as a cue to ask for additional information. The patient may then divulge that they made a New Year’s resolution to quit smoking and stopped “cold turkey” two weeks ago. The nurse will have determined the patient had smoked one pack per day for the last twenty-five years. The nurse recognizes that this patient qualifies for a low-dose lung cancer screening CT per USPSTF guidelines. These screening criteria include the following:

- age 50 to 80 years
- twenty-pack-year smoking history
- currently smokes cigarettes or quit within the past fifteen years

## Psychological Health Risks

The **psychological health risks** in young and middle-aged adults encompass many of the same risks as adolescents and older adults, including anxiety, depression, and suicide. However, underlying stressors, mental health challenges, and family dynamics differ significantly between individuals. Factors affecting psychological health for adults include work environment, family dynamics, changes in family structure, financial strain or stress, educational pursuits, social pressures, child-rearing, death of loved ones, and caregiver fatigue in caring for parents. While the causes and contributors can be different, the manifestations of mental health concerns are similar among adults.

## Anxiety

According to the American Psychological Association (APA) (n.d.-a), anxiety is a general term used to describe an emotional state in which an individual experiences tension, nervousness, and worry. Common physical symptoms associated with anxiety include elevated blood pressure, sweating, dizziness, and tachycardia (elevated heart rate). Anxiety is typically worry focused on future events or anticipated threats that are not readily identifiable. Anxiety encompasses several mental health disorders, including the following:

- generalized anxiety disorder (GAD)
- panic disorder
- specific phobias
- agoraphobia (fearing places or situations that might cause feelings of being trapped)
- social anxiety disorder

According to the APA (2023), nearly one-third of individuals experience acute or chronic anxiety at some point in adulthood. Data from the CDC in 2022 indicated that 12.5 percent of adults reported experiencing anxiety (CDC, 2022c).

Anxiety may be related to specific life circumstances or develop with other mental health disorders, such as depression. Mild anxiety is more common than severe anxiety and can often be treated without medication, as interpersonal therapeutics and coping strategies are often effective. In moderate to severe anxiety disorders, individuals are limited in their ability to maintain normal daily function due to intrusive thoughts and worries that are out of proportion to actual or perceived threats. These **intrusive thoughts** are disruptive thoughts or mental images that are associated with anxiety triggers that interrupt normal thought processes. These thoughts, in turn, cause behaviors such as avoiding specific circumstances, individuals, or groups. Treatment is necessary when anxiety levels affect an individual's ability to perform work, take care of their family, manage daily tasks, or feel contentment.

The APA (2023) lists the percentage of adults who experience common anxiety disorders in adults:

- specific phobias (8 to 12 percent)
- social anxiety disorder (7 percent)
- panic disorder (2 to 3 percent)
- generalized anxiety disorder (2.9 percent)

While specific phobias are highly variable, social anxiety disorder is common among adults. It occurs when a person worries about experiencing embarrassment, humiliation, and rejection from others during social interactions. Common responses to social anxiety are avoidance of activities such as public speaking, participating in activities requiring meeting new people, and significant group situations (Mayo Clinic, 2018).

A **panic disorder** is characterized by anxiety associated with recurrent panic attacks (Mayo Clinic, 2018). Panic attacks are often associated with other mental health disorders, such as depression. A **panic attack** may look different for different individuals but typically includes a combination of physical symptoms that may include the following:

- chest pain
- sweating
- trembling
- tachycardia
- dizziness
- throat tightening
- tingling in the face or extremities
- chills
- nausea

## LINK TO LEARNING

---

Differences between the [symptoms of a heart attack and the symptoms of a panic attack \(https://openstax.org/r/77HrtAttackSymp\)](https://openstax.org/r/77HrtAttackSymp) are explained by the American Heart Association. Nurses can educate patients who experience panic attacks on how to read clues from their bodies to help differentiate these symptoms.

---

### Depression

A mental health disorder known as depression is one in which individuals feel persistent and extreme sadness that leads to despair, interferes with normal daily activities, and disrupts sleep and energy patterns. The following are common symptoms experienced by adults with depression:

- trouble sleeping
- lack of interest in previously enjoyed hobbies and activities
- guilt
- low energy
- trouble concentrating
- change in appetite leading to weight loss or weight gain
- symptoms of anxiety or panic
- thoughts of death or suicide

Depression is highly prevalent, with the CDC (2023a) reporting that nearly 5 percent of adults in 2022 experienced depressive symptoms at some point in their lives. In that same timeframe, 11 percent of medical office visits were related to depression.

Anxiety and depression are commonly linked, with these disorders often occurring simultaneously or in succession. Nurses can help identify individuals experiencing depression by administering the Patient Health Questionnaire-9 (PHQ-9), a self-administered screening tool used to assess the severity of depression symptoms in individuals, per facility protocol, and monitoring for changes in patient affect. Monitoring for risk factors such as illness diagnosis, bereavement, significant life transitions, recent traumatic events, medication adverse effects, and substance use, which may exacerbate or precipitate depression, is another proactive approach nurses can take in identifying this mental health condition.

## LINK TO LEARNING

---

The [PHQ-9 Questionnaire \(https://openstax.org/r/77PHQ9Questions\)](https://openstax.org/r/77PHQ9Questions) helps nurses and healthcare providers quickly screen individuals for depression whether or not they are actively seeking care for mental health.

---

### Suicide

The National Institute of Mental Health (NIMH, 2023) defines suicide as the act of intentionally causing one's own death through self-inflicted injury with the intent to end one's life. Suicide is closely linked to depression, abuse, emotional trauma, and other mental health disorders. Suicide is prevalent in the adult population. Among various demographic groups, adults between 25 and 34 years of age have the highest number of suicide deaths (NIMH, 2023). After the age of 35 years, the suicide rate is similar across adult age categories. Suicide is nearly four times more common in persons AMAB than persons AFAB across all age and racial groups. The overwhelming majority of suicides in the United States occur in White males (CDC, 2023e).

## LINK TO LEARNING

---

Nurses in all practice settings should be alert for signs of mental health crisis and encourage patients to use community services in times of crisis, such as the [National Suicide Lifeline \(https://openstax.org/r/77SuicideHelp\)](https://openstax.org/r/77SuicideHelp) where help is available.

---

## Psychosocial Health Risks

For young and middle-aged adults, psychosocial health risks are most prominently linked to home and workplace environments. Learning environments, such as college or university settings, are also related to psychosocial risks for adults of all ages. Physical activity and risk-taking are typically higher in younger adults; however, unintentional injuries are common in all adult age groups. Challenges with interpersonal violence can occur at various levels for adults, including domestic abuse, workplace hostility, verbal hostility, or physically violent interpersonal interactions. Substance use and misuse are common among adults and contribute to detrimental effects on mental health disorders, social interactions, mortality rates, and life satisfaction. It also puts individuals at risk for health disorders, both acute and chronic, associated with substance use disorders.

### Unintentional Injuries

Unintentional injuries are common in adults (CDC, 2023c). The cause of unintentional deaths has changed over the last forty years, from motor vehicle accidents (MVAs) being the most common to unintentional overdose being the most common in 2021 (CDC, 2023c). Unintentional injuries include injuries and death from, in order of prevalence, unintentional overdose (poisoning), MVAs or traffic accidents, drowning, and falls. Unintentional injuries are accidental but may be related to specific lifestyle risks, including substance use, impaired driving, and activities involving physical risks, such as high-intensity and risky sports.

### Interpersonal Violence

The intentional use of physical force or power against another person or group that results in or has a high likelihood of resulting in injury, death, psychological harm, or deprivation is **interpersonal violence**. It can be associated with both physical and emotional abuse and may be encountered in domestic relationships, the workplace, or altercations with strangers. Homicide has remained one of the five leading causes of death in adults between 1981 and 2021 (CDC, 2023c). The risk of homicide or other interpersonal violence is exacerbated by substance use and misuse.

Domestic or intimate partner abuse can include sexual violence, physical violence, stalking, and psychological aggression. Although this form of violence is more commonly experienced by persons AFAB, it can also be experienced by persons AMAB. Anyone, regardless of sexual identity, can be involved in an intimate relationship that becomes abusive or violent. In addition to intimate partner violence, the workplace is also a common place for individuals to experience violence or hostility.

The Occupational Safety and Health Administration defines workplace violence as the threat of violence or actual violence in the workplace. Workplace violence may include the following:

- physical violence (direct or indirect)
- verbal harassment
- sexual harassment
- threatening behavior or words

Workplace violence can involve coworkers, managers, supervisors, clients, and customers. The following are risk factors:

- exchange of money
- working with unstable individuals
- work environment where alcohol is served
- working alone
- working in isolated areas
- working late at night
- working in high-crime neighborhoods

The following are specific jobs or careers with a higher risk for workplace violence:

- delivery drivers
- healthcare professionals
- customer service agents
- public service personnel

- law enforcement personnel

Nurses can support patients by bringing awareness to workplace violence and ensuring that individuals know their rights to safety and how to seek assistance, when necessary.

## LINK TO LEARNING

In cooperation with the National Institute for Occupational Safety and Health, the CDC offers a [Workplace Violence Prevention for Nurses \(https://openstax.org/r/77NurseViolHelp\)](https://openstax.org/r/77NurseViolHelp) course.

### Alcohol and Drug Use

Alcohol and drug use is prevalent in the United States, and the widespread use and misuse of mind-altering substances are increasing. While moderate alcohol consumption may be safe for some individuals, it is essential to make informed decisions about alcohol use and consider individual circumstances and risks. Alcohol consumption in moderation may be safe for individuals without underlying health disorders such as liver disease, history of substance use or addiction, and mental health disorders. In addition, some medications have negative interactions with alcohol. Excessive alcohol use is associated with 20 percent of deaths in individuals between the ages of 20 and 49 years (Esser et al., 2022).

The CDC (2024a) reports that up to 16 percent of adults binge drink by consuming four to five or more drinks on one occasion; however, many consume up to eight drinks per occasion. The health effects of heavy and binge drinking include increased mortality due to health problems such as the following:

- hypertension
- heart disease
- stroke
- liver disease
- cancer (e.g., mouth, throat, larynx, esophagus, colon, liver, and breast)
- injuries (e.g., MVA, falls, drowning, burns)
- violence (e.g., homicide, suicide, sexual assault)
- poisoning (e.g., overdose with alcohol or combination with another substance)

Legal drugs associated with dependence and misuse include nicotine products such as cigarettes, vaping, and chewing tobacco. Illicit drug use or misuse involves the use of illegal or controlled substances. These include prescription opioids, marijuana, cannabinoids, cocaine, crack, hallucinogens, inhalants, and methamphetamine, among others. Excessive or improper use of drugs or alcohol that may result in physical, mental, and social harm is known as **substance misuse** or **substance abuse**. This category also includes the misuse of psychotherapeutic prescription drugs such as pain relievers, stimulants, sedatives, and tranquilizers. The National Institute on Drug Abuse (NIDA) defines **medication misuse** as using these medications in any way other than as directed by the prescribing healthcare provider (NIDA, 2020).

Between 1999 and 2022, opioid overdose deaths in the U.S. increased by 22 percent, with this significant rise attributable to the use of prescribed or illicitly manufactured synthetic opioids such as fentanyl (NIDA, 2024). While these drugs are commonly implicated in overdoses, drug combinations are frequently suspected in these cases. High-risk medications include other opioids, benzodiazepines, alcohol, psychostimulants, and antidepressants. Up to 40 percent of these deaths also involve stimulants.

Problematic drug use can encompass both prescription and illicit drugs. Illicit drug abuse includes substances such as cocaine, heroin, and fentanyl. The CDC (2023b) reports that between 2006 and 2016, the rate of death from drug overdose in the U.S. population increased by 72 percent ([Figure 40.6](#)).

**FIGURE 40.6** The number of opioid deaths from synthetic opioids has drastically increased in the last eight years, highlighting the cause of the opioid epidemic. (credit: modification of “3 waves of opioid overdose deaths. US timeline” by Centers for Disease Control and Prevention./Wikimedia Commons, Public Domain)

Nurses must consider the impact of the terms used to describe problematic substance use in their interactions with patients, families, and among other professionals. The term "abuse" is accepted and widely used in literature, research, education, and policies. However, the term can associate wrongdoing or blame with the patient, and may lead to explicit or implicit bias on the part of nurses as well as law enforcement, social workers, and others. While "abuse" and "abuser" need not be completely eliminated in the context of substances, they should be used with care, and replaced where possible with words like "misuse," which conveys the same meaning without the same negative stigma.

## PATIENT CONVERSATIONS

### Herbal Substance Use

**Scenario:** Candace is a 28-year-old patient who lives in a basement apartment of her parents' home. She moved into this apartment after losing her job as a barista and being unable to make rent payments. She has been looking for employment but is struggling to find a job close to her home because of limited transportation. She presents to her primary care provider's office to discuss her concerns about anxiety and ADHD. Candace becomes tearful as the nurse takes her vital signs, reporting that she feels out of control and like she can't get her life on track.

**Nurse:** How long have you been noticing these symptoms?

**Patient:** I started feeling anxious when I lost my job as a barista and had to move back in with my parents. Everything is going okay with my parents, they are supportive. But I feel overwhelmed. I wonder if I have ADHD because I just can't seem to concentrate, and I feel jittery a lot.

**Nurse:** Did you have any struggles with depression or anxiety when you were younger? Did you ever have to take medications for depression or anxiety?

**Patient:** No, I always did pretty well in school and was never a worrier.

**Nurse:** Are you using any legal or illegal drugs like alcohol, marijuana, or prescription medications?

**Patient:** I drink with my friends occasionally, maybe two drinks per week on average. I haven't been sleeping very well, so I have been drinking more energy drinks than usual, and I take an herbal supplement that is supposed to

help with energy.

**Nurse:** How many energy drinks do you have in a day? Do you know the name of the herbal supplement or what is in it?

**Patient:** I have one energy drink per day at the most. The herbal supplement is kratom; it is legal, and I buy it at the convenience store.

**Nurse:** I am concerned that if you have not struggled with ADHD or anxiety in the past, the kratom may be contributing to your symptoms. When kratom is digested, it affects the brain and body in a way similar to opioid drugs. It could cause you to feel symptoms ranging from jitteriness to alertness and sedation. The preparations available are not standardized, so it is difficult to be sure how much you are taking. Also, since these supplements work on opioid receptors in the brain, they can be hard to stop taking, and sometimes, you begin to feel that you need more to get the same effect. I will make sure your healthcare provider discusses alternatives for you and explains how you can stop taking this supplement without side effects.

**Patient:** Thank you for explaining this. I thought kratom was pretty safe since it is available everywhere. I hope my symptoms improve when I stop taking this.

---

## 40.4 The Nurse's Role in Preventing Illness

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify nursing considerations for young and middle-aged adults
- Recognize interdisciplinary team referrals for young and middle-aged adults

Nurses are instrumental in preventing accidents and illnesses among typically healthy young and middle-aged adults, with health promotion standing out as one of their paramount responsibilities. Educating individuals on age-appropriate health screening and coordinating care at the first sign of illness are crucial for early disease detection and minimizing the health consequences of disease. Through rapport and nonjudgmental relationship building with patients, nurses can identify risks and prevent injuries associated with drug use, mental health disorders, and metabolic diseases. Education on health-supporting habits is one of the primary tasks for nurses caring for young adults, as forming healthy habits in young adulthood correlates with a longer, healthier life. By using screening tools for mental health and substance use disorders, nurses can ensure that patients have the support tools they need to make choices that support their wellness throughout life.

### Nursing Considerations for the Young and Middle-Aged Adult

Nurses can lead education, health promotion, and risk prevention by understanding the biggest challenges for young and middle-aged adults. Nurses can strive to provide individualized and compassionate care in a nonjudgmental and inclusive environment, accepting each individual and the specific challenges they face. Essential aspects of nursing care in the adult population include self-care habits, such as healthy eating, exercise, and disease prevention. To address psychological challenges, nurses can recognize the need for mental health screenings. Nurses will also collaborate with specialists and ancillary healthcare professionals, including primary care providers, mental health specialists, disease-specific specialists, nutritionists, social workers, physical therapists, and occupational therapists.

#### Teach Self-Care Responsibilities

Young adulthood is an opportune time for nurses to focus on promoting adult self-care responsibilities. This is especially true for young emerging adults. One of the most basic self-care responsibilities is seeking appropriate health care for acute injuries or illnesses. Sleep hygiene is also of great importance, as chronic lack of sleep is associated with various health risks and conditions. Acute sleep deprivation results in poor judgment and coordination, which may result in injuries and poor work performance. Chronic lack of sleep is associated with many specific health consequences, including depression, anxiety, obesity, hypertension, and diabetes (Alexander, 2024). Nurses can encourage and teach simple sleep hygiene measures, such as limiting screen use within one hour of sleep, using meditation exercises, keeping a consistent bedtime, getting exposure to sunlight, not eating within two hours of going to bed, and managing caffeine intake.

Additional self-management practices that nurses can promote include time management, financial management, and unplugging from devices and screens. Nurses should freely offer patients advice on encouraging lifelong hobbies and finding a community with shared interests. Self-management also involves awareness of emotional well-being. Nurses can guide patients to recognize new or worsening mental health concerns and encourage them to seek professional care from a mental health specialist as needed.

## REAL RN STORIES

---

### Replacing Screen Time with Nature Time

**Nurse:** Roni, BSN

**Clinical setting:** Occupational health nurse

**Years in practice:** 18

**Facility location:** Arkansas

I've worked as an occupational health nurse for a large hospital for fifteen years. I work with healthcare providers, nurses, kitchen staff, maintenance staff, and others, helping them maintain health and recover after an injury or illness. In recent years, I have encountered many individuals who struggle to manage their screen time during and outside work. These patients report that this interferes with many parts of their lives, including work productivity, family time, and friendships. I've read a lot about including or reintroducing outdoor time and nature activities to improve a variety of health concerns, such as anxiety, feelings of stress, and interpersonal struggles. There has been a lot of research recently on the effect of nature on mental health and improving thinking and planning skills. I keep a list handy of the many benefits, including the following:

- increased mood
- sense of connection to place
- increased empathy
- improved ability to cooperate with others
- improved attention at work
- increased energy

(Weir, 2020)

There are many theories about why time in nature calms the brain and reduces stress. Regardless of the reason, the most important aspect that I discuss with my patients is that spending even small amounts of time in nature, and even if they live in urban areas, has a positive effect on their well-being. This is all based on up-to-date scientific evidence. Adding a walk that is a bit of exercise is an additional boost. I suggest a few quick ideas for engaging with nature, even during a stressful workday for my patients:

- Take a walk on your lunch break.
- Take your five-minute break outside without your phone.
- Do a five-minute breathing exercise outside before tackling a difficult task.
- Make note of nature sounds or smells outside as you walk to and from your car.
- Gaze at the stars instead of your phone during your break (for night shift workers).

---

Good health habits built in early adulthood set the stage for positive health habits throughout adulthood, which may help reduce the risk of disease over time. Nurses should encourage self-screening techniques, such as breast self-exams (BSEs) and testicular self-exams (TSEs). While these tests are not a replacement for mammograms or regular checkups with a healthcare provider, they encourage individuals to monitor their health and maintain an awareness of their bodies. Patients come to understand their body's norms and can immediately report changes to their healthcare provider. While focusing on building healthy habits in young adulthood is the most efficient way to help create lifelong self-care routines, adults of any age can be encouraged to learn and improve these habits.

## LINK TO LEARNING

The [BSE \(https://openstax.org/r/77BSE\)](https://openstax.org/r/77BSE) and [TSE \(https://openstax.org/r/77TSE\)](https://openstax.org/r/77TSE) are essential aspects of self-care in disease prevention. Nurses can review techniques to make patients aware of these important self-exams and properly educate patients on how to perform them.

### Provide Health-Related Screenings

A primary role of nurses in health promotion is to ensure that individuals know which health screenings are recommended for them and when. As individuals get older, additional health screenings will become important. The United States Preventive Services Task Force (USPSTF) provides screening guidelines based on research and healthcare organization specialty guidelines, such as the American Heart Association and the American Congress of Obstetricians and Gynecologists. These include blood tests, cytology, radiology, genetic counseling, and procedures ([Table 40.5](#)).

Screening Test	Young Adult Screening Recommendations	Middle-Aged Adult Screening Recommendations
<i>BRCA</i> genetic counseling	Brief familial risk tool, if positive, genetic counseling recommended	Brief familial risk tool, if positive, genetic counseling recommended
Breast cancer screening—mammography	<ul style="list-style-type: none"> <li>• Mammography based on special circumstances, family history before age 40 years</li> <li>• Begin routine yearly screening at age 40 years</li> </ul>	Once every two years between ages 50 and 74 years
Cervical cancer (persons assigned female at birth)—Pap smear cytology	Begin at age 21 to 29 years, every three years	Continue Pap smear cytology testing from ages 25 to 65 years, every three years
Sexually transmitted infection	Based on sexual activity and risk	Based on sexual activity and risk
Lipids—screening blood test	Begin screening at age 20 years	Continue yearly through age 80 years
Diabetes—screening blood test	Starting at age 20 years	Continue yearly through age 80 years
Colon cancer—colonoscopy	Earlier screening based on family or personal history	Start routine screening at age 45 years
Prostate (persons assigned male at birth)—PSA blood test	N/A	Start routine screening at age 50 years
Lung cancer screening—low-dose CT scan	N/A	Begin screening at age 50 years based on risks and smoking history

**TABLE 40.5** Preventive Screening Tests by Age (Adapted from USPSTF, 2024.)

Screening Test	Young Adult Screening Recommendations	Middle-Aged Adult Screening Recommendations
Osteoporosis—dual-energy x-ray absorptiometry scan	N/A	<ul style="list-style-type: none"> <li>• Persons assigned female at birth start age 65 years</li> <li>• Persons assigned male at birth based on risk</li> </ul>
Abdominal aortic aneurysm (AAA)—AAA ultrasound	N/A	Begin at age 65 years based on risk
Hepatitis C/HIV	Begin at age 18 years; all adults screened once	Additional screening based on risk

**TABLE 40.5** Preventive Screening Tests by Age (Adapted from USPSTF, 2024.)

## CULTURAL CONTEXT

### Cultural Beliefs in Breast Cancer Screening

The USPSTF recommends regular breast cancer screening for all persons AFAB beginning at age 40 years. A recent study found that the participation rate of Korean American persons AFAB in breast cancer screening is low in the United States. While access to care may explain part of the low screening rates, culture may also play a role. Cultural factors that affect whether individuals seek breast cancer screening can include the following:

- low level of family encouragement
- embarrassment
- lack of preventive health orientation
- crisis-oriented healthcare perspective
- language barriers
- belief in fatalism

Maintaining an accepting, nonjudgmental attitude toward patients' preventive care choices is crucial for nurses. Nurses can provide adequate, timely education on preventive screening, such as breast cancer screening. It may be necessary to include education on preventive screenings during visits for other health concerns, especially for individuals who do not actively seek preventive care.

### Teach Disease Prevention

Nurses are vital sources of information about disease prevention. This includes education on health promotion and screening as well as preventing specific acute and chronic diseases, such as diabetes, cardiovascular diseases, sexually transmitted infections (STIs), and community-acquired diseases. These may include teaching about the following:

- physical exercise
- mental health coping strategies
- prevention of STIs
- vaccine recommendations for preventing disease
- nutritious food choices that may help prevent disease

While many individuals will not achieve or maintain prime health status, an essential part of nursing is educating patients about choices that will support their best possible health. That said, health looks different for each individual and is based on their genetic and lifestyle risk factors.

## LINK TO LEARNING

Familiarize yourself with the [CDC's STI fact sheets \(https://openstax.org/r/77STIFactSheet\)](https://openstax.org/r/77STIFactSheet) to help guide patient discussions on STI prevention, risks, and treatments.

### Encourage Physical Activity

Physical movement is one of the most influential aspects of a healthy lifestyle and disease prevention. The benefits of physical exercise are well-known and include the following (WHO, 2022):

- reduces disease risk
- improves brain health
- increases muscle strength
- increases bone strength
- boosts mood and health neurochemicals
- relieves stress, anger, and anxiety
- reduces or maintains healthy weight
- improves sleep quality

Physical movement and exercise plans should be based on a patient's preferences and abilities and are not a one-size-fits-all plan. Adults of all ages should aim for 150 minutes of moderate-intensity physical movement per week, in addition to at least two days of muscle-strengthening activities ([Table 40.6](#)). While this goal is the standard recommendation, nurses can encourage each individual to create a physical movement plan according to their schedule and preferences. Many people find that mixing up activities within a predictable routine helps them consistently fit exercise into their daily lives. Gym memberships are one option; however, individuals should be encouraged to move their bodies even if a gym membership is not something they can afford or want to invest in. Modifications or individual health needs or limitations need to be considered to ensure an individual can stick with a movement plan over time. The goal of the plan should be health promotion and strength building.

Strength Training Exercises	Moderate Aerobic Exercises	Vigorous Physical Exercises	Mind-Body Exercises
Pilates	Swimming	Biking	Yoga
Weightlifting	Brisk walking	Uphill hiking	Tai chi
Body-weight training	Water aerobics	High-intensity interval training (HIIT)	Pilates
Resistance training	Dance	Running	Qigong
	Tennis	Lap swimming	
	Yard care	Basketball	
		Tennis	

**TABLE 40.6** Physical Exercise Categories

Exercise is a powerful way to combat the changes associated with aging. Exercise builds muscle, increases metabolism, helps control blood sugar, increases bone density, and relieves stress. However, fewer than half of midlife adults regularly exercise, and only about 24 percent exercise frequently and strenuously enough to achieve health benefits (Elgaddal et al., 2022). The best exercise programs are those that can be engaged in regularly, regardless of the activity. However, a well-rounded program that is easy to follow may include activities such as walking and weight training. Having a safe, enjoyable place to walk can make a difference in whether a patient takes

walks consistently as part of their daily habits. Weightlifting and stretching exercises at home can also be part of an effective movement program. Exercise is beneficial in reducing stress in midlife. Walking, jogging, cycling, or swimming can release the tension caused by stressors. Learning relaxation techniques can also have health benefits. Exercise can be considered preventive health care. Promoting exercise can reduce healthcare costs by reducing chronic disease risk and incidence and improve quality of life on an individual as well as societal level.

### Teach Coping Mechanisms

Nurses often encounter adults in the setting of acute illness or chronic illness, so teaching coping skills is another important task when providing care. Nurses can set an example by encouraging coping skills in themselves and coworkers. Nurses are subject to high levels of stress and **compassion fatigue**, which occurs when individuals in a caregiving role experience signs of burnout and emotional fatigue from caring for others. A state of emotional, physical, and mental exhaustion caused by prolonged stress and excessive workload is called **burnout** and is often associated with work-related responsibilities and caregiving roles. Coping mechanisms can help manage disorders such as depression and anxiety as well as have a bolstering effect when faced with acute stressors such as new medical diagnoses or injuries. Nurses can focus on teaching active and passive coping strategies to patients. Nurses should encourage adults to seek active coping strategies, such as support groups, calming techniques, yoga, meditation, social support groups, problem-solving, and active lifestyle change planning. Passive coping strategies refer to methods individuals use to deal with stress or difficult situations by avoiding or withdrawing from them rather than actively addressing or attempting to resolve them. Sometimes, engaging in passive strategies such as distraction, mindfulness, and relaxation is helpful before jumping into active coping.

## REAL RN STORIES

---

### Joyfulness as Self-Care

**Nurse:** Vi, BSN

**Clinical setting:** Outpatient oncology infusion

**Years in practice:** 20

**Facility location:** Pennsylvania

As a hospital nurse for fifteen years, I encountered many patients coping with acute illness who dealt with their diagnosis in a variety of ways, both positive and negative. Many of these patients were in acute crisis. I have worked in an oncology outpatient infusion center for five years now. It wasn't until I met Janine that I understood the importance of healthy coping strategies for maintaining health in the presence of disease. Janine is a 60-year-old grandmother who was diagnosed with recurrent breast cancer after a fifteen-year remission. She told me that during her first encounter with cancer, she felt high levels of stress, became emotionally depressed, and focused only on her disease treatment. She was determined to see her sons graduate high school. She also explained that during that time, she was given a lot of information on how to cope but was never really able to implement the "self-care" activities that others suggested. She explained that over time, she realized that the "best" coping strategy is the one that works for the individual. When she was diagnosed a second time, she made a conscious effort to keep her focus on her joys and gratitude. She continued seeing her grandchildren, taking long walks in the forest with her dog, and cooking nutritious meals with her husband. While the cancer treatment was necessary, she told me that her strategy for coping with stress was maintaining a balance between disease treatment and the joys in her life. I always keep this story in mind when counseling others on coping strategies. During infusions, I help patients identify coping strategies by discovering what is important to them, what activities bring them joy, and how they interpret health. We also talk about how health does not always mean the absence of disease—rather, it's a sense of well-being amid disease.

---

### Interdisciplinary Team Referrals

Nurses ensure that individuals receive proper referrals from interdisciplinary team members. These referrals are needed to address many aspects of patient care. In young and middle-aged adults, specialty healthcare providers are necessary to address specific health disorders beyond the scope of a primary care provider. Nurses help facilitate referrals by ensuring proper screening and documentation are completed, scheduling appointments, and communicating with patients and office staff. Communication with the interdisciplinary team members can be by

phone, email, and internal communication networks in larger healthcare facilities. Nurses can also ensure that patients understand the reason for the referral, know what to expect during the referral process, and have a plan for continuity of care in the interim. Referrals to other interdisciplinary team members correlate with specific patient needs such as mental health treatment, nutrition guidance, and case management services to address socioeconomic impacts of health.

### Mental Health

Screening with mental health questionnaires, such as the PHQ-9, guides nurses and healthcare providers through identifying individuals who need more specialized care. When caring for patients with mental health disorders, it is important to convey that they are not alone in their feelings and experiences. It is also critical to support appropriate medication adherence to help patients manage the symptoms of mental health disorders.

Depending on the mental health disorder, a specialist referral may be necessary. While depression and anxiety are frequently treated successfully in the primary care setting, a focus on behavioral health or mental health care is necessary for individuals with treatment-resistant disorders (such as depression) or complex disorders such as bipolar disorder, schizophrenia, and ADHD.

Screening for mental health and other behavioral conditions guides nurses in determining if a referral to a mental health specialist is indicated. Mental health specialists and psychiatrists are the key players in diagnosis and treatment. Other patients may need more assistance with counseling and adjunctive care, in which case referral to a counselor or cognitive behavioral therapist (CBT) is essential.

There is much research interest in developing more effective medications for mental health conditions, but individuals must have access to the newest treatments. Healthcare providers need to be skilled and knowledgeable in prescribing treatments. Even individuals who successfully manage their medications in the primary care setting may benefit from CBT or other types of counseling and therapy that require specially trained providers. The addition of CBT to pharmaceutical therapy significantly increases the likelihood of depression remission and sustained improvement (Gautam et al., 2020).

### Nutrition

As individuals age, their caloric needs typically decrease. In response to weight gain, many Americans turn to dieting. However, simply reducing food intake does not guarantee a balanced diet, often resulting in vitamin and mineral deficiencies. Consequently, middle-aged individuals frequently encounter such deficiencies when restricting their calorie intake. To address this issue, providers often advise middle-aged patients to incorporate vitamin supplements into their diets.

Nurses play a key role in providing nutrition education. Nurses can help patients develop healthy eating habits that align with their preferences and health conditions, such as diabetes, hypertension, high cholesterol, or gastric disorders. Focusing on whole foods, fruits and vegetables, and whole grains and encouraging the limitation of processed, refined, and manufactured foods are general dietary recommendations that benefit nearly all patients.

### Specialists

Specialists in many fields collaborate with nurses on the patient care team ([Table 40.7](#)). While many disorders in young and middle-aged adults are managed through a primary care provider, specialty physician consultation is often needed, particularly if the diseases are resistant to the usual treatment or require more advanced interventions or experimental therapies. In addition, consultation with experts in diabetes care, cancer care, and mental health is essential for providing optimal patient care.

Specialist Care	Diseases Treated
Endocrinology	<ul style="list-style-type: none"> <li>• Diabetes</li> <li>• Thyroid dysfunction</li> <li>• Hormone dysregulation</li> </ul>
Rheumatology	<ul style="list-style-type: none"> <li>• Rheumatoid arthritis</li> <li>• Acute vasculitis</li> </ul>
Hematology	<ul style="list-style-type: none"> <li>• Leukemia</li> <li>• Anemia</li> </ul>
Cardiology	<ul style="list-style-type: none"> <li>• Hypertension</li> <li>• Heart disease</li> <li>• High cholesterol</li> <li>• Heart dysrhythmias</li> </ul>

TABLE 40.7 Specialist Care

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Teamwork and Collaboration

**Definition:** Function effectively in an interdisciplinary team, focusing on appropriate communication and individualized patient care.

**Knowledge:** Nurses working in various settings must collaborate with diabetes educators. This may include

collaboration for individuals with new-onset diabetes, treatment-resistant disease, and those struggling to cope with the disease. A team approach will provide the patient with the most up-to-date care options and foster relationships with specialized providers such as diabetes educators who focus exclusively on promoting health in this population.

**Skill:** Nurses can be alert for signs of a patient struggling with diabetes management. The nurse can lead by suggesting a referral to a diabetes educator to collaborate on treatment. The nurse will keep the patient at the team's center, always providing input and encouraging choices to empower them to feel a sense of control over their health.

**Attitude:** Maintain good communication between the healthcare provider, diabetes educator, and patient, particularly during treatment changes and follow-up.

---

### Social Worker

Social workers are key collaborators for nurses, particularly in challenging cases. Social workers help guide care and resources for patients with substance use disorders, inadequate housing, financial distress, and life-threatening diseases. Social workers are also beneficial for adults with underlying mental health or chronic physical disorders that require long-term and complicated treatment plans. For example, nurses may work directly with social workers to create a long-term plan for a patient discharged from the hospital. In this case, the social worker evaluates the needs of the patient and family prior to discharge and helps the patient navigate community resources to meet their needs, such as financial relief, respite care, or nutrition services. Social workers will communicate with nurses working in inpatient, outpatient, long-term care, and specialty care settings and provide invaluable information about the ongoing and changing needs of the patient. Social workers and nurses work together to create care plans focusing on the whole person.

## Summary

### 40.1 Growth and Development Stages

The adult life span stage encompasses adults aged 18 to 64 years. Adults experience many significant changes over that period but with great variation that the nurse must be aware of. While many developmental changes follow a timeline, the challenges are not universal. Nurses across all specialties need to be equipped to provide individualized and flexible care for adults of all ages.

Prominent growth and development patterns in the young adult years include psychological changes associated with increased independence, changing social networks, and continued brain development. Physical health in young adulthood is often at peak levels. However, lifestyle choices during this stage may predispose individuals to disease later in life. Lifestyle choices made in young adulthood may have long-term health consequences affecting the person's risk for cardiovascular disease, diabetes, and mental health disorders.

Growth and development patterns in middle adulthood are based on a multitude of physical changes. These may be physical changes in the skin, musculoskeletal, and urinary systems, as well as physiological changes such as menopause and atherosclerosis. Changes in this stage depend on current and previous lifestyle factors.

By understanding physiological and physical changes that progress through an adult's life, nurses can tailor care to promote wellness for each patient. Nurses must be alert for lifestyle choices and heredity factors that may affect adults' physiological, psychological, and psychosocial development. Nurses can empower adults to improve their health at any stage by understanding their bodies, improving lifestyle choices, and managing and preventing chronic disease.

### 40.2 Theories Related to Growth and Development

Understanding developmental theories about young and middle-aged adults gives nurses guideposts for creating individualized care plans. Young and middle-aged adults develop along a continuum extensively described in developmental theories. Using Erikson's psychosocial development theory, Levinson's theory of adult development, and Vaillant's theory of adult development helps nurses understand the psychological and psychosocial struggles that adults may encounter. Nurses can identify individuals' specific needs based on their progression through these developmental stages and provide education, interventions, and collaborative care that addresses them.

Neugarten's theory can help nurses understand social pressure that may affect the health of individuals. This is crucial when creating a care plan that considers the physiological changes adults experience, as well as the interplay between psychological and psychosocial norms and pressures. Keeping the social clock theory in mind will help nurses limit age grading in their practice. Incorporating Kegan's CDT gives nurses the chance to develop wellness plans that match each individual's view of health. By creating developmentally appropriate interventions, nurses promote positive patient outcomes.

### 40.3 Health Risks for Young and Middle-Aged Adults

Young and middle-aged adults encompass a range of ages, and the health risks that may emerge within these stages of life are varied and many. Some adults have few health concerns or risks, while others have multiple risk factors for different diseases. Nurses can create effective care plans for health promotion and improvement if they fully understand each individual patient's risks.

Health risks fall into three categories: physiological, psychological, and psychosocial. There is significant overlap in the categories, with many physiological health risks contributing to psychological or psychosocial risks, and vice versa.

Physiological health risks typically increase as adults transition from young to middle-aged adults. Depending on an individual's overall health status, significant physiological health risks emerge in later young adulthood and include metabolic and cardiovascular diseases as well as various types of cancer. Psychological risks are prevalent across the adult stage but may have different triggers. Psychological concerns in young adulthood can also make individuals more prone to similar disorders in middle adulthood. Individuals with psychological risks such as depression or anxiety may be at higher risk for psychosocial risks such as violence, injuries, and drug and alcohol misuse.

Conversely, individuals who use drugs or alcohol are at much higher risk for mental health disorders, such as depression and anxiety. Specific tools such as the PHQ-9 are available for monitoring patients' mental health. Recognizing depression, anxiety, and addiction gives nurses the opportunity to address these concerns at an early stage and guide patients to appropriate services for treatment.

Psychosocial risk factors in this age group include unintentional injuries and injuries related to interpersonal violence. Interpersonal violence and hostility can be encountered in the workplace and within intimate relationships. Psychosocial risks such as injury, substance use, and addiction are closely tied with psychological risks such as depression and anxiety. Physiological, psychological, and psychosocial risk factors in adulthood are interrelated. By addressing all risk types, the nurse can create holistic and personalized care plans.

#### 40.4 The Nurse's Role in Preventing Illness

Nurses are partners in health promotion and disease prevention throughout the adult years. Nurses focus on specific patient physiological, psychological, and psychosocial factors to create a working wellness path. Health screenings are crucial for preventing illness, and nurse attitudes about preventive care and screenings can influence their patient's choices in seeking and following it. Routine assessment of mental health status, physical health, and psychosocial status allows nurses to adapt care plans for the needs of each patient.

Collaboration with other medical professionals and specialists expands the nurse's reach in providing comprehensive care. Referrals to medical specialists are necessary for many advanced and complicated health disorders. In making referrals, the nurse has an important role in educating the patient and ensuring a smooth transition to specialty care. Special support services tailored for specific treatment needs include diabetes educators and specialized support services for individuals with cancer. Nurses work closely with social workers to ensure continuity of care for patients with complex health needs. One of the primary roles of the nurse is identifying a specific need and leading the appropriate interdisciplinary team in providing care for each patient.

### Key Terms

**achlorhydria** condition in which not enough acid is produced in the stomach

**acid reflux** condition in which gastric acid moves up the esophagus, causing irritation

**andropause** reduction in testosterone production in males

**burnout** a state of emotional, physical, and mental exhaustion caused by prolonged stress and excessive workload, often associated with work-related responsibilities and caregiving roles

**compassion fatigue** the emotional toll experienced by individuals caring for others

**crystallized intelligence** the ability to draw and extrapolate from previously learned experiences

**end-organ damage** a complication associated with diabetes; caused by damage to vascular organ systems

**Erickson's psychosocial development theory** theory explaining social aspects of human development from infancy through adulthood, including personality development through the life span

**esophageal sphincter** the muscular closure between the esophagus and stomach

**executive functioning** the ability to develop plans, focus attention, perform from working memory, maintain self-awareness, initiate and execute complicated tasks, control impulses, and manage emotions

**fluid intelligence** the ability to reason, transform, or generate new information

**inhibitory functioning** the ability to focus on certain information while suppressing attention to less pertinent information

**interpersonal violence** intentional use of physical force or power against another person or group that results in, or has a high likelihood of resulting in, injury, death, psychological harm, or deprivation

**intrusive thoughts** disruptive thought or mental image associated with anxiety triggers that interrupt normal thought processes

**Kegan's constructive developmental theory** theory explaining that individuals change their thought processes over time as their cognitive development progresses

**Levinson's theory of adult development** theory suggesting that adults work through tasks as they progress through developmental stages

**medication misuse** any use of medications other than as directed by the prescribing healthcare provider

**menopause** for persons assigned female at birth, the cessation of the menstrual cycle for at least twelve months

**multigenerational household** home with three or more generations living together in one household

- Neugarten’s theory of adult development** the “social clock” theory describes a culturally determined timeline prescribing when individuals should achieve certain milestones and life events, such as marriage, parenthood, career advancement, and retirement
- neurogenesis** the brain’s capacity to renew itself through the generation of new connections
- neuroplasticity** the brain’s capacity to replenish itself through the strengthening of existing connections
- obesity** a disorder in which an individual’s weight is greater than the healthy maximum for their age and height
- osteoporosis** a condition characterized by loss of bone density, making bones weak and prone to fracture
- osteosarcopenia** muscle and bone tissue decline
- panic attack** a combination of physical symptoms in response to anxiety that may include chest pain, sweating, trembling, tachycardia, dizziness, throat tightening, tingling in face or extremities, chills, nausea
- panic disorder** anxiety associated with recurrent panic attacks
- perimenopause** the stage preceding menopause
- physical growth** changes in height and weight
- physiological change** a bodily function happening at a cellular level
- plaques** fatty deposit that develops on the inside of a blood vessel
- prediabetes** a chronic abnormal elevation in blood sugar levels; however, the level is not elevated enough to be considered diabetes
- presbycusis** age-related hearing loss
- presbyopia** loss of near vision
- psychological change** relating to the mind and emotions
- psychological health risks** anxiety, depression, and suicide
- psychosocial factor** interpersonal interaction, such as a relationship, work communication, and cooperation in living situations
- sarcopenia** loss of skeletal muscle mass
- substance abuse** excessive or improper use of drugs or alcohol, leading to physical, mental, and social harm(also referred to as substance use or misuse to avoid stigmatization)
- systolic blood pressure** the amount of pressure within the blood vessels when the heart contracts and pumps blood out of the heart
- transformation** a transition in Kegan’s constructive developmental theory in which individuals change their thinking and understanding of the world around them
- triglycerides** the most common lipid circulating in the body; derived from food intake
- type 2 diabetes mellitus** a disease defined by an impairment in glucose metabolism
- Vaillant’s theory of adult development** theory based on educational and physical health measures; proposes that higher education levels directly affect self-care and health monitoring over the adult life stage

## Assessments

### Review Questions

1. A 20-year-old patient is struggling with screen addiction. You understand that this challenge stems from incomplete development of what part of the brain?
  - a. occipital lobe
  - b. parietal lobe
  - c. temporal lobe
  - d. frontal lobe
2. Although many young adults are at prime physical ability, strength, and health during early adulthood, which medical disorder is present at epidemic rates in young adults?
  - a. sleep deprivation
  - b. obesity
  - c. multigenerational living
  - d. cancer
3. Excessive video gaming and screen use is correlated with a variety of health consequences, including which mental health disorder?

- a. vision problems
  - b. tendonitis
  - c. depression
  - d. drug use disorder
4. During late young adulthood and continuing into middle adulthood, strength and metabolism are affected by which condition that is characterized by a decrease in muscle mass?
- a. sarcopenia
  - b. osteoporosis
  - c. inflammation
  - d. neurogenesis
5. While cognitive factors such as working memory, neuroplasticity, and neurogenesis may decline in middle adulthood, this age demographic maintains which type of intelligence that results in the ability to integrate new ideas by extrapolating from prior experiences?
- a. executive functioning
  - b. fluid intelligence
  - c. crystallized intelligence
  - d. long-term intelligence
6. In what stage of Erickson's psychosocial development are most middle-aged adults?
- a. trust versus mistrust
  - b. identity versus confusion
  - c. intimacy versus isolation
  - d. generativity versus stagnation
7. According to Levinson's theory, what situation marks the midlife transition (ages 40 to 45 years)?
- a. beginning to think about starting a family
  - b. reassessing career aspirations
  - c. questioning social norms present in their family of origin
  - d. identifying core personal values
8. Which tasks are included in Vaillant's theory of adult development?
- a. generativity, career consolidation, autonomy, keeper of meaning
  - b. intimacy, trust, autonomy, identity
  - c. generativity, autonomy, intimacy, integrity
  - d. autonomy, trust, identity, initiative
9. What developmental theory suggests that social norms influence a social developmental clock, driving individual choices in clothing, marriage, and family and contributing to age grading?
- a. Levinson's theory of adult development
  - b. Vaillant's theory of adult development
  - c. Erickson's psychosocial development theory
  - d. Neugarten's theory of adult development
10. What does Kegan's constructive developmental theory suggest?
- a. Adults develop according to a social clock.
  - b. Adults experience thought process transformations during their development.
  - c. Adults experience transition times at ages 30 and 40 years.
  - d. Adults must complete specific social tasks to progress to a higher level of development.
11. By different mechanisms, hypertension and diabetes affect the vascular system, resulting in damage to the heart, eyes, kidneys, and nerves. What is the term for this resulting damage?

- a. peripheral damage
  - b. organ failure
  - c. end-organ damage
  - d. pain
- 12.** What is the most common nutritional disorder in the United States?
- a. anorexia nervosa
  - b. bulimia
  - c. micronutrient deficiency
  - d. obesity
- 13.** A nurse administers a PHQ-9 questionnaire for a new patient as per clinic protocol. The patient notes concern in areas such as sleep, concentration, and energy level but not in areas of self-esteem or interpersonal interactions. What is an appropriate follow-up question for the nurse to ask?
- a. Have you struggled in the past with depression or anxiety?
  - b. Are you suicidal?
  - c. Have you ever used your son's ADHD medications?
  - d. Is your sleep related to problems at work?
- 14.** Health disorders such as diabetes, obesity, substance misuse, cancer, and anxiety put individuals at risk for what other mental health disorder?
- a. bipolar disorder
  - b. depression
  - c. dementia
  - d. schizophrenia
- 15.** In what work environments are individuals most at risk for workplace violence?
- a. service jobs, health care, delivery driver, law enforcement
  - b. legal work, food preparation, grocery store, custodial
  - c. law enforcement, road construction, university professor, bartending
  - d. food preparation, preschool teaching, legal work, health care
- 16.** What statement most accurately identifies the effects of acute and chronic sleep deprivation?
- a. poor judgment, improved coordination, injuries, enhanced work performance
  - b. inability to concentrate, poor work performance, diabetes, high blood pressure
  - c. poor work performance, anxiety, depression, hypertension, obesity
  - d. depression, enhanced work performance, obesity, injuries
- 17.** What aspects of a physical movement plan are important for *all* individuals?
- a. The movement plan must include weight-training exercises and high-intensity cardiovascular exercise.
  - b. The movement plan requires at least 150 minutes of exercise each week.
  - c. The movement plan should be based on individual preferences and abilities and include a variety of exercises and movements to strengthen muscles.
  - d. The physical movement plan is best when implemented in a gym setting.
- 18.** Nurses collaborate with social workers to create a care plan addressing what aspects of care?
- a. a balanced diet
  - b. a mental health treatment plan
  - c. financial relief resources
  - d. a care plan for colon cancer
- 19.** Up to 16 percent of adults binge drink. What health effects may they experience with continued binge drinking?

- a. hypertension, heart disease, cancer, injuries
  - b. cancer, diabetes, kidney disease, injuries
  - c. heart disease, vision changes, hearing loss, liver disease
  - d. obesity, heart disease, kidney disease, violence
20. What medical specialty focuses on caring for individuals with treatment-resistant diabetes?
- a. rheumatology
  - b. gastroenterology
  - c. cardiology
  - d. endocrinology

### Check Your Understanding Questions

1. List three physiological processes that are at their peak in early adulthood.
2. List three symptoms associated with menopause.
3. Nurse Anne is taking care of Karen, who was recently diagnosed with type 2 diabetes. Based on her knowledge of metabolic syndrome, nurse Anne knows that Karen is also at risk for which other disease processes?
4. Explain the effect of heart contraction on systolic and diastolic blood pressure.
5. Describe ways in which nurses can watch for signs of depression and anxiety during interactions with patients.

### Reflection Questions

1. How do lifestyle choices, such as diet, exercise, and sleep patterns, contribute to physical well-being during early and middle adulthood?
2. A nurse is caring for a 29-year-old patient who is struggling with depression. During their visit, the patient expressed concern about not yet being married and feeling she is running out of time to have children. The patient states that her family is putting her under a lot of pressure to “start a family.” The patient is also struggling to decide if moving to a new city is the right choice. Explain the developmental stage this patient is experiencing based on Neugarten’s and Levinson’s theories.
3. Reflect on ways in which drug and alcohol use contributes to adults’ risk for unintentional injuries and interpersonal violence. Create a diagram showing the relationship between these psychosocial risk factors in adults.
4. Reflect on societal expectations and pressures related to body image and physical health during young and middle adulthood. How might the nurse influence and support positive self-care choices within this age group?

### What Should the Nurse Do?

1. Summer is a 48-year-old female who presents to a primary care clinic with concerns about her weight. She is noticing some weight gain, irritability, and changes in her menstrual cycle. She states, “I thought I still had a few more years before menopause.” How should the nurse respond?
2. A 25-year-old male presents to a visit to “get a medicine for ADHD.” As the nurse takes the health history, the patient reports up to seven hours per day using a computer or phone, primarily for gaming. He reports trouble concentrating and feels like he is just not motivated to do anything else. He is also having trouble falling asleep. How should the nurse respond?
3. Dacia is a 34-year-old single mom working full time as a restaurant server. Lately, she has been struggling with finances, interpersonal conflict with the father of her children, and mechanical car problems. She exercises daily and eats healthily but indulges in ice cream at night. She presents to a primary care clinic where Jessa works as a nurse. Dacia is worried about her heart and has wondered if she had a heart attack.

She tells Jessa that she almost went to the emergency room the other night because her heart was racing, but she felt better after talking with her mom. What additional questions should the nurse elicit from Dacia?

4. Dacia explains that she had similar symptoms during her divorce five years ago. She states that she usually feels better after talking with her family. Her main symptoms are a racing heart, the sensation of fear, throat tightening, chest tightness, tingling in the cheeks, and dizziness. Jessa knows that Dacia's symptoms are consistent with what mental health disorder?
5. During a routine wellness checkup for a 48-year-old female, the nurse noticed she had never had a mammogram. What is the best course of action for the nurse?

### Competency-Based Assessments

1. Jeff is a 57-year-old school principal. He is visiting his primary care provider's office for a wellness exam. He reports that he is feeling well overall. He is satisfied with his life, and he shows no clinical signs of depression. He has friends who like to ice-fish together, and he spends a lot of time volunteering with his church. Jeff is exhibiting successful progression through which of Erickson's social tasks?
2. Reflect on how Vaillant and Erickson's theories intersect. Draw or re-create a diagram showing how Vaillant added to Erickson's theory. Which addition applies to young and middle-aged adults?
3. Research the rise in opioid use in the United States over the past ten years. Create an infographic displaying the trends in opioid use disorder, specifically the rise in misuse of synthetic opioids in the last ten years. Demonstrate the factors that are contributing to this rise. Show how this relates to the relative stability of other opioid use during the same period.
4. Cara is discussing nutrition with Mr. Callaway. His recent lipid panel showed elevated total cholesterol and triglycerides. Cara is explaining how limiting saturated fats and highly refined sugars can reduce these risks and his risk for heart disease. Mr. Callaway asks what his sweet tooth has to do with his cholesterol. How should Cara respond?
5. Using the internet, explore various fad diets and compare these to the Mediterranean diet. What are the main differences, and how do these affect health positively or negatively?

### CHAPTER OUTLINE

- 41.1 Growth and Development Stages
- 41.2 Theories Related to the Older Adult
- 41.3 Health Risks for Older Adults
- 41.4 The Nurse’s Role in Preventing Illness

**INTRODUCTION** Adults pass through several stages of development, including early adulthood, middle adulthood, and older adulthood. The American Psychological Association (2023) explains that older adulthood begins when an individual is approximately 65 years old. The number of older adults in the United States is steadily increasing. According to the United States Census Bureau (2023), the number of older adults in the United States increased by more than 38 percent between 2010 and 2020. As of the 2020 census, 55.8 million older adults comprise more than 16 percent of the U.S. population. Similar to other age groups, older adults experience predictable changes. Many common changes are associated with aging; however, the physical, psychological, and psychosocial transitions are not universal. Although individuals pass through these stages at their own pace, nurses can identify patterns in aging to guide the nursing care process. How older adults experience developmental changes depends on lifestyle choices, disease states, health conditions, social circumstances, and social determinants of health (SDOHs).

Nurses working across various specialties encounter older adults in their practice. Providing exceptional care depends on how well nurses understand the general changes associated with each life stage and how to apply nursing care during those stages. A range of developmental theories associated with aging inform day-to-day

practice for nurses, such as the psychosocial development theory, disengagement theory, activity theory, and the human needs theory. Theories related to the progression of psychological changes in adulthood help nurses prepare individuals for expected and unexpected health events and transitions.

Health risks in older adults are not universal and depend on lifestyle factors, age, and heredity. However, since some health risks are more common as individuals age, nurses can be attentive to opportunities for delivering care and education aimed at mitigating these risks through health promotion and disease prevention. A nurse's role in preventing illness is varied. Nurses are poised on the frontlines to promote wellness for all individuals regardless of their risk for chronic disease. Nurses can empower individuals to improve their health, even as they age.

## 41.1 Growth and Development Stages

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify growth and development patterns for the older adult
- Explain how individuals adjust to the changes of older adulthood

During older adulthood, individuals experience physiological, psychological, and psychosocial changes. Physiological changes often result in physical changes that **older adult** (adults 65 years of age or older) can feel and see. When physiological and physical changes manifest in declining health status or progression of chronic diseases, these changes also affect psychological well-being and social interactions. These individual changes may alter how older adults interact with others, function in the community, and maintain a sense of belonging. Older adults may struggle with discrimination based on one's age, new or progressive diseases, and cognitive changes. Adjusting to these many changes requires resiliency to maintain a sense of individual health.

### Older Adult Stage

Older individuals undergo a range of physiological, physical, and psychological transformations. These may have little effect on older adults' day-to-day life or on how they function. For older adults, these developmental changes are often accentuated by underlying health problems and may contribute to worsening overall health. Changes that are physiological are those bodily functions happening at a cellular level, and the presence of chronic disease also plays a role in the psychological changes that older adults experience. Changes that are psychological are those relating to the mind and emotions. The psychosocial factors relate to interactions between individuals, such as relationship changes, financial issues, living situations, and SDOHs. These factors interplay with physical and psychological changes to create challenges and rewards for older adults.

### Physiological Development

Older adults experience a wide range of **physical changes** that are outward expressions of change in the body during this developmental period. In addition to visible physical changes, older adults experience internal physiological changes that affect metabolism, energy level, hormone balance, and disease progression ([Table 41.1](#)). Physical developmental changes in older adults affect every organ system in the body. Nurses can anticipate many typical and expected physical changes in older adults; though, each individual progresses through physiological and physical changes at a different rate.

Organ System	Expected Physiological Changes	Possible Physical Changes
Cardiovascular	<ul style="list-style-type: none"> <li>• Possible blood vessel thickening, narrowing, and loss of elasticity</li> <li>• Possible calcification of valves</li> <li>• Decreased peripheral circulation</li> <li>• Decreased cardiac output</li> </ul>	<ul style="list-style-type: none"> <li>• Elevated baseline blood pressure</li> <li>• Varicose veins</li> <li>• Heart murmur</li> </ul>
Respiratory	<ul style="list-style-type: none"> <li>• Decreased cough reflex</li> <li>• Increased chest wall rigidity</li> <li>• Decreased lung compliance</li> <li>• Fewer alveoli</li> </ul>	<ul style="list-style-type: none"> <li>• Reduced stamina (tolerance to physical exertion)</li> </ul>
Musculoskeletal	<ul style="list-style-type: none"> <li>• Loss of muscle mass</li> <li>• Reduced joint mobility</li> <li>• Loss of bone density</li> <li>• Decreased proprioception</li> </ul>	<ul style="list-style-type: none"> <li>• Reduced muscle strength</li> <li>• Joint pains</li> <li>• Changes in balance</li> </ul>
Genitourinary	<ul style="list-style-type: none"> <li>• Decreased renal perfusion</li> <li>• Decreased bladder capacity</li> <li>• Female: reduction in sphincter tone</li> <li>• Male: prostate enlargement</li> </ul>	<ul style="list-style-type: none"> <li>• Overactive bladder</li> <li>• Incontinence</li> <li>• Urinary frequency</li> </ul>
Gastrointestinal	<ul style="list-style-type: none"> <li>• Decreased salivary and gastric secretions</li> <li>• Decreased gut motility</li> <li>• Impaired rectal sensation</li> </ul>	<ul style="list-style-type: none"> <li>• Dry mouth</li> <li>• Changes in bowel patterns</li> <li>• Hemorrhoids</li> <li>• Constipation</li> </ul>
Integumentary	<ul style="list-style-type: none"> <li>• Decreased elasticity of skin</li> <li>• Slower nail growth</li> <li>• Sweat and oil gland atrophy</li> </ul>	<ul style="list-style-type: none"> <li>• Skin pigment changes</li> <li>• Graying hair</li> <li>• Dry skin</li> <li>• Lesions such as seborrheic keratosis and skin tags</li> </ul>
Endocrine	<ul style="list-style-type: none"> <li>• Altered hormone production</li> <li>• Reduced ability to adapt to stress</li> <li>• Decreased thyroid function</li> <li>• Insulin resistance</li> <li>• Decreased core temperature</li> </ul>	<ul style="list-style-type: none"> <li>• Weight changes</li> <li>• Glucose intolerance</li> <li>• Increased stress levels</li> </ul>
Immune	<ul style="list-style-type: none"> <li>• Decreased thymus size</li> <li>• Decreased T-cell function</li> </ul>	<ul style="list-style-type: none"> <li>• Increased susceptibility to infections</li> </ul>

**TABLE 41.1** Expected Physiological and Physical Changes in Older Adulthood

Organ System	Expected Physiological Changes	Possible Physical Changes
Sensory	<ul style="list-style-type: none"> <li>• Thickening of eardrum</li> <li>• Deterioration of inner ear bones</li> <li>• Less sensitive cornea</li> <li>• Decreased pupil size</li> <li>• Decreased lens flexibility</li> <li>• Reduced eye muscle motion</li> <li>• Fewer taste buds</li> <li>• Smaller taste buds</li> <li>• Decreased saliva</li> <li>• Decreased smell receptors in the nose</li> <li>• Decreased blood flow to nerve endings</li> <li>• Thinning skin</li> </ul>	<ul style="list-style-type: none"> <li>• Reduced hearing</li> <li>• Alterations in balance</li> <li>• Tinnitus</li> <li>• Earwax buildup</li> <li>• Slow reaction to changing light</li> <li>• Clouding of the lens</li> <li>• Presbyopia</li> <li>• Trouble with night driving</li> <li>• Alteration in visualizing colors</li> <li>• Eye floaters</li> <li>• Dry eyes</li> <li>• Decreased taste sensation</li> <li>• Decreased sense of smell</li> <li>• Reduced appetite</li> <li>• Decreased temperature sensitivity</li> <li>• Trouble sensing skin injuries</li> </ul>
Reproductive	<ul style="list-style-type: none"> <li>• Female: decreased estrogen level; atrophy of uterus</li> <li>• Male: erectile dysfunction</li> </ul>	<ul style="list-style-type: none"> <li>• Vaginal and breast atrophy</li> <li>• Vaginal dryness and irritation</li> <li>• Erectile dysfunction</li> </ul>

**TABLE 41.1** Expected Physiological and Physical Changes in Older Adulthood

### Psychological Development

Psychological changes vary widely in older adults. Psychological transitions relate to accepting the aging process, the development of acute or progressive cognitive impairments, and the occurrence of mental health disorders. According to the National Institute on Aging (2021), some cognitive impairments are related to acute medical issues, while others develop into progressive loss of brain function resulting in cognitive decline, known as **dementia**. Psychological problems may also develop in response to grief and loss. These include loneliness, anxiety, and depression. Other triggers for depression include changing body image, decreased social interaction, decreased physical activity level, loss of driving ability, chronic health conditions, and medications.

## REAL RN STORIES

### Dementia Versus Delirium

**Nurse:** Cara, RN, BSN

**Clinical setting:** Surgical department

**Years in practice:** 13

**Facility location:** Central Iowa

I've worked with postsurgical patients for six years, but I previously worked for five years in an assisted living facility with two additional years in a memory care unit. I'll never forget the time I witnessed a patient experiencing true delirium. During a three-day work week, I cared for Edith, a 77-year-old patient who had undergone a right hip replacement. Edith progressed as expected during the first day. Her pain was well controlled, she began ambulating as expected, and she tolerated the urinary catheter without problems. She had several visitors, including her grandchildren, and enjoyed talking with the nurses about her family.

Edith attempted to get out of bed without assistance on the second evening of her stay. She stated she was feeling strong enough to go home. I explained that she needed to call for help and that the surgeon would need to clear her

before she was released. The previous day-shift notes indicated that Edith had been slightly confused about the time of day; however, her family explained that she occasionally mixed up dates and times. Edith repeatedly called out as the night shift progressed, asking to go home, and seemed unaware of her recent surgical procedure. I felt Edith was becoming more disoriented. I remembered Edith did not exhibit any signs of severe confusion the day before. While Edith had a history of mild cognitive decline and forgetfulness, she did not have a history of dementia.

I brought up my concerns with the charge nurse, who encouraged me to discuss my concerns with the surgeon. The surgical wound was clean and without signs of infection. Edith had no fever, and her other vital signs were normal. I knew the new onset of confusion might be delirium, a sudden-onset confusion related to a physical illness or infection, rather than her mild cognitive decline. After hearing my concerns, the surgeon ordered blood work and urinalysis from the urinary catheter. Edith's test results showed an elevated white blood cell count, and her urinalysis was positive for infection. She was treated appropriately with antibiotics. Although Edith spent two extra days in the hospital for a urinary tract infection, her mental status cleared, and she resumed her baseline cognitive functioning.

---

### Psychosocial Development

Psychosocial changes in older adults vary depending on health and social circumstances and relate to adjustments in changing family and community dynamics. Social factors that may affect psychosocial interactions include changes in living situations, death of family or friends, and the effects of **ageism** (a form of prejudice and stereotyping related to a person's chronological age) in the community. Health factors such as decreased mobility, chronic disease, and cognitive decline can negatively impact social interactions with others. Psychosocial changes can also be triggered by retirement. Worrying regarding retirement timing and long-term financial security is common in older adults. Retirement and changes in work abilities also correlate with ageism and societal retirement pressures.

As an individual progresses through adulthood, psychosocial factors also relate to relationships with children and significant others and may involve **role reversal**, a circumstance where children take on the role of caregiver, and older adults take on a more dependent role. Individuals with many health issues require frequent assistance from family and other caregivers for many years, while others live independently and without assistance until very old age. Role reversal can be challenging for the older adult and for the children who provide care. Role reversal is not a universal transition in older adulthood. Older adults without children or those with strained parent-child relationships may not have the option for direct family care. In many families, children may not have the time, resources, or proximity to provide individual care to their aging parent. In these cases, older adults do not experience role reversal but may experience strain regarding securing the necessary resources and care.

## LIFE-STAGE CONTEXT

---

### Role Reversal and the Aging Adult

The concept of role reversal between older adults and their adult children is complex and challenging. Role reversal is the idea that a child takes on a parenting role while a parent takes on a child's role. Caring for an aging parent, particularly one with dementia or other chronic illnesses requiring intense physical or emotional caregiving, may seem like a role reversal. While it might appear as a role reversal, with the child now taking on a caregiving role for their parent, some experts argue that this is not a role reversal. Instead, they propose the concept of a role shift, emphasizing the older adult's identity as a parent and the caregiver's identity as a child are maintained. In this way, it acknowledges a change in responsibilities without completely altering the fundamental identities within the parent-child relationship. Nurses must maintain caution when thinking of care in a role-reversal pattern, as it can inadvertently remove dignity and respect from the older adult who has lived a full and complex life. Think of this as providing respectful care rather than "parenting" the older adult.

---

### Adjusting to Changes in Older Adulthood

Older adults make conscious and unconscious changes in their daily lives to cope with the physical, psychological, and psychosocial changes that face them. Some changes are progressive, requiring permanent alterations in lifestyle, while others are temporary, requiring in-the-moment coping mechanisms. Progressive changes, such as

muscle loss, pain, and cognitive decline, require individuals to make adaptations including using assistive devices in their home, relying on others for transportation, and using outside caregiver services. More temporary changes, such as an illness, injury, or death of a family member, may require short-term coping mechanisms, such as attending physical therapy, adjusting to facilitate the healing process, and coping with acute grief.

### Strength and Mobility

Older adults can maintain strength and mobility through intentional, continued physical activity and strength training. However, many older adults experience a progressive decline in mobility related to joint pain related to arthritis, reduced flexibility, and changes in bone structure, which can increase their risk of falls. Older adults can adapt to these changes by recognizing early signs of mobility decline and maintaining daily physical movement, adapting physical exercise to fit their abilities. Maintaining bone health is also crucial and can be achieved through exercise and good nutrition. Weight-bearing activities such as walking, jogging, dancing, and resistance training stimulate bone remodeling and help prevent bone loss. Adequate intake of calcium and vitamin D is essential for maintaining strong and healthy bones. Dairy products, leafy green vegetables, fortified foods, and supplements can be valuable sources of these nutrients.

Older adults may experience varying levels of pain and fatigue. While pain may relate to prior injuries, joint deterioration, or chronic diseases, maintaining strength and mobility can limit the effect of pain in day-to-day life. A sedentary lifestyle either beginning in older adulthood or continuing through life leads to an overall loss of muscle strength and muscle mass that can in turn lead to generalized fatigue. Efforts to maximize mobility within their individual ability can help reduce pain and fatigue.

### Nutrition

Many changes develop for older adults surrounding nutrition. Changes associated with older adulthood that affect nutrition include the following:

- decreased hunger sensation
- decreased appetite
- decreased taste sensation
- decreased thirst response
- change in nutrient absorption
- decline in oral health

Changes in dietary habits can have cascading effects on the functioning and health of multiple organ systems, such as the heart, kidneys, and liver. Older adults can focus on incorporating functional foods to boost nutrition, maintain vitamin and mineral intake, regulate elimination, improve skin integrity, and increase energy levels (Jones, 2002). These **functional foods** are nutrient-dense foods that benefit health and functioning in ways other than maintaining calorie and energy intake and include such foods as fruits, vegetables, yogurt, and nuts (Jones, 2002; Temple, 2022). For example, fruits not only provide simple sugars, fluid, and calories for nutrition, but they also provide additional benefits in the form of soluble fiber that promotes healthy digestion and elimination. Yogurt and other fermented foods provide healthy caloric intake but also provide probiotic cultures to help maintain healthy intestinal microbial balance (Leeuwendaal et al., 2022).

### Cognition

Older adults must adapt to psychological and cognitive changes. Individuals experiencing **mild cognitive impairment (MCI)**, which is prevalent in older adults, present with forgetfulness, short-term memory loss, and thinking impairment, such as difficulty recalling names or words. Mild cognitive impairment affects self-esteem, independence, social interactions, and an individual's ability to perform self-care. It is often distressing to older adults. The National Institute on Aging (2021) explains that in some individuals, MCI may progress to worsening or progressive dementia, particularly in those with multiple chronic health conditions. However, not all MCI is progressive, and older adults in good health can minimize the effects of MCI by maintaining an active lifestyle, interacting in social situations, reading, and learning skills.

### Retirement and Finances

As adults move through the aging process, they notice both social and financial changes that affect their daily lives. Retirement is a turning point for many adults that can significantly change how they see themselves and their

societal value. For some, retirement signifies the end of a career and a time to enjoy more time with family and hobbies. Others may find retirement lonely or need more direction and focus. This can lead to depression if older adults do not have a support system. Financial changes include modifying spending patterns, revising budgets to align with savings goals, and making adjustments to accommodate changes in tax situations. Many older adults struggle financially and depend on government aid to maintain their expected lifestyle. The cost of prescriptions may increase if chronic diseases progress, leading to the need for additional medications, or if newer, more expensive medications become necessary for the treatment of the disease. Some seniors may need to decide between food and medication purchases. As a result, they may cut pills in half to save money, only to worsen their disease/illness.

### Relationships and Grief

Relationships change drastically during the later adult stage of life. Some older adults may find that they rely on their children for assistance. Others may find great joy in providing care for young grandchildren. In addition, as generations age, older adults experience more loss of same-age counterparts in their friend groups and extended family. The death of a spouse, friends, and family are often significant turning points for many older adults. Older adults must learn to cope with grief and learn the signs of depression to get help when needed.

### Ageism and Stereotypes

Ageism is a form of prejudice and stereotyping related to a person's chronological age. Ageism can apply at any age but is most common in older and younger adults. Ageism has negative effects on the developmental changes of older adults and can lead to the following:

- anxiety
- increased mortality risk
- slower recovery time
- poor mental health
- depression

By respecting older adults and monitoring their behavior during interactions to avoid talking down to them or using oversimplified speech not required for them to understand, nurses create an environment of mutual respect between older adults and nurses. Experiencing a sense of respect within the community helps older adults maintain autonomy, independence, and a sense of belonging and purpose. Ageism can also be a self-directed sense of diminished self-worth due to aging. In this context, ageism is not just imposed by others; it can also manifest as an individual's own sense of reduced self-worth or value attributed to the aging process. It highlights the impact of societal attitudes and stereotypes about aging on an individual's self-perception and self-esteem, contributing to a negative view of one's worth as they grow older. Nurses can help individuals recognize their value, encouraging others to see them as functioning members of society.

## PATIENT CONVERSATIONS

### Addressing Ageism

**Scenario:** Jane is an active 73-year-old who enjoys swimming, hiking, walking her dog, and volunteering at the animal shelter. She follows up for her annual wellness exams and screening tests but takes no prescription medications. Darien works as a nurse in the primary care medical office, where Jane is a patient. While Darien measures her vital signs, Jane brings up a struggle she is experiencing.

**Nurse:** Do you have any specific questions for the healthcare provider today?

**Patient:** I have been struggling with some poor attitudes at my volunteer job lately. Some of the younger employees seem to think I can't properly care for the animals. They say I should not be outside on the walking trails with the dogs for fear of falling.

**Nurse:** I can understand why this is distressing for you, considering how active and strong you are. You are likely experiencing ageism, which is when someone is stereotyped based on their age. This is unfortunate, but there are a few things that you can do to help others understand that all people age differently, and older age does not mean

frailty.

**Patient:** Great, I'd love to hear your tips.

**Nurse:** First, by understanding your coworkers and their values, you can create a stronger bond, especially since you have a common bond of affection for animals. Second, putting yourself in the position of a mentor will significantly improve their respect for you. Give them great tips to help them interact with a difficult animal or the trick to get the shy cat to curl up in their lap. Another idea is to be very vocal about your active lifestyle and how walking the animals helps keep you strong and fit. By remaining positive and curious, you'll show by example that older adults are happy, open, and able to learn. You may also be able to connect with some of your youngest coworkers by being conscious of ageism toward younger adults and always showing respect for these younger individuals.

---

## 41.2 Theories Related to the Older Adult

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Explain the psychosocial developmental theory in relation to older adults
- Recognize the disengagement theory in relation to older adults
- Summarize the activity theory in relation to older adults
- Describe the human needs theory in relation to older adults
- Discuss the age stratification theory in relation to older adults

A variety of theories seek to explain the process adults experience during aging. These theories relate to basic human needs, activity levels, disengagement, and psychosocial development. Since the mid-1900s, theorists have developed and adapted theories about human development throughout the life span. Some theories remain relevant today with concepts that endure despite changing cultural and social norms, while others have been subsequently disregarded. Most theories attempt to make sense of how the aging process occurs. The most important aspect of the currently accepted theories is that while aging is universal, how individuals experience aging is individual and unique.

Nurses with a strong understanding of the psychosocial theories of aging have a unique ability to individualize care for patients in various clinical settings. They can see commonalities and differences stemming from their patients' diverse geographic and cultural backgrounds and incorporate these to enhance care.

### Psychosocial Development Theory

Erik Erikson, a life-stage theorist, explained the **psychosocial development theory**, which emphasizes the social nature of human development from infancy through older adulthood. Erikson proposed that personality development takes place throughout the life span. Erikson suggested that how people interact with others affects their sense of self.

Erikson proposed that we are motivated by a need to achieve competence in certain areas of our lives. According to his theory, individuals experience eight stages of development over their life span, during which a conflict or task needs to be resolved. Completing each developmental task results in a sense of competence and a healthy personality, whereas failure to master these tasks leads to feelings of inadequacy. According to Erikson (1963), individuals progress through a predictable series of developmental stages ([Table 41.2](#)).

Stage	Erikson's Developmental Stage	Age Range per Developmental Stage	Description
1	Trust versus mistrust	0 to 1.5 years	Trust (or mistrust) that basic needs, such as nourishment and affection, will be met
2	Autonomy versus shame and doubt	1.5 to 3 years	Develop a sense of independence in many tasks
3	Initiative versus guilt	3 to 5 years	Take initiative on some activities—may develop guilt when unsuccessful or boundaries overstepped
4	Industry versus inferiority	5 to 12 years	Develop self-confidence in abilities when competent or sense of inferiority when not
5	Identity versus role confusion	12 to 18 years	Experiment with and develop identity and roles
6	Intimacy versus isolation	18 to 40 years	Establish intimacy and relationships with others
7	Generativity versus stagnation	40 to 65 years	Contribute to society and be part of a family
8	Ego integrity versus despair	65 years and older	Assess and make sense of life and meaning of contributions

**TABLE 41.2** Erikson's Psychosocial Stages of Development

According to Erikson, the late adulthood task relates to ego integrity versus despair. He stated that during older adulthood, individuals reflect on their lives and experience a sense of either satisfaction or failure. People with few regrets and a sense of integrity often feel pride in their accomplishments. People who struggle with this stage may feel as if their life has been wasted. Focusing on how life experiences “would have,” “should have,” and “could have been” can lead to bitterness, depression, and despair.

In nursing practice, Erikson's theory allows nurses to understand the complex dynamics that shape an individual's health and wellness path throughout life. Nurses can provide highly individualized care by understanding that personality development continues to evolve and change even in older adulthood. Applying Erikson's theory in real-life nursing situations may look like this:

- encouraging physical activity based on ability
- connecting individuals with grief support networks
- recommending community groups based on interest
- referring to nutrition services to support healthy eating
- providing continuity of care between medical specialists and support services
- showing respect for clients in older adulthood

### Disengagement Theory

The disengagement theory is one of the earliest theories on aging. It was proposed by Elaine Cumming and William Earl Henry in 1961. The disengagement theory suggests that withdrawing from society and social relationships is a natural part of growing old. There are several main points to the theory. First, because everyone expects to die one day, and individuals experience physical and mental decline as they approach death, it is natural to withdraw from individuals and society. Second, as older adults begin to withdraw, they receive less reinforcement to conform to social norms. Therefore, this withdrawal allows greater freedom from the pressure to conform. The theorists

described the experience of social withdrawal differently for men and women because traditionally, men focused on work and women focused on marriage and family. The disengagement theory states that when individuals withdraw, they will be unhappy and directionless until they adopt a role to replace their accustomed role compatible with the disengaged state (Cumming & Henry, 1961).

While the disengagement theory served as a springboard for ongoing research into aging, the foundations of the theory imply a negative connotation with aging. Historically, the theory was not well received due to this negative portrayal of older adults within society. Subsequent studies suggested that engagement and activity, rather than disengagement, is the basis by which older adults progress through the aging process. Additionally, some critics of the disengagement theory cite several concepts within the theory that tend to discredit it, including the following ideas:

- Disengagement in older adulthood is universal.
- Disengagement is involuntary.
- Disengagement is inevitable.

These ideas do not fit with the currently accepted cultural beliefs about aging. Adults have vastly different experiences with the aging process depending on social, physical, and emotional factors. Even as Cumming and Henry proposed the disengagement theory, other researchers worked to define aging in a more positive and individualized way. The focus shifted from disengagement to personal and community engagement.

### Activity Theory

The social withdrawal that Cumming and Henry recognized (1961), and its notion that older adults need to find replacement roles for those they have lost, is addressed anew in the activity theory. According to the **activity theory**, activity levels and social involvement are critical to the process of finding replacement roles and keys to happiness (Havighurst, 1961; Havighurst et al., 1968; Neugarten, 1964). According to this theory, the more active and involved an older person is, the happier they will be. Critics of this theory point out that access to social opportunities for activity are not equally available to all. Moreover, not everyone finds fulfillment in the presence of others or participation in community activities. Reformulations of this theory suggest that participation in informal activities, such as hobbies, most affects later life satisfaction (Lemon et al., 1972).

The activity theory is highly adaptable to nursing practice because it considers the whole individual and assumes that engagement and activity improve quality of life. As nurses work to create care plans for older adults in a variety of settings, the activity theory informs specific actions. For example, maintaining physical movement through independent activity of daily living (ADL) or group activities is crucial for patients living in long-term care facilities. For older adults living in the community, nurses can tailor care to include community gatherings, social groups, and fitness activities depending on the individual's health status. The activity theory inherently focuses on wellness and how individuals can adapt to older age in healthy ways.

### Hierarchy of Needs

Abraham Maslow (1943) proposed the hierarchy of needs, a commonly known concept that explains individuals' wide-ranging physiological and psychological needs throughout their life span. Physiological needs create the foundation for this theory, with other needs developing if physiological needs are met. These needs are often depicted as a pyramid ([Figure 41.2](#)).

**FIGURE 41.2** Maslow's hierarchy of needs remains relevant for older adults as they continue to require basic physiological necessities, seek safety and security, value social connections and belonging, strive for recognition and self-esteem, and pursue personal growth and meaning in their lives, highlighting the enduring importance of these fundamental human needs throughout the aging process. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

At the pyramid's base are all the physiological needs necessary for survival. Basic requirements for security and safety follow physiological needs. Next, the hierarchy focuses on the need to be loved and have a sense of belonging, and finally, the need to have self-worth and confidence. The top tier of the pyramid is self-actualization, which is a need that essentially equates to achieving one's full potential, which can only be realized when needs lower on the pyramid have been met. Maslow suggested that self-actualization is an ongoing, lifelong process and that only a small percentage of people achieve self-actualization (Francis & Kritsonis, 2006; Maslow, 1943).

According to Maslow (1943), one must satisfy lower-level needs before addressing those higher in the pyramid. So, for example, if someone is struggling to find enough food to meet their nutritional requirements, it is quite unlikely that they would spend an inordinate amount of time thinking about whether others viewed them as a good person. Instead, their energies would be geared toward finding something to eat. However, it should be pointed out that Maslow's theory has been criticized for its subjective nature and inability to account for phenomena that occur in the real world (Geller, 1982). Late in life, Maslow proposed a self-transcendence level above self-actualization to represent striving for meaning and purpose beyond the concerns of oneself (Koltko-Rivera, 2006). For example, people sometimes make self-sacrifices to make a political statement or in an attempt to improve the conditions of others. Mohandas K. Gandhi, a world-renowned advocate for independence through nonviolent protest, went on hunger strikes several times to protest a particular situation. People may starve themselves or otherwise put themselves in danger, displaying higher-level motives beyond their own needs.

The vital aspect of Maslow's hierarchy of needs for nurses is the understanding that older adults may need support in each area of the pyramid throughout the aging process. [Table 41.3](#) lists nursing actions that support the most essential levels of need. Maslow's hierarchy is not a progressive process but a fluid motion of changing needs. Physiological needs, safety and security, and love and belonging are the most critical and action-based levels where nursing care is administered. However, nurses can also work to maintain self-esteem and the process of self-actualization for each patient. The needs portrayed in the pyramid can develop concurrently. For example, an individual may have a short-term increased physiological need related to an acute illness but still require love, belonging, and safety. Individuals receiving hospice care may require significant nursing care related to physiological needs. However, they may also require from nurses and spiritual leaders significant care focused on

self-esteem, security, and belonging at the end of life.

Maslow's Needs	Nursing Actions
Physiological needs	<ul style="list-style-type: none"> <li>• Dressing</li> <li>• Bathing</li> <li>• Maintaining oral hygiene</li> <li>• Maintaining hydration</li> <li>• Managing chronic disease states</li> <li>• Administering medications</li> <li>• Managing acute illnesses</li> <li>• Promoting physical activity</li> </ul>
Safety and security	<ul style="list-style-type: none"> <li>• Implementing fall prevention protocols</li> <li>• Assisting with mobility</li> <li>• Monitoring for acute symptom changes</li> <li>• Maintaining adequate nutrition status</li> <li>• Assisting with hygiene to prevent illness</li> <li>• Managing medications</li> <li>• Screening for depression</li> </ul>
Love and belonging	<ul style="list-style-type: none"> <li>• Encouraging social interaction</li> <li>• Supporting family needs</li> <li>• Coordinating cross-specialty care</li> <li>• Encouraging connection with spiritual leaders</li> </ul>
Self-esteem	<ul style="list-style-type: none"> <li>• Avoiding ageism</li> <li>• Maintaining respect</li> <li>• Individualizing care</li> <li>• Encouraging independence</li> </ul>
Self-actualization	<ul style="list-style-type: none"> <li>• Focusing on patient dignity</li> <li>• Encouraging safe tasks that they “always wanted to try”</li> </ul>

**TABLE 41.3** Nursing Tasks that Fulfill Maslow's Hierarchy of Needs in Older Adults

## LINK TO LEARNING

This [interactive exercise \(https://openstax.org/r/77mashier\)](https://openstax.org/r/77mashier) will help you better understand Maslow's hierarchy of needs.

## Age Stratification Theory

While we now have an increased awareness of the concept of ageism, the **age stratification theory** was the first to suggest that members of society might be stratified by age, just as they are stratified by race, class, and gender. Since age serves as a basis of social control, different age groups will have varying access to social resources such as political and economic power. Within societies, behavioral age norms, including norms about roles and appropriate behavior, dictate what members of age cohorts may reasonably do. These norms are specific to each age group, developing from culturally based ideas about how people should “act their age.”

Thanks to amendments to the Age Discrimination in Employment Act (ADEA), which drew attention to how our

society is stratified based on age, U.S. workers no longer must retire upon reaching a specified age. As first passed in 1967, the ADEA protected against a broad range of age discrimination and specifically addressed termination of employment due to age, specification of age limits or preferences in advertised positions, and denial of healthcare benefits to those over 65 years old (U.S. Equal Employment Opportunity Commission, n.d.).

## LINK TO LEARNING

---

More than 2.7 million children in the United States are being raised by grandparents and other relatives (Casey et al., n.d.). Learn more about [the Grandfamily Housing Act \(https://openstax.org/r/77granfamact\)](https://openstax.org/r/77granfamact) proposed by U.S. Senators Bob Casey (D-PA), Susan Collins (R-ME), and Sherrod Brown (D-OH) to support grandparents taking care of their grandchildren.

---

Nurses must also know that age stratification rarely explains behaviors and social norms. Factors such as gender, socioeconomic status, geographic location, and other cultural factors may play a role in the stratification of older adults.

## LIFE-STAGE CONTEXT

---

### The Evolving Role of Grandparenting

According to the American Association of Retired Persons (AARP) (2019), in the last twenty years, the number of adults in the United States who are grandparents has increased from 56 million to over 70 million. The AARP (2019) also suggests that up to 96 percent of adults over age 65 years are grandparents. The grandparenting role varies widely depending on age, culture, proximity to family, and values. Some individuals experience grandparenting in a traditional role of general family support and older adult status. Others have a much more complex grandparent-grandchild relationship. While this is a reciprocal relationship, it is often the choice of the grandparent to determine the extent of interaction and connection they have with their grandchildren. This intergenerational support promotes healthy growth and development for the next generation. AARP (2019) states that up to 10 percent of grandparents live in the same home with their grandchildren.

Due to the broad age range of grandparents, the United States Census Bureau reports that over 3 million grandparents remain in the workforce ([Figure 41.3](#)). More than 400,000 of these individuals over 60 years of age are responsible for the care of grandchildren they live with (United States Census Bureau, 2019). In addition, grandparents are core caregivers for many grandchildren while their parents work. Grandparent caregiving may be full time or part time, depending on the family's needs. Grandparents may step into a caregiving role at different times due to the shortage of caregiver opportunities for young children. In the changing economy, grandparents hold a significant role in early childcare and child-rearing. Regardless of the number of parents in the household, parents now work more hours than throughout history. This requires childcare, and the cost of childcare is steadily increasing. Since early childcare is not a federally required benefit for working families, families are turning to grandparents as a childcare option, particularly those parents with irregular work hours. Because up to 2.7 million children live in a household with grandparents, some of whom work to help raise the children, legislation has been proposed to provide financial and housing assistance (Casey et al., n.d.). One such bill, the Grandfamily Housing Bill, seeks to provide government funds to create stable and affordable housing for families headed by grandparents (Casey et al., n.d.).

**FIGURE 41.3** Over 3 million grandparents are in the labor force. Of those, over 1 million are responsible for most of the basic care of their coresident grandchildren. (credit: “American Community Survey” by United States Census Bureau, Public Domain)

Grandparents as caregivers can be a desirable circumstance for families. A robust intergenerational bond between grandparent and grandchild in healthy family relationships promotes health across these age groups. Strong relationships with grandchildren are also a significant benefit for older adults. This relationship can create rich multigenerational support for older adults. Healthy grandparent-grandchild relationships offer considerable benefits to grandchildren and grandparents, including the following:

- encouraging family values
- providing mentorship
- building self-esteem
- fostering respect
- dispelling fear of aging
- dispelling ideas related to ageism

## 41.3 Health Risks for Older Adults

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify physiological health risks for the older adult stage
- Discover psychological health risks for the older adult stage
- Recognize psychosocial health risks for the older adult stage

Health risks for older adults correlate with long-term lifestyle choices, heredity, social circumstances, and SDOHs. While health risks depend on individual circumstances, nurses must be aware of the range of health risks for older adults. By understanding health risks in older adults, nurses can manage and promote disease prevention and appropriate management of existing health conditions. Nurses can focus on high-risk areas, including cognition,

nutrition, mobility, and safety. In preventing illness in older adults, nurses across specialties can focus on physiological, psychological, and psychosocial health risks in caring for older adult clients. Because health status depends on age and coexisting illnesses, nurses must diligently provide individualized care, rather than generalized care, in this age group.

### Physiological Health Risks

The physiological health risks are those factors affecting the normal biological function of the individual. These risks can range from acute to chronic illness, injuries, nutrition, and mobility issues. Many of these risks are interconnected. As individuals age, they face various physiological changes that elevate their susceptibility to specific health risks. The cardiovascular system undergoes alterations, heightening the chances of heart disease, high blood pressure, and atherosclerosis due to changes in blood vessels and the heart. Osteoporosis becomes a concern as bone density decreases, leading to an increased risk of fractures and falls. Arthritis, marked by joint cartilage degeneration and inflammation, contributes to pain and reduced mobility. Vision and hearing impairments intensify, affecting overall quality of life and increasing the likelihood of accidents. The aging process also involves a reduction in muscle mass and strength, contributing to frailty and a heightened risk of falls. Immune function weakens, making older adults more susceptible to infections and illnesses. Digestive issues, metabolic changes, respiratory problems, renal decline, and alterations in skin integrity further characterize the physiological health risks for older adults. Tooth loss introduces challenges like the use of dentures and the risk of malnutrition or choking from inadequately chewed foods. Elimination issues, including incontinence and constipation, present additional concerns.

Proactive measures, including maintaining a healthy lifestyle, regular exercise, a balanced diet, and consistent medical checkups, are essential to mitigating these risks. Additionally, staying socially active and mentally engaged contribute to overall well-being in aging individuals. Regular communication with healthcare providers is crucial for managing and addressing specific health concerns associated with the aging process. Nurses will find that by paying close attention to client needs, they can identify the interplay between physiological, psychological, and psychosocial risks to create a plan that simultaneously addresses multiple concerns.

### Chronic Illness

A chronic illness can be described as a condition requiring medical attention or limiting usual daily activities for over one year (Centers for Disease Control and Prevention [CDC], 2022a). While chronic illness is not inevitable in older adulthood, it is prevalent. According to the National Council on Aging (NCOA) (2023), most adults older than 65 years of age have one chronic illness (95 percent), and a large majority have at least two chronic illnesses (80 percent). The NCOA (2023) also reports the most common and costly chronic illnesses are dementia, cancer, diabetes, and depression. Other high-cost, chronic conditions include hypertension, stroke, heart disease, lung disease, and arthritis. Chronic illness affects nearly all other physiological factors affecting older adults. Nurses must understand the distinct pathophysiology of specific diseases and the interrelationships between chronic illnesses that affect patient outcomes.

### Accidental Injuries

Accidental injuries in older adults may include falls, burns, inappropriate medication ingestion, and transportation-related injuries. These injuries can range from mild to severe. Falls are one of the most common causes of injury in older adults. Falls are often linked to other health problems, such as high blood pressure, dizziness, poor mobility, weakness, and vision impairment. Identifying fall risk is crucial in protecting patients from acute injuries such as fractures, head injury, and skin injury, as well as sequelae of these acute injuries that may affect or worsen other health conditions.

### LINK TO LEARNING

The CDC offers a [fall risk prevention checklist \(https://openstax.org/r/77fallrisk\)](https://openstax.org/r/77fallrisk) to assist nurses, patients, and caregivers in evaluating fall risks in the home.

### Functional Ability

Ramnath et al. (2018) describe functional ability as an individual's ability to effectively complete ADLs without

limitations related to pain or fatigue. Functional ability varies widely in the older adult population and is often related to chronic health conditions. Functional ability is related less to age than to overall wellness. Functional ability often determines an individual's ability to remain independent. The longer a person can remain independent, the better is their quality of life. Nurses can assess areas of declining functional ability and create care plans to address these problems before they impede overall daily functioning. This relates primarily to completing ADLs such as bathing, home care, hygiene, cooking, and cleaning.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Analyze Cues: Tuning in to Functional Ability

The nurse is caring for an older adult in an assisted living facility. The patient has returned recently from a hospital stay after a fall. Prior to the fall, this patient was independent in all ADLs except showering. The nurse notices that the patient has not finished dressing before it is time for breakfast. The nurse also finds that the patient's hair is ungroomed, and her dentures are still by the bathroom sink. The nurse considers possibilities for the change in patient ability to perform ADLs. The nurse remembers the patient had an injury to her shoulder from the recent fall. The nurse recognizes the patient will need assistance with more tasks that require upper body mobility until her injury completely heals.

#### Mobility

Mobility also varies widely in the older adult population. Some individuals continue to hike, bike, and engage in other strenuous physical activities, while others have severe limitations in mobility. Mobility is affected by lifestyle, weight, pain, and cardiovascular health. Focusing on maintaining the maximum mobility for an individual affects illness status, nutritional status, elimination status, and psychological status. Mobility changes are correlated with a higher risk for falls, changes in cognition, increased pain, increased symptoms of depression, and an overall reduction in quality of life (Musich et al., 2018).

Nursing interventions promote a patient's mobility and prevent the adverse effects of immobility. To avoid or minimize complications of immobility, mobilize the patient as soon as possible and to the fullest extent they are able to. Mobilization efforts, ranging from dangling on the edge of the bed, sitting up in a chair, and assisting with early ambulation, depend on the patient's unique circumstances. Encourage the patient to perform ADLs independently and participate in prescribed physical therapy. Encourage or perform active or passive range of motion exercises as the physical therapist prescribes. Maintaining mobility also promotes balance, flexibility, and strength. By helping older adults improve overall mobility, nurses help reduce individual fall risk and improve overall safety of their patients. Be aware that pain and fear of falling can deter a patient's willingness to ambulate or perform physical therapy.

#### Nutritional Imbalances

Nutritional status is also associated with various chronic health conditions, including dementia, kidney disease, heart failure, and chronic respiratory disease. In addition to the physical health of the individual, environmental and financial changes also affect the nutrition status of older adults. While up to 10 percent of older adults struggle with undernutrition, overnutrition and obesity are even more prevalent. Up to one-third of older adults experience the effects of overnutrition (Health in Aging, 2023).

Poor nutrition can contribute to health challenges for older adults, including the following (Norman et al., 2021):

- frailty
- fatigue
- increased fall risk
- worsening dementia
- increased fracture risk
- reduced skin integrity
- poor immune function

## PATIENT CONVERSATIONS

---

### Nutritional Supplement Safety

**Scenario:** Vicki is a retired 70-year-old who enjoys walking her dog, painting, and reading. She sees her primary care provider every six months for follow-up on her hypertension and hypercholesterolemia. Claire works as a nurse in the primary care medical office, where Vicki is a patient. While Claire records her current medication list, Vicki discloses a long list of supplements she has recently started on the recommendation of her daughter-in-law. Claire remembers the CDC (2021c) reported that more than 50 percent of adults take one or more vitamins, mineral, or herbal supplements.

**Nurse:** Vicki, I don't see these supplements in your medication history. About how long have you been taking these supplements?

**Patient:** I haven't been taking them for a long time, maybe a month or so.

**Nurse:** What is your goal with the variety of supplements you are taking?

**Patient:** My daughter-in-law thinks I am not active enough and had me start some of these to help with my energy, like the B-vitamin complex and the vitamin D supplement. Also, I am trying to manage my cholesterol naturally, so I have started the red rice yeast supplement and a probiotic. Sometimes I have trouble sleeping, so I take melatonin several nights weekly, which has helped. I also started an immunity vitamin and a multivitamin to help prevent illness this winter.

**Nurse:** I understand that there are many vitamin and supplement preparations to choose from. Did you bring your vitamin bottles in today, or do you remember what is in the combination supplements you mentioned for energy and immunity?

**Patient:** Yes, I did remember to bring in the bottles.

**Nurse:** That's great. We'll look at them together, and then you and the provider can discuss it further. I see that both the immunity and multivitamins contain vitamin D and calcium. There are also some B vitamins in the immunity preparation. Your provider will review the total amounts with you to determine whether the doses are safe. Another concern we'll want you to talk with the provider about is taking the red rice yeast supplement and your prescription cholesterol-lowering medication, as these can interact with each other and affect your liver.

**Patient:** I didn't realize that. Vitamins are natural and safe, right? Do I really need to worry about taking too much?

**Nurse:** Vitamins and other supplements should always be considered like a medication. Many vitamins significantly benefit immunity, bone health, and gut health. However, taking too much of some vitamins or supplements can cause problems with your prescription medications. You did the right thing by bringing these in to discuss so your provider can help you safely manage your supplements.

---

### Fluid and Electrolyte Imbalances

As individuals age, hydration status can become a significant concern. In individuals with chronic illness, hydration status can be affected by illnesses, medications, overall nutrition, and mental status changes. Hydration is directly related to nutrition status since it affects taste, swallowing ability, elimination, digestion, and nutrient absorption. Some older adults develop a decreased sense of thirst, contributing to dehydration risk. Therefore, it is crucial to check on older adults more frequently during heat waves to ensure they are adequately hydrated and to prevent dehydration-related complications. Older adults who experience dehydration are at higher risk for falls, urinary tract infection (UTI), constipation, skin damage, electrolyte imbalances, altered mental states, and kidney injury. Healthy electrolyte balance is directly related to hydration status; however, it can also be affected by certain medications, such as diuretics and blood pressure medications.

### Psychological Health Risks

The psychological health risks include cognitive and emotional responses to aging and life changes. Some are short-term responses and are related to life events; others are progressive and associated with factors such as the death

of family and friends, diagnosis of acute or chronic illness, debility from illness, loss of function or ability, and loss of independence. These factors may relate to emotional responses such as loneliness, hopelessness, and depression.

### Dementia

Older adults are at high risk for cognitive impairment, including dementia. The CDC (2019) explains that dementia is a general term applied when an individual has trouble with daily functioning due to difficulty remembering, thinking, or making decisions. According to the National Institute on Aging (2022), various forms of dementia exist, such as vascular dementia, frontotemporal dementia, and Lewy body dementia; however, Alzheimer disease is the most prevalent. **Alzheimer disease** is a progressive disorder and general loss of cognitive function that presents with memory loss, behavior changes, and personality changes (National Institute on Aging, 2022).

The National Library of Medicine describes MCI as a decline in memory or thinking to a greater degree than expected for a person's age. This cognitive decline may include forgetfulness and trouble with word-finding. Mild cognitive impairment (MCI) is often associated with a higher risk of developing other dementias. According to the CDC (2019), 5.6 million older adults live with dementia. As dementia progresses, individuals develop a profound difficulty performing ADLs. All types of dementia put older adults at risk for injury, infections, social isolation, and reduced quality of life (Figure 41.4).

**FIGURE 41.4** Take preventive action to help patients understand the risks of developing common types of dementia. (credit: “Did you know that there are known risks for Alzheimer’s disease and related dementias?” by Center for Disease Control, Public Domain)

### LINK TO LEARNING

Information about [memory problems \(https://openstax.org/r/77memprob\)](https://openstax.org/r/77memprob) is provided in this quick video by the National Institute on Aging that clarifies the features of early dementia compared with simple forgetfulness.

### Delirium

Older adults with chronic illnesses or those undergoing surgical procedures are at high risk for delirium. A sudden onset of confusion secondary to a physical illness is termed **delirium**. Medication metabolism in older adults changes due in part to changes in how the body excretes medications. Sometimes, delirium can occur because of issues related to hydration, kidney function, or medication metabolism. Often dose adjustments are required depending on age. Medication interactions are also a risk factor for delirium. In particular, anesthesia-associated medications can often trigger a state of delirium. Acute infections are also a significant risk factor for delirium. The

onset of delirium is a common sign of an infection, such as a UTI, in an older adult. Delirium can present as acute confusion in an adult with normal cognitive function or worsening dementia in an adult with an underlying cognitive disorder.

## REAL RN STORIES

### Strategies for Navigating Sundowning

**Nurse:** Jerelynn, RN

**Clinical setting:** Home Health

**Years in practice:** 20

**Facility location:** California

I've cared for individuals in their homes for fifteen years in practice; before that, I worked with individuals in a long-term care facility memory care unit. While many people with severe dementia reside in long-term care facilities, there is usually a period during dementia progression when they remain at home. Over the years, I've developed some tips for family members dealing with fluctuating levels of dementia and confusion. In sundowning, patients have increased confusion and agitation in the later afternoon or evening. I remember a patient named Bob as a good example. He was pleasant and spent his days visiting with his wife and watching television. During my home visits, his wife, Ruth, showed signs of anxiety and worry when I would leave later in the afternoons. Also, the personal care attendants documented increasing agitation during the afternoon and evening shifts.

Ruth explained that Bob would often get agitated with their television program, attempt to go outside in the middle of the night, or become angry with Ruth when she tried to explain they had already eaten dinner or that it was time to sleep. In listening to Ruth and reviewing Bob's daily documentation, I noticed several things:

1. He watched television most of the day.
2. He watched television in a dim room because the sunlight glared at the screen.
3. Bob would often doze during the day while watching television.
4. Bob and Ruth ate dinner at 4:30 p.m.
5. Bob complained of lower back pain.
6. Ruth had a recent foot surgery that did not allow her to take lengthy walks as they had done previously.

Based on these findings, I could attribute Bob's sundowning to several things:

1. He was overstimulated with the television throughout the day.
2. He did not have enough daylight exposure during daylight hours.
3. He was hungry later in the evening due to an early evening meal.
4. He had pain related to extensive sitting and minimal physical exercise.

I spoke with the personal care attendants and Ruth, and we developed some action items to help reduce Bob's sundowning syndrome. I recommended that Bob spend less time watching television, especially after lunch. I recommended audiobooks, crafts, folding laundry, visiting with family or friends, or reading magazines. During the evening, I recommended minimal stimulation from television and calming music. Since they are used to eating early, I recommended that the personal care attendants prepare a substantial evening snack that will remove the burden from Ruth and satiate any hunger that Bob feels. Also, the personal care attendants and Bob and Ruth's family created a daily activity plan, including a daily walk in the early afternoon. This helped reduce Bob's back pain and his overall agitation level.

While Bob's sundowning did not resolve completely, and his dementia did progress to a point where he moved to a memory care facility, I believe our interventions helped Bob remain active, independent, and living in his home for as long as possible.

### Depression

Older adults are at risk for depression in similar proportions to younger adults. However, the American Psychological Association (2022) reports a significant increase in depression in older adults in the last fifty years. Despite this increase, the CDC (2022b) reports a low percentage (1 to 5 percent) of older adults with depression. For adults

requiring in-home or hospital care, the number increases significantly. Factors that put older adults at risk for depression include the following:

- chronic disease diagnosis or progression
- physical limitations
- reduced physical activity
- stress
- social isolation
- sleep disorders

### Grief

Grief can play a significant role in the mental health of older adults ([Figure 41.5](#)). This grief may relate to the death of a spouse, friend, or other family member. Older adults may also experience grief over loss of function and independence. Understanding that the grief process is highly individual is crucial for nurses. Depending on the effectiveness of the individual's coping strategy, grief may progress healthily or progress to mental health concerns, such as depression.

**FIGURE 41.5** Grief in older adults is a complex emotional response to loss that may manifest differently due to factors such as death, accumulated life experiences, health status, and coping mechanisms. (credit: “grief and loss” by Thomas8047/Flickr, CC BY 2.0)

The normal grief process, explained initially by psychiatrist Elisabeth Kübler-Ross ([Figure 41.6](#)), has a somewhat predictable pattern. However, the timeline for grief response is highly specific to each individual. Normal grief includes the common feelings, behaviors, and reactions to loss. Normal grief reactions to a loss can include the following:

- physical symptoms such as hollowness in the stomach, tightness in the chest, weakness, heart palpitations, sensitivity to noise, breathlessness, tension, lack of energy, and dry mouth
- emotional symptoms such as numbness, sadness, fear, anger, shame, loneliness, relief, emancipation, yearning, anxiety, guilt, self-reproach, helplessness, and abandonment
- cognitive symptoms such as a state of depersonalization, confusion, inability to concentrate, dreams of the deceased, idealization of the deceased, or a sense of the presence of the deceased
- behavioral signs such as impaired work performance, crying, withdrawal, overreactivity, changed relationships, or avoidance of reminders of the deceased

**FIGURE 41.6** The Kübler-Ross grief cycle explains the normal grief process and can inform nurses when a patient is experiencing a form of complicated grief. (attribution: Copyright Rice University, OpenStax, under CC BY 4.0 license)

The state of **complicated grief** is prolonged, delayed, or exaggerated in which individuals have trouble coping and progressing through the normal grief process. Complicated grief is seen in 10 to 20 percent of individuals experiencing the death of a romantic partner, with higher estimates for parents who have lost a child. Risk factors for developing complicated grief include sudden or traumatic death, suicide, homicide, a dependent relationship with the deceased, chronic illness, death of a child, multiple losses, unresolved grief from prior losses, concurrent stressors, witnessing a difficult dying process such as pain and suffering, lack of support systems, and lack of a faith system. Complicated grief may require professional assistance, depending on its severity. Factors contributing to complicated grief in older adults include lack of a support network, concurrent losses, poor coping skills, and loneliness. According to the End-of-Life Nursing Education Consortium, there are four types of complicated grief: **chronic grief** (normal grief reaction that does not subside), **delayed grief** (normal grief reaction that is suppressed or postponed), **exaggerated grief** (an intense reaction to grief), and **masked grief** (occurs when the survivor is unaware of behaviors that interfere with normal functioning due to the loss) (Table 41.4).

Grief Type	Patient Behaviors
Chronic grief: normal grief reactions that do not subside and continue over very long periods	Carol lost her son in a motor vehicle accident ten years ago. She has ongoing depression and rumination about the day of the accident. Nearly daily, she cries and feels hopelessness for the loss of her son. She has been unable to work since the accident.
Delayed grief: normal grief reactions that are suppressed or postponed by the survivor consciously or unconsciously to avoid the pain of the loss	James's wife died of colon cancer one year ago. Since that time, he has not discussed her death with friends or family and sometimes states, "it still feels like she might come through the door."
Exaggerated grief: an intense reaction to grief that may include nightmares, delinquent behaviors, phobias, and thoughts of suicide	Jana's sister died after contracting pneumonia two years ago. Jana continues to feel extreme fear about contracting an illness and rarely leaves her home even to shop.
Masked grief: grief that occurs when the survivor is unaware of behaviors that interfere with normal functioning due to the loss	Since the death of his wife, Gerald attends many social functions each day. By the time he arrives home, he is too tired to cook or care for his home. His family has noticed the decline in his physical appearance and his home.

**TABLE 41.4** Identifying Complicated Grief

### Loneliness

Grief is often tied to loneliness, particularly in older adults who have spent many years with a life partner. Losing close friendships or other familial relationships can also trigger loneliness. Loneliness can be a risk factor for and a

result of social isolation. The term **loneliness** is defined as a subjective feeling of distress related to being alone or separated from other people (Cacioppo et al., 2014). The National Institute on Aging (2019) reports that loneliness in older adults may be associated with a variety of health effects, including the following:

- high blood pressure
- obesity
- poor immunity
- depression
- anxiety
- dementia

Social isolation may be associated with loneliness and depression, but research has found that feeling lonely is possible even while among other people. The same research shows that individuals can live alone and not experience loneliness (Cacioppo et al., 2014).

### Hopelessness

A severe psychological state that involves a deep sense of failure or despair is called **hopelessness**. In older adults, hopelessness may develop from untreated depression, grief, or loneliness. Other contributors to hopelessness may be chronic pain, loss of independence, and abuse. Hopelessness may also stem from long-term difficulty moving through life stages and may relate to Erikson's theory of integrity versus despair.

### Psychosocial Health Risks

The psychosocial health risks encompass factors that affect both psychological and social well-being. Examples include chronic stress, social isolation, interpersonal conflicts, lack of social support, and exposure to adverse life events. Changes in living arrangements, limited transportation, and decreased financial resources may impede social interaction for some older adults. Older adults are at risk for health risks associated with a decrease in available and accessible resources. A decline in social interactions may lead to loneliness and depression. Role reversal is also a psychosocial issue for older adults as they navigate changing relationships with children and other caregivers. These factors can have a significant impact on mental health, emotional well-being, and the ability to cope with life's challenges. Addressing psychosocial health risks is crucial for promoting a holistic approach to wellness.

### Living Arrangements

Older adults' living arrangements depend on physical independence, cognition, physical strength, financial security, and culture. A recent study reports that a similar number of older adults live with their spouse, children, or others compared to those living alone (Bolina et al., 2021). The same study concluded that while living arrangements significantly affect quality of life, each living arrangement has benefits and challenges for older adults. Some adults living with children, for example, experience less autonomy and social interaction. Adults who continue to live alone may experience continued autonomy; however, they may also experience less intimacy when not living with a significant other (Bolina et al., 2021). Loss of physical function is often associated with considering long-term care facilities, assisted living facilities, and cohabitation with adult children. Some older adults embrace a move that will afford them more assistance, while others grieve losing their home and independence.

### Social Isolation

In older adults, **social isolation** refers to a condition where individuals experience limited social interaction and engagement. It can result from various factors, such as living alone, having few social connections, physical health challenges, mobility issues, lack of transportation, or the loss of friends and family. Social isolation is most prominent in older adults who live alone (Cacioppo et al., 2014). Social isolation can have detrimental effects on mental, emotional, and physical well-being, contributing to feelings of loneliness, depression, and a decline in overall health. Addressing social isolation involves fostering social connections, promoting community engagement, and providing support to enhance the social aspects of older adults' lives.

### Decreased Resources

Financial hardship is a prominent risk for many older adults. The National Council on Aging (2021) reports that up to 47 million older adults face financial concerns or the risk of financial insecurity. Financial strain may result from planned retirement, reduced ability to perform previous work skills, or chronic health issues. Older adults are also at

risk for sudden changes in financial security, such as job loss, death of a spouse, acute illness, and injuries. Older adults may struggle to pay for monthly medications, long-term care, food, or basic living expenses. Nurses must also understand the concept of health resources and how this concept applies to healthcare access and health disparity (systematic differences in health outcomes and access to healthcare between distinct groups, often associated with social, economic, or environmental disadvantages) among geographic and cultural groups.

### Caregiver Role Strain

Caregiver role strain is a layered issue affecting many older adults. Individuals with declining health begin to rely on a spouse or partner for more intense care or assistance. Often, the care of older adults with increased frailty or progressive disease states falls to younger family members and children. Caregivers can experience stress from increased physical demands, increased responsibility in financial management, or reduced living space when an older adult moves in. Individuals taking on more caregiving tasks can quickly experience caregiver fatigue. Finding appropriate and consistent support is crucial for patients and their families. Nurses can support caregivers by acknowledging struggles and providing access to community and healthcare support services. This includes informing caregivers about adult day healthcare programs, which offer a way to keep a loved one at home while providing a much-needed break for caregivers.

### CLINICAL JUDGMENT MEASUREMENT MODEL

#### Take Action: Caregiver Support

A home health nurse is providing in-home wound care for an 89-year-old male with dementia who lives with his son. The son is very attentive and attends each visit in order to learn the proper way to care for the wound between nurse visits. The nurse notices the son seems fatigued and opens a conversation to discuss how the son is feeling. He breaks down and expresses intense feelings of being overwhelmed with working at home, caring for his father, and performing household duties. He has felt more caregiver strain as his father's dementia progresses. The nurse expresses empathy in the moment and forms a plan for reducing the son's caregiver strain. During the next two weeks the nurse is able to secure additional in-home care for the patient, arrange transportation services for appointments, and arrange for a case manager to help manage ongoing resource needs. She also encourages the son to attend a dementia caregiver support group at the local community center.

### Elder Abuse

The CDC (2021b) reports that up to 10 percent of older adults living at home experience some form of abuse, neglect, or mistreatment. This **elder abuse** encompasses all direct actions and neglectful actions by a caregiver that cause harm or risk of harm to an older adult. The CDC (2021b) explains that elder abuse can occur in a variety of settings, including the patient's home or long-term care facility. Several physical and psychological characteristics put an older adult at risk for abuse, including dementia, mental health disorders, and substance misuse. Psychosocial risk factors for abuse include social isolation, financial dependence, and low socioeconomic status. Forms of elder abuse identified by the CDC (2021b) include physical, sexual, psychological, financial, and neglect. Examples of elder abuse include inflicting physical harm through actions like hitting or restraining, engaging in nonconsensual sexual contact, causing emotional distress through threats or verbal abuse, illegally using an older adult's financial resources, and neglecting to provide essential care and support for basic needs like food and medical care. While older adults often experience a higher risk for injury, awareness of frequent injuries or patterns

can alert nurses to the possibility of abuse (Table 41.5).

Physical	Psychological
<ul style="list-style-type: none"> <li>• Scratches</li> <li>• Bruises</li> <li>• Fractures</li> <li>• Sprains</li> <li>• Frequent falls</li> <li>• Repeated injuries</li> <li>• Poorly healing wounds</li> <li>• Medication overdose</li> <li>• Signs of physical restraint</li> <li>• Inconsistent injury patterns</li> <li>• Dehydration</li> <li>• Malnutrition</li> </ul>	<ul style="list-style-type: none"> <li>• New-onset anxiety</li> <li>• Emotional distress</li> <li>• Withdrawal from activities</li> <li>• Poor self-care</li> <li>• Trouble with communication</li> <li>• Fearfulness</li> <li>• Tearfulness</li> <li>• Depression</li> </ul>

**TABLE 41.5** Physical and Psychological Signs of Elder Abuse

## 41.4 The Nurse's Role in Preventing Illness

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify nursing considerations for the older adult
- Recognize interdisciplinary team referrals for the older adult

Nurses are key to illness prevention and health promotion for older adults. Coordination of care is crucial for minimizing the health consequences of disease and ensuring that appropriate health screenings are completed on time. Primary prevention with available screening tools helps prevent illness and ensures early detection of disease. Nurses can help prevent injuries and falls with diligent safety awareness. By using screening tools for functional health and mental health disorders, nurses can ensure patients have the support tools they need to maintain a good quality of life throughout older adulthood.

### Nursing Considerations for the Older Adult

Nurses working in a wide variety of clinical settings will encounter older adults. With a strong knowledge of the nursing theories relating to older adults, developmental changes, and health risks associated with aging, nurses can lead the care team for older adults. Nurses are critical in ensuring that older adults receive individualized care, including ancillary therapies (additional or supplementary therapeutic interventions that are used alongside primary or main forms of treatment), specialty medical evaluations, nutritional support, and screening tests. Nurses are often responsible for assessing functional health, nutritional status, and gaps in care requiring referrals.

While nurses working in most settings will care for older adults, it is important to note there is a specialized branch of nursing, **geriatric nursing**, dedicated to the comprehensive care of older adults. Geriatric nurses undergo specific training to understand and address the complex healthcare needs associated with aging. Their role encompasses a holistic approach that considers not only the physical health but also the psychological and social aspects of older individuals. They play a vital role in health promotion, educating and guiding older adults on practices that contribute to healthy aging. By tailoring care plans to the unique needs of older adults, geriatric nurses contribute significantly to promoting optimal well-being and improving the quality of life for older individuals.

### Assess Functional Health

Nurses are vital in maximizing the quality of life for older adults, particularly those struggling with chronic illnesses. An individual's ability to complete necessary daily tasks is called **functional health**. By assessing functional health, nurses create a springboard for various treatment modalities to help older adults maintain their maximum quality of life. Mishra et al. (2020) lists several specific functional health patterns important for integrating nursing and other medical care. The patterns include the following:

- health perception
- ADLs
- cognitive ability
- self-perception

Nurses can utilize various assessment tools aimed at older adults for evaluating the baseline functional health of older adults ([Table 41.6](#)).

Assessment Tool	Nursing Application
Activities of daily living (ADLs)	<ul style="list-style-type: none"> <li>• A wide variety of tests to evaluate a person's ability to perform common self-care tasks</li> <li>• Assesses tasks such as bathing, oral care, dressing, grooming, and toileting</li> <li>• Can give clues to level of independence, fall risk, safety, and quality of life</li> </ul>
Instrumental activities of daily living (IADLs)	<ul style="list-style-type: none"> <li>• Tools to assess the ability of individuals to live and function independently within in the community</li> <li>• Evaluates more complex tasks such as making phone calls, cleaning, preparing meals, managing medications, managing finances, and mode of transportation</li> </ul>
Mini-Mental State Exam (MMSE)	<ul style="list-style-type: none"> <li>• Assesses for mild cognitive impairment, cognitive decline, and early dementia</li> </ul>
Geriatric Depression Scale (GDS)	<ul style="list-style-type: none"> <li>• Assesses for signs of depression</li> <li>• A screening tool only, does not take the place of an evaluation by a mental health professional</li> </ul>
Short Form 12 (SF12)	<ul style="list-style-type: none"> <li>• Assesses the effects of health on everyday functioning</li> <li>• Includes measures of pain, social and physical activity, mental health, energy, and health perceptions</li> <li>• Strong indicator of quality of life</li> </ul>

**TABLE 41.6** Assessment Tools for Functional Health

## LINK TO LEARNING

The [Geriatric Depression Scale \(https://openstax.org/r/77gerdepress\)](https://openstax.org/r/77gerdepress) and [Geriatric Depression Scale \(short form\) \(https://openstax.org/r/77gerdeprsrst\)](https://openstax.org/r/77gerdeprsrst) can help nurses understand a patient's baseline mental health status.

A **comprehensive geriatric assessment** (CGA) is a detailed assessment that includes many health indexes. A CGA evaluates ADLs, IADLs (activities that allow an individual to live independently in a community, such as cooking, cleaning, and managing medications), mental health, fall risk, pain, **polypharmacy** (simultaneous use of multiple medications), nutrition, sensory issues, dentition, and advanced care preferences. Nurses work with primary care providers and social workers in developing an individualized CGA.

## REAL RN STORIES

Risk Assessment: SPICES Tool

**Name:** Vivian, BSN

**Clinical setting:** Surgical Department

**Years in practice:** 17**Facility location:** Minnesota

I've spent all seventeen years of my nursing career working with inpatients recovering from surgical procedures. The surgical procedures include gynecological procedures, orthopedic joint replacements, traumatic surgical repairs, and cancer-related treatments. When I work with nursing students and new nurses, I always refer to the SPICES tool for understanding individual patient risks. SPICES stands for these conditions:

- S—Sleep disorders
- P—Problems with eating
- I—Incontinence
- C—Confusion
- E—Evidence of falls
- S—Skin breakdown

This helps both new and experienced nurses maintain awareness of complication risks and adapt care plans to keep patients safe and help them recover quickly. I recall an 85-year-old patient named Julie who received a hip pinning after a fall in her home left her with a broken hip. Before her fall, she lived independently. She had one daughter who lived an hour away. She had medical diagnoses of high blood pressure, hypothyroidism, and osteoporosis. Julie had difficulty arousing from anesthesia and spent several more days on the surgical unit than expected. During my time caring for her, I applied the SPICES tool.

S—Julie had trouble regaining her sleep-wake pattern after anesthesia. This was related to confusion and medication interactions. While caring for Julie, I discussed a sleep aid with her surgeon, who felt this was appropriate to help her maintain adequate sleep for healing. Because of the nature of the sleep aid, a bed alarm was employed to maintain her safety.

P—Julie did not have a specific problem with eating, but she did have trouble with elimination. Stool softeners and laxatives were required to resume her bowel function before discharge.

I—Julie did not struggle with incontinence. However, she had urinary retention after removing her urinary catheter, which required another call to the surgeon for straight catheter orders. As she became more mobile, Julie resumed her usual urinary patterns.

C—Julie did have significant confusion the first twenty-four hours after her procedures. She required a bed alarm and close monitoring to prevent falls.

E—Julie had many risk factors for falls, and her entire care plan focused on preventing another fall.

S—Since Julie experienced confusion after her procedure, she could not begin mobility work as soon as planned. Due to a decreased ability to move in bed and safely move her hip, we implemented a turning and toileting schedule. During these scheduled turns, I assessed for any skin breakdown.

Overall, Julie was a high-risk individual, and keeping the SPICES in mind helped me create a care plan that prevented further falls and complications. Julie was discharged to a rehabilitation facility and, after three weeks, was released to live with her daughter.

---

### Provide Health Screenings

Nurses can help manage health screening in older adults. Awareness of age-appropriate health screening is essential for creating a comprehensive nursing care plan that promotes disease prevention. Some health screenings are offered at the community level, such as cholesterol screenings and nutritional assessments. Other screenings require healthcare provider input to determine appropriateness and test ordering. The U.S. Preventive Services Task Force (n.d.) is an excellent source for determining the screening tests recommended for older adults of varying ages. For older adults living in long-term care facilities, some health screenings are done routinely for all individuals. Health screenings may involve comprehensive functional assessments, lab values, and specialty tests such as ultrasounds, mammograms, computed tomography scans, and colonoscopies. Screening test standards for older adults may include the following:

- colon cancer screening

- mammograms
- prostate-specific antigen testing
- cholesterol testing
- osteoporosis screening
- abdominal aortic aneurysm (AAA) screening
- fall risk evaluation
- comprehensive geriatric assessments
- nutritional assessments
- functional assessments

## LINK TO LEARNING

The U.S. Preventive Services Task Force offers [comprehensive graded recommendations for screening tests](https://openstax.org/r/77screentest) (<https://openstax.org/r/77screentest>) across the life span.

### Pain Management

As with individuals of all ages, older adults may experience acute pain from injuries, procedures, or medical treatments. Chronic pain is also prevalent in older adults and can range from minor to severe. Common causes of chronic pain in older adults include arthritis, degenerative spine disorders, cancer-related pain, and neuropathy. The pain threshold in older adults may be lower due to changes in circulating neurotransmitters (Ali et al., 2018). Pain management in older adults may be complicated by the following factors:

- cognition
- medication interactions
- kidney function
- fall risk
- sleep disturbance
- depression

Pain management in older adults can be complex due to various factors that contribute to the challenges of assessment and treatment. One significant factor is cognition, as many older individuals may experience cognitive decline, including conditions like dementia or Alzheimer disease. This decline can impede effective communication about pain symptoms, making it difficult for healthcare providers to accurately assess and address pain levels. Additionally, the use of multiple medications to manage various health conditions can result in interactions that impact the effectiveness or safety of pain medications. Kidney function, which tends to change with age, is another consideration, as it can influence the choice and dosage of pain medications. Furthermore, pain itself may contribute to a higher risk of falls, impacting mobility and balance. Sleep disturbances, depression, and other mental health factors can further complicate the overall picture of pain management in older adults. Healthcare professionals must carefully navigate these complexities to develop tailored and effective pain management strategies for this population. One effective strategy is to assess pain levels before and after pain medication administration by observing facial expressions and other indicators of discomfort using the Wong-Baker FACES Pain Rating Scale, especially considering the challenge some patients face in describing their pain.

The American Geriatrics Society offers specific guidelines on pain management in older adults ([Table 41.7](#)). Medications are classified as low to high risk based on the side effect profile and risk-benefit analysis. There is a balance between safe treatments for pain and untreated pain. Low-risk medications typically exhibit few interactions with other medicines and do not produce side effects that may increase fall risk or affect kidney or liver function at proper dosing.

Low-risk pain medications (used as first-line treatments)	<ul style="list-style-type: none"> <li>• Tylenol</li> <li>• Oral nonsteroidal anti-inflammatory drugs (NSAIDs)</li> <li>• Topical NSAIDs</li> <li>• Topical lidocaine</li> <li>• Capsaicin</li> <li>• Serotonin-norepinephrine reuptake inhibitors (SNRIs)</li> <li>• Tricyclic antidepressants (TCAs)</li> </ul>
High-risk pain treatments	<ul style="list-style-type: none"> <li>• Opioids</li> <li>• Benzodiazepines</li> <li>• Muscle relaxants</li> <li>• Cannabinoids</li> </ul>

**TABLE 41.7** American Geriatrics Society Pain Medication Guidelines

In addition to medication, pain management modalities may include the following:

- physical therapy
- occupational therapy
- physical exercise
- chiropractics
- procedural injections
- stress management
- meditation

## PATIENT CONVERSATIONS

### Managing Arthritis Pain

**Scenario:** Raelynn is a 67-year-old who lives in an apartment attached to her daughter’s home and spends significant time caring for her three grandchildren. She has osteoarthritis in multiple joints and degenerative disk disease in her lower back. She has had one knee replacement that resulted in a postoperative infection. This has healed, but she is too nervous to undergo a knee replacement on the other leg after her experience. She needs to remain active and spend time outdoors with her family. Josiah is an RN in the pain specialty clinic where Raelynn is a patient. While Josiah records her vital signs, Raelynn explains her pain symptoms and expresses frustration with not being able to do small hikes with her young grandchildren. Josiah initiates a conversation about Raelynn’s pain to facilitate a productive treatment discussion with the orthopedic specialist.

**Nurse:** How would you describe the pain you experience in your knee? Please rate your pain between zero being no pain and ten being the worst pain you’ve experienced.

**Patient:** I’ve had knee pain for years. It just keeps getting worse, and I can do less and less of the things I like to do with my family. I have tried topical creams like lidocaine over the counter. And I take acetaminophen regularly, as my primary care provider suggested. When I first get up, my pain can be as high as an eight, but it hovers around a four once I get moving. I do use some topical cannabis ointment that does give me some relief, but it doesn’t last long.

**Nurse:** It sounds like you’ve tried several things to improve your pain. Does any physical exercise seem to help?

**Patient:** Well, I was doing yoga for a while, which did help, but I can’t afford the gym membership now.

**Nurse:** Yoga is great; we work cooperatively with a wellness center to provide low-cost movement classes, like yoga, to our patients. Would this be something you would be interested in?

**Patient:** Yes, I'd like to try this option. I would also like to get back in with a physical therapist, as this has helped me in the past as well. I want to avoid any medications that will make me tired. I care for my grandchildren while my daughter works, and I need to be alert and interactive.

**Nurse:** I'll note your interest so the provider can discuss options with you, and we can get these referrals processed. The provider will also discuss other medication options with you that are nonsedating. The provider will also be able to tell you if any injections in your joint might be helpful for a more extended period.

### Promote Physical Activity

Physical movement is crucial for older adults. High- and low-intensity activity helps maintain muscle mass, improve balance, improve circulation, and minimize fat deposition. Group exercise in community settings or long-term care facilities promotes mental functioning. By focusing on physical activity, nurses can promote healthy elimination and digestion. The CDC (2021) explains that even short-duration physical activity, such as brisk walking, can help manage symptoms of most chronic illnesses. Physical exercise also improves alertness and plays a role in reducing anxiety and depression. Nurses in various clinical settings can help clients resume or begin physical activity after setbacks due to illness or injury (Table 41.8). Nurses can guide clients to community exercise groups, outdoor walking groups, and senior centers offering gentle motion classes. The CDC recommends 150 minutes of moderate-intensity exercise weekly for older adults and muscle-strengthening exercises at least two days per week.

Fall Risk Factor	Nursing Interventions
Altered mental status	<ul style="list-style-type: none"> <li>Assess for delirium.</li> <li>Delegate additional trained supervision for patients showing signs of agitation.</li> <li>Consider the use of safety measures such as low beds, mats for each side of the bed, nightlight, gait belt, and a "STOP" sign to remind patients not to get up.</li> </ul>
Impaired mobility	<ul style="list-style-type: none"> <li>Provide direct assistance with mobility as indicated by the patient's condition.</li> <li>Ensure assistive devices for mobility are within safe reach.</li> </ul>
Frequent toileting needs	<ul style="list-style-type: none"> <li>Create a regular toileting schedule.</li> <li>Ensure safety handles are in good repair to assist with toileting.</li> </ul>
Visual impairment	<ul style="list-style-type: none"> <li>Maintain clean corrective lenses.</li> <li>Ensure corrective lenses are within reach.</li> <li>Remind patient to wear corrective lenses when walking.</li> </ul>

**TABLE 41.8** Nursing Interventions Based on Fall Risk Factors

Fall Risk Factor	Nursing Interventions
High-risk medications	<ul style="list-style-type: none"> <li>• Be aware of medications that have the potential to increase fall risk.</li> <li>• Consult with healthcare provider and pharmacist regarding medications that may increase fall risk.</li> <li>• Check orthostatic blood pressures routinely.</li> <li>• Educate the patient and their caregivers about fall risk and steps to prevent falls when the patient is taking these medications.</li> </ul>
Frequent falls	<ul style="list-style-type: none"> <li>• Assess ongoing fall risk related to disease and medications.</li> <li>• Evaluate the environment to ensure safety and reduce fall risk obstacles.</li> </ul>

**TABLE 41.8** Nursing Interventions Based on Fall Risk Factors

### Medication Education

Medication education is vital during several key patient interactions. Nurses have opportunities to explain medication treatments during admission assessments, medication administration, discharge planning, patient education sessions, outpatient clinics, follow-up visits, and home health visits, ensuring patients understand the purpose, potential side effects, and proper administration of their medications. Nurses work directly with pharmacists and prescribers to maintain patient safety with medication treatments. During hospital stays, nurses administer medications routinely. In addition to the five rights, medication administration involves educating patients on the purpose of the prescribed medications. Medications for pain are tailored specifically for each patient's level of pain.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

### QSEN Competency: Safety

**Definition:** Reducing a patient's risk of harm by incorporating individual quality performance standards and system effectiveness.

**Knowledge:** Chronic disease prevalence in the older adult population increases the risk of polypharmacy and associated complications in this age group. Polypharmacy refers to using multiple medications simultaneously to treat one or more medical disorders. Typically, polypharmacy refers to the use of five or more medications. With each addition of medication, the risk for drug-drug interactions significantly increases. There is a risk for compounded side effects and a risk to organs such as the kidney and liver.

**Skill:** Nurses can always be alert for polypharmacy, monitor for any medication indication duplication, and be aware of when medications can be stopped. It is appropriate to bring concerns about polypharmacy to the attention of healthcare providers, particularly in long-term care settings where several patients' medications are stored.

**Attitude:** Polypharmacy is common; nurses also play a role when new medications are added, understanding and being proactive about checking medication interactions, discussing medication management with patients, and keeping open communication with pharmacists about minimizing side effects and interactions.

The AGS Beers Criteria, formulated by the American Geriatrics Society, serve as a crucial reference tool for healthcare professionals in identifying potentially inappropriate medications for older adults (Cleveland Clinic, 2023). Among the medications commonly listed are benzodiazepines like diazepam, lorazepam, and alprazolam, frequently prescribed for anxiety or insomnia. The caution arises from the heightened risk of falls, cognitive impairment, and other adverse effects associated with the use of these drugs in older individuals. Additionally,

nonbenzodiazepine hypnotics, such as zolpidem, commonly prescribed for sleep-related issues, are flagged due to their potential contribution to drowsiness, falls, and impaired cognitive function.

The role of a nurse becomes pivotal when medications listed on the AGS Beers Criteria are identified during patient care. The nurse's responsibilities encompass a comprehensive assessment of the patient's medication history, with a keen focus on prescriptions and over-the-counter drugs, and diligent documentation of any medications flagged by the Beers list. Effective communication with pharmacists, prescribers, and the broader healthcare team is paramount, fostering collaborative discussions to explore safer alternatives. Patient education becomes a crucial aspect, with the nurse providing clear explanations of potential risks associated with identified medications and actively involving the patient in decisions about their health care.

## LINK TO LEARNING

The American Geriatrics Society updates [the AGS Beers Criteria \(https://openstax.org/r/77AGSBeers\)](https://openstax.org/r/77AGSBeers) every three years (Cleveland Clinic, 2023). At this website, you can learn more about the AGS Beers Criteria, including the medication classes that are not recommended for use in the older adult population.

### Assess for Neglect or Abuse

Nurses must always remain diligent in monitoring for signs of abuse and neglect in older adult populations. This is especially true for individuals with dementia, those who live alone, and those with financial strain. Nurses can employ a variety of abuse screening tools, such as the Elder Abuse Suspicion Index and the Vulnerability to Abuse Screening Scale, in the event of abuse suspicion (National Center on Elder Abuse, 2016). These assessment tools focus on physical care, medical management, emotional abuse, sexual abuse, financial abuse, and neglect. It is important to note these tools are not diagnostic but serve as indicators for further assessment and intervention. Professionals using these tools must follow appropriate protocols and ethical guidelines when suspicions of abuse or neglect arise, involving appropriate authorities and support services as needed.

## CLINICAL JUDGMENT MEASUREMENT MODEL

### Fall Risk Assessment in Clinical Practice

In caring for older adults, nurses can rely on the Clinical Judgment Measurement Model (CJMM) to guide client assessment, individualize care based on clinical cues, and evaluate the effectiveness of nursing interventions across practice sites. Fall risk assessment offers a clear example of application in clinical practice ([Table 41.9](#)).

CJMM Step	Clinical Application
Recognize clues	The nurse notices a patient has an uneven gait, shows physical weakness, and expresses dizziness. The nurse witnesses a near fall and sees several bruises on the patient's forearms.
Analyze clues	The nurse determines the patient is at high risk for falls. The nurse understands that medications, general weakness, floor rugs, and lack of assistive device are playing a role in fall risk.
Prioritize hypotheses	The nurse prioritizes the need to improve the physical environment of the client and then reporting physical symptoms of dizziness, weakness, and possible medication effects to the healthcare provider.
Generate solutions	The nurse creates a plan with the patient, family, and other caregivers to improve the physical environment by removing floor rugs, obtaining a walker, and creating a plan for toileting to avoid rushing.

**TABLE 41.9** Clinical Judgment Measurement Model in Independently Living Older Adults with Fall Risk

CJMM Step	Clinical Application
Take actions	The nurse requests an order for a walker and enlists family to help keep floor areas free of debris.
Evaluate outcomes	The nurse notices a reduction in injuries over the next several months. The patient vocalizes a sense of safety when moving around the home.

**TABLE 41.9** Clinical Judgment Measurement Model in Independently Living Older Adults with Fall Risk

### Interdisciplinary Team Referrals

Working within the medical community means nurses must work closely with colleagues in other specialties. In caring for older adults, nurses will frequently collaborate with nurses and other healthcare providers in specialties such as orthopedics, endocrinology, cardiology, pulmonology, and dermatology. Additionally, ancillary specialty services play a key role in the health of older adults, and nurses will frequently interact with physical therapists, occupational therapists, cardiac rehabilitation specialists, and mental health professionals, among others. Collaborative care is essential for quality and streamlined patient care. Nurses may work in formal interdisciplinary teams or document and forward referrals to specialists for additional care. When a patient requires specialty care, a nurse will provide a **referral** for these services by forwarding appropriate records, arranging appointments, and coordinating care.

### Nutritional Support

Nutritional support may relate to general health eating or may focus on specific disease management. Nutritional support is necessary for many common chronic disease states, including the following:

- diabetes
- heart disease
- colitis
- celiac disease
- obesity
- high cholesterol
- hypertension

Nurses rely on nutritionists to educate older adults with diabetes on proper nutrition to manage the disease and minimize complications. Nutrition services are essential in long-term care facilities and for individuals living at home. Some older adults struggle with financial strain and may struggle to afford food. Nurses can guide these clients to community resources, such as meals-on-wheels and the Older Americans Act nutrition programs, to minimize hunger in the adult population.

### LINK TO LEARNING

At this website, facts about the [Older Americans Act Nutrition Programs \(https://openstax.org/r/77oldamact\)](https://openstax.org/r/77oldamact) are available.

### Specialty Referrals

Specialty referrals are common for patients discharged from the hospital and those seeking care through a primary care provider ([Table 41.10](#)).

Physician Specialties	Indication for Referral
Allergy and immunology	Asthma, allergies, hives
Behavioral health	Depression, anxiety, bipolar disorder
Cardiology	Heart attack, heart murmur, chest pain, heart palpitations, stroke
Dermatology	Skin cancer, rash, cysts
Endocrinology	Diabetes, thyroid dysfunction
Gastroenterology	Diarrhea, constipation, rectal bleeding, gastroesophageal reflux disease (GERD), abdominal pain
Hematology	Blood cell abnormalities, anemia, leukemia
Neurology	Cognitive decline, neuropathy, carpal tunnel
Oncology	Any cancer diagnosis
Ophthalmology	Acute or chronic vision changes, eye pain, temporal arteritis
Orthopedics	Arthritis, degenerative disk disease, traumatic injuries, joint pain
Pulmonology	Chronic obstructive pulmonary disease, chemical lung exposures, sleep apnea
Rheumatology	Joint pain, elevated arthritis markers
Urology	Prostatitis, elevated prostate-specific antigen test, hematuria, prostate enlargement, overactive bladder

**TABLE 41.10** Indications for Specialty Referrals

For older adults, accessing a range of ancillary specialty services can significantly contribute to their comprehensive health care. These specialized services cater to diverse aspects of health and functional well-being. Physical therapy focuses on enhancing mobility and strength, while occupational therapy addresses daily living skills. Speech therapy becomes crucial for managing communication disorders and swallowing difficulties. Respiratory therapy specializes in improving lung function and managing breathing difficulties, particularly beneficial for individuals with conditions like chronic obstructive pulmonary disease. Wound care specialists play a vital role in assessing and treating wounds to prevent complications and promote healing. Nutritionists offer guidance on dietary habits, diabetes educators provide support for managing diabetes, and weight management specialists address weight-related concerns. Pain management specialists assess and treat chronic pain conditions, aiming to improve the overall quality of life. This collaborative approach involving various ancillary services, alongside primary care, ensures a holistic and tailored care plan for older adults, addressing their unique needs and enhancing their overall health and functionality.

### Community Resources

Community resources for older adults play a crucial role in enhancing their well-being and overall quality of life. While community resources vary by location and size of the city, many communities have volunteer services for older adults, such as senior centers, exercise classes, meals, library book delivery, and read-aloud services. Senior centers serve as social hubs, offering a range of activities, educational programs, and wellness services to promote

engagement and connectivity among older community members. Meals-on-wheels programs provide a valuable service by delivering nutritious meals to seniors at home, addressing concerns related to food preparation and ensuring they maintain proper nutrition. Transportation services designed for older adults help address mobility challenges, ensuring they have access to essential services, medical appointments, and community activities. Other community resources might include grief support groups, disease-specific support groups, and hobby groups. These resources collectively contribute to creating an age-friendly community that supports the independence, health, and social connections of older individuals. It is important for seniors and their caregivers to be aware of and utilize these community resources to enhance their overall well-being.

### Caregiver Resources

Nursing care for older adults often involves caring for the family and other caregivers. For individuals caring for older adults, there are various caregiver resources available to provide support and guidance. Local aging agencies often offer assistance in the form of information, counseling, and respite services. The term **respite** refers to a short period of rest or relief, typically provided to caregivers who are responsible for the continuous care of individuals with special needs, disabilities, or chronic illnesses. During respite, caregivers can take a temporary break from their caregiving duties to recharge, attend to their own needs, or engage in activities that promote their well-being. Support groups, whether in-person or online, provide caregivers with opportunities to connect, share experiences, and receive emotional support from others facing similar challenges. Educational programs and workshops help caregivers develop essential skills for managing the physical, emotional, and logistic aspects of caregiving. Additionally, online platforms and helplines offer information on specific health conditions, legal matters, and financial planning related to caregiving. Accessing these resources empowers caregivers with the knowledge and assistance needed to navigate the complexities of providing care for older adults and maintain their own well-being in the process.

Caregivers may find valuable support from organizations such as the Family Caregiver Alliance, Caregiver Action Network, and various support groups, including those focused on grief. The Caregiver Action Network, in particular, offers comprehensive resources to assist family members in their caregiving responsibilities. Nurses can play a vital role in supporting caregivers by facilitating access to these support services, attentively listening to their concerns, and ensuring that caregivers are informed about where to seek assistance for any questions or challenges they may encounter. This collaborative approach helps create a supportive network for caregivers, enhancing their ability to provide effective care while prioritizing their own well-being.

## Summary

### 41.1 Growth and Development Stages

When providing care for older adults, it is crucial to understand how your patients develop and change over time. Older adults experience many challenges with their physiological, psychological, and psychosocial environment. Developmental changes and challenges are common but are not universal. Nurses across all specialties must provide compassionate and individualized care for older adults.

Physical changes in older adulthood affect all organ systems. By understanding physiological and physical changes that develop with age, nurses can tailor care to promote wellness for each patient. Nurses must diligently monitor for psychological changes that may signal mental health disorders or cognitive decline in older adults.

With a strong understanding of the older adult developmental stage, nurses can empower their clients with positive coping strategies. Patients must adapt to physical, cognitive, emotional, and social changes, and nurses are an excellent resource for maximizing older adult wellness.

### 41.2 Theories Related to the Older Adult

Clearly understanding theories of aging puts nurses at an advantage when caring for older adults. Older adults' physical abilities, disease burden, and cognitive functioning vary significantly. This variation may be related to advancing age but is more often unique to each individual. Using Erikson's psychosocial development theory and Maslow's hierarchy of needs as a springboard, nurses can target specific needs and risks for each patient to create an individualized care plan.

Havighurst's activity theory is highly applicable to nursing practice. Nurses practicing activity-focused care create a positive patient wellness and healing environment. Tailoring interventions based on each patient's level of engagement encourages a sense of belonging and acceptance regardless of their physical abilities.

By applying theories that provide accurate depictions of aging, nurses can modify their mindset and learn how to provide age-appropriate care that produces positive patient outcomes. A strong understanding of these theories can help the nurse to dispel the many myths around aging.

### 41.3 Health Risks for Older Adults

Health risks vary widely among older adults. While some adults have few health concerns, nurses need to understand the common health risks in this population. Awareness of the risks allows nurses to make informed treatment plans. Health risks fall into three categories: physiological, psychological, and psychosocial. The health risks in these categories frequently overlap. Physiological changes can strain psychosocial interactions, and cognitive decline may affect physical and psychosocial functioning.

Physiological health risks include changes that lead to illness or injury. Older adults are at risk for mobility, nutrition, and overall functional ability changes. Psychological changes such as cognitive decline and dementia are often progressive. Psychological changes often affect the functional ability of the patient. Nurses must diligently monitor for progressive and acute mental status changes that can affect patient outcomes. Tools are available for nurses to monitor the mental health of their patients. Recognizing depression, grief, and loneliness is the first step in maintaining a healthy outlook during older adulthood.

Psychosocial changes in older adulthood put individuals at risk for mental health disorders such as depression and loneliness. Nurses play a role in assisting older adults in developing coping skills to deal with changes in living environment, transportation, and available resources. Nurses must always be alert for signs of abuse and maintain an awareness of health disparity that may affect the quality of life of their patients.

### 41.4 The Nurse's Role in Preventing Illness

Nurses care for older adults in primary care, specialty care, home care, and long-term care settings. Regardless of the setting, the key roles of nurses are illness prevention and wellness maintenance. Nurses must promote health screening options by following current medical guidelines. Working with healthcare providers to perform functional and comprehensive health assessments allows nurses to tailor care to each individual. Routinely performing assessments enables nurses to identify risks and recommend appropriate referrals.

Nurses continuously collaborate with other medical professionals in specialty clinics. This might include interdisciplinary teams, including physician specialists, mental health professionals, physical therapists, pharmacists, occupational therapists, and speech therapists. Collaboration with support services, including social workers, spiritual leaders, and counselors, is also crucial. Nurses may create active treatment plans or ensure that specialist referrals are processed. The ability to identify a need and enlist the appropriate collaborative team members is a unique strength of nurses.

## Key Terms

**activity theory** a theory on aging that suggests that the more active and involved an older person is, the happier they will be

**age stratification theory** a theory suggesting that members of society might be stratified by age, just as they are stratified by race, class, and gender

**ageism** prejudice and stereotype based on a person's chronological age

**Alzheimer disease** a progressive disorder and general loss of cognitive function that presents with memory loss, behavior changes, and personality changes

**chronic grief** normal grief reaction that does not subside and continues over a very long period of time

**complicated grief** a state of grief that is prolonged, delayed, or exaggerated in which individuals have trouble coping and progressing through the normal grief process

**comprehensive geriatric assessment** a detailed assessment that includes many health indices including ADLs, IADLs, mental health, fall risk, pain, polypharmacy, nutrition, sensory issues, dentition, and advanced care preferences

**delayed grief** normal grief reaction that is suppressed or postponed by the survivor consciously or unconsciously to avoid the pain of the loss

**delirium** an acute but reversible condition characterized by confusion and disorientation secondary to a physical illness

**dementia** alteration and progressive loss of brain function resulting in cognitive decline

**disengagement theory** a theory suggesting that withdrawing from society and social relationships is a natural part of aging

**elder abuse** all direct actions and neglectful actions by a caregiver that cause harm or risk of harm to an older adult

**exaggerated grief** an intense reaction to grief that may include nightmares, delinquent behaviors, phobias, and thoughts of suicide

**functional foods** foods that serve a useful purpose for the body in addition to energy intake

**functional health** an individual's ability to complete necessary daily tasks

**geriatric nursing** specialized branch of nursing dedicated to the comprehensive care of older adults

**hopelessness** a severe psychological state involving a deep sense of failure or despair

**loneliness** a subjective feeling of distress related to being alone or separated from other people

**masked grief** grief that occurs when the survivor is unaware of behaviors that interfere with normal functioning due to the loss

**mild cognitive impairment (MCI)** forgetfulness, short-term memory loss, and thinking impairment

**older adult** adults 65 years of age or older

**physical changes** relating to outward expressions of changes in the body

**polypharmacy** the use of multiple medications simultaneously to treat one or more medical disorders

**psychosocial development theory** a theory that emphasizes the social nature of human development from infancy through older adulthood

**referral** the act of forwarding records, coordinating care, and arranging appointments with specialty healthcare services

**respite** refers to a short period of rest or relief, typically provided to caregivers who are responsible for the continuous care of individuals with special needs, disabilities, or chronic illnesses

**role reversal** a situation in which a child takes on the role of a caregiver and a parent may take on the role of a dependent

**social isolation** an objective physical separation from other people that causes distress

## Assessments

### Review Questions

1. A nurse is caring for an older adult who has recently retired from a career as a dental hygienist. The patient is exhibiting signs of sadness, loneliness, and depression. The nurse recognizes the patient is experiencing an effect of what type of developmental change?
  - a. physical
  - b. physiological
  - c. psychosocial
  - d. psychological
2. The nurse observes a patient in the long-term care facility is experiencing a reduced appetite. The patient states that food does not taste good and lacks flavor. The nurse associates these changes with what expected physiological change of older adulthood?
  - a. heightened sense of smell
  - b. reduced taste sensation
  - c. weight loss
  - d. decreased close-up vision
3. What developmental transition in older adulthood directly relates to relationships with family members and others in the community?
  - a. ageism
  - b. psychosocial changes
  - c. physical changes
  - d. dementia
4. What description provides an example of role reversal in older adulthood?
  - a. an older adult providing financial assistance to a 28-year-old son
  - b. a 30-year-old financial adviser providing advice to a 68-year-old couple
  - c. a 26-year-old woman providing care for her 70-year-old mother who is bedridden
  - d. a 30-year-old man and his family moving in with his 70-year-old mother to save money to buy a house
5. An older patient tells the nurse about her diminished sense of hearing. What should the nurse say to explain hearing changes from aging?
  - a. "The eardrum begins to show damage sustained from past practices of listening to music at high volumes."
  - b. "As we age, the eardrum thickens, and the inner ear bones weaken."
  - c. "Less hormones related to hearing are produced as we age."
  - d. "Forgetting to have wax removal is a common occurrence in older adults."
6. A nurse is caring for an older adult whose husband recently died from colon cancer. The patient is expressing concerns about her financial situation and the choices she and her husband have made over the years. She is also exhibiting signs of sadness and loneliness. The nurse knows that the patient is working through what task in Erikson's psychosocial theory?
  - a. initiative versus guilt
  - b. intimacy versus guilt
  - c. integrity versus despair
  - d. industry versus inferiority
7. The nurse observes that a patient in the long-term care facility seems withdrawn. Several of the other staff members mention that she does not come to the dining room for meals or other activities. The nurse creates a plan to encourage the patient to join at least one meal per day and two weekly activities in the community area. The nurse uses her knowledge of what theory of aging to create a care plan for this patient?

- a. disengagement theory
  - b. activity theory of aging
  - c. Erikson's psychosocial theory
  - d. age stratification theory
8. In what theory of aging can older adults move from one level to another depending on specific health and disease circumstances?
- a. activity theory
  - b. Erikson's psychosocial theory
  - c. age stratification theory
  - d. Maslow's hierarchy of needs
9. In addition to the ADEA, what legislation aims to reduce the negative effects of ageism and minimize age stratification?
- a. the Elder Justice Act
  - b. the Grandfamily Housing Act
  - c. the Older Americans Act
  - d. the Social Security Act
10. What patient profile describes the idea of role replacement as described in the disengagement theory?
- a. A 70-year-old female begins playing pickleball on a league at her local gym.
  - b. An 80-year-old female stops participating in a weekly dance class in order to find a hobby that is more age appropriate.
  - c. A 90-year-old male replaces his daily walk with an exercise class at his assisted living facility during the winter months.
  - d. A 65-year-old male begins transporting his granddaughter to soccer practice to help reduce the driving stress for his daughter.
11. A nurse working in home health notices that one of her patients relies on walls, furniture, and counters to stabilize herself as she moves through her home. The nurse determines the patient is experiencing dizziness after starting a new blood pressure medication. The nurse knows the patient is having trouble with mobility and is at high risk for what health risk?
- a. poor hydration
  - b. nutrition deficiency
  - c. falls
  - d. dementia
12. A patient tells the nurse that he is taking various herbal and nutritional supplements to "enhance" his health. Since the patient also takes multiple prescription medications, the nurse understands the patient is at risk for what health risk?
- a. medication interactions
  - b. decreased mobility
  - c. fluid imbalance
  - d. fall-related injuries
13. The nurse is caring for an older adult who states she is concerned that she has dementia because she is having trouble finding words on occasion and lost her keys last week. The nurse understands the patient is showing signs of what psychological health risk?
- a. depression
  - b. Alzheimer disease
  - c. delirium
  - d. mild cognitive impairment

- 14.** A nurse is concerned about a patient who recently moved into an assisted living facility. The patient had to give up her pet and her home during the move. She also tells the nurse that it is now difficult for her daughter to drive her to her weekly card game. The nurse knows that in addition to loneliness and grief, the patient is also at risk for what psychological health risk?
- caregiver strain
  - depression
  - nutritional imbalance
  - delirium
- 15.** A hospitalized older adult patient who was previously alert and oriented is now confused about place and time. The patient also attempted to leave the hospital and had a near-miss fall. The nurse understands that this patient may be experiencing what acute disorder?
- depression
  - loneliness
  - hopelessness
  - delirium
- 16.** During a routine wellness checkup for a 68-year-old female, the nurse notices she has never had colon cancer screening. What is the best course of action for the nurse?
- Tell the patient that she needs a colonoscopy immediately.
  - Focus on the fact that colon cancer screening is overdue.
  - Explain the importance of colon cancer screening and available options.
  - Make an immediate referral to a gastroenterologist.
- 17.** A nurse performs an IADL assessment on a home care patient. The patient begins explaining the self-care activities that she is able to do independently. What is the best question to ask in relation to the IADLs?
- What does your weekly transportation routine look like?
  - Do you need assistance with bathing?
  - Do you have any difficulty dressing yourself?
  - How frequently do you typically need to use the bathroom?
- 18.** An emergency room nurse is assessing an older patient with suspected UTI. The daughter is present during the exam and is answering most of the questions. The patient keeps wondering where they are and requesting breakfast although it is 5 p.m. The daughter states, “my mom is usually so sharp, she never seems confused like this.” The nurse knows the patient is at risk for what health risk?
- dementia
  - depression
  - falls
  - poor nutrition
- 19.** A nurse in a primary care office is interviewing an older adult during a follow-up visit. The patient states that the medication prescribed for insomnia during his last visit seems to have made his headaches worse. The nurse sees that this patient has already tried several other medications for insomnia and has had chronic headaches for five years. The nurse can anticipate a referral to what specialty service?
- neurology
  - dermatology
  - endocrinology
  - cardiology
- 20.** The nurse is interviewing a patient being seen in an orthopedic office for follow-up on a broken wrist from a fall. The patient reports being very sleepy during the day and having difficulty getting their usual daily tasks done, but their arm is not hurting at all. The nurse discovers the patient takes the prescribed pain medication every four hours regardless of pain level, rather than as needed. What action can the nurse anticipate after

discussing the patient's symptoms with the provider?

- a. stop all pain medication
- b. a reduced dose of pain medication
- c. recommend the patient get more sleep
- d. recommend the patient have her daughter help with daily tasks

### Check Your Understanding Questions

1. Discuss the concept of self-directed ageism. How can individuals be encouraged to minimize self-directed ageism?
2. List two ways nutritional changes can affect older adults.
3. Discuss the concept of grandparenting. How can social and cultural values affect the experience of grandparenting?
4. A nurse cares for a patient at a primary care clinic. The patient describes recurrent hand pain and some swelling. The patient says she has been treated with acetaminophen and prescription NSAIDs in the past, and these were not effective. She explains that her mother had arthritis, but she is not sure what type. What interdisciplinary team referrals can the nurse expect?

### Reflection Questions

1. As a nurse, you care for an older adult in her home. Her daughter is also providing care each day. Both the daughter and the patient express concern regarding possible role reversal. The patient seems distressed by being treated like “a child” by her family. Her family expresses concern that she is not able to care for herself. How would you convey information about role reversal while addressing the concerns and maintaining respect for the patient and her family member?
2. According to Maslow's hierarchy of needs, what type of needs must first be met before an individual can focus on building self-esteem and confidence?
3. During a home health visit, a patient's daughter expresses concern about her ability to care for her father who has early dementia. She states she hardly has time to care for her own children, since her father requires assistance with most ADLs. What services can the nurse suggest to help the daughter cope with caregiver strain?
4. An emergency room nurse is preparing to transfer a patient to the medical floor. The patient is being admitted for congestive heart failure and has significant edema. The patient also has dementia. Although no fall was reported, the nursing assessment revealed several healing wounds and bruises. What risk factors for falls does this patient exhibit?
5. Discuss safety issues in opioid prescribing for older adults. How do state and federal opioid prescribing regulations affect older adults?

### What Should the Nurse Do?

1. While the nurse is checking in a 67-year-old male for his wellness exam, the patient becomes emotional about the death of his wife. He states that he thinks about her death much of the day and says, “I still can't believe she's gone.” He tells the nurse that his wife died five years ago in a car accident. What should the nurse do?
2. Dan is a 70-year-old with severe dementia who lives in a memory care facility. Dan is generally calm and follows a routine in his day. However, over the past several months, he has become more agitated with staff, especially at night and during mealtimes. In understanding sundowning and other safety issues for people with dementia, what are some restraint-free nursing interventions that may help Dan?
3. While performing an initial assessment on a 75-year-old female admitted to the emergency room after a fall, the nurse notices that the patient has dry lips and a thin appearance. The nurse notes that the patient has lost significant weight since she was last seen for a UTI three months ago. The patient says she has a hard time

staying hydrated—that her room does not have a sink and that the bathroom is a distance from her room. She also explains that it is hard for her family to help her to the bathroom frequently, so she tries to avoid drinking too much fluid. The nurse has some concerns about neglect. What should the nurse do?

4. The nurse is caring for a 65-year-old patient who had bilateral knee replacements. The patient states that his pain is terrible and that he needs more medication. The nurse checks the medication administration records and determines that it is too early to administer additional pain medication. What should the nurse do to help this patient?

### Competency-Based Assessments

1. Develop a short presentation to share with colleagues on preventing ageism when working with patients. Consider action items that are practical for application in clinical practice.
2. Use the internet to research proposed state or federal congressional acts that may impact working grandparents.
3. Utilize resources from your state’s Department of Public Health website to research health disparities among older adults in your state. Then, extend your analysis by comparing your state’s data with neighboring states and other regions across the country. How do states differ in their approach to minimizing health disparities in the older adult population?

## CHAPTER 42

# Caring for Patients with Disability and Chronic Illness

**FIGURE 42.1** Disability and chronic conditions can impact an individual's quality of life. Special healthcare considerations should be taken to ensure all the patient's needs are addressed, such as by providing guidance on using a piece of equipment in the workplace. (modification of "Sgt. Joshua Elliott uses a Primus RS machine during physical therapy" by Official U.S. Navy Page/flickr, Public Domain)

### CHAPTER OUTLINE

- 42.1 Characteristics of Disability
- 42.2 Healthcare Approach to Disability
- 42.3 Chronic Disease and Chronic Illness
- 42.4 Healthcare Approach to Chronic Conditions

**INTRODUCTION** Disabilities may be acute or chronic, lasting a few months to a lifetime. Nurses encounter individuals with a wide range of disabilities that encompass physical, cognitive, and emotional impairments. Disability is a physical or cognitive impairment that limits an individual's ability to interact in expected ways in their environment (CDC, 2020a). Nurses must exhibit confidence, competence, and respect in caring for these individuals. Specific cultural attitudes and legal parameters regarding disabilities guide nurses in making informed

and individualized decisions in caring for individuals with disabilities. The nurse's role in providing care involves creating an accurate view of different aspects of disability and incorporating these ideas into compassionate and individualized care plans. Nurses must understand disability from various viewpoints to provide comprehensive care. By incorporating social, personal, emotional, physical, cognitive, and community care, nurses empower each individual to reach their maximum capacity for health and wellness. Because some disabilities are present for an individual's life span, nurses must incorporate coping strategies to address challenges that arise and change over a lifetime.

Chronic disease and illness are widespread. With ever-changing and improving healthcare treatment and care, people in the United States live longer overall. Because the average adult life span is longer, many individuals live longer with chronic illnesses or conditions such as heart disease, diabetes, and cancer (Kochanek et al., 2022). Nurses play a crucial role in the support of individuals with chronic disease. From education regarding medications and coping skills for managing new diagnoses to social considerations for managing a chronic disease and family interactions in the face of illness, nurses empower individuals to live a life of wellness in the face of disease. Understanding the pathophysiology of disease states is important, but the nurse's ability to comprehend the human response to chronic disease and illness is also important in providing patient-centered care. This will vary from person to person, so nurses can offer critical knowledge and compassion in caring for these individuals. Although the incidence of chronic disease increases with age, some diseases begin in childhood and are lifelong, requiring the nurse to understand the concepts of disease in relation to life stage and development.

Nurses face unique and evolving situations with multiple chronic diseases in caring for many individuals simultaneously and over many years. Nurses must be equipped to address the emotional toll of chronic disease as well as its impacts on family and other social structures. Nurses must be prepared to navigate detailed and complex discussions with patients while controlling their emotions.

## 42.1 Characteristics of Disability

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the definitions of a disability
- Recognize the prevalence of disability
- Describe different categories and types of disability

Understanding the complexities of disability helps nurses care for specific individuals with single or multiple disabilities. Nurses must know how a physical, cognitive, or social impairment affects an individual, their interactions with others, and the appropriate level of care required. Nurses also must understand the prevalence of disability to create a culture of acceptance and inclusion for individuals with disabilities. Definitions of disability guide federal regulations and societal participation. The interplay between different types of disability is also vital in creating an individualized care plan.

### Definitions of Disability

A mental or physical condition that limits an individual's ability to engage in daily activities in a typical way is called a **disability** and affects individuals, interpersonal relationships, families, and communities. Nurses must recognize specific impairments and know how to respond to individuals with these impairments. Care planning maximizes the quality of life for individuals navigating an impairment, whether mental, physical, cognitive, or developmental. The Centers for Disease Control and Prevention (CDC) and the World Health Organization (WHO) define a disability as a restriction of an individual's ability to perform specific physical or cognitive activities in their environment within the expected range for individuals of their same demographic group (CDC, 2020a).

### Impairment

An **impairment** occurs when the loss of one's physical or mental ability inhibits usual or expected functioning, such as vision loss, limb immobility, and memory loss. By this definition, an impairment may lead to a disability. Disability and impairment are closely related, with an impairment typically causing or resulting in a functional disability. The Americans with Disabilities Act (ADA) and the CDC further add that disability from physical or mental impairment limits at least one significant life activity and creates participation restrictions by limiting specific interactions with one's environment and community (ADA National Network, 2024).

A **structural impairment** describes problems with an external or internal part of the body, whereas **functional impairment** describes restrictions or difficulties in the ability to perform activities effectively due to the loss of functioning in a body part. For example, structural impairments may include hearing damage, congenital blindness, or limb amputation, causing a patient to face hearing, seeing, or mobility challenges. Functional impairments may result from conditions such as chronic pain associated with arthritis or cognitive decline related to progressive disorders such as dementia, causing a patient to be unable to perform self-care or properly manage finances.

### Societal Participation

Based on the International Classification of Functioning, Disability, and Health (ICF), individual activity level and social participation relate to specific functional abilities (CDC, n.d.). Activity level and societal involvement exist on a continuum. By understanding these concepts, nurses can identify barriers for individuals with specific disabilities and provide care plans and advocacy to improve care, quality of life, and overall community functioning. An individual's **activity level** refers to their ability to perform specific actions, including:

- achieving transportation throughout the community
- applying newly learned information
- changing body positions
- managing home-care tasks
- managing self-care tasks
- moving independently within their home
- moving items within their environment
- performing activities of daily living (ADLs)
- using mobility assistance devices

An individual's **participation level** often refers to their ability to function in the wider community and participate in activities and social roles such as:

- engaging in community events and activities
- engaging in social activities
- family care (e.g., cooking, cleaning, transportation)
- life roles (e.g., parenting)
- maintaining or obtaining employment
- managing finances
- seeking education (e.g., going to school, personal learning)

Because individuals with disabilities often encounter barriers, **accommodations** (adjustments and modifications in the physical environment to meet the needs of individuals with disabilities) are often necessary. These accommodations may include providing interpreters, modifying or adjusting a job or job site, providing headphones or other accessible technology to reduce challenges and allow individuals with disabilities to perform personal actions, maintaining independence, and engaging in the community and society effectively (CDC, 2020b).

Studies show that individuals experience many challenges associated with societal participation regardless of the type of disability (Kim & Namkung, 2023). Barriers may be socioeconomic or related to social policy and can affect the overall health and social inclusion of individuals with disabilities. Barriers can be seen in the accessibility of buildings, access to health care, social engagement, and **discrimination** (actions or beliefs that show an unjust distinction between people on the grounds of sex, age, ethnicity, or disability) behaviors of others (Kim et al., 2023). If an individual with a disability is restricted from entering a public university event because modifications are not in place to accommodate their disability, this is an example of discrimination. Although these barriers can lead to a sense of isolation, nurses can advocate for healthy interactions and appropriate accommodations to reduce barriers for those with disabilities (Kim et al., 2023). External support is crucial, and this is where nurses can work to empower individuals and community members to create an atmosphere of inclusion and acceptance (Figure 42.2). Nurses can empower individuals to seek out opportunities for social engagement. By embracing their disability, individuals can seize opportunities to enlighten others about their diverse spectrum of abilities and share their unique experiences in navigating daily life with these distinctive attributes.

**FIGURE 42.2** A community group gathers together to celebrate and bring awareness about disabilities and rehabilitation. (modification of “06659jf39th National Disability Prevention and Rehabilitation Week Celebrationvf” by “Judgefloro”/Wikimedia Commons, CC0 1.0 PD)

### Prevalence of Disability

The prevalence of disability among U.S. adults is high, with up to one-fourth of the population experiencing some physical, cognitive, functional, or sensory disability (CDC, 2021). The most common disabilities are related to impairments in mobility (1 in 7) from disease states such as multiple sclerosis (MS), arthritis, or cerebral palsy and impairments in cognition (1 in 10) from disorders such as dementia, autism spectrum disorder (ASD), and brain injury (CDC, 2016). This proportion is higher in rural communities, with up to one-third of these populations experiencing disability, particularly multiple disabilities (CDC, 2021). People living in rural settings may also lack support services, have limited healthcare access, and experience barriers related to long-distance transportation. In adults older than 65 years, the incidence of disability increases to nearly 40 percent in the general population (CDC, 2020). The CDC also reports that in adults, disability is more prevalent in women, older adults, and those of low socioeconomic status (CDC, 2020). Interestingly, despite a higher rate of disability, older adults may have increased access to support services and healthcare programs compared with younger adults, due to federally funded insurance programs.

Statistics show that 17 percent of children from toddlers to teens (aged 3-17 years) live with a disability, and many live with more than one condition (CDC, 2021; Health.gov, 2020). These disabilities encompass all types of impairments; however, there has been a shift in prevalence from physical conditions to developmental and behavioral disabilities (Health.gov, 2020). Some recent reports suggest that nearly one-fourth of teens struggle with a mental, emotional, developmental, or behavioral disability that affects their daily lives (Cornell University, 2018).

### Multiple Disabilities

It is not uncommon for individuals to experience multiple disabilities simultaneously. Structural and functional impairments are often interrelated and create a wide range of disabilities; for example, a physical impairment associated with cerebral palsy may lead to a difficulty accessing buildings with stairs (Table 42.1). These may include sensory, mobility, self-care, and cognitive disability. Having multiple disabilities can affect individual activity levels as well as societal participation on many levels. Individuals may have difficulty performing day-to-day functions as well as accessing learning, employment, and healthcare opportunities in the community. Although disability does not equate to poor health, the CDC reports that individuals with disabilities have significantly higher rates of chronic illness as well (CDC, 2023). Specifically, individuals reporting at least one disability also have higher rates of depression, obesity, diabetes, and heart disease (CDC, 2023). Multiple disabilities can accumulate over time due to aging, injuries, or disease progression. Individuals may also have a simultaneous disability from a young age. These disabilities are typically related to conditions such as cerebral palsy, developmental delays, genetic disorders, intellectual disability, sensory impairments, and ASD.

Impairment	Possible Resulting Disability
An individual is deaf or has a significant hearing impairment	<ul style="list-style-type: none"> <li>• Cognitive</li> <li>• Self-care</li> <li>• Sensory</li> </ul>
An individual is blind, legally blind, or has a significant vision impairment	<ul style="list-style-type: none"> <li>• Mobility</li> <li>• Self-care</li> <li>• Sensory</li> <li>• Transportation</li> </ul>
A person has trouble concentrating, remembering, and making decisions, because of a mental condition	<ul style="list-style-type: none"> <li>• Cognitive</li> <li>• Independent living</li> <li>• Self-care</li> </ul>
A person struggles walking up and down stairs, maneuvering with an assistive device, has frequent falls related to physical weakness	<ul style="list-style-type: none"> <li>• Independent living</li> <li>• Mobility</li> <li>• Self-care</li> </ul>

**TABLE 42.1** Impairments and Disability

### Federal Legislation

Federal laws, legislation, and rules are in place nationally and in most states in the United States to protect and provide an atmosphere of inclusion for individuals with disabilities. These laws protect the rights of individuals with disabilities to receive equal opportunities for services, employment, transportation, education, and health care. Sections of the **Americans with Disabilities Act (ADA)**, initially signed in 1990, protect the rights of individuals with disabilities and prescribe requirements for appropriate accommodations. These accommodations are seen throughout the community in stores, hotels, schools, movie theaters, doctors' offices, and homeless shelters (U.S. Department of Justice, 2020). Federal legislation also mandates appropriate accommodations for communication through telecommunications relay services for those with hearing and speech disabilities. The ADA requires employers, schools, and places of business to provide accommodations such as:

- entrance for service animals
- furniture spacing
- interpreters
- ramps
- restroom modifications
- schedule flexibility
- screen reading and computer software
- video phones

In addition, multiple acts of legislation have been passed to ensure accommodations for voting access for individuals with disabilities, including assistance with filling out forms, accessing voting sites, and accessing electronic voting options. The **Individuals with Disabilities Education Act (IDEA)**, enacted in 1975, requires that all children with disabilities receive appropriate and free education through the public education system. The regulations require special education and outline guidelines for creating individualized education plans (IEPs) for children with disabilities.

## LINK TO LEARNING

---

IDEA requires that all children with disabilities receive an IEP as part of their inclusion in public school. This site details [the school nurse's role \(https://openstax.org/r/77SchoolNurse\)](https://openstax.org/r/77SchoolNurse) in creating an IEP.

---

### Categories and Types of Disability

Although not all individuals experience disability in the same way, recognizing specific categories of disability will help nurses anticipate possible barriers and better address the environment to accommodate specific impairments. The ADA regulations cover many disabilities and impairments caused by chronic or progressive conditions. Disabilities covered include sensory impairment, mobility impairment, intellectual disabilities, developmental disabilities, and cognitive disabilities. The ADA also includes specific medical conditions that may cause specific impairments as well as cancer, diabetes, post-traumatic stress disorder (PTSD), human immunodeficiency virus (HIV), autism spectrum disorder, epilepsy, and depression, among other conditions and illnesses.

Disabilities may be acquired throughout life, or an individual may be born with impairments that lead to disability. Depending on the underlying condition or cause, individuals may have one or multiple impairments contributing to disability.

## LINK TO LEARNING

---

Individuals with various disabilities struggle with digital accessibility, which creates significant barriers to communication and overall accessibility to information. The information at this link addresses [these difficulties \(https://openstax.org/r/77DigitalAccess\)](https://openstax.org/r/77DigitalAccess) and helps nurses adjust communication and education techniques.

---

### Sensory Disability

A **sensory impairment** includes any difficulty an individual has with one of their five senses. In contrast, **sensory disability** encompasses a broader range of limitations related to sensory processing and integration, affecting not only the reception but also the interpretation and response to sensory stimuli, potentially affecting various aspects of daily functioning. When an individual experiences loss of a sensory function, such as vision, the way they interact with the environment is affected. For example, when individuals gradually lose their vision, their reliance on other senses to receive information from the environment is often enhanced. Approximately one-half of individuals aged 75 years of older have hearing loss (NIDCD, 2024). Good hearing depends on a series of events that change sound waves in the air into electrical signals. The auditory nerve conducts these electrical signals from the ear to the brain through a series of steps. Age-related hearing loss (**presbycusis**) gradually occurs in most individuals as they age (Cheslock & De Jesus, 2023). Typically, low-pitched sounds are easiest to hear, but it often becomes increasingly difficult to hear normal conversation, especially over loud background noise. Hearing aids are commonly used to enhance hearing.

Vision impairment is also a common sensory impairment that can lead to disability. Specific impairments or vision disorders that affect vision include macular degeneration, cataracts, glaucoma, diabetic retinopathy, and **presbyopia** (loss of near vision).

Kinesthetic impairments, such as peripheral neuropathy, affect the ability to feel sensations. Symptoms of peripheral neuropathy include pain, burning, tingling, and numbness in the extremities that decrease a person's ability to feel touch, pressure, and vibration. Position sense can also be affected, making it challenging to coordinate complex movements, such as walking, fastening buttons, or maintaining balance when one's eyes are closed. Peripheral neuropathy is caused by nerve damage that commonly occurs in patients with diabetes mellitus or peripheral vascular disease. Physical injuries, infections, autoimmune diseases, vitamin deficiencies, kidney diseases, liver diseases, and some medications can also cause peripheral neuropathy.

Sensory impairments become disabilities when these impairments result in challenges and barriers to independence. Depending on the severity of the impairment, sensory disabilities require accommodations to assist individuals to function in their homes and the broader social environment. Individuals with sensory impairments are

at increased risk for falls and injury, so it is essential to encourage basic safety features in the environment, including adequate lighting, availability of handrails and grab bars, hazard-free walkways, and appropriate settings on water heater controls.

## PATIENT CONVERSATIONS

---

### Vision Impairment

**Scenario:** Joanna is an 81-year-old patient who lives next door to her daughter's family. She lives independently, continues to drive, and does her own grocery shopping, housework, and yard work. She presents to her primary care provider's office to discuss concerns about worsening eyesight. After the nurse, Summer, takes her vital signs, Joanna states she is worried that her family is going to take away her driver's license.

**Nurse:** Tell me why your family is worried about you driving.

**Patient:** I was diagnosed with macular degeneration a few years ago, but I'm starting to notice more trouble with my vision. I am mainly worried about not being able to get to my activities because my daughter is so busy shuttling her children to activities. I'm so used to being independent, but I don't want to get in an accident. I did hit our mailbox with my car a few weeks ago, pulling into the driveway.

**Nurse:** It sounds like you may also be worried about your driving ability, but you don't want to lose your independence, is that right?

**Patient:** Yes, exactly. I take my vitamins and eat healthy, but my eye doctor says this is not curable. I'm wondering what else I can do.

**Nurse:** Our community has an excellent public transportation system, and buses are small and have grab bars for getting on and off. Let's look at the map to see if it follows routes that would be helpful for you. Also, did you know that the community senior center offers a rideshare program?

**Patient:** I'm not sure I'll be able to afford the bus passes, but I'm interested in the rideshare program.

**Nurse:** Based on your vision impairment, the provider may be able to help with paperwork to get you discounted access to public transportation. I will start the paperwork and get you the rideshare contact information.

**Patient:** Thank you for your help. This helps me feel less afraid. It's hard enough to lose my vision slowly, but losing all my independence is just as hard.

---

### Physical Disability

A **physical disability** refers to any condition that limits a person's physical functioning or mobility. Physical challenges commonly affect an individual's mobility, often stemming from impairments in their legs, arms, or fingers. According to the CDC (2020b), mobility disabilities are the most reported disability in adults. Physical disabilities are five times as common in adults with low socioeconomic status than in those with higher incomes (CDC, 2020b). These impairments and resulting disabilities may be short or long term and may be temporary or permanent. Because movement is impaired to some degree, these individuals struggle with walking, navigating stairs, reaching, lifting, carrying, and gripping.

## LINK TO LEARNING

---

Learn more here about [how you can assist your patients with mobility disabilities \(https://openstax.org/r/77mobilitydisab\)](https://openstax.org/r/77mobilitydisab) to obtain a disability parking permit, including where to find applications and state-specific eligibility criteria.

---

Permanent mobility impairments may be static or progressive but do not improve over time. Nursing care for these permanent disabilities focuses on the management of associated disease factors, achieving the highest possible quality of life, and managing complications associated with physical impairment. Injuries, disorders, and diseases that may lead to physical disability include arthritis paralysis, amputation, spinal injury, muscular dystrophy (MD),

MS, cerebral palsy, and traumatic brain injury (TBI).

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### Quality and Safety Education for Nurses (QSEN) Competency: Teamwork and Collaboration

**Definition:** Function effectively in an interdisciplinary team, focusing on appropriate communication and individualized patient care.

**Knowledge:** Nurses must collaborate with a team of other providers when providing care for individuals with physical disabilities. Team members will depend on individual patient circumstances. This may include collaboration for individuals with acquired physical disability, disease-related progressive disability, or congenital physical impairments. A team approach will enhance patient care options and strengthen relationships with specialized providers such as physical, occupational, speech, and psychological therapists.

**Skill:** Nurses can be alert for signs of progressive physical impairment, new barriers to mobility, and challenges in coping with physical disability. The nurse can show leadership by advocating for additional therapies, updated mobility assistance devices, and mental health support. The nurse focuses first on the patient's needs and desires. Incorporating patient input empowers patients with a physical disability with autonomy and independence.

**Attitude:** Effective and positive communication techniques enhance the relationship between the healthcare provider, patient, and nurse, creating an atmosphere of collaborative support.

---

### Developmental Disability

A **developmental disability** (a condition due to an impairment in learning, language, behavior, or physical function) are often **congenital** (a condition present at birth) or develop during childhood and may be related to impairments from specific disorders such as ASD, cerebral palsy, Down syndrome, fetal alcohol syndrome and spina bifida. Developmental disabilities may also result from genetic disorders that are not known until later in childhood, brain injury, and intellectual differences. Developmental disabilities are those impairments that affect an individual's ability to develop along a standard childhood timeline. These disabilities may make it difficult for them to learn, grow, and progress intellectually at expected rates. The CDC reports that one in six children has a developmental disability (CDC, 2021). Developmental disabilities may be related to fetal injury or infections during a mother's pregnancy, to chromosomal conditions, or birth complications. Developmental impairments may also be associated with disorders such as attention-deficit/hyperactivity disorder (ADHD), attention-deficit disorder (ADD), hearing and vision problems, and learning difficulties.

Autism spectrum disorder is both a developmental and neurological disorder (NIMH, 2024). The CDC recognized ASD as affecting social functioning, communication, and maintaining appropriate behavior (CDC 2024a). The condition has many variations in symptoms and severity. Autism spectrum disorder can be difficult to identify through physical attributes, and the severity of ASD varies widely between individuals. The CDC states that ASD symptoms typically begin before the age of 3 years; however, they may not be noticed or identified until much later, even into adulthood (CDC, 2024a). Some individuals live and function independently, whereas others may need constant support. Common comorbid disorders include depression, anxiety, ADHD, and learning differences.

## REAL RN STORIES

---

### Autism Spectrum Disorder

**Nurse:** Cora, RN

**Clinical setting:** Behavioral health

**Years in practice:** 20

**Facility location:** Milwaukee, Wisconsin

I've worked as a behavioral health nurse in an outpatient behavioral health center for 15 years. I work with children, teens, adults, and families struggling with behavioral and mental health issues. In recent years, the number of

individuals with ASD has significantly increased. One of the most interesting changes I've noticed is the reaction and response of individuals who are diagnosed with ASD in adulthood. Many of these individuals have a less severe form of ASD, where they do not have intellectual or communication impairments. However, this does not mean they do not have trouble communicating.

I recall a 53-year-old woman named Jayda who first came to our clinic with concerns about anxiety. She reported difficulty maintaining relationships, working, and interacting with others in social situations. She often felt awkward and socially different. Upon further discussion, she reported a history of sensitivity to light, such as in stores with fluorescent lights, and sensitivity to loud noises and rapidly changing volume. She also reported difficulty with flexibility in performing job functions and tasks of daily life. She liked a particular routine and felt extreme agitation when things did not go as expected. After seeing the neuropsychologist at our office, she was diagnosed with ASD. During her subsequent visits, Jayda expressed her relief in understanding her differences. She felt empowered to take classes as a transcriptionist and started her own home-based transcription business. She was able to work with therapists in our clinic to improve her coping skills, which allowed her to seek social connections and eventually get married. By understanding her disorder and feeling heard by her healthcare team, she overcame her anxiety and found success.

---

### Cognitive Disability

A **cognitive disability** refers to a condition in which a person has limitations in cognitive functioning and adaptive behavior stemming from disorders in brain functioning. Disorders that can cause cognitive disability include TBI, stroke, or dementia. In the case of dementia, cognitive disability is progressive and causes greater difficulty for the individual, caregivers, and family over time. Nursing care focuses on maintaining safety, autonomy, and quality of life. Acute damage to the brain, such as stroke or TBI, causes variable levels of disability depending on the severity of the injury and the part of the brain affected. Due to the complexities of brain functioning, damage to the brain and cognitive disability may also be associated with sensory and physical disabilities.

---

### Intellectual Disability

An **intellectual disability** is a neurodevelopmental condition characterized by significant limitations in intellectual functioning and adaptive behavior, which manifest during the developmental period. These limitations affect areas such as reasoning, problem-solving, communication, and social skills, affecting an individual's ability to effectively navigate daily life and engage in age-appropriate activities. Intellectual disabilities share some commonalities with cognitive, developmental, and psychiatric disabilities. Intellectual disabilities are a type of developmental disability that affects cognitive rather than physical abilities. Intellectual disabilities such as ADHD, dyslexia, and other learning differences may affect one's behavior, ability to learn on an expected timeline, and function as expected in social situations. Intellectual disabilities may arise from congenital and genetic disorders such as Down syndrome, birth trauma, prenatal infections, or even infections in the neonatal period. Intellectual disabilities often become more apparent as the child ages.

### Psychiatric Disability

A **psychiatric disability** refers to a condition characterized by mental health challenges or disorders that significantly impact an individual's cognitive, emotional, or behavioral functioning, leading to difficulties in daily life and social interactions. Some mental health disorders may coexist with cognitive disorders, such as ASD, dementia, and brain injuries. Not all mental health disorders are disabilities. When mental health disorders begin to disrupt daily functioning at home, work, and in the community, disability may result. Examples of mental health disorders that can progress to a state of disability include eating disorders, PTSD, anxiety, depression, bipolar disorder, schizophrenia, obsessive compulsive disorders, and phobias.

Nurses must understand that psychiatric disabilities may have varying causes. For example, individuals may experience PTSD and anxiety related to childhood trauma, a car accident, or exposure to war. Triggers for these types of disabilities are highly dependent on each response. Two individuals experiencing the same traumatic event

may have vastly different responses; one person may develop disabling PTSD and anxiety, and the other may not. Substance abuse disorders may also trigger short-term or long-term disability in individuals, based on the severity of the substance use disorder and the presence of other mental health disorders.

Psychiatric disabilities may affect how individuals interact in school, the workplace, or social situations. They may affect sleep and cause a variety of other symptoms, such as agitation, trouble concentrating, suicidal ideation, and appetite changes. A mental health disorder becomes a disability when someone is unable to manage the symptoms of the disorder to maintain normal daily function.

### Acquired Disability

An **acquired disability** refers to physical, cognitive, sensory, or psychological impairments that occurs after birth, typically as a result of injury, illness, or environmental factors. Unlike congenital disabilities, which are present at birth, acquired disabilities develop later in life and can be caused by various factors such as accidents, trauma, infections, chronic health conditions, or degenerative diseases. These disabilities may vary in severity and can have significant impacts on an individual's functioning, independence, and quality of life. In injury-related disability, individuals experience a significant and often sudden change in functional ability. Examples of diseases and injuries that may result in acquired disabilities include head trauma, brain tumors, eye damage, ear damage, MS, stroke, amputation, musculoskeletal injury, emotional trauma, and severe infection.

Acquired disabilities may pose different physical and emotional challenges for individuals due to the significant change in their ability to function. These changes and perceived loss of function can result in a grief response. For individuals with progressive diseases, this can be an ongoing struggle to cope with declining function. Nurses not only must take care to address the functional aspect of an acquired disability but also the emotional impact the experience of loss has on an individual.

## 42.2 Healthcare Approach to Disability

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze different models of disability used in health care
- Identify barriers to health care for patients with a disability
- Explain how to ensure quality health care for people with a disability

Models of disability define disability in the context of healthcare access, social engagement, and interpersonal interaction. These models explain the effects of impairments, barriers, social stereotypes (widely held and oversimplified beliefs or ideas about a particular group of people or things), and environmental structures on an individual's access to health care. Understanding these models helps nurses ensure provision of quality health care through patient-centered and individualized care. A nurse's role in preventing discrimination is crucial in providing quality health care for individuals with disabilities. Identifying and reducing these barriers is a key action for nurses. These barriers may be encountered at any point during healthcare delivery and may fluctuate depending on each individual's needs and desires for their care. Nurses are essential in identifying ways to promote wellness for all individuals regardless of their disability status. Nurses serve as advocates for these patients and play an essential role in maintaining patients' autonomy in the presence of a disability.

### Models of Disability

Models of disability explain the social, emotional, and physical aspects of disability. These models explain how individuals with disabilities interact in social situations, how they cope with a disability, and how disability affects their quality of life. Models of disability also provide insight into how individuals without disability view disability, explain how a stereotype is formed, and explain social programs and regulations in place to safeguard individuals with disability. For nurses, models of disability can improve overall patient care for individuals with disabilities by framing the social, physical, and emotional challenges that these individuals face. By confronting stereotypes and social **stigma** (a negative attitude or incorrect belief toward a certain group of people) of disability, nurses empower their community to embrace individuals with differences and provide compassionate, inclusive care. Each model offers relevant ideas to help nurses, the public, and families understand the experience of and provide support for individuals with disabilities.

### Moral Model

The **moral model of disability** is a long-standing belief pattern that explains disability as a defect in functioning related to the individual's moral character. Traditionally, this model described individuals with a disability as weak and often having brought about the disability through some negative action or inherent weakness in their character. Although this model does not represent the current social acceptance of disability, some core aspects persevere in specific cultures and general society. Stigma related to obesity, drug addiction, and type 2 diabetes are examples of lingering beliefs in the moral model. For example, an individual in **recovery** who is receiving addiction treatment and remaining drug-free is covered under the ADA employment and disability benefits, but an individual who continues to use drugs or relapses into drug use after recovery is not (ADA National Network, 2024b). Overall, the moral model does not uphold inclusion, equality, or individual rights but rather blames the individual for disability and promotes stigma and negative social attitudes toward disability. By recognizing this model and associated stigma, nurses can better advocate for individuals with a disability.

## CULTURAL CONTEXT

### Ableism

The concept of **ableism** explains the adverse reactions that individuals without a disability have in response to encountering individuals with a disability. Unfortunately, these interactions can be negative, particularly if the able individual holds negative stereotypes toward those with disabilities. These stereotypes are often promoted through social conditioning and social norms, personality and educational factors, and negative moral beliefs about disability. Factors that contribute to ableism include the idea that disability must be cured and that disability is inferior to ability. Ableism may look like (Dunn, 2021):

- anxiety during encounters with individuals with a disability
- belief that individuals or their families are to blame for their disability
- concern over perceived contagiousness
- fear of disability or death
- misunderstanding the type or severity of disability
- negative attitudes toward individuals with disability

In addition to these behaviors, ableist language perpetuates negative perceptions of disability. Examples of ableist language include (Examples of ableist..., 2023):

- Using outdated terms like “handicap” or “handicapped” instead of current, respectful terms like “disability” or “disabled,” which can emphasize disadvantage and lack of agency.
- Describing people as “able-bodied,” which can imply that those with disabilities lack “able bodies” or lead less fulfilling lives; terms like “non-disabled” or “people without disabilities” are preferred.
- Using the phrase “suffers from” to describe a disability, which equates having a disability with a life of suffering; it is more accurate and respectful to say someone “has” a condition (e.g., “has diabetes”).
- Using “crazy” or “insane” to describe something undesirable or irrational, which can perpetuate negative stereotypes about mental health conditions.
- Focusing on limitations when discussing disabilities, such as saying someone “can’t see/hear/talk,” which highlights what a person is not able to do; instead, discuss disabilities neutrally and emphasize strengths when relevant.
- Using euphemisms like “special needs” or “physically challenged,” which can be patronizing; addressing disabilities directly (e.g., “a child with Down syndrome”) is more respectful and straightforward.

Although nurses cannot simply change cultural, social, or personal beliefs, they can strive to recognize ableism in their belief patterns and strive to provide inclusive and compassionate care that is free from the effects of ableism.

### Medical Model

The **medical model of disability** explains disability as a consequence of a trauma, illness, or congenital health condition that is out of the control of the individual. The medical model views disability as a problem stemming from a disorder within a body system (UCSF, n.d.). This disorder causes the individual to have physical or cognitive

abilities outside the established norm for age, gender, and demographic group. Medical diagnoses often guide the intervention and treatment processes in the medical model rather than focus on the individual's lived experience of disability. Therefore, interventions based on the medical model focus on identifying the cause of the disability, treating this cause, preventing complications, and, in some cases, curing the disability. The medical model also assumes that individuals with disabilities (Association of University Centers on Disabilities, n.d.):

- compare their functional level with that of others
- have problems associated with their disability
- must learn to cope with physical and cognitive differences
- must rely on experts for treatment and health
- need help and support from others

Although the medical model does have merits in working toward treating and curing disability to help individuals integrate into society, there is also a high potential for the creation of a stigma by assuming there is something wrong with individuals with a disability and that the disability needs to be fixed. Individuals with disability, particularly those with long-standing or congenital disability, may not see themselves as having a problem; rather, they accept their cognitive and physical functions for what they are and learn to move through life in a way that is normal for them. Consider an individual born with deafness. The medical model will try to apply assistive devices and create a hearing pattern closest to what is considered normal. However, individuals with deafness may not see treatment or cure as a path. They may accept their hearing impairment and use accommodations and specialized language to interact in society.

### Functional Model

The **functional model of disability** is closely related to the medical model and assumes a cause-and-effect relationship between a physical or cognitive deficit and limitations in daily function. The functional model of disability emphasizes the interaction between individuals and their environment, focusing on removing barriers and accommodating diverse abilities to promote equal participation and access. It considers disability as a social construct shaped by environmental factors, rather than solely focusing on individual impairments. The functional model focuses more heavily on the impairment caused by an underlying medical disease or condition and the way this impairment affects an individual ability to perform necessary daily functions. In contrast to the medical model, in which the medical condition itself is the focus of treatment, interventions, and support, the functional model focuses on impairments experienced by the individual, such as (UCSF, n.d.):

- difficulty with self-care activities
- impaired decision-making skills
- impaired mobility
- inability to live independently
- inability to work or produce income

### Rehabilitation Model

The **rehabilitation model of disability**, sometimes referred to as the functional limitations model, conceptualizes disability as a single impairment or a collection of impairments or deficits experienced by an individual that can be improved through rehabilitation. In this model, **rehabilitation**, or returning to a previous state of health, assumes that a disability can be cured or treated to bring an individual back to better health. This model focuses on restoring function and maximizing independence through medical interventions, therapies, and assistive devices. It views disability as a result of impairments that can be mitigated or managed through rehabilitation efforts. The goal of this model is to enable individuals to adapt to their impairments, learn new skills, and maximize their participation in various aspects of life. The rehabilitation model operates under the assumption that individuals have previously experienced little to no impairment. However, this premise may not be true for individuals with congenital impairments or progressive diseases leading to disability. This model also relies on the idea that specialized rehabilitation caregivers and specialists are necessary for the treatment and care of patients with disability. It may apply, however, to some individuals with acquired disability or impairments that are expected to improve over time, for example, in some instances of TBI, musculoskeletal injuries, and stroke.

### Social Model

The **social model of disability** focuses on disability in the context of the individual's physical and social

environment rather than on an individual bodily impairment. The social model explains limitations and difficulties experienced by individuals with disabilities due to environmental, social, and community factors (Association of University Centers on Disabilities, n.d.). In the social model of disability, the individual's physical condition is considered an impairment and becomes a disability when physical and social environments create barriers to functional life. Consider an individual with MS who uses a wheelchair and is attempting to enter a restaurant with a stairway at the entrance. In the social model, disability is viewed only because no alternate access (e.g., a ramp) is available, in contrast to a medical model view, which explains the disability in terms of the physical impairment of the individual causing the inability to climb the stairs. Although disabilities are seen as individual impairments in the medical and functional models, the social model views disabilities in a more generalized sense. This way, accommodations to buildings, educational platforms, schools, hospitals, and other public spaces can be equipped with accommodations that will benefit many people who struggle with similar barriers regardless of their specific disability.

### Biopsychosocial Model

The **biopsychosocial model of disability** views impairments as the interplay between medical diagnoses and associated impairments and societal barriers. This model combines ideas and concepts from the medical and social models of disability. In this framework, medical diagnoses associated with impairments are considered in conjunction with societal barriers that individuals with these impairments face. By incorporating both concepts, the biopsychosocial model creates a more comprehensive view of disability as experienced by the individual and within society. This theory was first proposed by George Engle in 1980 and is currently used as the framework for the WHO ICF (Petasis, 2019). By addressing the specific impairments of each individual and incorporating techniques to reduce societal barriers, individuals with a disability can experience more inclusion, fewer obstacles, and limited discrimination on a community level. The ICF model considers similar concepts as the biopsychosocial model, including (CDC, n.d):

- ability of individuals to participate in society
- activity limitations
- beliefs and attitudes about impairment (psychosocial)
- environmental factors that are obstacles to individuals with disabilities (social)
- impairments in body function and structure (biological)

### Barriers to Health Care

Depending on the type and severity of disability, individuals experience a range of barriers in seeking appropriate health care. Physical barriers, such as doorway width, counter height, unstable flooring, noise level, and text size, are common but may be unseen by an individual without a disability. Nurses can be perceptive in identifying possible physical barriers and eliminating these before people with disabilities encounter them. Additional barriers are related to stereotypes, negative attitudes, and intentional or unintentional discrimination. Although active discrimination is unlawful, more subtle stereotyping, prejudice, and negative interaction are encountered on an individual basis. Nurses or other healthcare professionals sometimes may not even recognize their own prejudice. Biases among healthcare professionals that may affect those with disabilities include

- lack of adjustable equipment (e.g., not having equipment that can be adjusted or modified to accommodate the specific needs of patients with disabilities, such as adjustable examination tables or chairs for patients who use wheelchairs or have mobility limitations)
- lack of staff to assist with accessing programs (e.g., healthcare facilities may offer various programs, services, or educational resources that could benefit patients with disabilities; however, if there is a lack of staff trained to assist individuals with disabilities in accessing and participating in these programs, patients may miss out on important opportunities for health promotion, education, or support)
- lack of staff to assist with mobility (e.g., patients may require help getting onto examination tables, navigating hallways, or using restroom facilities; when healthcare facilities do not have adequate staff trained to assist with these mobility needs, patients may experience delays in care or be unable to access necessary services)
- scheduling inflexibility (e.g., scheduling can be problematic for individuals who require additional time for appointments, due to mobility issues, transportation constraints, or medical needs; without flexible scheduling options, patients may face barriers in accessing timely healthcare services)
- use of inaccessible health education techniques (e.g., assuming all individuals can participate in hands-on

demonstrations or activities without considering how these may exclude individuals with physical disabilities; not integrating assistive technologies, such as screen readers or captioning services, into digital health-education materials for individuals with hearing impairments)

- use of **medical jargon** (technical, medical language) (e.g., medical terminology or complex language may be difficult for individuals with intellectual disabilities or cognitive impairments to understand)
- use of written educational information (e.g., relying on printed materials or presentations without providing accessible alternatives such as large print, Braille, or audio formats for individuals with visual impairments)

## LINK TO LEARNING

Increase your awareness of [stereotype threats \(https://openstax.org/r/77Stereotypes\)](https://openstax.org/r/77Stereotypes) in health care.

### Structural Barriers to Accessibility

Structural barriers to health care depend on rural versus urban settings, transportation options, and building layout. Specific structural barriers in and around healthcare facilities include narrow doorways, manual doors, high countertops, elevated exam tables, lack of bathroom grab bars, street curbs, stairways, and lack of public transportation. Structural barriers compound other limitations in healthcare access. These are often the last barriers encountered after an individual has overcome stereotypes and secured an available location to acquire healthcare services.

## PATIENT CONVERSATIONS

### ADA Compliant Barriers

**Scenario:** Zia is a 37-year-old patient who has recently moved to Wyoming with her family and is presenting as a new patient to a primary care clinic. She requires a wheelchair for mobility since a spinal cord injury 20 years ago left her without the use of her legs. She gives feedback on the functional barriers she encounters in the healthcare facility. Upon her arrival, the patient requested to use the bathroom to empty her indwelling urinary catheter bag. She was directed to the restroom and then into the exam room.

**Nurse:** Hi Zia, I'm Stephanie. I'll be checking you in and getting your vital signs today.

**Patient:** Nice to meet you, too.

**Nurse:** Do you have any specific questions for the healthcare provider today?

**Patient:** Not really. I am just setting up care so that I can continue my regular medications. I did have a little trouble using your restroom though. Do you have other patients that use wheelchairs?

**Nurse:** I'm sorry for that. What trouble did you have?

**Patient:** Well, I was able to maneuver into the bathroom, but it was very tight trying to turn around and get near enough to the toilet to empty my catheter bag. The trash can was on one side, and the wall was on the other. I managed okay, though. Also, I can tell that the sink is ADA compliant in height, but I couldn't reach the soap dispenser because I couldn't get close enough to that side of the sink.

**Nurse:** That's frustrating. Thank you for bringing this to our attention. The office staff, providers, and I will brainstorm some ways to remove these barriers. Do you have any specific suggestions? I know that this office was not ADA-compliant initially and had to be upgraded, but sometimes, it's the things that we can't anticipate that still pose a challenge.

**Patient:** It may help just to rearrange the trash can and consider a soap dispenser that can be mounted lower. Thank you for being receptive and listening to my concerns.

### Stereotypic Attitudes

A **stereotypic attitude** is a fixed, oversimplified, and generalized perception of individuals in a specific demographic

group that stems from internal and external biases. Although stereotypes are the generalizations themselves, stereotypic attitudes are the individual perceptions or responses influenced by those generalizations. The term **internal bias** refers to individual thinking patterns that affect how an individual person views and treats others. An **external bias** is based on societal attitudes and cultural beliefs but also affects how others treat individuals. Stereotypes contribute to discrimination, both unintentional and overt, as well as stigma and prejudice. Unfortunately, stereotyping often leads to **prejudice**, in which an individual, even a healthcare provider, makes a judgment or opinion about a person with a disability before obtaining knowledge of their circumstance. These prejudices may be based on prior personal interactions, cultural perceptions, or lack of knowledge. Stereotyping and prejudice lead to stigma related to disability. A common stereotype of individuals with disabilities is the assumption that disability parallels a poor quality of life. In addition, some individuals see disability as an unhealthy state. Stigma may also affect the way individuals with disabilities perceive themselves within a social environment. Stigma leads to labeling and can harm the mental health of individuals with disabilities if care providers do not take special care to address and reduce stigma. Nurses must provide inclusion and support without overcompensating and contributing to the additional stigma of overdependence.

Stigma and stereotyping can lead to both internal and external consequences, such as social avoidance, internalizations, shame, discrimination, blaming, and violence. In contrast, individuals with disabilities who feel empowered may find strength in positive interactions, including diversity pride, social integration, acceptance, patience, inclusion, and education.

The most important role of the nurse in recognizing, preventing, and avoiding stereotypes and bias is advocating for patients. Nurses must strive for an atmosphere of respect. In developing an attitude of advocacy, the nurse tries to deeply understand the patient experience, with empathy and compassion, and build a framework of care and planning around this.

### Lack of Access

Lack of access may occur on a small or large scale. Individuals may encounter inaccessibility or trouble with communication at one facility or on a systemic level in a community without updated infrastructure and funding to provide these updates. Specific access concerns include living environment, transportation, and information access.

Transportation barriers may be associated with inaccessible vehicles, lack of public transport, lack of affordable transportation options, and inclement weather–associated issues. These may be affected by urban versus rural living, because rural-living adults experience significantly more physical barriers to care than their urban-dwelling counterparts (RHIfhub, 2024). Another important factor that affects individuals' willingness to seek health care is financial security. Individuals who are uninsured or **underinsured** with a lack of adequate health insurance often delay seeking healthcare treatment until dire circumstances require entry into the healthcare system. Although disabilities are not rare overall, many conditions with associated disabilities are rare. This may limit individual healthcare providers' knowledge of specific conditions. This can be overcome by healthcare provider education, but initial encounters may present a barrier to care for these individuals.

### Quality Health Care for People with Disability

Individuals with disabilities encounter persistent and repeated barriers to functionality, quality of life, and even health care. Nurses must ensure that all patients receive quality health care regardless of their functional ability. Rules and regulations help ensure fair and quality care for everyone. The Centers for Medicare & Medicaid Services (CMS) Office of Minority Health aims to ensure that individuals with disabilities receive quality care with the fewest barriers to care (CMS, 2024).

These barriers are addressed in a multifaceted way to create improved overall access through accommodations and health insurance coverage. Communication must be maximized to promote individualized and streamlined care, appropriate physical accommodations, and effective interpersonal interactions. Patients with disabilities who experience quality health care feel a sense of empowerment and control in their care. By providing compassionate and equal care to individuals regardless of disability type, nurses advocate for ongoing, accessible care and reduce disparities in health and healthcare access.

Nurses are primary advocates for patients with disability. Advocacy empowers all healthcare team members to include the healthcare consumer in care decisions. Advocacy also embraces diversity, equity, inclusivity, health

promotion, and health care for diverse patients, including those with disabilities. By understanding federal regulations that affect patients with disabilities, nurses promote policies, regulations, and legislation to improve healthcare access and delivery of health care.

### Communication Strategies

Individuals with disabilities have legal rights to accessible care. This care must include appropriate communication to provide the individual with a treatment plan and health recommendations that they can understand. Using person-first language, such as referring to “individuals with disabilities” rather than labeling them by their disabilities, emphasizes their personhood and dignity (CDC, 2022). For instance, it is best to say an “individual with diabetes” instead of a “diabetic patient,” as this approach emphasizes their identity as a person first, with diabetes being only one aspect of who they are. For individuals with intellectual disabilities, treatment, and care planning may directly involve a caregiver or family member. However, many people with disabilities live independently and manage their own health care and daily lives.

Regardless of whether a disability is sensory, intellectual, or physical, appropriate communication is critical. Some effective communication strategies are universal and can be applied to individuals with varying impairments. Other disabilities, such as vision and hearing impairment, or developmental, cognitive, or intellectual disabilities, require specific communication techniques and accommodations ([Table 42.2](#)).

<b>General communication techniques</b>	<ul style="list-style-type: none"> <li>• Allow extra time for movement during an exam if mobility is an issue.</li> <li>• Ask before providing physical assistance.</li> <li>• Ask how people prefer to communicate (NLN, 2017).</li> <li>• Maintain a normal tone of voice.</li> <li>• Make eye contact.</li> <li>• Sit at eye level.</li> <li>• Speak directly to the individual even if a caregiver is participating in care.</li> <li>• Respect the personal space of the individual.</li> <li>• Use active listening.</li> </ul>
<b>Communication techniques for patients with vision impairment</b>	<ul style="list-style-type: none"> <li>• Be specific in offering directions.</li> <li>• Ensure the patient has an assistive device (e.g., glasses) if one is required.</li> <li>• Face the person when speaking.</li> <li>• Respect companion or service animal boundaries.</li> </ul>
<b>Communication techniques for patients with hearing impairment</b>	<ul style="list-style-type: none"> <li>• Ensure the patient has an assistive device (e.g., hearing aids) if one is required.</li> <li>• Face the person when speaking.</li> <li>• Repeat yourself, if necessary</li> <li>• Speak clearly and as slowly as necessary.</li> </ul>
<b>Communication techniques for patients with developmental, cognitive, or intellectual disabilities</b>	<ul style="list-style-type: none"> <li>• Allow time for questions.</li> <li>• Ask open-ended questions, but only one question at a time.</li> <li>• Avoid making assumptions, such as about reading ability.</li> <li>• Base communication style on the person’s preference (NLN, 2017).</li> <li>• Be flexible in communication.</li> <li>• Clarify what is said and what is heard.</li> <li>• Limit the number of directions given at one time.</li> </ul>

**TABLE 42.2** Communication Techniques for Empowering Interactions

Qualified sign language interpreters, assistive listening devices, and Braille or large-print reading material are other possible accommodations for these sensory disabilities. Ensuring that an interpreter is accessible is required by law.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Patient-Centered Care: Hearing Impairment

**Definition:** Recognize the importance of treating patients as partners in their care by considering their values, needs, and preferences.

**Knowledge:** Individual preferences vary about the management of hearing impairment. Respect for individual preferences is crucial. Depending on the severity of their hearing impairment, individuals may use a variety of accommodations to assist in communication, such as:

- assistive listening devices
- auditory implants
- digital translators
- hearing aids
- in-person sign language translator
- lip reading
- sound amplification devices
- written communication

**Skills:** Communication between nurses and patients with hearing impairment should be agreed upon before engaging in important clinical conversations about care. Federal law requires reasonable accommodations to enhance communication for these individuals. The nurse must recognize the need for an accommodation to ensure patient understanding during the clinical encounter.

**Attitudes:** Patients and family members must understand their care and treatment plan to ensure positive health outcomes.

---

### Accessibility of the Health Care Facility

All individuals, despite their physical, cognitive, or psychological ability level, have the right to access safe, quality health care in their community. Full and equal access for all individuals is required by law under the ADA. This encompasses physical accessibility, appropriate communication, and other reasonable modifications to ensure access by all. All healthcare facilities, including hospitals, outpatient primary care and specialty clinics, pharmacies, and dental practices, must comply with ADA rules for providing accommodations. In addition to the ADA regulations, legislation is in place to maintain the accessibility of health care for individuals with disabilities. The **Rehabilitation Act** protects individuals against discrimination based on disability at any federally funded facility or any facility receiving federal financial assistance. This includes many hospitals, clinics, and ancillary healthcare facilities. Although they are not held to stricter requirements, healthcare facilities must ensure accommodations similar to that provided in other public spaces. The U.S. Department of Justice upholds enforcement to ensure that requirements are met.

### Accommodations

In some cases, policy modifications may be necessary to accommodate individuals with a disability, such as allowing a companion to accompany the patient into a procedure for assistance and allowing for service animal access. Adjusting schedule flow and timing to accommodate psychological impairments such as anxiety is another possible accommodation. Accessible health care also includes allowing for and ensuring adequate digital access to records. Creating options for video telehealth and telephonic visits, as appropriate, for individuals with a significant disability that limits their ability to present in person for healthcare evaluation is crucial. Facility accessibility focuses primarily on physical aspects of the building environment and includes the following specific factors outlined by the ADA (ADA National Network, 2024a):

- appropriate width of doorways and passages
- dedicated disability-accessible parking spaces
- lever-style door handles
- wheelchair-accessible bathrooms with grab bars ([Figure 42.3](#))
- wide and clear pathways through the facility

This may mean that facilities make changes to improve physical access, such as installing ramps, revising entry and doorways to comply with ADA requirements, or providing an alternative entrance.

**FIGURE 42.3** A community park provides an ADA accessible bathroom and a pool access chair for individuals with disabilities. (credit: modification of “Pool access chair in accessible toilet, Runcorn Swimming Pool, Runcorn DSCF6197” by John Robert McPherson/Wikimedia Commons, CC0 1.0 Public Domain)

The concept of universal design emphasizes an inclusive approach to structural building and design. Instead of adding accommodations after the structural design, a universal design begins with a plan to make the environment accessible and functional for most individuals. Due to building age, this idea may only be standard in some healthcare buildings. However, it is essential to consider accessibility when creating new spaces, upgrading medical buildings and environments, and considering community infrastructure upgrades (CMS, 2017).

### Federal Health Insurance Program

Several federally funded health insurance programs cover individuals with a disability. Federally funded insurance programs that cover individuals with disability include Medicare, Medicaid, and Social Security disability. Individuals who qualify for Social Security Disability Income, based on their qualifying disability, are candidates for federal Medicare insurance coverage after a 24-month waiting period. Depending on the income level of the family or individual, Medicaid or other private insurance options are available. Federal rules and regulations protect individuals with a disability from discrimination by insurance companies based on their disability. The Affordable Care Act created a variety of changes to protect individuals with disabilities, including (Health.gov, 2020):

- health insurance provisions to eliminate discrimination
- prohibition of denial of coverage for preexisting conditions
- regulations on accessibility of facilities

Because individuals with disabilities may require prolonged treatments or support, having health insurance coverage is essential. Access to care, quality of care, and long-term outcomes are directly related to an individual's ability to access health care financially.

## 42.3 Chronic Disease and Chronic Illness

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Define chronic disease and chronic illness
- Recognize the prevalence and causes of chronic conditions
- Explain different categories of chronic conditions

Chronic disease and chronic illness are prevalent in our society. Nurses must understand the definitions and types of chronic conditions and recognize the social implications that these conditions have for individuals. The prevalence of different chronic diseases varies by age, location, family circumstance, social environment, and lifestyle choices.

By understanding categories of chronic conditions, nurses can understand the correlation between disease states. They can promote health in individuals regardless of the type or number of chronic conditions the individuals experience. An understanding of various chronic conditions enables nurses to recognize changes in patient health that may require further healthcare provider evaluation and treatment to prevent the progression of disease or complications.

## Definitions

The terms **disease** (a disorder within the body that is identifiable as a medical condition) and **illness** (the perceived experience of a disorder within the body) are often used interchangeably. This is true in the lay population and the medical community. There is ongoing debate about the classification of these terms and whether human disorders should be referred to as diseases or illnesses. An enduring explanation differentiates chronic disease and illness by medical classification and personal experience, respectively (Martin, 2007).

Nurses must understand the subtle differences between chronic disease and chronic illness to provide compassionate and individualized care. A working definition of health is crucial in understanding disease and illness, providing patient care, and working in a collaborative relationship with other medical professionals. The World Health Organization (WHO) suggests that in a state of health, an individual experiences well-being in physical, mental, and social aspects of their life (WHO, n.d.). Because this definition of health focuses on individual well-being, it is also important to realize that it is more than simply the absence of disease. Health and illness exist on a continuum, with many factors playing a role in an individual's experience of illness or health. In real-world applications, health may not be the complete absence of disease. Individuals who live with one or more chronic diseases may experience a high level of emotional, social, physical, or overall health. For example, an individual with social anxiety disorder may have excellent physical health, a strong social network, and stable emotional patterns stemming from active coping mechanisms such as physical exercise, individual and group therapy, and active participation in social support groups. Chronic disease and chronic illness can be grouped together as a collection of chronic conditions that have overlapping causes as well as treatments.

## Chronic Disease

Long-standing definitions describe **chronic disease** as a state of being that includes a biomedical disease (Martin, 2007). The CDC classifies a disease state as chronic when a condition lasts 1 year or longer. Although disease presentations and circumstances vary widely between individuals, most chronic diseases require ongoing medical treatment and intervention and may affect a person's ability to perform daily activities (CDC, 2022a). Several diseases affect individuals over an extended period and are considered chronic. Common chronic diseases in the United States include heart disease, hypertension (HTN), epilepsy, stroke, mood disorders, cancer, diabetes, asthma, chronic obstructive pulmonary disease (COPD), arthritis, dementia, psoriasis, osteoporosis, obesity, autoimmune disorders, and chronic pain.

Some chronic diseases are preventable based on lifestyle factors. Although there is some debate regarding whether a **communicable disease** passed from person to person is a chronic disease, most definitions include these conditions. Examples of communicable diseases that may be considered chronic diseases are HIV and acquired immunodeficiency syndrome (AIDS), malaria, and hepatitis C. Chronic diseases typically develop over a prolonged period, sometimes without overt symptoms. Chronic diseases are often implicated in the onset of more acute health complications. Others are hereditary or genetic without any other identifiable cause. Chronic diseases may have an identifiable cause, such as epilepsy, diabetes, and asthma. In others, it may be challenging to identify a specific cause. Some chronic disease states are modifiable with lifestyle and treatment modalities. Chronic diseases typically are not cured by medical treatment but may be modified to an extent to create a remission, reduction, or disappearance of symptoms of a disease. Other conditions, disorders, and syndromes may meet some criteria of chronic disease but more commonly contribute to or result from chronic disease states ([Table 42.3](#)).

Chronic Condition	Contributes to	Results from
Dental caries	Chronic pain Infection	Diabetes Inflammatory bowel disease Malnutrition Sjögren disease
Grief	Anxiety Depression Insomnia	Cancer Terminal disease
Malnutrition	Anemia Diabetes Heart disease Infection Osteoporosis	Cancer Dementia Inflammatory gastrointestinal disease
Sarcopenia	Osteoporosis Type 2 diabetes	Chronic lung disease Obesity Rheumatoid arthritis

**TABLE 42.3** Conditions That Contribute to and Result from Chronic Diseases

### Chronic Illness

In contrast to chronic disease, **chronic illness** describes an individual's experience with a chronic condition. Chronic illness may result from the onset or progression of a chronic disease. The outward expression of chronic illness is seen in the way individuals live and cope with chronic disease and the disruptions it causes in their daily activities. Individuals can have many symptoms of chronic illness, depending on the associated disease process. Symptoms may include fatigue, weakness, pain, headaches, negative self-image, social withdrawal, inability to work, decreased physical function, stress, mood disorders, anxiety, sleep disturbance, and cognitive changes.

There can be an overlap in some symptoms of certain chronic diseases and chronic illnesses. For example, an individual may experience migraine headaches as an independent chronic disease or as a symptom associated with chronic illness. These headaches may progress over time and create dysfunction in many aspects of life. Another individual may experience headaches as part of chronic illness experiences in response to a cancer diagnosis. These headaches may be caused by stress or treatment or may have a biophysical cause. Regardless of the cause of the symptoms, they are usually treatable and can often be modified with lifestyle modifications.

### Prevalence of Chronic Conditions

Chronic conditions are prevalent in the United States. The CDC (2022b) reports that up to 60 percent of adults have one chronic disease. Because chronic diseases such as heart disease, stroke, cancer, and diabetes are so prevalent, these diseases also represent the leading causes of death and acquired disability. Care, treatments, and interventions for the most common chronic conditions make up the majority of healthcare costs in the United States. The CDC reports that 90 percent of healthcare costs annually are spent on diagnosing and managing these chronic conditions (CDC, 2022b). Disease cost estimates also include the cost of lost productivity and income due to the inability to perform work functions due to chronic conditions. Rates for chronic conditions are staggering ([Table 42.4](#)). The high prevalence of common behavioral risk factors for these conditions, such as sedentary lifestyle, tobacco use, and unhealthy nutrition habits, suggests a continued or increasing disease prevalence over time (Rus et al., 2023).

Chronic Condition	Prevalence among U.S. Adults	Annual Cost
Arthritis	25% (58.5 million)	\$303 billion
Cancer (all types)	2 million people (annual diagnosis rate)	\$185 billion
Cardiovascular disease (heart disease and stroke)	50% (121 million)	\$407 billion
Diabetes	11% (37 million)	\$327 billion
Epilepsy	3.5 million	\$8.6 billion
Obesity	42% of adults 20% of children	\$173 billion
Pain	20% (100 million)	\$560 billion

**TABLE 42.4** Prevalence of Common Chronic Conditions in the United States (Sources: AHA, 2019; CDC, 2022b, 2023a, 2023b.)

### Causes of Chronic Conditions

Chronic conditions may result from a discrete cause or have a complex causality. Multiple factors often lead to single or multiple chronic conditions. Many chronic conditions arise from a few detrimental lifestyle factors, including tobacco use, secondhand smoke exposure, improper nutrition, sedentary lifestyle, and substance use disorders (CDC, 2022b). Genetic or hereditary factors are also responsible for certain chronic diseases. A family history of specific disorders puts an individual at a higher risk for these same chronic conditions. Some conditions are directly linked to specific genes that increase an individual's risk, such as genes associated with colon and breast and ovarian cancers. Other chronic conditions may result from environmental exposures, infectious disease, and complications from injuries. Many chronic conditions have an overlap in symptoms, pathophysiology, and cause. One chronic disease may contribute to the onset or worsening of another.

### Multiple Chronic Conditions

The CDC (2022b) reports that up to 40 percent of adults in the United States have two or more co-occurring chronic conditions. These conditions may stem from the same cause or risk factors or develop independently. In addition, some chronic conditions create secondary disorders that, over time, develop into additional chronic conditions. Consider an adult with obesity who develops type 2 diabetes; over time, this individual may experience the effects of diabetes, with impaired kidney function, heart disease, peripheral vascular disease, or retinal damage. Studies indicate that women, non-Hispanic White adults, older adults, and those adults receiving public insurance have higher rates of multiple chronic conditions (Boersma et al., 2020). The interaction between multiple disorders is responsible for many interrelated symptoms and **comorbid medical conditions** (multiple medical conditions that are simultaneously present). Because of this interplay of symptoms, it is sometimes difficult to differentiate or treat conditions separately.

### LINK TO LEARNING

Increase your awareness of [metabolic syndrome \(https://openstax.org/r/77MetabolicSynd\)](https://openstax.org/r/77MetabolicSynd) by watching this video. Metabolic syndrome is a cluster of comorbid conditions that significantly increase a person's risk of stroke, heart disease, and type 2 diabetes.

### Categories of Chronic Conditions

Chronic conditions are broadly categorized by type of disease and the organ system most affected. However, many chronic conditions affect multiple organ systems directly or indirectly. Treatments and interventions for one condition may negatively affect another chronic condition or create problems in associated organ systems. For example, radiation treatment for cancer may cause circulatory problems, chronic pain, or cognitive issues,

depending on the location of treatment. Many chronic conditions overlap; for example, an individual with diabetes has a high risk of developing progressive kidney damage and, ultimately, chronic kidney disease (CKD).

### Cancers

Cancers affect individuals of all ages, with the prevalence of different cancer types varying by age, demographic, and risk-exposure group. Although known risk factors for certain cancers are predictable, it is impossible to predict which individuals will develop cancer during their lifetime. Cancers are highly variable in their onset, progression, and treatment response. So many different factors play a role in the components of this disease. Although some cancers are more common in children and young adults, advancing age is the most significant risk factor for developing many types of cancer. In addition, the common risk factors for all chronic diseases also correlate with cancer risk, such as tobacco use, lack of physical activity, poor nutrition, and obesity.

## PATIENT CONVERSATIONS

---

### Living with Cancer

**Scenario:** Sonja is a 67-year-old female who works part-time as a grocery store clerk. She lost both her mother and sister to breast cancer. She was devastated 2 years ago when she was also diagnosed with breast cancer. During her follow-up visit to her primary care provider's office, she expressed a sense of gratitude for the new cancer treatments that allow her to "live with cancer."

**Nurse:** Hello, Sonja. It's been a while since we saw you for a wellness exam.

**Patient:** Yes, I have seen my specialist so many times over the past 2 years for testing and treatment that I figured I didn't need another doctor visit.

**Nurse:** How is your treatment progressing?

**Patient:** I am feeling really well. I am past my initial surgeries and radiation treatments. Now, my oncologist tells me I am just "living with cancer." He says that because of these new treatments, cancer can now be considered a chronic disease.

**Nurse:** Tell me your maintenance medication regimen, and I will update your medication list.

**Patient:** I take a hormone therapy pill, and I go in every 3 weeks to the infusion center for a maintenance infusion. My job is to eat healthily, move my body, and continue health maintenance. That's why I'm here!

**Nurse:** I'm glad you are doing so well. Your healthcare provider will be in shortly to discuss additional health screening options and perform a wellness exam.

---

### Cardiovascular

Cardiovascular diseases (CVDs) encompass many disorders and are the leading cause of death. These conditions affect the heart and blood vessels, including large vessels and tiny capillaries. These conditions compound one another to create a progressively higher risk for acute disease and death. Common chronic diseases associated with the cardiovascular system include HTN, hyperlipidemia, coronary artery disease, peripheral vascular disease, heart failure, valvular disease, and atrial fibrillation.

Although CVD risk may be familial, poor lifestyle choices significantly increase an individual's risk of developing CVD. In particular, a sedentary lifestyle and poor nutritional choices contribute significantly to plaque buildup in large vessels, leading to coronary artery disease. Other lifestyle factors that increase CVD risk include smoking and excessive alcohol use. Because of the effects of CVD on the vessels and heart, acute damage to these organs can occur and have a high risk of mortality and morbidity. These acute diseases include stroke, heart attack, aneurysm, and heart valve disease.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Evidence-based Practice

**Definition:** Describe reliable sources for locating evidence reports and clinical practice guidelines.

**Knowledge:** Nurses must distinguish between clinical opinion-based reports and those referencing clinical evidence and research summaries. Because nurses provide most patient education on CVD and associated conditions and risk factors, they must continually review recommendations that guide clinical practice. Focusing on guidelines from the American Heart Association, reviewing evidence-based reports on new treatment options, and familiarizing themselves with outcome goals gives nurses an advantage in providing the most up-to-date care for their patients.

**Skill:** Nurses can be alert for progressive changes in biomarkers such as serum lipid tests, blood pressure changes, edema, and subtle chest pain. The nurse can empower their patients to pursue lifestyle modification by providing clinical education based on evidence-based data that clearly show the benefit of these actions. Depending on patient motivation and health literacy, nurses can adjust the level and depth of teaching while still promoting evidence-based practice. The nurse focuses on patient needs and concerns while incorporating contemporary treatment guidelines to fit the individual patient's circumstances.

**Attitude:** A focus on evidence-based practice enhances the nurse's professional presence, promotes the best outcomes for patients, and guides patient-centered care.

---

### Cognitive

Chronic cognitive disorders are those disorders that affect the thinking process, memory, and brain processing. Cognitive disorders may be acquired from trauma or stroke, or may result from mental health disorders. Common cognitive disorders include TBI, stroke, dementia, Alzheimer disease, and Parkinson disease.

Cognitive impairments may also be seen in individuals with other chronic disorders that affect oxygenation. There is some overlap between cognitive disorders and neurological disorders. Aging may also be associated with some cognitive decline, such as mild cognitive impairment, and compounded with other chronic conditions. Cognitive disease in younger individuals may result from early-onset dementias as well as TBI. Although most TBIs are related to an acute event, repetitive brain injury is associated with long-term effects that may cause lasting and significant impairments in brain function (CDC, 2024). Cognitive impairments may also arise secondarily to primary benign or cancerous brain tumors or tumors associated with cancer metastases.

## LINK TO LEARNING

---

Increase your awareness of [chronic traumatic encephalopathy \(https://openstax.org/r/77encephalopath\)](https://openstax.org/r/77encephalopath), which is an acquired chronic cognitive condition that can develop from repeated head injuries or concussions, which occur often in athletes.

---

### Mental Health

Although some mental health disorders present as an acute change in psychiatric stability, many mental health disorders are considered chronic conditions. Chronic mental health conditions include generalized anxiety disorder, social anxiety disorder, PTSD, depression, obsessive-compulsive disorder, bipolar disorder, schizophrenia, borderline personality disorder, and eating disorders.

Mental health disorders can be present in the absence of any other physical health conditions or can be triggered by these conditions. In addition, some mental health disorders are exacerbated or triggered by other chronic disorders, such as depression and anxiety. Nurses must address these topics with compassion and respect, thereby erasing the stigma that has been present historically regarding mental health disorders. Although there is often overlap in mental health conditions, treatment is undertaken by addressing each specific component. Mental health professionals, counselors, primary care providers, and nurses all play a role in maintaining health and quality of life

in individuals with chronic mental health disorders.

### Immune System

Chronic immune disorders originate in the immune system but can affect nearly all organ systems in the body. The immune system performs many functions in protecting the body and preventing illness. Disorders of the immune system can lead to specific conditions as well as the inability of the body to fight infection. Immune disorders can be classified into three major categories: immunodeficiency disorders, overactive immune disorders, and autoimmune disorders.

An **immunodeficiency disorder** is a condition or disease that is caused by a weakened immune system that impairs the body's ability to fight off disease or infection. Immunodeficiency disorders can be congenital or acquired (resulting from exposure to a toxin or pathogen, such as HIV). Congenital immune disorders are often present at birth and are uncommon in the general population. Acquired immune deficiency disorders are much more common. Viruses, medications, and medical treatments trigger chronic immune deficiency disorders. Examples of acquired immune deficiency disorders include AIDS, cancers of the immune system, and multiple myeloma. Immune deficiency can also be triggered by toxins introduced into the body, as with smoking, alcohol consumption, and poor nutrition.

An **overactive immune disorder** occurs when the immune system develops a hyperresponse to normally harmless environmental substances. These are often more common disorders and are typically much easier to identify and treat. These disorders cause symptoms commonly experienced as breathing disorders, skin reactions, and nasal congestion. Some of these conditions include asthma, eczema, allergic rhinitis, and anaphylaxis.

An **autoimmune disorder**, or a rheumatological condition, arises from the body's immune system attacking and damaging its cells and organs. Autoimmune disorders may be challenging to diagnose and have various presenting symptoms related to general inflammation in the body. These symptoms may include joint pain and damage, rash or other skin disorders, organ dysfunction, dry mouth, metabolic abnormalities, and chronic pain.

Specific autoimmune disorders can be diagnosed through clinical evaluation and blood testing. Autoimmune disorders affect various organs in the body, causing persistent and sometimes progressive damage, mainly if not treated ([Table 42.5](#)).

Autoimmune Disorder	Organ System Affected
Celiac disease	Gastrointestinal
Inflammatory bowel disease	Gastrointestinal
Pernicious anemia	Blood cells
Rheumatoid arthritis	Musculoskeletal (joints)
Systemic lupus erythematosus	Systemic, multiple organ systems
Thyroiditis	Thyroid
Type 1 diabetes	Pancreas, metabolism

**TABLE 42.5** Autoimmune Disorders and Organ Systems

### Endocrine

The endocrine system is spread among multiple organs and glands throughout the body ([Figure 42.4](#)). Because the endocrine system affects many organ systems simultaneously, an intricate balance is necessary to maintain health.

**FIGURE 42.4** The endocrine system is a complex system spread throughout the body. (modification of “Blausen 0345 EndocrineSystem Female2” and “Blausen 0346 EndocrineSystem Male2” by “BruceBlaus”/Wikimedia Commons, CC BY 3.0)

Endocrine disorders are associated with hormone production and use within our bodies. Complex interactions between hormones produced by endocrine organs throughout the body affect metabolism. Examples of these complex interactions include sleep, reproduction, digestion, glucose metabolism, blood pressure, fluid balance, temperature regulation, and appetite (Table 42.6).

Organ/Gland	Location	Endocrine Action	Chronic Disorders
Adrenal glands	Abdomen	Blood pressure Blood sugar regulation Electrolyte balance Heart rate Sleep-wake cycle Stress response	Addison disease Cushing syndrome Pheochromocytoma
Hypothalamus	Brain	Appetite and thirst Blood pressure Body temperature Mood Sex drive Sleep-wake cycle	Diabetes insipidus Hypopituitarism

**TABLE 42.6** Endocrine System

Organ/Gland	Location	Endocrine Action	Chronic Disorders
Ovaries/testes	Pelvic	Reproduction	Amenorrhea Erectile dysfunction Infertility Polycystic ovarian syndrome
Pancreas	Abdomen	Food digestion Glucose regulation	Diabetes Pancreatitis
Parathyroid glands	Neck	Calcium, phosphorus, and magnesium regulation in blood and bones	Hypoparathyroidism Osteopenia
Pineal Gland	Brain	Sleep-wake cycle	Sleep disturbance
Pituitary gland	Brain	Growth Metabolism Reproduction	Acromegaly Cushing disease Prolactinoma
Thymus	Chest	Pubertal changes T-cell maturation and specialization	Myasthenia gravis Pure red cell aplasia
Thyroid gland	Neck	Bone maintenance Heart function Metabolism Muscle function	Graves disease Hashimoto thyroiditis Hyperthyroidism Hypothyroidism

**TABLE 42.6** Endocrine System

Many endocrine disorders can be discovered by evaluating blood tests for hormone under- or overproduction. Because symptoms of endocrine disorders may be subtle and similar, nurses must maintain diligence in recognizing possible signs of endocrine dysfunction.

## REAL RN STORIES

### Polycystic Ovarian Syndrome (PCOS)

**Nurse:** Ayla, RN

**Clinical setting:** Women's health clinic

**Years in practice:** 24

**Facility location:** Kentucky

I've worked as a women's health nurse for 22 years. While doing clinical rotations at an OB-GYN [obstetrician-gynecologist] office during nursing school, I knew this was my calling. During that clinical rotation, I finally understood what was "wrong with me." Since puberty, I have struggled with being overweight, irregular menstrual cycles, unwanted hair growth on my body, and severe acne. My family was not very open about discussing our bodies or health concerns, and I was too afraid to seek out help elsewhere. During my clinical rotation, I heard people describing the same symptoms. The difference was that they were seeking care and receiving a diagnosis. I asked my preceptor questions, and she encouraged me to make an appointment with one of the providers in the clinic for a formal evaluation.

I was terrified when I came in for the appointment. However, after telling my story and explaining my symptoms, the provider performed a complete physical, including vital signs, a pelvic exam, blood tests, and a pelvic ultrasound.

The blood tests evaluated for hormone levels, cholesterol levels, thyroid function, kidney and liver function, and blood sugar. The pelvic ultrasound enabled the provider to evaluate my uterus and ovaries. After reviewing all of these tests, my provider diagnosed me with PCOS. Although he did say I could have received treatment much sooner, he commended me for seeking care. He started some medications for both treatment and prevention of other complications like diabetes, high blood pressure, and infertility.

Since seeking care, I have been able to manage my disorder successfully, receive support through support groups, and have children. I feel fortunate to be able to help other women along this journey.

---

### Neuromuscular

Neuromuscular conditions arise from complex interactions between the neurological and muscular systems. These disorders can be congenital or acquired later in life. These conditions result from a dysfunction in the innervation of muscles throughout the body. Most neuromuscular disorders are associated with some level of progressive physical impairment. Examples of neuromuscular disorders include MD, amyotrophic lateral sclerosis (ALS), peripheral neuropathy, polymyositis, congenital myasthenia syndrome, and MS.

The commonality in neuromuscular disorders is muscle weakness and physical dysfunction. This can occur peripherally in the limbs, but, as in MD, it can also affect internal organs, causing complications in organ functions such as elimination and breathing. Muscular dystrophy is a progressive genetic disorder that results in the body's inability to make appropriate proteins for muscles. Neuromuscular disorders can put individuals at risk for complications such as difficulty with running, jumping, and walking; abnormal gait; falls; delayed growth; and learning disabilities (Mayo Clinic, 2022).

Disorders such as ALS affect nerve cells in the brain and spinal cord, causing progressive loss of muscle control, including muscles that control vital life processes such as eating and breathing. Neuromuscular disorders are rarely curable, but many have effective and evolving treatments to improve quality of life and minimize associated disability.

### Neurological

Neurological chronic diseases can be classified as strictly neurological or neurodevelopmental.

Neurodevelopmental disorders include autism spectrum disorder (ASD), ADHD, or ADD. Neurodevelopmental disorders commonly coexist with mental health disorders such as anxiety and may be addressed and treated by a mental health professional. Some learning disabilities are also considered neurological disorders that require some treatment and accommodation over a person's lifetime. Some neurological diseases develop over the life span, whereas others arise from injury. Examples of neurological disorders include Huntington disease, epilepsy, spinal cord injuries, headache syndromes, Guillain-Barré syndrome, and restless leg syndrome.

Neurological disorders frequently require prolonged medication treatments. Because these diseases may present slightly differently in each individual, they are notoriously difficult to diagnose and treat. The nurse's role is to maintain awareness of any new neurological symptoms that patients report, particularly symptoms that persist and change over time.

### Kidney

Most CKD is acquired and results in a progressive loss of kidney function. Kidney disease typically has an insidious onset with few outward symptoms. If the disease progresses, the patient will begin to develop symptoms, which may include nausea and vomiting, fatigue, sleep disturbance, urinary changes, decreased cognition, muscle cramping, peripheral edema, pruritis (itching), resistant HTN, chest pain, and shortness of breath (CDC, 2022a). Kidney disease is closely tied to other metabolic disorders such as diabetes, HTN, heart disease, and obesity. For example, HTN and diabetes negatively affect the small vasculature in the kidneys, causing damage and progressive loss of function.

In addition, medical treatment and medication for other chronic disorders may put increased stress on the kidney, leading to a progressive decline in kidney function. Nurses must understand that early treatment of associated conditions is the key to preventing the progression of CKD and the need for dialysis.

---

### Respiratory

Respiratory diseases are common chronic conditions. They include disorders of the nasal passages, trachea, and lungs. Chronic respiratory conditions range in severity from mild to life-threatening. Some common respiratory conditions include chronic rhinitis, asthma, COPD, sleep apnea, pulmonary fibrosis, and cystic fibrosis. These disorders cause problems with air exchange, inflammation in the lung and airway passages, and progressive lung remodeling. Some diseases, such as asthma, require long-term management but remain stable or improve during the life span. Others, such as COPD and pulmonary fibrosis, are typically progressive, causing increasing dysfunction and symptoms.

Pulmonary fibrosis may be idiopathic or related to environmental exposures such as silica, coal dust, or asbestos. Idiopathic pulmonary fibrosis develops without a known cause; however, age and smoking history do increase the risk. There is no definitive heredity component in pulmonary fibrosis. Chronic obstructive pulmonary disorder is a progressive lung disorder causing obstructive changes in the lungs. The most significant risk factor for COPD is smoking, followed by occupational exposure, air pollution, and a genetic  $\alpha$ -1 antitrypsin deficiency.  $\alpha$ -1 Antitrypsin deficiency is a complex disorder in which a person's body does not produce the protein  $\alpha$ -1, which blocks enzymatic damage from the neutrophil elastase enzyme, which can cause damage to the lungs.

Cystic fibrosis is a disorder that significantly affects the lungs but also affects other organ systems, including the digestive tract. The inherited disorder is progressive and causes a thickening of mucous secretions within the body that can plug air passages and other internal ducts. Individuals with cystic fibrosis have a shortened life span of between 30 and 50 years (Mayo Clinic, 2021).

---

Sleep apnea and rhinitis are disorders of the upper airways. Rhinitis causes inflammation and increased mucous production, contributing to chronic cough and impaired air exchange if inflammation restricts air movement. Sleep apnea is a prevalent disorder that directly affects breathing patterns and oxygenation of the body. The primary cause is pharyngeal narrowing and weakened pharynx muscles that cause the pharynx to close during sleep. Increased neck circumference creates increased pressure on the pharynx, causing a repetitive partial collapse. Sleeping on one's back, smoking, alcohol use, and sedatives can all contribute to sleep apnea. Risk factors for sleep apnea include obesity, male sex, and advancing age. Untreated sleep apnea can cause a host of additional problems in various organ systems, including congestive heart failure, coronary artery disease, HTN, stroke, atrial fibrillation, sudden cardiac death, headaches, daytime fatigue, reduced work productivity, and glaucoma (Blackwell et al., 2019).

## LINK TO LEARNING

---

The [STOP-BANG questionnaire \(https://openstax.org/r/77STOPBANGquest\)](https://openstax.org/r/77STOPBANGquest) helps nurses screen patients for sleep apnea and can help nurses educate patients about the risk factors for sleep apnea.

---

## 42.4 Healthcare Approach to Chronic Conditions

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze different healthcare considerations for chronic conditions
- Identify how to ensure quality health care for people with chronic conditions
- Explain nursing care of patients with chronic conditions

Although chronic conditions vary in severity, treatment needs, and support requirements, nursing care for individuals with chronic conditions focuses on providing access to all individuals. Nurses maintain a strong awareness of individual needs by considering various factors that affect healthcare delivery and access. By creating care plans focused on these specific needs, nurses promote autonomy by creating an atmosphere in which the patient is an expert on their own health. Caring for individuals with chronic conditions requires collaboration and knowledge of medication and therapeutic regimens. Patient-centered care and improving quality of life are also of high importance in caring for individuals with chronic conditions

### Healthcare Considerations for Chronic Conditions

Many social, environmental, and personal factors affect healthcare delivery. Nurses will address considerations that affect patients on a personal level, such as psychological and ethical issues. Other considerations include environmental factors, financial concerns, and family dynamics. Other factors, such as social interactions, at-risk populations, and support services, also guide nursing care for individuals with chronic conditions.

#### Psychological Considerations

Psychological considerations in chronic disease relate to the person's day-to-day experience living with a chronic disease. Individuals may experience grief related to a loss of ability over time. In addition to grief, chronic diseases pose additional mental health challenges. Chronic conditions are associated with a high rate of depression (Ma et al., 2021). Mental health conditions triggered by chronic disease may be exacerbated by fatigue, chronic pain, and fear.

Chronic pain is common in many long-term disorders and has a high correlation with depression. Up to 30 percent to 50 percent of individuals with chronic pain have coexisting depression (Meda et al., 2022). Depression may also precede chronic pain. Nurses can focus on promoting support groups and providing education on the importance of psychotherapy to help develop coping strategies for chronic illnesses. The burden of chronic disease may also cause interpersonal, family, and relationship conflicts related to caregiver strain, financial stress, loss of work ability, increased healthcare costs, and increased time burden. Common are feelings of sadness, grief, and discouragement, which can fluctuate over time depending on the immediate health condition. Grief in chronic disease is an important topic that nurses can help patients navigate. Losing ability, facing death, or developing progressive syndromes can lead to a specific grief response.

#### Ethical Considerations

Ethical considerations in caring for individuals with chronic diseases are an important aspect of care for nurses. The ethics of care, particularly for individuals with **multimorbidity**, the co-occurrence of two or more chronic disease states, revolves around patient autonomy and dependence. Studies show there is a fine line between autonomy and dependence in caring for patients with chronic disease (Coronado-Vázquez et al., 2020). Promoting quality of life and autonomy are two of the primary roles of the nurse; however, the vision of autonomy balanced with support must be shared among the healthcare team and the patient. A sense of autonomy empowers patients to feel a sense of control and produces improved well-being and measurable health outcomes and quality of life. The ethical considerations nurses must consider include the financial burden of chronic disease, particularly multimorbidity at an individual level as well as at community and societal levels. Beneficence and nonmaleficence also play a role in the nursing care of individuals with chronic disease. This is easily demonstrated by considering the effects of polypharmacy on patient health and well-being. Multiple medications meant to improve patient health can have harmful effects due to drug-drug interactions and organ system reactions. Diligence on the part of the nurse can identify problematic medication combinations, particularly in patients who, because of multiple chronic diseases, are seen by many specialty healthcare providers. In this instance, nurses take on the care coordinator role for patient wellness while maintaining treatment plans across medical specialties.

### Social Considerations

Social considerations about chronic disease focus on the ethical issue of healthcare equity, fairness in healthcare access, and disparities among social and demographic groups. The nurse's role is to level the field and reduce disparities while respecting and understanding social and cultural determinants of health. Social determinants of health include social practices, lifestyle, work, living situation, and community environment. These can range from health choices such as smoking, drug or alcohol use, and poor nutrition, to violence in neighborhoods, domestic violence, pollutants in the environment, unemployment, and high-stress employment. These all point back to the toll that social constraints and factors play on an individual's health and the health of a community in which people dwell. Social determinants of health also have a significant impact on personal well-being and can affect friendships, interactions with coworkers, access to leisure activities, and participation in hobbies.

## PATIENT CONVERSATIONS

---

### A Family in Transition

**Scenario:** Dara is a 39-year-old patient who is seeking care for her 14-year-old daughter, Lana, who is struggling with depression and anxiety. Lana does not want to be at the appointment today and offers little verbal interaction. They are seeking a referral to a mental health specialist as well as guidance in obtaining a social worker. Dara lost her job about a year ago and she and Lana have been sleeping in their van and staying with friends on and off since then.

**Nurse:** Good afternoon, I'm Finn. It looks like we're seeing you today to discuss some emotional challenges you are dealing with.

**Patient:** We've had a lot of challenges this year and they're starting to take a toll on Lana. I'm noticing her withdrawing and becoming increasingly anxious and angry. She's lost some friends who seem repelled by our situation, and I think she's being teased about being homeless, too. I don't have much hope in changing our situation right now, either.

**Nurse:** It sounds like you're really worried about Lana and maybe you are struggling as well.

**Patient:** Yes, I am, but I want to get Lana some help in managing depression and anxiety. I feel that if we had a social worker to help us navigate the system, we might have a better chance of finding an affordable place to live.

**Nurse:** It took a lot of courage for you to come in today. I know the healthcare provider can evaluate Lana today and get her on the right track to feeling better and coping with these hard times.

**Patient:** Can you refer us to a social worker, too?

**Nurse:** Yes, we can refer your family to a social worker. I think a referral for counseling that is covered by your insurance may also be beneficial for you and Lana. Are you willing to see a counselor?

**Patient:** Yes, I think seeing a counselor individually and together would really give us a boost. Thank you for your help today.

**Nurse:** Great, we'll get the referrals going, and the healthcare provider will be in shortly to see you.

---

In contrast, social determinants of health can also guide disease prevention and health promotion (see [4.1 Defining Health and Wellness](#) for more on social determinants of health). Perceived discrimination and the strength of social networks also play a role in health. Focusing on these factors, nurses must address the negative impacts of social factors on health. Focusing on positive impacts, such as strong family bonds and community support, promotes an overall sense of health and potentially reduces the risk of chronic disease among individuals in high-risk social groups (Cockerham et al., 2017).

On an individual level, nurses can encourage patients to embrace their social environment and existing support networks by:

- becoming experts in their own care
- joining support groups

- learning about their disease process
- talking to others about their illness
- understanding their medications and treatment

### Financial Considerations

Chronic disease is responsible for an individual financial cost as well as an overall financial burden nationwide. Chronic and mental health disease make up 90 percent of healthcare spending in the United States each year (CDC, 2023). Treatments, medications, and interventions for chronic disease are significant expenses for individuals, particularly those with multiple chronic diseases. Additional costs are incurred with health insurance premiums as well as lost productivity when individuals are unable to work or work in the same way due to chronic illness.

### Family Considerations

Chronic disease can affect families in both financial and emotional ways. The burden of care on families is high and can increase financial burden if caregivers must lose work productivity to perform care duties. Additional effects on families include emotional worry and caregiver burnout. A family-centered approach to care may be beneficial, particularly in families providing much of the caregiving. Nursing actions may include advocating for respite care, providing education to the patient and family regarding the disease process, and providing support services to ease financial burden.

### Environmental Considerations

Environmental considerations include factors associated with continued exposure to risk factors and positive and stable environments to promote well-being. This may involve addressing environmental determinants of disease, including risk factors such as smoking, alcohol use, and lifestyle habits. Other environmental determinants are housing stability, nutrition, food security, financial security, and physical safety or violence. Stressful events trigger heightened emotional states and may exacerbate symptoms of chronic disease or create a scenario of limited coping. For older adults and those with disabilities, environmental considerations must include whether an individual can live independently, in an assisted living facility, or in a long-term care facility. Living situations depend on each patient's specific abilities and safety. Nurses will help individuals cope with changes in living situations, such as moving from their family home, due to falling risk, to an assisted living facility.

### Considerations of At-Risk Populations

Individuals in at-risk demographic groups may be at higher risk for chronic disease and have more difficulty accessing adequate care for chronic disease. Pregnant women and children may require increased support in obtaining healthy nutrition, accessing maintenance health care, and maintaining safe living situations. Older adults may require special care due to financial concerns, lack of support, fall and safety risks, and dementia. Veterans may have a higher risk for mental health disorders, suicide, PTSD, and chemical exposure–related diseases. Other at-risk demographic populations include individuals who:

- are unemployed
- are unhoused or have housing insecurity
- are uninsured or underinsured
- experience addiction
- experience food insecurity
- experience poverty

Due to a lack of resources, this individual may delay seeking treatment and enter the healthcare system only during a health crisis. When creating care plans, nurses must consider challenges these people face. By focusing on health promotion and disease prevention, nurses help prevent healthcare crises.

### Ensuring Quality Health Care

Quality care is the responsibility of society, the individual, and the healthcare team. Collaborative teamwork is crucial in creating affordable, accessible health care for all. It is also important to focus care at an individual level to promote autonomy and discourage a sense of dependence. Quality health care must empower individuals to understand their disease and treatment plans, manage multiple disease states, and advocate for themselves to maintain the best quality of life and sense of well-being.

### Therapeutic Regimens

Therapeutic regimens vary widely depending on the disease process, patient preferences, available services, and financial costs. Managing multiple chronic illnesses requires a more complex plan and more frequent follow-up and re-evaluation of the plan to maintain a positive trajectory in care. Nurses play a role in ensuring that patients fully understand their treatment plan, the purpose of treatments and medications, and expected outcomes. Nurses also are a link between healthcare providers and patients and work to coordinate appropriate specialty care and follow-up. Nurses are key in providing education regarding therapeutic plans in an understandable and clear way for patients. They are often the first to answer questions and explain patient changes and outcomes.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Informatics

**Definition:** Effectively apply appropriate technology to communicate, manage therapeutic regimens, and improve safety.

**Knowledge:** Nurses must recognize gaps in education or therapeutic regimen monitoring that may benefit from technology-based interventions. For example, an individual with difficult-to-control type 2 diabetes expresses concern about pain with finger sticks, trouble remembering to check her blood sugar, and erratic blood sugar levels throughout the day. The nurse knows the patient has been unable to tolerate many medications. The patient also expresses fear about the provider's recommendation for insulin therapy, because she is afraid of having low blood sugar while at work.

**Skill:** The nurse can relay the patient's concerns to the healthcare provider and advocate for technology-based continuous glucose monitoring (CGM). The nurse can help the patient understand the benefits of CGM in monitoring and improving the outcomes of her insulin regimen. The patient can forward blood sugar logs to the office and receive prompt feedback on adjusting her long-acting insulin.

**Attitude:** The nurse can present these technological-based options to the patient enthusiastically to promote better health, less hassle, and improve the healthcare provider's ability to adjust her medication regimen quickly and efficiently.

---

### Enabling Self-Management

A key to promoting health and well-being is a focus on empowerment, autonomy, and self-management. The level of self-management varies greatly depending on the type of illness, but nurses can hone their ability to identify the level of self-management possible for everyone. For example, in young adults managing type 1 diabetes, nurses can empower their patients to make healthy lifestyle choices, proper nutrition, and safe insulin management to prevent long-term complications. For older adults with multiple chronic diseases, understanding their medication regimen and maintaining daily movement and nutrition to continue independent living creates a sense of autonomy. In older adults with severe and progressive dementia, providing small choices in food and encouraging self-hygiene encourages a continued sense of autonomy even when full supervision is required for safety.

### Patient-Centered Care

Patient-centered care focuses on each individual's differences and how they experience chronic disease. Patients may have different choices regarding treatment and different views on lifestyle changes and quality of life. Regardless of a patient's choices, offering respect and acceptance is an important role of the nurse. Patient-centered care always involves the patient and incorporates their choices in treatment plans. Active listening ensures that patients are and feel heard and empowers them to take an active role in their health. This positively affects health outcomes overall, even in the face of chronic disease. A comprehensive approach to patient care varies from person to person but includes the same important aspects ([Table 42.7](#)).

	Patient 1	Patient 2
Disease history	31-year-old male diagnosed with type 2 diabetes during a routine screening	68-year-old male diagnosed with type 2 diabetes when he sought care for a foot wound
Lifestyle	<ul style="list-style-type: none"> <li>• Does not exercise</li> <li>• Eats fast food for most meals delivered by a service</li> <li>• Lives with his fiancé</li> <li>• Spends 8–10 hours on his computer for work and recreation daily</li> </ul>	<ul style="list-style-type: none"> <li>• Does odd jobs</li> <li>• Eats at community meal centers</li> <li>• Fluctuates in housing security, sometimes camping or living with friends</li> <li>• Walks daily because he does not have a car</li> </ul>
Healthcare access	<ul style="list-style-type: none"> <li>• Gets yearly check-ups</li> <li>• Has comprehensive health insurance</li> </ul>	<ul style="list-style-type: none"> <li>• No health care for &gt;10 years</li> <li>• No health insurance</li> </ul>
Additional medical diagnoses	<ul style="list-style-type: none"> <li>• Elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol</li> <li>• Joint pain</li> <li>• Obesity (body mass index of 40)</li> <li>• Plantar fasciitis</li> </ul>	<ul style="list-style-type: none"> <li>• Bipolar disorder</li> <li>• HTN</li> <li>• Kidney disease</li> <li>• Obesity (body mass index of 33)</li> </ul>
Motivation	<ul style="list-style-type: none"> <li>• Wants to feel better overall</li> <li>• Wants to get healthy so he can get married</li> <li>• Wishes to start a family</li> </ul>	<ul style="list-style-type: none"> <li>• Does not see himself following up regularly</li> <li>• Wants to avoid hospitalization</li> <li>• Wishes for health insurance</li> </ul>
Preferences	<ul style="list-style-type: none"> <li>• Enjoys technology and digital products</li> <li>• Has considered joining a gym</li> <li>• Will try any medication type to improve his health</li> </ul>	<ul style="list-style-type: none"> <li>• Enjoys being outdoors</li> <li>• Uses his phone only for important communication</li> <li>• Will only accept oral medications</li> </ul>

TABLE 42.7 Patient-centered Care

	Patient 1	Patient 2
Family resources	<ul style="list-style-type: none"> <li>• Discussed couples therapy and group exercise</li> <li>• Nutrition resources for shared meals</li> </ul>	<ul style="list-style-type: none"> <li>• No family support</li> </ul>
Patient-centered care provided by the nurse	<ul style="list-style-type: none"> <li>• Aggressive medication management to reduce blood glucose</li> <li>• Focus on healthy nutrition with fiancé</li> <li>• Involve significant other to promote wellness</li> <li>• Medical gym membership with guided health program</li> <li>• Offer detailed education to promote long-term health</li> <li>• Support group for type 2 diabetes</li> <li>• Use digital nutrition, medication, and movement tracking</li> </ul>	<ul style="list-style-type: none"> <li>• Connect with social worker to determine qualification for public health insurance</li> <li>• Focus medication and treatment on affordable oral options</li> <li>• Maintain flexibility in follow-up to help ensure compliance with medications</li> <li>• Offer education on monitoring for complications and managing current disease</li> <li>• Resources for obtaining stable housing</li> </ul>

**TABLE 42.7** Patient-centered Care

### Managing Multiple Conditions

Multimorbidity is common in chronic disease. Managing multiple conditions is difficult for providers as well as patients. Interactions between medication and treatments and the risks and benefits of performing the treatment and beginning new medications must be considered. As noted, many chronic conditions may trigger other conditions or contribute to compounding symptoms. Managing multiple conditions requires coordination between healthcare providers and must consider patient preferences and abilities. A patient-centered approach considers that individuals have different conditions, take different medications, and choose different treatments.

### Collaborative Management

Collaborative management of chronic disease includes physician specialists, nurses, and various other healthcare and ancillary team members ([Table 42.8](#)). Nurses often serve as team coordinators and patient advocate. Creating a collaborative team depends on the diseases present, patient preferences, financial resources, and availability of team members.

Disease Type	Collaborative Team Members
Cancer, depending on type	Geneticist Hospice nurse Massage therapist Mental health professional Nutritionist Oncologist Palliative care specialist Physical therapist Plastic surgeon Radiation oncologist Surgeon
Cardiovascular diseases	Cardiac rehabilitation nurse Cardiologist Cardiovascular surgeon Mental health professional Physical therapist Pulmonologist
Respiratory	Allergist Pulmonologist Respiratory therapist Speech therapist
Kidney	Cardiologist Dialysis nurse Home health nurse Mental health professional Nephrologist Occupational therapist Palliative care specialist
Cognitive	Mental health professional Neurologist Occupational therapist Physical therapist Social worker Speech therapist
Neurological	Mental health professional Neurodevelopmental psychologist Occupational therapist Physical therapist Social worker Speech therapist

**TABLE 42.8** Collaborative Management Teams

Neuromuscular	Mental health professional Neurologist Neurosurgeon Occupational therapist Physical therapist Speech therapist
Metabolic	Endocrinologist Mental health professional Nutritionist Physical therapist
Immune	Infectious disease specialist Mental health professional Nutritionist Occupational therapist Physical therapist Rheumatologist

**TABLE 42.8** Collaborative Management Teams

## Nursing Care of Patients with Chronic Conditions

Nursing care of patients with chronic conditions encompasses care along the life span continuum from infancy through older adulthood. Patient-centered care is an essential component that links all aspects of nursing care for these individuals. Specific nursing actions must consider each patient's physical and functional abilities and how these change over time. Many chronic conditions require long-term medical management, including medication therapy. Nurses play a key role in helping patients manage these medication regimens to maintain the safety and efficacy of the treatment. As with all other nursing specialties, chronic disease management requires ongoing and patient-tailored education. Education is not a one-and-done nursing intervention but an ongoing and evolving process of helping patients manage and cope with chronic disease diagnosis, progression, treatment, and complications. Supportive care involves the emotional support of individuals dealing with chronic conditions. In addition, supportive care focuses on symptom management and improving quality of life rather than treating or changing the course of the disease.

### Assessing Physical and Functional Status

Nurses play an important role in assessing physical changes that may signal the onset or progression of chronic conditions. Nurses perform various physical assessments depending on the hospital, outpatient, long-term care, or home care setting. These often are head-to-toe assessments during a hospital or long-term care facility admission. Head-to-toe assessments offer a baseline of current physical status and allow nurses, physicians, and other healthcare professionals to gauge changes in the patient's condition over time. This type of physical assessment includes inspection, auscultation, palpation, and measurement of vital signs. A targeted physical assessment will focus on documenting mobility, organ system abnormalities, sensory issues, and wounds and incisions.

Through a functional assessment, nurses aim to paint a picture of how individuals function in various life situations, such as self-care, activities of daily living, transportation, medication management, social interactions, and family roles. Understanding an individual's functional status allows nurses to gauge the need for specific support services for the individual and the family. Routine assessment of functional status allows nurses to make appropriate referrals to ancillary healthcare providers such as physical therapists, occupations therapists, respiratory therapists, and social workers.

### Managing Medication Regimens

In the management of chronic conditions, medication management can be complex. Patients may need help understanding the function of their medications and managing the day-to-day regimen. The effectiveness and safety

of medication self-management depend on cognitive function, the complexity of the regimen, and the type of medications prescribed. Nurses are frequently required to explain the function of medications to patients. Nurses must explain the details in a way that each patient can understand. This may require written or visual communication; for others, it may simply be a verbal explanation. Understanding the complex interactions between medications and monitoring for medication side effects and interactions between multiple medications is also critical. Drug-drug interactions are common; however, sometimes, the benefit of the medication outweighs the risk of an interaction. This is when nurses monitor for adverse reactions and report them to the healthcare provider. Educating and encouraging patients to report any changes in their condition or how they feel is also essential. Nurses will need to teach medication administration for injectable medications, inhaler use, topical preparations, and other nonoral medications. Nurses must also watch for high-risk knowledge gaps, such as an individual needing help understanding the reason for a medication, the timing, or the fact that it must be taken consistently to provide effective results.

## REAL RN STORIES

---

### Closing the Gap with Medication Education

**Nurse:** Rosa, RN

**Clinical setting:** Outpatient Clinic

**Years in practice:** 8

**Facility location:** Austin, Texas

I've worked in an outpatient primary care clinic since becoming an RN. One of the best parts of my job is educating patients on their treatments and seeing relief on their faces when they gain understanding. One example I remember was a 22-year-old patient with environmental allergy-triggered asthma. She came into our clinic really worried about the new treatment from her allergy and asthma specialist. She couldn't get to their office, so she came in for advice. She said she had been using the inhaler as directed, but she lost the list of side effects and other information about the medication. After about a week of use, she started having a burning sensation in her mouth, and was experiencing whitish patches on her cheeks and tongue. She stated it seemed to be helping with her wheezing, but she was worried she was having a side effect of the medication. She stopped using the inhaler 2 days prior to her visit and had some recurrence of her wheezing. She said she had used another inhaler in the past without any problems. I reviewed her medication list and determined that her new medication was a budesonide formoterol inhaler twice daily.

I then asked her about her inhaler regimen at home. She stated she used it twice daily as directed and used her other albuterol inhaler as needed. I immediately recognized her knowledge gap, and after the healthcare provider evaluated and made a plan for treating thrush, or oral candidiasis, I gave her more information on medication safety. We discussed why this medication can cause this side effect and gave tips for preventing this in the future, including rinsing her mouth thoroughly after every use. She was relieved to know that she had not done something wrong and that she could continue to use the medication, because it was working well for her asthma.

---

### Providing Education

Education encompasses all aspects of treatment and care for chronic illness. Nurses must rely on appropriate communication techniques tailored to each patient when providing education, to ensure the best possible reception of the information. Repeating the teaching multiple times may be necessary. A teach-back method is effective for teaching medication administration, the pathophysiology of the disease, and family teaching. Based on individual learning preferences, nurses may provide questions and answer discussions, handouts for visual assistance, and video learning to solidify learning.

Nurses providing education on chronic conditions must consider each individual's health literacy and the ability of an individual to understand and apply health-related information. The teach-back method allows patients to explain in their own words the information provided and demonstrate their ability to perform a medication administration such as insulin injection or inhaler use. Regardless of health literacy, the teach-back method gives patients an advantage in understanding their health conditions and treatments. The teach-back and show-me methods are crucial for patients with chronic conditions, due to the complex nature of these conditions and the common

multimorbidity present (AHRQ, 2024).

---

### Supportive Care

The supportive care nurses provide focuses on patient needs that may be directly associated with or triggered by their disease. These supportive measures focus on physical or emotional needs. Supportive measures address disease symptoms, side effects of medications, and social and emotional aspects of coping with a disease that the treating healthcare provider may not typically address. Supportive care involves a way of providing care as well as specific actions. By striving to provide a supportive atmosphere of care, nurses can exercise compassion, build confidence, identify areas for growth, and create a sense of safety. Specific actions that nurses may perform in providing supportive care include using encouraging words and actions, using active listening, engaging in educational dialogue, and collaborating with healthcare providers to provide patient-centered care (PCC).

## Summary

### 42.1 Characteristics of Disability

The terms disability and impairment are often used interchangeably. However, most definitions explain impairments as physical or mental deficits or differences that can be seen or perceived. Disability relates to how impairments affect an individual's ability to function in their home and community environment. Physical, cognitive, and congenital impairments often result in disabilities. Disabilities are the consequence of impairments that limit the ability of individuals to perform physical actions, cognitive processes, learning tasks, or communication in expected ways. Physical disabilities may arise at birth, develop over time, or occur as a result to an acute injury. Cognitive, intellectual, developmental, and psychiatric impairments result in a wide variety of disabilities. Disabilities are common at all ages, but the type of disability varies during the life span. Although congenital and developmental disabilities are often diagnosed in childhood, the effects of these disabilities on functioning persist throughout an individual's life. Older adults commonly develop disability related to mobility and sensory changes associated with disease and the aging process. These disabilities affect an individual's daily functioning at home, school, and in the wider community. Disabilities can be congenital, progressive, or acquired, and a person's response to disability depends on factors such as the severity of the disability, available support, and grief response.

### 42.2 Healthcare Approach to Disability

Models of disability are essential for framing patient-centered care planning and creating an awareness of how healthcare professionals and the broader community view disability. These models relate to the morals, medical care, social interactions, functional abilities, rehabilitation, social, and biopsychosocial aspects of caring for individuals with disabilities. Although each model can be understood independently, understanding the interplay between these concepts is key to providing individualized care. Individuals with disabilities experience a wide range of barriers, from physical difficulty accessing a building to the inability to communicate effectively with their healthcare provider. By recognizing barriers, nurses can eliminate physical obstacles and social bias in their care setting. Helping individuals access affordable care, navigate insurance requirements, and feel accepted and included are all ways that nurses can ensure quality health care for people with disabilities.

### 42.3 Chronic Disease and Chronic Illness

Chronic conditions are prevalent in our society. The most prevalent chronic diseases in the United States are CVD (50 percent), obesity (42 percent), and arthritis (25 percent). Other prevalent chronic diseases include diabetes, cancer, epilepsy, and pain. Chronic diseases encompass many disorders that can be identified by specific medical criteria. Chronic illness, on the other hand, describes the patient's experience with a chronic condition, including symptoms, time frame, and treatment responses. It is also common for individuals to have multiple chronic conditions simultaneously. Often, symptoms may overlap, and different disorders may contribute to the development of other chronic conditions. Chronic conditions can develop in any organ system, ranging in severity from mild to life-threatening. Chronic conditions last longer than 1 year and typically have ongoing symptoms that require continued medical monitoring or treatment. Chronic conditions may be genetic or acquired and may progress and change over a person's life span. The majority of the acquired chronic conditions, such as heart disease, type 2 diabetes, obesity, and high blood pressure, are associated with a very short list of risk factors: smoking, excessive alcohol use, and a sedentary lifestyle. Recognizing symptoms of common conditions is crucial for nurses in day-to-day practice. Awareness of rare disorders will improve the nurse's ability to identify concerning symptoms early in the course of the disease.

### 42.4 Healthcare Approach to Chronic Conditions

Nurses must consider many aspects of an individual's circumstances when caring for chronic conditions. Keeping in mind ethical considerations is crucial for providing patient-centered care. At-risk populations include pregnant women, children, older adults, and those with housing instability. These individuals may require more creative and individualized care based on their specific support needs. All individuals experience the effects of social factors, financial status, and environmental circumstances. These factors directly affect outcomes related to chronic conditions. Nurses must always consider family dynamics during patient care and include family in care planning if appropriate and preferred by the patient. Physical and functional assessments set the stage for nursing interventions focused on chronic disease management. Assessments may be head to toe or focused on specific

concerns. These assessments must occur periodically to monitor for change over time. Education about therapies, medications, progression, and expectations is an ongoing process in chronic disease care. Nurses will also collaborate with other healthcare providers and ancillary specialties in providing supportive care. Supportive care addresses disease management and symptoms and consequences of the disease process.

## Key Terms

**ableism** a concept that explains the negative reactions that individuals without a disability have in response to encountering individuals with a disability

**accommodations** adjustments and modifications in the physical environment to meet the needs of individuals with disabilities

**acquired** resulting from exposure to a toxin or pathogen such as HIV

**acquired disability** physical, cognitive, sensory, or psychological impairment that occurs after birth, typically as a result of injury, illness, or environmental factors

**activity level** one's ability to perform specific actions

**Americans with Disabilities Act (ADA)** initially signed in 1990, protects the rights of individuals with disabilities and prescribes requirements for appropriate accommodations

**autoimmune disorder** condition that arises from the body's immune system attacking and damaging its cells and organs

**biopsychosocial model of disability** focuses on the interplay between medical diagnoses and associated impairments and societal barriers

**chronic disease** a state of being that includes having a biomedical disease for at least 1 year

**chronic illness** a condition requiring medical attention or limiting usual daily activities for greater than one year

**cognitive disability** limitation in cognitive functioning and adaptive behavior stemming from disorders in brain functioning

**communicable disease** disease passed from person to person

**comorbid medical conditions** multiple medical conditions are simultaneously present

**congenital** a condition present at birth

**developmental disability** condition due to an impairment in learning, language, behavior, or physical function

**disability** a mental or physical condition that limits an individual's ability to engage in daily activities in a typical way

**discrimination** actions or beliefs that show an unjust distinction between people on the grounds of sex, age, ethnicity, or disability

**disease** a disorder within the body that is identifiable as a medical condition

**external bias** based on societal attitudes and cultural beliefs but also affects how others treat individuals

**functional impairment** restriction or difficulty in performing activities effectively due to the loss of functioning in a body part

**functional model of disability** a cause-and-effect relationship between a physical or cognitive deficit and limitations in daily function

**illness** the perceived experience of a disorder within the body

**immunodeficiency disorder** a condition or disease caused by a weakened immune system impairs the body's ability to fight off disease or infection

**impairment** loss of one's physical or mental ability that inhibits usual or expected functioning **Individuals with Disabilities Education Act (IDEA)** enacted in 1975, requires that all children with disabilities receive appropriate and free education through the public education system

**intellectual disability** neurodevelopmental condition characterized by significant limitations in intellectual functioning and adaptive behavior that manifest during the developmental period

**internal bias** individual thinking pattern that affects how an individual person views and treats others

**medical jargon** technical medical language

**medical model of disability** disability as a consequence of a trauma, illness, or congenital health condition that is out of the control of the individual

**moral model of disability** a long-standing belief pattern that explains disability as a defect in functioning related to the individual's moral character

**multimorbidity** co-occurrence of two or more chronic disease states

**overactive immune disorder** when the immune system develops a hyperresponse to normally harmless environmental substances

**participation level** often refers to a person's ability to function in the wider community

**physical disability** any condition that limits a person's physical functioning or mobility

**prejudice** when an individual makes a judgment or opinion of a person with a disability before obtaining knowledge of their circumstance

**presbycusis** age-related hearing loss

**presbyopia** loss of near vision

**psychiatric disability** condition characterized by mental health challenges or disorders that significantly affect an individual's cognitive, emotional, or behavioral functioning, leading to difficulties in daily life and social interactions

**recovery** receiving addiction treatment and remaining drug-free

**rehabilitation** returning to a previous state of health

**Rehabilitation Act** legislation that protects individuals against discrimination based on disability at any federally funded facility or any facility receiving federal financial assistance

**rehabilitation model of disability** conceptualization of disability as a single impairment or a collection of impairments or deficits experienced by an individual that can be improved through rehabilitation

**sensory disability** limitation related to sensory processing and integration, affecting not only the reception but also the interpretation and response to sensory stimuli, potentially affecting various aspects of daily functioning

**sensory impairment** any difficulty an individual has with one of their five senses

**social model of disability** disability in the context of the individual's physical and social environment

**stereotypic attitude** fixed, oversimplified, and generalized perception of individuals in a specific demographic group, stemming from internal and external biases

**stigma** negative or incorrect belief about individuals with disabilities

**structural impairment** limitation experienced in specific body parts

**underinsured** lacking adequate health insurance

## Assessments

### Review Questions

- Identify the difference between disability and impairment.
  - Impairment is the functional restriction of ability; disability is the restriction of ability within an expected range and in a specific environment.
  - Impairment is related to physical dysfunction; disability refers to cognitive dysfunction.
  - Impairment can be cured; disability cannot be cured.
  - Impairment does not change over time; disability may progress over time.
- A nurse is developing a care plan for a patient with a significant vision impairment. What would be most appropriate question for determining whether the patient has an associated mobility disability?
  - Have you had any recent falls?
  - Where is your walker?
  - Have you followed up with your eye doctor recently?
  - Do you experience headaches?
- The incidence of disability in the adult U.S. population is \_\_\_\_\_ percent, with the rate being even higher at \_\_\_\_\_ percent in older adults.
  - 50%, 60%
  - 20%, 50%
  - 25%, 40%
  - 35%, 40%
- A home health nurse is doing an initial assessment for an older adult living independently. Because the patient uses a wheeled walker, due to severe rheumatoid arthritis, the nurse knows the assessment must consider possible challenges for the patient. What activities would be critical for the nurse to assess?

- a. lifting, carrying objects, navigating stairs, eating
  - b. walking, reading, eating, lifting
  - c. navigating stairs, reading, eating, walking
  - d. navigating stairs, carrying objects, gripping, walking
5. The nurse cares for a patient with Down syndrome. The nursing care plan should include considerations that address what type of disability?
- a. mobility
  - b. psychiatric
  - c. developmental
  - d. acquired
6. An adult patient is admitted to a rehabilitation center after sustaining a TBI in a car accident. His neurologist expects that rehabilitation will help the patient make continual improvement in his functioning as he works toward regaining function. What models of disability is the neurologist working under?
- a. medical, social
  - b. biopsychosocial, medical
  - c. social, rehabilitation
  - d. medical, rehabilitation
7. What model of disability considers the underlying cause of disability, how the individual functions in society, and the effect of disability on the individual patient?
- a. rehabilitation model
  - b. medical model
  - c. biopsychosocial model
  - d. social model
8. What communication technique indicates the nurse is not considering an individual's hearing impairment?
- a. The nurse is facing the computer screen during the interview.
  - b. The nurse takes care to speak clearly.
  - c. The nurse repeats the instructions several times.
  - d. The nurse asks if the hearing aids are working correctly when she notices the patient has trouble hearing.
9. A patient's family member asks what legislation protects her son from discrimination when receiving health care. The nurse knows that the \_\_\_\_\_ protects individuals from discrimination in facilities receiving financial assistance from the federal government.
- a. ADA
  - b. IDEA
  - c. Department of Justice
  - d. Rehabilitation Act
10. A nurse notices that her coworker makes negative comments about American Indian patients and that this coworker tries to avoid providing care for these specific patients. The nurse recognizes that this co-worker may be expressing which of the following?
- a. prejudice
  - b. structural barrier
  - c. stigma
  - d. blaming
11. The nurse cares for a patient with obesity and type 2 diabetes. The patient is struggling with fatigue, social withdrawal, negative self-image, and anxiety. What does the nurse recognize that in addition to these chronic biomedical diseases, this patient is experiencing?

- a. arthritis
  - b. pain
  - c. disease progression
  - d. chronic illness
- 12.** Chronic conditions are defined by persistent symptoms or biomedical diseases that require ongoing medical treatments and interventions for what minimum length of time?
- a. 3 months
  - b. 2 years
  - c. 1 year
  - d. 6 months
- 13.** The vast majority of chronic conditions result from a few risk factors. What risk factors are associated with the vast majority of chronic conditions?
- a. smoking, poor nutrition, injuries
  - b. smoking, sedentary lifestyle, poor nutrition
  - c. smoking, sedentary lifestyle, injuries
  - d. smoking, injuries, excess alcohol intake
- 14.** What is an essential concept in understanding chronic conditions of the immune system?
- a. Viruses cause most chronic immune conditions.
  - b. Immune deficiency and an overactive immune system result in disorders with similar symptoms.
  - c. Autoimmune disorders result from the body's immune system attacking its cells and organs.
  - d. Immune disorders are easily recognizable by a typical set of symptoms.
- 15.** In what body regions do endocrine organs reside?
- a. chest, abdomen, brain, neck
  - b. chest, neck, brain, and bone marrow
  - c. neck, brain, bone marrow, pelvis
  - d. brain, abdomen, pelvis, spleen
- 16.** What concept of ethics in chronic disease care ensures patients maintain control in their care and treatment?
- a. autonomy
  - b. beneficence
  - c. nonmaleficence
  - d. multimorbidity
- 17.** How can a nurse advocate for family members of patients with chronic conditions?
- a. by taking over care
  - b. by referring to a specialist
  - c. by advocating for respite care
  - d. encouraging long-term care placement
- 18.** What is an essential concept in helping patients manage multiple chronic conditions?
- a. The nurse must always include the family in decision-making.
  - b. The nurse understands that the specialist will provide the medication and treatment education.
  - c. The nurse makes a referral to a specialist for a patient with borderline HTN but not an additional disorder.
  - d. The nurse can explain the overlap among chronic diseases, causes, and treatments.
- 19.** A functional assessment includes an evaluation of what factor(s)?
- a. vital signs
  - b. depression screening

- c. lung sounds
  - d. mobility
20. Nurses can easily create a patient-centered and supportive care atmosphere by including what actions?
- a. exercise compassion, identify areas for growth, provide education
  - b. create a sense of safety, use active listening, document vital signs
  - c. update the medication list, build confidence, use encouraging words
  - d. explain medication interactions, identify areas for growth, practice beneficence

### Check Your Understanding Questions

1. Describe physical and communication accommodations required by the ADA.
2. List mental health disorders that can progress to a state of disability.
3. Describe how transportation may be a barrier for individuals with disabilities.
4. Describe the organ systems and functions of the endocrine system. Include a description of common chronic disorders arising from the endocrine system.

### Reflection Questions

1. Explain the difference between a congenital and an acquired disability.
2. Explain how intellectual disabilities such as ADHD, dyslexia, and other learning differences may affect an individual.
3. Explain how healthcare providers may inadvertently present bias during patient interactions.
4. Explain why the rehabilitation model of disability may not apply to individuals with progressive or congenital disability.

### What Should the Nurse Do?

1. During a routine wellness checkup for a 6-year-old child, the nurse observes that the child's speech is difficult to understand and expresses fear as expected for a much younger child. How should the nurse begin conversing with the parent to gather more information about her communication and behavior functioning?
2. A nurse is assigned to discharge a patient after a heart attack. The patient and her husband have hearing and vision impairments. The cardiologist explained the discharge medication, but the nurse noticed that the patient and her husband looked confused. How can the nurse provide patient-centered education before discharge?
3. A nurse cares for an 18-year-old patient recently diagnosed with type 2 diabetes. At discharge, the patient remains hesitant about checking her blood sugar and administering insulin injections. She asks her mom to help each time. How can the nurse help?
4. A 72-year-old patient presents to the outpatient clinic for a follow-up of her HTN, arthritis, and insomnia. The patient states that her diseases are stable but she is concerned about persistent diarrhea. What is an initial step the nurse should take?
5. The nurse identifies that the patient is taking supplements in addition to her prescription medications. She is taking an over-the-counter sleep aid with magnesium. What is the nurse's next step?

### Competency-Based Assessments

1. Outline the nurse's role in applying the biopsychosocial model to improve patient care.
2. Develop a presentation for a new nurse conference explaining how nurses can support individuals with neurodevelopmental disorders, particularly ASDs that have a wide range of presenting symptoms and severity.

3. Develop a sample patient-nurse dialogue and focused assessment guide using the STOP-BANG questionnaire to guide an assessment of sleep apnea risk
4. Explain how self-management leads to patient-centered care.

## CHAPTER 43

# Clinical Judgment and Critical Thinking

**FIGURE 43.1** Critical thinking in nursing is a goal-oriented, outcome-directed thought process used to improve patient care outcomes. (credit: modification of work "220202-A-QC081-993.JPG" Army Spc. Logan Ludwig/Joint Base San Antonio, Public Domain)

### CHAPTER OUTLINE

43.1 Clinical Judgment Measure Model

43.2 Developing Critical Thinking

43.3 Unfolding Case Study Dissection

**INTRODUCTION** Picture this: You're a new graduate nurse fresh off orientation on a critical care unit. You get report on two of your patients, one of whom is on a ventilator after a head injury, and the other is being treated for heart failure. The nurse giving you report mentions that the patient with heart failure has been receiving a large dose of furosemide, a diuretic medication, and has been having some irregular heartbeats, according to the monitor. Reflecting on your nursing knowledge, you remember that abnormal potassium levels can affect the heart's rhythm, so you pull up the patient's chart to see what their potassium level is. The potassium level is very low, likely from the high dose of diuretics being administered. You quickly get in contact with the treating clinician to ask for a potassium replacement and regulate the patient's levels back to normal. Had you not made this connection, the patient could have experienced cardiac arrest or other life-threatening symptoms related to their low potassium level. You used your nursing knowledge to make a clinical judgment call that most likely saved your patient's life. The ability to critically think and exhibit clinical judgment in practice are imperative skills for nurses to have. This chapter explores the shift in nursing practice and education that is occurring currently to better prepare new graduates for situations like this.

## 43.1 Clinical Judgment Measure Model

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Identify the purpose for development of the Clinical Judgment Measurement Model (CJMM)
- Explain how to apply the Clinical Judgment Measurement Model (CJMM) to the nursing practice

Historically, nursing was often viewed as a “task-oriented” career, meaning that nurses were to take orders from physicians without question and carry out nursing tasks. These tasks were usually simple, such as bed linen changes, helping patients use the toilet, and providing hygiene care. However, the profession of nursing has evolved into a more complex, autonomous career over the past several decades. Nurses now use **clinical judgment**, which is the thought process that allows nurses to arrive at a conclusion, based on objective and subjective information about a patient, to achieve positive patient outcomes. Many times, nurses are the care providers tasked with making clinical decisions that will significantly affect the lives of their patients. In recent years, nursing education has also evolved to better train nurses to critically think and use clinical judgment in practice. To achieve this, the Clinical Judgment Measurement Model (CJMM) was developed. This model allows nurse educators to teach, assess, and measure the development of clinical judgment skills of nursing students. It assists nursing students to connect knowledge learned in the classroom to provide exceptional clinical care in practice. This model is the new foundation for nursing critical thinking and skill development and is discussed in more detail throughout this chapter.

### Purpose for Development of the CJMM

Before development of the CJMM, there was not a good way to measure the clinical judgment and decision-making skills of nursing students. Developing these skills was a priority focus of most nursing programs, but there was no tangible way to measure it to ensure it was being taught effectively. This was the basis for the development of the CJMM. Researchers at the National Council of State Boards of Nursing (NCSBN) used nursing literature and research studies, in combination with data analysis and input from nursing students, to develop the CJMM. This model is used not only as a teaching tool within nursing school curricula, it is also used as a guiding framework for the development of new types of questions on the National Council Licensure Examination (NCLEX) to assess nursing student’s clinical judgment and critical thinking skills. By using the CJMM, nurse educators can be more confident that they are preparing nursing students to enter practice with a high level of critical thinking and the ability to make sound clinical judgments when caring for their patients. It also provides students with a structured approach for decision-making, improves students’ decision-making, and supports quality and safety.

### LINK TO LEARNING

You can learn more about [the new NCLEX examination \(https://openstax.org/r/77NCLEXexam\)](https://openstax.org/r/77NCLEXexam) that incorporates concepts from the CJMM and get prepared for test day.

### Comparing Different Nursing Process Models

Before development of the CJMM, the nursing process was “ADPIE,” which stands for Assessment, Diagnosis, Planning, Implementation, and Evaluation. This nursing framework was developed in the 1950s and continues to be used in some capacity today, though most nursing schools have replaced it with the CJMM, which further expands the nursing process into more measurable components. A description of each of the steps of the original nursing framework is given in [Table 43.1](#).

Steps	Description
Assessment	<ul style="list-style-type: none"> <li>• Data can also be collected from electronic health records.</li> <li>• Data collection (both subjective and objective)</li> <li>• Data are collected from the patient directly and/or from family and caregivers in addition to physical assessment of the patient performed by the nurse.</li> </ul>
Diagnosis	<ul style="list-style-type: none"> <li>• Formulation of a nursing diagnosis</li> <li>• The International North American Nursing Diagnosis Association maintains a list of nursing diagnoses that can be used to describe a patient's situation.</li> <li>• Note that nursing diagnoses are separate from medical diagnoses; for example, a patient with a medical diagnosis of heart failure might have a nursing diagnosis of "decreased cardiac output."</li> </ul>
Planning	<ul style="list-style-type: none"> <li>• Goals and patient outcomes are developed.</li> <li>• Goals should be patient specific and mutually agreed upon with the nurse and patient.</li> <li>• Goals should be "SMART," meaning they are specific, measurable, attainable, realistic, and timely.</li> <li>• Nursing care plans are developed to ensure that care provided will help achieve patient goals.</li> </ul>
Implementation	<ul style="list-style-type: none"> <li>• Actions by the nurse</li> <li>• Carrying out the nursing interventions planned in the previous step (e.g., administering medications)</li> </ul>
Evaluation	<ul style="list-style-type: none"> <li>• Reassess patient after interventions are provided.</li> <li>• Determine whether patient goals have been met and if and how care plan needs to be revised.</li> </ul>

**TABLE 43.1** Steps of the Nursing Process

Using the nursing process has many benefits for nurses, patients, and other members of the healthcare team. The benefits of using the nursing process include:

- decreases omissions and duplications
- encourages collaborative management of a patient's healthcare problems
- identifies a patient's goals and strategies to attain them
- improves patient safety
- improves patient satisfaction
- increases the likelihood of achieving positive patient outcomes
- promotes quality patient care
- provides a guide for all staff involved to provide consistent and responsive care saves time, energy, and frustration by creating a care plan or path to follow

## LINK TO LEARNING

Learn more about the [CJMM \(https://openstax.org/r/77CJMM\)](https://openstax.org/r/77CJMM) to explore new ways of testing clinical judgment in nursing as part of the NCLEX.

## Application of the CJMM to Nursing Practice

There are several layers to the CJMM framework. Layer 0, at the top, is the broadest layer and the layers get more specific as they reach the bottom at layer 4. As nurses move through layers 2 through 4, they are working through a cognitive process that helps them make clinical decisions for patients, using clinical judgment to do so (as represented by the broad layers 0 and 1 at the top of the model). The more specific layers (2–4) are discussed in more detail in the following sections.

### Form, Refine, and Evaluate Hypotheses

Layer 2 of the CJMM is composed of three different parts: form hypotheses, refine hypotheses, and evaluation. The nurse uses specific patient assessment findings (“cues”) to develop hypotheses, or educated guesses, about the patient’s condition. The nurse uses the cues in combination with their foundational clinical knowledge to determine potential explanations for the patient’s situation. As more cues are assessed and more information about the patient is obtained, the nurse can refine their initial hypothesis and determine its accuracy. As the nurse moves through the steps in layers 3 and 4 to make clinical decisions, they are also checking in with the parts of this layer to continuously re-evaluate the plan of care. As you will read in the next section, each of the cognitive skills in layer 3 corresponds to a component of layer 2. As the nurse assesses and cares for a patient, they can determine whether their actions have satisfied the goals of care. If the goals are not satisfied, the nurse can move again through the steps in layers 3 and 4 to revise the care plan and make different clinical decisions that, hopefully, will assist in better meeting the patient’s needs.

### Application of Cognitive Skills

Layer 3 of the CJMM is composed of six steps that involve a repetitious process that improves with time and nursing experience. Eventually, these steps become second nature to a more experienced nurse, but they serve as a framework for nursing students and early-career nurses to use as a more deliberate guide for making clinical decisions. These six cognitive skill steps (also known as clinical judgment functions) are described in more detail in [Table 43.2](#).

Cognitive Skill	Description
Recognize cues	<ul style="list-style-type: none"> <li>• Assessment data are collected. These can be subjective from the patient or family or objective from physical assessment performed by the nurse.</li> <li>• Data can also be collected from the electronic health record.</li> <li>• Nurse uses these assessment data to look for cues that may be indicative of what is going on with the patient.</li> <li>• Nurse tries to determine what information is relevant, what is the most important, and if there is anything that is of immediate concern.</li> </ul>
Analyze cues	<ul style="list-style-type: none"> <li>• Nurse takes the assessment data collected from the previous step and considers how they relate to the patient’s history and current situation.</li> <li>• Nurse considers whether the cues collected in the previous step are consistent with the patient’s current condition, if any of the cues are immediately concerning, and if there are additional data that need to be collected.</li> <li>• Nurse attempts to link recognized cues to the patient’s clinical presentation and establish probable patient needs, concerns, or problems.</li> </ul>
Prioritize hypotheses	<ul style="list-style-type: none"> <li>• Nurse examines all possibilities for the patient’s situation based on collected cues.</li> <li>• Nurse determines which possibilities are most likely, which are most serious, and which are the highest priority to treat first.</li> <li>• Priorities of care are established on the basis of the patient’s current health problems and cues assessed in the first two steps.</li> </ul>

**TABLE 43.2** Cognitive Skills in the CJMM

Cognitive Skill	Description
Generate solutions	<ul style="list-style-type: none"> <li>Using hypotheses for the patient's condition from the previous step, nurse plans specific actions to achieve goals and outcomes.</li> <li>Actions can be classified as "indicated," "contraindicated," or "nonessential" to help determine priority actions.</li> <li>During this step, the nurse should identify outcomes that are expected with each nursing action and plan care that addresses patient's current needs.</li> </ul>
Take action	<ul style="list-style-type: none"> <li>Nurse performs interventions, which may be further assessment, monitoring, teaching, or actual interventions, depending on the patient's needs.</li> <li>Actions are based on nursing knowledge, priorities of care, and planned outcomes to achieve optimal health outcomes for the patient.</li> </ul>
Evaluate outcomes	<ul style="list-style-type: none"> <li>Nurse reviews patient response to actions and interventions.</li> <li>Nurse compares observed outcomes with expected outcomes to determine if the plan of care needs to be revised.</li> </ul>

**TABLE 43.2** Cognitive Skills in the CJMM

### Expected Responses and Behaviors

For each cognitive skill, there are specific responses and behaviors the nursing student is expected to exhibit. When expected responses are performed by the student, it indicates that the cognitive skill has been adequately demonstrated, thus the student is using clinical judgment effectively. Expected responses and behaviors by the student that would indicate they can successfully recognize cues include recognizing assessment data pertinent to the patient's condition, identifying subtle changes in the patient's condition, and using knowledge and experience to thoroughly assess the patient.

To analyze cues, it is expected that the student can recognize abnormal assessment findings, anticipate patient needs, identify potential complications that may arise, and begin to prioritize patient problems. When prioritizing hypotheses, the student nurse should be able to organize data and findings based on patterns and trends and prioritize the patient's goals and needs. During the generate solutions (planning) step, the student nurse is expected to collaborate with the interprofessional care team to establish goals of care, prioritize nursing interventions based on the patient's needs, and continuously modify the plan of care based on patient condition changes. When the student begins to the take action step, it is expected that they will accurately perform nursing interventions based on previously established patient priorities and needs, document care appropriately, and provide education to the patient and family. When evaluating outcomes, expected behaviors include reassessing the patient's condition to determine whether goals and outcomes have been met, evaluating how effective nursing interventions were, and modifying patient goals and priorities as needed.

### Consideration of Factors

While using clinical judgment to make practice decisions, it is important to do so within the context of environmental and individual factors. These factors are specific to each patient and help the nurse make informed, personalized decisions.

### Environmental Factors

Environmental factors are things within the external environment that may affect the clinical decision-making process. These factors include:

- culture (e.g., diet, religion, language, literacy)
- individual medical information, including medical history, laboratory and diagnostic test results, intake and output, medications, and current treatments
- patient demographics

- resources (e.g., supplies, staffing, open beds)
- setting (e.g., hospital, long-term care, community health center)
- situational factors (e.g., safety considerations, available equipment, surroundings)
- time pressure related to emergent orders and changes in patient condition

## CULTURAL CONTEXT

---

### Cultural Context within the CJMM

Cultural factors must be considered as part of the clinical judgment process. Without this context, it may be difficult to ascertain the cause of the patient's condition. For example, in some cultures, a vegetarian diet is common. In the context of this factor, the nurse must consider that a lack of protein and vitamin B12 may be the cause of certain medical issues within this population. Although considering cultural factors is important, it is even more important not to generalize information about cultures, because this can border on perpetuating stereotypes. There is a difference between generalizing information about all members of a population versus asking questions about the patient's culture to get specific information that can help the nurse make informed clinical decisions.

---

### Individual Factors

Individual factors that must be considered during the clinical judgment process are more related to the nurse than the patient. These factors include:

- cognitive load of the nurse (e.g., demands, job stress, problem solving skills, memory)
- nurse characteristics, including attitudes, prior experiences, amount of nursing experience
- nurse specialty, knowledge, and skills

## REAL RN STORIES

---

### Floating to Different Units: Considering the Nurse's Experience

**Nurse:** Gabby, BSN

**Clinical setting:** Medical-surgical unit

**Years in practice:** 3

**Facility location:** Small community hospital in rural Georgia

After clocking in for my shift, I was notified by the charge nurse that I would be floating to a different unit for the night. She told me I would need to go to the labor and delivery unit to help out because there were several patients being admitted who would be delivering babies that night. I had only ever worked on a medical-surgical unit, so I expressed that I was concerned and uncomfortable taking care of this patient population. The charge nurse shrugged her shoulders and informed me I was floating to the unit anyway.

Once I got to the unit, the labor and delivery charge nurse told me I would be taking care of a patient who had just delivered a baby 2 hours ago. I again expressed my discomfort, because I had never taken care of postpartum mothers or babies. The charge nurse seemed surprised by this and stated, "I was told they were sending down a nurse with obstetrics experience. Let me make a call real quick."

When the charge nurse came back from making her phone call, she informed me that there had been a mistake and a different nurse with obstetrics experience was supposed to float to the unit, not me. I breathed a huge sigh of relief and headed back to my home unit, thankful that I advocated for myself and the patients.

---

## 43.2 Developing Critical Thinking

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Analyze the types of thinking used in nursing
- Recognize when to use the different types of thinking in nursing
- Explore the application of knowledge to thinking in nursing
- Apply Critical Thinking Indicators (CTIs) to decision making

Thinking is something we usually do subconsciously, because we are not usually “thinking about thinking.” However, with the ever-increasing autonomy being afforded to nurses, there is also an increased need for nurses to be able to critically think effectively and intentionally. Being able to critically think helps nurses’ problem solve, generate solutions, and make sound clinical judgments that affect the lives of their patients. Keep reading to learn more about how nurses use critical thinking in practice and how you can develop your own critical thinking skills.

### Types of Thinking Used in Nursing

Nurses make decisions while providing patient care by using critical thinking and clinical reasoning. In nursing, **critical thinking** is a broad term that includes reasoning about clinical issues such as teamwork, collaboration, and streamlining workflow.” On the other hand, **clinical reasoning** is defined as a complex cognitive process that uses formal and informal thinking strategies to gather and analyze patient information, evaluate the significance of this information, and weigh alternative actions. Each of these types of thinking is described in more detail in the following sections.

#### Cognitive Thinking

The term **cognitive thinking** refers to the mental processes and abilities a nurse uses to interpret, analyze, and evaluate information in their practice. Basically, it encompasses how nurses think about the practice decisions they are making. Cognitive thinking and critical thinking go hand in hand because nurses must be able to use their knowledge and mental processes to devise solutions and actions when caring for patients. Using critical thinking means that nurses take extra steps to maintain patient safety and do not just follow orders. It also means the accuracy of patient information is validated and plans for caring for patients are based on their needs, current clinical practice, and research. Critical thinkers possess certain attitudes that foster rational thinking:

- confidence: believing in yourself to complete a task or activity
- curiosity: asking “why” and wanting to know more
- fair-mindedness: treating every viewpoint in an unbiased, unprejudiced way
- independence of thought: thinking on your own
- insight into egocentricity and sociocentricity: thinking of the greater good and not just thinking of yourself. Knowing when you are thinking of yourself (egocentricity) and when you are thinking or acting for the greater good (sociocentricity)
- integrity: being honest and demonstrating strong moral principles
- intellectual humility: recognizing your intellectual limitations and abilities
- interest in exploring thoughts and feelings: wanting to explore different ways of knowing
- nonjudgmental: using professional ethical standards and not basing your judgments on your own personal or moral standards
- perseverance: persisting in doing something despite it being difficult

Cognitive thinking is significant to nursing because it provides a foundation on which nurses can make rapid and accurate decisions in clinical practice. Nurses must be able to think quickly and make informed decisions to promote optimal patient outcomes.

#### Effective Thinking

To make sound judgments about patient care, nurses must generate alternatives, weigh them against the evidence, and choose the best course of action. The ability to clinically reason develops over time and is based on knowledge and experience. Inductive and deductive reasoning are important critical thinking skills. They help the nurse use clinical judgment when implementing the nursing process. Effective thinking in nursing involves the integration of clinical knowledge and critical thinking to make the best decisions for patients. For example, if a nurse was caring

for a patient who presents with hypertension and new-onset left-sided weakness, it is important that the nurse be able to quickly consider potential causes for the weakness and implement immediate stroke protocols. Without the ability to critically think, the nurse may overlook the weakness as being unrelated to the hypertension and not consider the possibility of stroke, leading to a poor patient outcome. Thus, it is imperative that nurses develop effective thinking skills.

### Inductive Reasoning

The term **inductive reasoning** involves noticing cues, making generalizations, and creating hypotheses. Cues are data that fall outside of expected findings and give the nurse a hint or indication of a patient's potential problem or condition. The nurse organizes these cues into patterns and creates a generalization. A **generalization** is a judgment formed on the basis of a set of facts, cues, and observations and is similar to gathering pieces of a jigsaw puzzle into patterns until the whole picture becomes clearer. On the basis of generalizations created from patterns of data, the nurse creates a hypothesis regarding a patient problem. Remember, a **hypothesis** is a proposed explanation for a situation. It attempts to explain the "why" behind the problem that is occurring. If a "why" is identified, then a solution can begin to be explored. No one can draw conclusions without first noticing cues. Paying close attention to a patient, the environment, and interactions with family members is critical for inductive reasoning. As you work to improve your inductive reasoning, begin by first noticing details about the things around you. Be mindful of your five primary senses: the things that you hear, feel, smell, taste, and see. Nurses need strong inductive reasoning patterns and be able to act quickly, especially in emergency situations. They can see how certain objects or events form a pattern (or a generalization) that indicates a common problem.

Consider this example: A nurse assesses a patient who has undergone surgery and finds the surgical incision site is red, warm, and tender to the touch. The nurse recognizes these cues form a pattern of signs of infection and creates a hypothesis that the incision has become infected. The provider is notified of the patient's change in condition, and a new prescription is received for an antibiotic. This is an example of the use of inductive reasoning in nursing practice.

### Deductive Reasoning

Another type of critical thinking is **deductive reasoning**; it is referred to as "top-down thinking." Deductive reasoning relies on using a general standard or rule to create a strategy. Nurses use standards set by their state's Nurse Practice Act, federal regulations, the American Nursing Association, professional organizations, and their employer to make decisions about patient care and solve problems.

Think about this example: On the basis of research findings, hospital leaders determine patients recover more quickly if they receive adequate rest. The hospital creates a policy for quiet zones at night by initiating no overhead paging, promoting low-speaking voices by staff, and reducing lighting in the hallways. The nurse further implements this policy by organizing care for patients that promotes periods of uninterrupted rest at night. This is an example of deductive thinking, because the intervention is applied to all patients regardless of whether they have difficulty sleeping or not.

## Identify the Purpose of Thinking

Rationalizing the purpose of thinking is probably not something you do often, but it is the foundational first step in critical thinking. To effectively use critical thinking in practice, the nurse must first identify the purpose of thinking. For example, the nurse is caring for a patient who presents with fever, tachycardia, and shortness of breath. The patient also has an open, infected wound on the left foot that is not healing. The nurse must recognize that the patient is exhibiting signs and symptoms that may be indicative of an underlying problem. At this point, the nurse must be able to identify that the purpose of thinking with regard to the patient is to consider what might be happening with the patient and formulate a plan of care. This begins the process of critical thinking, which involves several steps: thinking ahead, thinking in action, and reflection on thinking.

### Thinking Ahead

Thinking ahead in nursing involves considering what may be going on with the patient to anticipate potential outcomes and complications that may arise. Remember competent nurses are proactive versus reactive. Reactive nursing is letting situations arise and then responding to the change, but proactive nursing is recognizing cues behaviors and patterns that are leading up to a complicated event. Additionally, the nurse will formulate goals of

care and must try to anticipate specific needs the patient will have. Considering the patient discussed in the preceding paragraph, the nurse should begin the process of thinking ahead about potential outcomes and complications. The nurse may hypothesize that the patient is starting to develop sepsis from the open wound on the foot so severe sepsis and/or septic shock could be a complication to begin preparing for. The nurse thinks ahead about goals of care for the patient and determines that wound care to prevent infection spread and sepsis is the priority goal at this time.

### Thinking in Action

Thinking in action encompasses the thought processes occurring while the nurse is performing interventions. So, if the nurse in our example begins performing wound care, they are thinking about the best dressing to use, how to clean the wound, and if antibiotics should be considered. All of these thoughts are likely occurring as the nurse is providing the care; thus, they are examples of how the nurse is using thinking in action.

### Reflection on Thinking

After performing interventions or making decisions, the nurse should reflect on the thinking that occurred. The nurse will use this thinking process to determine if the decision was reactive or responsive. Reactive decision-making involves responding to situations after they have occurred, often in a hurried or unplanned manner. These decisions tend to be impulsive and are driven by immediate needs or crises. Responsive decisions, on the other hand, involve careful deliberation about how to address a situation based on careful consideration of information. In our example, the nurse's decision appears to have been responsive. The patient was exhibiting some altered vital signs, but nothing indicated that the situation had become emergent yet. The nurse was able to think carefully about the patient's situation and determine that wound care was the highest priority and begin to implement care in a calm, deliberate manner. In an ideal world, all nursing decisions would be responsive, but in a lot of cases, they must be reactive because of situation severity and medical emergencies.

### Application of Knowledge

During the outset of the critical thinking process, nurses must judge whether their knowledge is accurate, complete, factual, timely, and relevant. This can be done by applying knowledge to nursing practice in a multitude of ways, including drawing from past education and experience in nursing and using professional resources and standards. Each of these is discussed in more detail in the following sections.

### Knowledge Base

Becoming a nurse requires years of schooling, which contributes to the development of a robust knowledge base. Nurses receive formal education and training that provides them foundational knowledge in anatomy, physiology, pharmacology, and patient care techniques, among many others. Additionally, nurses are required to complete continuing education courses specific to their chosen practice setting, further developing their knowledge base. When applying knowledge in practice, nurses can draw from their knowledge base and make informed decisions about patient care.

### Experience in Nursing

Nursing is considered a practice. Nursing practice means we learn from our mistakes and our past experiences and apply this knowledge to our next patient or to the next population we serve. As nurses gain more experience, they can use what they have learned in practice and apply it to new patient situations. Each new encounter with a patient presents unique challenge and learning opportunities that contribute to the development of clinical expertise. Reflecting on these experiences allows nurses to recognize patterns, anticipate patient outcomes, and refine their decision-making processes. Whether they are identifying effective nursing interventions for common conditions, adapting care plans to individual patient needs, or navigating complex situations with compassion, nurses draw upon their accumulated knowledge base from clinical experience to provide high-quality, patient-centered care. Through reflection and continuous learning from past experiences, nurses enhance their clinical skills, ultimately improving patient outcomes.

### Professional Resources and Standards

In addition to foundational knowledge bases and experience, nurses can also use professional resources and standards to gain and apply knowledge in practice. Nurses can refer to clinical practice guidelines that have been established by professional organizations and healthcare institutions to help provide a framework for implementing

nursing interventions based on the best evidence. By following the guidelines, nurses are ensuring that their care aligns with established standards and promotes optimal patient outcomes. Additionally, nurses should remain up to date about new and emerging research in their practice area, which can be obtained by reading professional journals and publications and attending conferences, workshops, and other trainings. Nurses can use the information learned from these resources to influence practice and ensure the highest standards of care are being performed in their practice setting. By staying informed about the latest developments in nursing and health care, nurses enhance their knowledge base and can adapt their practice to incorporate new evidence and innovations. Along with professional development and staying current with professional practices, nursing students should actively seek and join professional organizations such as critical care nursing or oncology nursing societies because this will lead the student to become expert in that subject and stay relevant with current evidence and practice guidelines.

## CLINICAL SAFETY AND PROCEDURES (QSEN)

---

### QSEN Competency: Evidence-Based Practice

**Definition:** Providing quality patient care based on up-to-date, theory-derived research and knowledge, rather than personal beliefs, advice, or traditional methods.

**Knowledge:** The nurse will describe how the strength and relevance of available evidence influences the choice of intervention in provision of patient-centered care.

**Skill:** The nurse will:

- subscribe to professional journals that produce original research and evidence-based reports related to their specific area of practice
- become familiar with current evidence-based clinical practice topics and guidelines
- assist in creating a work environment that welcomes new evidence into standards of practice
- question the rationale for traditional methods of care that result in sub-par outcomes or adverse events

**Attitude:** The nurse will appreciate the importance of regularly reading relevant professional journals.

---

### Critique of Decision

After determining the best course of action based on the application of knowledge, the nurse can critique the decisions that were made. Specifically, the nurse will use self-reflection to review their actions and thoughts that led them to the decision. The nurse will consider the outcomes of their chosen interventions, reflect on the effectiveness of their approach, and identify areas of improvement. Additionally, the nurse may seek feedback from colleagues to obtain different perspectives about decisions made. Soliciting input from others helps the nurse gain insight and learn from their peers to further inform their future practice. Reflection questions that the nurse may ask themselves to critique their decision include the following:

- Was the patient goal or outcome met?
- Could the intervention have been done differently? Could it have been done better?
- What are alternative decisions that could have been made? What are the merits of each?

### Critical Thinking Indicators

Certain behaviors that demonstrate the knowledge, skills, and attitudes that promote critical thinking are called **critical thinking indicators (CTIs)**. Critical thinking indicators are tangible actions that are performed to assess and improve your thinking skills.

#### 4-Circle CT Model

There are many models and frameworks within nursing and other disciplines that attempt to explain the process of critical thinking. One of the most popular is Alfaro-LeFevre's 4-Circle CT Model (Alfaro-LeFevre, 2016). This model breaks critical thinking into four components: personal characteristics, intellectual and cognitive abilities, interpersonal abilities and self-management, and technical skills. These four components overlap, forming interconnections in critical thinking.

## LINK TO LEARNING

Learn more here about the [4-Circle CT Model \(https://openstax.org/r/77circle\)](https://openstax.org/r/77circle) and see an illustration of it.

### Personal Critical Thinking Indicators

Personal CTIs are behaviors that are indicative of critical thinkers. Some of these behaviors that are most relevant to nursing include:

- confidence and resilience: showing ability to reason and learn and overcoming problems
- curiosity and inquisitiveness: asking questions and looking for the “why” behind things
- effective communication: listening well, showing understanding for others thoughts and feelings, and speaking and writing with clarity
- flexibility: changing approaches as needed to obtain the best results
- honesty: looking for the truth and demonstrating integrity while adhering to moral and ethical standards
- self-awareness: being able to identify one’s own knowledge gaps and acknowledge when thinking may be negatively influenced by emotions or self-interests.

### Personal Knowledge and Intellectual Skills

Personal knowledge and intellectual skills encompass the knowledge gained from nursing school and clinical experiences. Examples of each of these kinds of skills are listed in [Table 43.3](#).

Personal Knowledge	Intellectual Skills
<ul style="list-style-type: none"> <li>• Behavioral health and disease management</li> <li>• Ethical and legal principles</li> <li>• Normal and abnormal function (biological, psychological, social, cultural, and spiritual)</li> <li>• Nursing and medical terminology</li> <li>• Nursing process and theories</li> <li>• Related anatomy, physiology, and pathophysiology</li> <li>• Risk management and infection control</li> <li>• Safety standards</li> <li>• Scope of nursing practice</li> <li>• Signs and symptoms of common problems and complications</li> <li>• Spiritual, social, and cultural concepts</li> </ul>	<ul style="list-style-type: none"> <li>• Assesses systematically and comprehensively</li> <li>• Communicates effectively</li> <li>• Determines individualized outcomes and uses them to plan and provide care</li> <li>• Distinguishes normal from abnormal; identifies risks for abnormal</li> <li>• Distinguishes relevant from irrelevant; clusters relevant data together</li> <li>• Identifies assumptions and inconsistencies; checks accuracy and reliability (validates data)</li> <li>• Identifies problems and their underlying cause(s) and related factors</li> <li>• Reassesses to monitor outcomes (responses)</li> <li>• Recognizes changes in patient status; takes appropriate action</li> <li>• Recognizes missing information; gains more data as needed.</li> <li>• Sets priorities and makes decisions</li> </ul>

**TABLE 43.3** Personal Knowledge and Intellectual Skills Included in the 4-Circle CT Model

### Interpersonal and Self-Management Skills

Interpersonal and self-management skills encompass the knowledge and skills needed for effective collaboration. These include:

- addressing conflicts fairly
- advocating for patients, self, and others
- dealing with complaints constructively
- establishing empowered partnerships
- facilitating and navigating change
- fostering positive interpersonal relationships and promoting teamwork

- giving and taking constructive criticism
- leading, motivating, and managing others
- managing stress, time, and energy
- promoting a learning and safety culture
- upholding healthy workplace standards
- using skilled communication in high-stake situations

### Technical Skills

Technical skills in nursing refer to the practical abilities and competencies that nurses use in the delivery of patient care. These skills are typically learned through education, training, and hands-on experience. Some common technical skills in nursing include:

- administering medications
- assisting with personal hygiene and activities of daily living
- documentation and charting
- inserting intravenous catheters
- inserting urinary catheters and nasogastric tubes
- performing tracheostomy care
- performing wound care
- taking vital signs

## 43.3 Unfolding Case Study Dissection

### LEARNING OBJECTIVES

By the end of this section, you will be able to:

- Examine the clinical decisions based on patient needs in the case study
- Recognize steps in application of patient care in the case study
- Identify patient care outcomes in the case study

In this section, we will examine the critical thinking and clinical decision-making used in Unfolding Case Study #4, previously provided in [Chapter 19 Oxygenation and Perfusion](#), [Chapter 22 Activity](#), [Chapter 24 Skin Integrity](#), [Chapter 26 Urinary Elimination](#), and [Chapter 30 Pain Assessment](#).

### UNFOLDING CASE STUDY

#### Unfolding Case Study #4

Mrs. Jenson, a 72-year-old female, presents to the emergency room with worsening shortness of breath, fatigue, and swelling in her lower extremities over the last week. She reports increasing difficulty performing activities of daily living (ADLs) due to weakness and increased dyspnea.

Past Medical History	<p><b>Medical history:</b> Hypertension, type 2 diabetes, heart failure (class III), osteoarthritis</p> <p><b>Family history:</b> No significant family history reported.</p> <p><b>Social history:</b> Widowed ten years ago, currently living in an assisted care facility. No children.</p> <p><b>Current medications:</b></p> <ul style="list-style-type: none"> <li>• Lisinopril 20 mg PO once daily</li> <li>• Metformin 500 mg PO twice daily</li> <li>• Metoprolol 50 mg PO once daily</li> <li>• Aspirin 81 mg PO once daily</li> <li>• Furosemide 40 mg PO once daily</li> <li>• Losartan 25 mg PO once daily</li> <li>• Ibuprofen 400 mg PO Q6 hours PRN mild arthritic pain</li> </ul>
Nursing Notes	<p><b>0830: Assessment</b></p> <p><b>Neurological:</b> Alert and oriented x4, follows commands appropriately</p> <p><b>Respiratory:</b> Labored and shallow breathing pattern, bilateral crackles in bases</p> <p><b>Cardiovascular:</b> Bilateral lower extremity edema, tachycardia</p> <p><b>Abdominal:</b> Bowel sounds present in all four quadrants, no pain or tenderness noted</p> <p><b>Musculoskeletal:</b> Limited range of motion in bilateral shoulder joints, patient reports pain in wrist joints related to osteoarthritis</p> <p><b>Integumentary:</b> Generalized pallor</p>
Flow Chart	<p><b>0845: Assessment</b></p> <p>Blood pressure: 158/89 mm Hg</p> <p>Heart rate: 111 beats/minute</p> <p>Respiratory rate: 27 breaths/minute</p> <p>Temperature: 98.9°F (37.2°C)</p> <p>Oxygen saturation: 88 percent on room air</p> <p>Pain: 6/10 (joint pain)</p>
Provider's Orders	<ul style="list-style-type: none"> <li>• Admit to telemetry unit.</li> <li>• Perform 12-lead ECG.</li> <li>• Administer oxygen therapy to maintain oxygen saturation &gt; 92 percent.</li> <li>• 20 mg furosemide IV STAT.</li> </ul>
Nursing Notes	<p><b>1200:</b></p> <p>12-lead ECG completed; results show sinus tachycardia. 2 L oxygen via nasal cannula applied, patient reports slight improvement in dyspnea. IV placed in right AC, 20 mg furosemide IV administered. Patient instructed to call before getting up to use bathroom. Patient has not voided since admission. Patient admitted to room on cardiac unit and handoff given to telemetry nurse.</p>
Flow Chart	<p><b>1230: Assessment</b></p> <p>Blood pressure: 150/82 mm Hg</p> <p>Heart rate: 108 beats/minute</p> <p>Respiratory rate: 22 breaths/minute</p> <p>Temperature: 98.9°F (37.2°C)</p> <p>Oxygen saturation: 93 percent on 2 L nasal cannula</p> <p>Pain: 6/10 (joint pain)</p>

Flow Chart	<p><b>1300: Assessment</b>  Blood pressure: 142/80 mm Hg  Heart rate: 98 beats/minute  Respiratory rate: 20 breaths/minute  Temperature: 98.9°F (37.2°C)  Oxygen saturation: 94 percent on 2 L nasal cannula  Pain: 6/10 (joint pain)</p>
Nursing Notes	<p><b>1315:</b>  Patient reports experiencing persistent joint pain, particularly in the shoulders and wrists, rated at 6/10 on the pain scale. Patient states that pain interferes with daily activities, such as getting dressed and cooking. Patient also reports stiffness in affected joints, especially in the morning or after prolonged periods of rest, which improves with movement throughout the day.</p>
Provider's Orders	<p><b>1400: New Orders</b></p> <ul style="list-style-type: none"> <li>• Occupational therapy referral.</li> <li>• Acetaminophen 1,000 mg PO Q6 hours PRN.</li> </ul>
Nursing Notes	<p><b>1500:</b>  Occupational therapy referral sent per provider's orders. Acetaminophen administered and patient reports improvement in pain level to a 2/10.</p> <p><b>1530:</b>  During shift assessment, nonblanchable redness was noted on the patient's sacrum. When asked about it, patient reports tenderness in the area that gets worse with prolonged sitting. Patient describes the sensation as a mild "stinging" feeling.</p> <p><b>1600:</b>  Focused skin assessment performed. Open wound noted on bottom of left foot. Patient reports stepping on broken glass about a month ago but states, "I assumed my foot was fully healed because it doesn't hurt at all." Upon assessment, the wound is red with purulent drainage and surrounded by edematous tissue. Prophylactic dressing applied to sacral area. Wound consultation placed.</p>
Provider's Orders	<ul style="list-style-type: none"> <li>• Consultation with wound care team.</li> <li>• Consultation with diabetes educator.</li> <li>• Apply nonadherent gauze dressing on foot.</li> </ul>
Flow Chart	<p><b>1730: Assessment</b>  Blood pressure: 132/80 mm Hg  Heart rate: 94 beats/minute  Respiratory rate: 18 breaths/minute  Temperature: 98.9°F (37.2°C)  Oxygen saturation: 94 percent on room air  Pain: 7/10 (joint pain)</p>

Nursing Notes	<p><b>1800:</b> Patient pressed call light to request to use the bathroom. Ambulated with x1 assist from nurse due to unsteady gait. Patient was unable to void. Focused pain assessment performed. Patient reports 7/10 lower back pain that began last night. The patient states, "I think it's coming from the hospital bed because I can't get comfortable." Patient says that pain is worse with immobility but improves slightly with ambulation.</p>
Provider's Orders	<p><b>1830: New Orders</b></p> <ul style="list-style-type: none"> <li>• Ketorolac (Toradol) 15 mg IV Q6 hours PRN severe pain</li> <li>• Physical therapy referral.</li> </ul>

## Clinical Decisions Based on Patient Needs

Referring to the scenario in Unfolding Case Study 4, as soon as the patient arrived at the emergency room, the nurse began the process of critically thinking about what needed to be done. The nurse assessed the patient's situation and then recognized, analyzed, and prioritized the patient's needs. Once the needs were prioritized, the nurse made clinical decisions about care to be provided and developed and refined planned nursing interventions. Each of these actions by the nurse is discussed in more detail in the following sections.

### Assessment of Patient Situation

The nurse began to assess the patient as soon as they arrived at the hospital. The patient's complaints about worsening shortness of breath, fatigue, and swelling in her lower extremities were important cues to notice because these symptoms were what led her to the hospital to seek care. Additionally, another important cue that was recognized by the nurse was the patient's past medical history, which the nurse hypothesized might have been relevant to their symptoms. Specifically, the nurse took note of all medications the patient was currently taking, because that often provides even more information about a patient's situation. The nurse noticed that the patient was taking shallow breaths and heard bilateral crackles in the bases of the lungs, both of which are consistent with the patient's chief complaint of shortness of breath. During the assessment, the nurse obtained more information including musculoskeletal, integumentary, and pain assessments to use as baseline comparisons later.

### Recognize, Analyze, and Prioritize Patient Needs

The nurse recognized that the most concerning vital signs were the low oxygen saturation and elevated respiratory rate. Because airway and breathing are always the top priority, the nurse implemented interventions to address those issues first. The nurse anticipated that the provider would order supplemental oxygen to improve the oxygen saturation level and maybe a diuretic medication to clear the excess fluid from the lungs. The patient also reported 6/10 joint pain, but this was not the priority concern at the time of ER admission. The nurse chose to address the patient's pain later because it was not as important as stabilizing the patient's respiratory status.

### Develop and Refine Interventions

Based on the provider's orders, the nurse performed a 12-lead ECG and saw that the patient was experiencing sinus tachycardia on the monitor. The nurse also applied supplemental oxygen via nasal cannula based on the provider's order to keep the oxygen saturation greater than 92 percent. Other nursing interventions included admitting the patient to the telemetry unit, administering IV furosemide, monitoring electrolyte levels, and accurately recording intake and output. As you can see in the new vitals taken after applying oxygen, nearly all parameters were improved. If they did not show improvement, the nurse would have revised the plan of care and refined interventions to treat the patient's condition more effectively. After the patient's respiratory status was more stable, the nurse began to gather more information about the patient's joint pain. The nurse performed a functional assessment and determined that the patient was unable to perform ADLs effectively because of the pain. The nurse relayed these findings to the provider who then ordered acetaminophen and a referral to occupational therapy.

### Application of Nursing Care

Application of nursing care in the case study included the interventions mentioned in the previous section as well as counseling the patient about the importance of maintaining skin integrity. While performing a skin assessment, the

nurse noticed that the patient had an open wound on the bottom of her foot but the patient reported that it did not cause her any pain. The nurse recognized that the patient has a history of diabetes and peripheral neuropathy, which affects both the skin-healing process and the patient's ability to feel pain on her lower extremities. The nurse counseled the patient about the importance of maintaining skin integrity, especially on the feet, and put in a referral to meet with a diabetes educator who could provide her with more resources.

### Incorporate Factors Affecting Patient Care

Shortly after the nurse applied a dressing on the patient's foot wound, the patient pressed the call light to ask for assistance to walk to the bathroom. The nurse assisted the patient to the bathroom, but the patient was unable to void. At this point, the nurse became concerned that the patient had not voided in more than six hours, especially since she had received an IV diuretic earlier. The nurse recognized that a contributing factor to being unable to void could be embarrassment. Urinary elimination is highly personal, and it can be difficult for patients to void when they feel as though healthcare staff is watching them. The nurse performed a bladder scan and determined that the patient had a significant amount of urine in her bladder. Because of this, the nurse anticipated that the provider would order straight catheterization. If the nurse were to perform this procedure, it would be important to make the patient as comfortable as possible and provide support as needed, as this procedure can be uncomfortable or embarrassing for some patients.

### Revise Application of Care

Later in the shift, the patient reported new onset of 7/10 back pain, requiring a revision of the patient's plan of care. The nurse performed a focused pain assessment and noted that the patient's pain is worse with immobility and improves slightly with ambulation. The nurse reported these findings to the provider who ordered IV ketorolac (Toradol) and a referral to physical therapy.

### Evaluate Outcomes

After performing interventions, the nurse evaluated outcomes by assessing the patient's vital signs and their understanding of provided education. By assessing these parameters, the nurse was evaluating previous nursing actions that had been taken.

### Evaluate Nursing Actions

Specifically, the nurse evaluated the action of applying supplemental oxygen by assessing the patient's vital signs. The nurse noticed that the patient's oxygen saturation went up to 93 percent after applying 2 L of oxygen via nasal cannula. This finding indicated that this intervention and nursing action were effective. Additionally, the nurse noticed that the patient's heart rate, blood pressure, and respiratory rate all improved slightly, further confirming that supplemental oxygen was an effective nursing action. After administering the ketorolac for the patient's back pain, the nurse reassessed the patient's pain level, looking for a decreased pain level.

### Revise Plan of Care

The nursing interventions were successful, as indicated by the improvement in vital signs. If they had not improved, the nurse would have revised the plan of care to treat the patient's condition more effectively. This may have included alerting the provider about the lack of improvement in the patient's condition, increasing the flow of supplemental oxygen, educating the patient about deep breathing exercises to improve respiratory status, or requesting alternate analgesic medications. The nurse was continually assessing the patient's condition, monitoring for signs of worsening or improvement to use as a guide for revising the plan of care as necessary.

## Summary

### 43.1 Clinical Judgment Measure Model

Historically, nursing was often viewed as a task-oriented career, but in recent years, the profession has grown in terms of autonomy and clinical judgment. Some of this growth was due to the development of the CJMM, a tool designed to measure critical thinking and clinical judgment in nursing students. This tool allows educators to assess the development of nursing student's critical thinking skills to help ensure they are ready to practice as a nurse after graduation. This tool involves several steps that have expanded upon the traditional nursing process model, making it an excellent framework to guide new nurses in making clinical judgment calls in practice.

### 43.2 Developing Critical Thinking

Nursing involves several types of thinking, of which one of the most important is critical thinking. Critical thinking involves applying knowledge to make care decisions that reflect evidence-based practice and consider patient preferences. Thinking is a subconscious process, but there are several models that have been developed to focus upon developing more improved thinking skills. Specifically, the 4-Circle CT model demonstrates characteristics that are vital to develop critical thinking skills. The development of critical thinking skills is especially important within nursing because nurses are constantly making clinical judgment calls when caring for sick patients.

## Key Terms

- clinical judgment** thought process that allows nurses to arrive at a conclusion based on objective and subjective information about a patient
- clinical judgment measurement model (CJMM)** a model allowing nurse educators to teach, assess, and measure the development of clinical judgment skills of nursing students
- clinical reasoning** a complex cognitive process that uses formal and informal thinking strategies to gather and analyze patient information, evaluate the significance of this information, and weigh alternative actions
- cognitive thinking** mental processes and abilities a nurse uses to interpret, analyze, and evaluate information in their practice
- critical thinking** reasoning about clinical issues such as teamwork, collaboration, and streamlining workflow
- critical thinking indicators (CTIs)** certain behaviors that demonstrate the knowledge, skills, and attitudes that promote critical thinking
- deductive reasoning** type of thinking that involves using a general standard or rule to create a strategy
- generalization** proposed explanation for a situation
- hypothesis** judgment formed from a set of facts, cues, and observations
- inductive reasoning** type of thinking that involves noticing cues, making generalizations, and creating hypotheses

## Assessments

### Review Questions

1. What best describes the purpose of the CJMM?
  - a. to help new graduates become critical care nurses after graduation
  - b. to measure the ability of nursing students to take the NCLEX exam
  - c. to help nursing students develop their clinical judgment skills
  - d. to make sure that new nurses know how to run a code blue
  
2. The emergency room nurse is caring for a patient who presents with cough and shortness of breath. The nurse asks the patient about their medical history and notes they have a history of heart failure. The nurse determines that the cough and shortness of breath are likely related to heart failure exacerbation. What cognitive skill of the CJMM is the nurse exhibiting in this situation?
  - a. recognize cues
  - b. analyze cues
  - c. prioritize hypotheses
  - d. take action

3. Which situation best reflects the nursing student prioritizing hypotheses?
  - a. The student measures a patient's blood pressure.
  - b. The student checks the patient's chart to look at laboratory test results.
  - c. The student determines that the patient's wound is infected and needs intervention.
  - d. The student performs skin care on the patient's open wound.
  
4. The nursing student is working within an interdisciplinary care team to establish care goals for a patient. The student is actively engaging in what part of the CJMM?
  - a. recognize cues
  - b. analyze cues
  - c. generate solutions
  - d. evaluate outcomes
  
5. What individual factor should the nurse consider when making clinical judgment calls in practice?
  - a. care setting
  - b. resource availability
  - c. cultural preferences
  - d. nurse skill level
  
6. The student nurse is caring for a patient and, realizing they are unsure about how to perform a skill, they ask the supervising nurse for help. What attitude is the student exhibiting?
  - a. independence of thought
  - b. intellectual humility
  - c. perseverance
  - d. sociocentricity
  
7. What would a nursing student exhibiting egocentricity in practice be doing?
  - a. The student nurse takes a lunch break before giving a patient pain medication.
  - b. The student nurse provides care for a patient who has religious beliefs different from the student's own.
  - c. The student nurse asks the supervising nurse why certain medications are being given.
  - d. The student nurse realizes they are unsure about how to turn a patient in bed and asks for help.
  
8. The nurse assesses a patient and notes that they are clammy and fatigued. On the basis of the patient's history, the nurse determines the patient is experiencing a hypoglycemic emergency. What kind of reasoning did the nurse use to come to this conclusion?
  - a. deductive reasoning
  - b. inductive reasoning
  - c. reductive reasoning
  - d. productive reasoning
  
9. The nurse suspects a patient's cough is related to their underlying heart failure. What term describes the nurse's conclusion?
  - a. generalization
  - b. inductive reasoning
  - c. hypothesis
  - d. recognizing cues
  
10. What action represents an intellectual skill included in the 4-Circle CT Model?
  - a. The nurse can place a peripheral intravenous catheter.
  - b. The nurse recognizes there is missing information and obtains more data.
  - c. The nurse describes various nursing models and theories.
  - d. The nurse addresses a workplace conflict fairly.

## Check Your Understanding Questions

1. What is the difference between the ADPIE nursing process and the CJMM?
2. What are some of the most important attitudes for a nurse to possess to be a good critical thinker?

## Reflection Questions

1. Why do you think it was important for the CJMM to be developed?
2. Why do you think critical thinking is so important in nursing?
3. What do you think is the purpose of thinking in nursing?

## Competency-Based Assessments

1. Write an example of a clinical story showing how a nurse effectively uses all parts of the CJMM to make a decision that positively influences a patient outcome.
2. In a small group, create a skit that represents one of the attitudes involved in critical thinking. Perform the skit for the rest of the class and have them guess which attitude the group is representing.

## Adult Lab Values

### Complete Blood Count (CBC)

Red blood cell (RBC)	4.5 – 5.0 million cells/mm <sup>3</sup> (female) 4.7 – 6.2 million cells/mm <sup>3</sup> (male)
White blood cell (WBC)	5,000 – 10,000 cells/mm <sup>3</sup>
Hemoglobin	12 – 16 g/dL (female) 14 – 17.4 g/dL (male)
Hematocrit	35 – 47% (female) 42 – 53% (male)
Platelets	150,000 – 400,000/mm <sup>3</sup>

### Complete Metabolic Panel (CMP)

Blood urea nitrogen (BUN)	6 – 24 mg/dL
Serum creatinine	0.6 – 1.2 mg/dL
Estimated Glomerular Filtration Rate (eGFR)	> 60 mL/min/1.73m <sup>2</sup>
Carbon dioxide	23 – 29 mmol/L
Glucose	65 – 110 mg/dL
Chloride	96 – 106 mEq/L
Potassium	3.5 – 5.1 mEq/L
Sodium	135 – 145 mEq/L
Calcium	8.6 – 10.2 md/dL
Phosphorus	3.0 – 4.5 mg/dL
Magnesium	1.6 – 2.6 mEq/L
Serum osmolality	285 – 295 mOsm/kg H <sub>2</sub> O
Albumin	3.4 – 5.4 g/dL
Total protein	5.5 – 8.3 g/dL

TABLE A1

Bilirubin	0.1 – 1.2 mg/dL
Liver Function Tests (LFTs)	
Aspartate Aminotransferase (AST)	9 – 25 units/L (female) 10 – 40 units/L (male)
Alanine Aminotransferase (ALT)	7 – 20 units/L (female) 10 – 55 units/L (male)
<b>Arterial Blood Gas (ABG)</b>	
pH	7.35 – 7.45
Partial pressure of oxygen (PaO <sub>2</sub> )	80 – 100%
Partial pressure of carbon dioxide (PaCO <sub>2</sub> )	35 – 45 mmHg
Bicarbonate (HCO <sub>3</sub> )	22 – 26 mEq/L
<b>Coagulation Labs</b>	
International Normalized Ratio (INR)	0.8 – 1.2 2 – 3 is normal for patients on warfarin
Prothrombin time (PT)	11 – 13 seconds 1.5-2x longer if on anticoagulants
Partial Thromboplastin Time (PTT)	60 – 70 seconds 1.5 – 2x longer if on anticoagulants
Activated Partial Thromboplastin Time (aPTT)	25 – 35 seconds 1.5 – 2x longer if on anticoagulants
<b>Lipid Panel</b>	
High Density Lipoprotein (HDL)	> 40 mmol/L
Low Density Lipoprotein (LDL)	< 100 mmol/L
Triglycerides	< 120 mmol/L
Total Cholesterol	< 170 mmol/L
<b>Hemoglobin A1C</b>	
Normal	< 5.7%
Prediabetes	5.7 – 6.4%
Diabetes	> 6.5%

## Chapter 2

### Unfolding Case Study

1. One of the first major findings that is relevant in this case is the fact that this patient does not speak English. Proper communication is key to establish rapport with patients and provide a thorough nursing assessment. Patients who do not speak English as their preferred language should be provided with a trained medical interpreter or interpreting service to ensure that communication is clear. It is not appropriate for a family member, particularly a young child, to interpret for a patient due to the mature and complicated medical content, medical terminology, and risk for inaccurate interpretation. Although nonverbal communication, such as hand gestures and body language, can be used during the assessment, an experienced healthcare interpreter will ensure that a thorough nursing assessment can be conducted. The patient is also grabbing at her ear, which is an example of nonverbal communication.
2. More information should be obtained about the patient's reported ear pain. The nurse should perform a focused pain assessment, determining if the pain is constant, what it feels like, and whether anything makes it better or worse. Additionally, the nurse should inquire about the cough. Specifically, the nurse should ask how long the patient has had the cough, if anything makes it better, and if she has ever had a similar symptom, such as during the two occasions when she had COVID-19. The nurse should also ask the patient about any history of hypertension diagnosis or treatment, as her blood pressure reading is slightly elevated at this visit.
3. The main factor that makes communication between the nurse and patient difficult is the language barrier. Additionally, while the son is attempting to help interpret, it is hard to know if the interpretation is accurately reflected to both parties, which could further complicate the situation. The nurse utilized a picture board for communication, which is a great option. The nurse may also consider using electronic translation services and communication until the trained interpreter arrives.
4. The foundation of the transactional model is that it allows for two-way communication between the nurse and patient as opposed to one-way communication from just the patient or just the nurse. Specifically, the nurse must be able to interpret the patient's communication in the context of their culture and language. Using the transactional model in this situation, it would be helpful for the nurse to use nonverbal feedback from the patient because of the existing language barrier. An example would be assessing the patient's facial expressions to interpret their pain level and then reassessing for nonverbal feedback after administration of pain medication to determine whether it was effective. Ideally, the patient exhibits less grimacing or crying, which would indicate improvement and positive feedback that the nurse can use as a guide for providing further intervention.
5. There are many ways the nurse can use therapeutic communication to address the patient's concerns. First, the nurse should allow the patient to express and share their feelings. Specifically, the patient has reported feeling anxious about leaving her older mother at home alone, so the nurse should allow the patient to express their anxiety. The nurse should remain empathetic, telling the patient they hear and understand the patient's concerns and that they are valid. If appropriate, the nurse may use gentle touch to convey understanding and empathy. The nurse could also ask the patient relevant questions about her concerns, such as, "Do you have any neighbors or family that could go check on her?" or "Would you like to call your mom to check on her? I can help you call her." Above all, the nurse should practice active listening throughout all interactions with the patient, which is the foundation of therapeutic communication.
6. Because the patient does not speak English, the nurse will have to rely on the interpreter to ensure understanding of provided information. Health literacy, an individual's ability to obtain, understand, and apply basic health information and services to make informed health decisions, is important, especially for patients with language or other barriers. The nurse should collaborate with the interpreter to have the patient "teach back" the information to ensure understanding.

## Chapter 5

### Unfolding Case Study

1. A. Rationale: The patient appears to be stable currently. The nurse should recognize the need for an interpreter as the priority to improve communication because the patient does not speak English.
2. C. Rationale: Pain is whatever the patient says it is. In this case, it is likely that the patient's culture processes pain and the meaning of pain differently than what the nurse expects to see. In some cultures, it is common to remain stoic, regardless of how severe the pain is. This highlights the importance of obtaining a thorough history and assessment so that cues are not missed.
3. Health disparities are health outcomes that are worse in certain populations. The social determinants of health are external factors such as the neighborhood people live in or access to health care and have a direct impact on health disparities. In this particular case, the patient reports that income is inconsistent, likely classifying the patient as from a low socioeconomic status, which is a social determinant of health. Having a limited (or inconsistent) amount of income directly impacts the patient's ability to provide for her family and obtain healthcare services, both of which contribute to the development of health disparities.
4. First, the nurse should attempt to obtain more information about the patient's situation. This needs to be done with care as this can be sensitive to talk about. In this case, the nurse also needs to request assistance from the interpreter because the patient does not speak English. Once more information about the patient's finance and home situation obtained, the nurse can initiate appropriate referrals. Often this includes a referral to a social worker or counselor who can assist the patient in finding community and other resources to address economic or social needs.
5. First, the nurse will determine what the patient considers to be the problem and what they call it. In this case, the nurse may ask the patient, "What do you call your illness?" or "What does your illness mean to you?" Second, the nurse should ask the patient what they think caused the illness. In some cultures, it is believed that illness is caused by imbalances in the body or is a punishment from God. The nurse should accept the patient's answer without judgment, even if it does not align with the nurse's personal beliefs. Next, the nurse should ask what the patient is doing to cope with the problem. The nurse should take note of any cultural differences in the way the patient handles the illness, such as use of folk remedies or nontraditional healers, which could impact the patient's care plan. Last, the nurse will ask the patient how concerned they are about the illness. Some cultures view illness as "God's will" and are not concerned, while others express more concern. In this case, specifically, the nurse may also want to ask how concerned the patient is about their finances and access to health care as it has been determined that the SDOH are likely impacting the patient's overall health.
6. Many times, nurses provide patients with resources and referrals while in the hospital but then have no idea if they followed through and got the assistance they needed. To combat this, the nurse can do a few different things. First, the nurse should work closely with the social worker to ensure that appropriate resources are available and that the patient's contact information is provided and all follow-ups are scheduled. This helps ensure that contact with the patient is not lost after discharge. Additionally, the nurse should continuously assess the patient's social needs while they are in the hospital, initiating appropriate referrals as needed. In many cases, nurses and patients build a rapport during the hospital stay which allows the patient to confide in the nurse and allows the nurse to assist the patient with resources. The nurse can ask the patient questions such as "Did I address all of your concerns?" or "Is there anything you are worried about that we haven't talked about yet?" to determine whether the patient's social needs have been completely addressed.

## Chapter 6

### Unfolding Case Study

1. The patient is stable and appears to have basic physiological needs met. However, she expresses concern about employment and finances, indicating that her security needs are not currently met. This is the next-highest priority after physiological needs, so the nurse should address these concerns as the priority.
2. The patient reports being worried about affording medications and care for her mother, so the nurse should ask about health insurance coverage and/or access to medication discount programs. Also, the nurse should ask about the patient's living situation to determine if there are any safety or environmental concerns. Any of

these concerns should be escalated to the social worker so that they can be addressed before discharge.

3. The nurse should address the patient's anxious feelings, as mentioned in the previous question. Additionally, the nurse should inquire about any other emotions the patient is experiencing about her own condition, such as fear. When she presented to the hospital, she was experiencing severe dyspnea and decreased oxygen saturation, which was likely scary. The nurse should discuss those feelings with the patient and address any lingering emotions before discharge.
4. The main concerns the patient has listed currently involve finances and resources for caring for her older mother. The priority action by the nurse is to provide resources and support for the patient. Typically, the best way to do this is to connect the patient with a social worker who is knowledgeable about financial assistance or community support programs that may be able to help ease the financial and emotional burden of caring for her mother. It is important that the nurse connect the patient with the social worker well before discharge to ensure the patient receives the resources they need.
5. First, the nurse should ask open-ended questions about the patient's faith, religion, and spirituality beliefs. This should be done in a nonjudgmental manner, and the nurse should closely assess the patient's comfort level throughout the conversation. Some patients will be comfortable talking about this subject while others will not, so it is important to be mindful when asking questions. If the patient is comfortable talking about this topic, the nurse should ask about various factors that may influence the patient's spirituality, including family influence and previous beliefs and life events.
6. Many times, nurses provide patients with resources and referrals while in the hospital, but then have no idea if they followed through and got the assistance they needed. To improve this, the nurse can do a few different things. First, the nurse should work closely with the social worker to ensure that appropriate resources are available, and that the patient's contact information is provided and all follow-ups are scheduled. This helps ensure that contact with the patient is not lost after discharge. Additionally, the nurse should continuously assess the patient's social needs while they are in the hospital, initiating appropriate referrals as needed. In many cases, nurses and patients build a rapport during the hospital stay, which allows the patient to confide in the nurse and allows the nurse to assist the patient with resources. The nurse can ask the patient questions to determine whether the patient's social needs have been completely addressed: Did I address all of your concerns? Is there anything you are worried about that we haven't talked about yet?

## Chapter 8

### Unfolding Case Study

1. Cues that confirm the need for inpatient medical treatment include severe chest pain, elevated blood pressure, tachycardia, tachypnea, low oxygen saturation, and shortness of breath.
2. Based on the cues and provider's orders, it can be inferred that the patient is experiencing a myocardial infarction, or heart attack. The patient has a history of coronary artery disease, which is another sign that she may be having a heart attack. The admitting provider is likely going to treat the patient's symptoms as if they were a myocardial infarction until it is ruled out because if not treated in a timely manner, severe heart damage may occur.
3. The patient is likely going to the cardiac unit because they are exhibiting signs/symptoms of myocardial infarction. The patient may end up in the cardiac catheterization lab eventually, but for the moment, the patient is reporting improvement in symptoms and is stable. If the patient were to become unstable at any point, it is likely that they would be transferred to the intensive care unit.
4. The emergency room nurse should include the reason for the patient seeking care, pertinent symptoms, and any interventions performed. In this case, the nurse would include that the patient presented for 7/10 chest pain with shortness of breath and interventions included a 12-lead ECG, blood work, supplemental oxygen administration, and administration of IV nitroglycerin. The nurse will want to report any pertinent details about those interventions such as what dosage of nitroglycerin is currently infusing, how much oxygen has been applied, and results of the lab tests. The nurse should end the report with any relevant provider orders that have not been addressed yet and let the nurse know what the next steps in the plan of care are.
5. The emergency room nurse should ensure that the cardiology nurse has been provided with an adequate report and is ready to receive the patient. The nurse should make sure that all of the patient's belongings are transferred with the patient to their new room. If the patient wishes for family to be notified of the transfer,

the nurse should initiate making those phone calls. Additionally, the nurse should assess the patient's mobility status to determine the most appropriate method of physical transfer to the new unit.

6. The patient will report comfort during and after the physical transfer to the new unit and room. Additionally, the patient will report that all personal belongings are present in the new room and that their family members have been made aware of the transfer. Lastly, the nurse will ensure the patient is left in a safe position (e.g., bed low and locked, fall alarm on) before leaving the unit.

## Chapter 9

### Unfolding Case Study

1. The most concerning cue is the patient's inability to remain safely in bed. It is also concerning that the patient is restless and agitated, as this may be indicative of an underlying problem.
2. Based on the cues assessed, the nurse should be concerned about the patient's increased risk for falls. Additionally, the nurse may have concerns related to the patient's mental status since they are exhibiting signs of restlessness and agitation following the procedure.
3. The patient was given oxycodone, which could alter their mental status and their ability to remain safe when out of bed. Additionally, the patient just returned to the unit from a procedure where sedation and pain medications were likely administered. Other factors that may potentially be affecting the patient's ability to remain safely in bed include age, sensory impairments, and/or vision problems. It is important for the nurse to assess for and address these underlying issues to decrease the patient's risk for falls.
4. The nurse should implement fall risk precautions including moving the patient's room closer to the nurse's station, applying fall risk socks and arm bands, keeping the bed locked and in the lowest position, and turning on the bed alarm. The nurse should assess why the bed alarm was off and if the patient is able to turn it off themselves. If they can do so, other interventions such as a 1:1 sitter may need to be initiated.
5. Before anything else, the nurse must ensure that the patient is safe and uninjured from the fall. After getting the patient back to bed, the nurse should conduct a thorough physical assessment and document any apparent bruising or marks left from the fall. The nurse should also notify the provider about the fall, as they may want to order imaging to look for internal injury, especially of the head. After confirming that the patient is not injured from the fall, an incident report must be filed by the nurse.
6. The patient should remain safely in bed and free from harm after the implementation of fall precautions. The patient and patient's family members should also express understanding of the care plan and need for fall risk precautions. If the patient continues to get up from the bed without assistance, the care plan will need to be revised and reevaluated to find more effective solutions.

## Chapter 10

### Unfolding Case Study

1. The patient is exhibiting several concerning respiratory cues, including low oxygen saturation, crackles in the right lung, dyspnea, increased shortness of breath, and cough with yellow sputum.
2. Based on the cues, it can be inferred that the patient has developed pneumonia. Because the patient has been in the hospital for the last several days, this can be classified as a hospital-acquired infection.
3. The patient likely developed pneumonia through contact with infected droplets. This is most likely related to poor hand hygiene, one of the major causes of healthcare-associated infections. The patient may also have underlying health conditions that put them at an increased risk for developing infection.
4. The provider has ordered a sputum culture to determine the causative agent of the pneumonia. The patient was started on vancomycin at first because it is a broad-spectrum antibiotic. However, once the sputum culture comes back, the antibiotic may be changed to one that is more specific for the type of pathogen causing the infection. Supplemental oxygen was ordered because the patient is experiencing shortness of breath and dyspnea secondary to the infection. Droplet precautions have been initiated to prevent the spread of infection to staff and other patients on the unit.
5. The patient has been placed on droplet precautions, which requires the nurse to wear a mask when entering the room. If the patient requires transport outside of the room, the nurse should ensure the patient is wearing a surgical mask.

6. Findings that would indicate an improvement in the patient's condition include improved oxygen saturation with less supplemental oxygen needed, improved crackles in the lungs, no fever, normal respiratory rate, and improvement in shortness of breath. If the patient is not improving, it may require a change in antibiotics because the patient has MRSA, which is resistant to several kinds of antibiotics.

## Chapter 16

### Unfolding Case Study

1. The highest priority concern at this time is that the patient is requesting to discuss palliative care options. It is important for the nurse to ensure the patient has all the resources she needs to make an informed decision about her medical care.
2. Autonomy is the most relevant ethical principle to the patient's current condition. Autonomy refers to the patient's right to make their own care decisions, and in this case, the patient is advocating for herself to make the decision to pursue palliative care.
3. There are many reasons why the patient may not want her family to know about her decision to receive palliative care. She may not be close with her children or may not want them to feel sad about her condition, especially since they lost their father in a car accident only a few years ago. Ultimately, because she is of sound mind, she can make this decision for herself, and the nurse should respect her autonomy. However, the nurse could have a conversation with the patient about contacting her children to make sure that's really what she wants. The nurse must have this conversation in a nonjudgmental way, allowing for the patient's concerns to be expressed and then following her wishes as expressed.
4. The nurse has three options: The first option is to leave the situation alone and respect the patient's wishes to not contact her family. The second option is to go ahead and contact the family since the nurse knows they will want to know about her condition. The third option is to continue to discuss the situation with the patient and hope she changes her mind about contacting her family.
5. The nurse is obligated to honor the patient's autonomy, which means that contacting the family without the patient's consent would be inappropriate. This action would violate boundaries and disregard the patient's wishes, demonstrating a lack of respect for their autonomy. The nurse should maintain an open dialogue with the patient about contacting her family but should do so in a nonjudgmental way without trying to coerce the patient to do it. If the nurse is unable to have these kinds of conversations without patronizing the patient, it would be best for the nurse to proceed with option one, which is to respect the patient's wishes and leave the situation as is.
6. Moral distress in nurses often manifests as physical symptoms including headaches, gastrointestinal upset, and depression. If the nurse's distress has improved, these symptoms should be improved or resolved altogether. If the nurse is experiencing these symptoms or has feelings of dread or anxiety when caring for the patient, the distress is likely still present. If that is the case, it is important for the nurse to reflect on their feelings and values and actively find ways to resolve the internal distress.

## Chapter 17

### Check Your Understanding Questions

1. Answers will vary but should include at least three options from the following: knowledge allowing better choices, activities, understanding of health, wellness, medications; increased physical activity, improved nutrition, decreased risks; hygiene of self and environment.
2. Answers will vary; options include remembering different information; supporting, encouraging, and connecting with one another; asking different questions; fostering asking questions; fostering all learning methods.
3. Answers will vary but should include that direct instruction involves active participation or involvement of the teacher, and indirect instruction includes using other tools to fulfill and complete assignments without direct interaction with the teacher. Direct instruction examples include lecture, discussion, question and answer, demonstration, and video; indirect instruction examples include mention of problem-based learning, inquiry-based learning, experiential learning, and question and answer sessions specific to a laboratory class or clinical, demonstration of laboratory or clinical skills.

- Answers will vary but should include the notion that health teaching and health promotion is one of the standards of nursing practice, and provide example(s) from the seven competencies.
- Answers will vary but should capture that checklists can demonstrate completion of tasks, whether accomplished, and, if necessary, whether accomplished at increasing levels of skill, up to and including fully understanding and acquiring the task.

## Chapter 19

### Unfolding Case Study

- The nurse should first recognize the patient is exhibiting signs of respiratory distress, including a low oxygen saturation level on room air, tachypnea, worsening shortness of breath, dyspnea, and crackles in the lungs. The nurse should also recognize the patient is experiencing tachycardia, hypertension, 6/10 pain, bilateral lower extremity edema, and fatigue.
- Many of the patient's symptoms recognized in the previous question (e.g., crackles, tachypnea) are consistent with the patient's past medical history of heart failure. Additionally, the patient's blood pressure is elevated, which is consistent with her history of hypertension. The patient is also reporting 6/10 joint pain, which is likely related to her history of osteoarthritis.
- The patient is likely experiencing a mix of both types. The patient is exhibiting crackles in the lungs, dyspnea, and tachypnea, which are consistent with left-sided heart failure. The patient is also experiencing bilateral lower extremity edema, which is more prevalent in cases of right-sided heart failure. Because this patient has a history of heart failure, it is possible that it originally started on the left but then began to affect the right side of the heart over time.
- The provider has ordered that the patient be admitted to the telemetry unit. This is likely because the patient is exhibiting symptoms that are indicative of heart failure exacerbation, which will require close cardiac monitoring. The rationale for the 12-lead ECG is to monitor the electrical activity of the heart to make sure the patient is not experiencing any abnormal underlying cardiac dysrhythmias. The oxygen has been ordered because the patient's oxygen saturation is low (88 percent on room air). This indicates that the patient is not receiving an adequate amount of oxygen to perfuse the lungs and other tissues of the body, which can be improved with application of supplemental oxygen. The IV furosemide is ordered because it appears the patient is in a fluid overload state, related to her heart failure, as evidenced by the crackles in the lungs and bilateral lower extremity edema.
- The nurse needs to keep a close watch on the patient's electrolyte levels due to the administration of an IV diuretic. Diuretics, especially when administered intravenously, can deplete electrolytes in the circulatory system, which can quickly become life-threatening if not replaced. The nurse should also closely monitor the patient's output, as the IV diuretic will cause the patient to urinate more frequently. She has not yet used the bathroom, so that will be something to monitor closely.
- The patient's blood pressure, respiratory rate, oxygen saturation, and heart rate have all slightly improved, indicating that the interventions were effective. The patient is still reporting 6/10 joint pain, so this aspect of her condition is not showing signs of improvement. Now that the patient's vital signs are stabilizing, it is important for the nurse to address and treat the pain.

## Chapter 22

### Unfolding Case Study

- The nurse would first assess the patient's respiratory and circulatory systems (based on the ABCs of prioritization). The patient's vital signs have improved since arriving at the emergency room and she is currently stable. At this point, it is most important for the nurse to recognize the patient is reporting moderate pain in the joints, rated 6/10 on the numerical scale.
- The nurse would want to gather more information about the patient's pain. Using a mnemonic, such as OLD CARTES, the nurse will assess onset, location, duration, characteristics, aggravating factors, radiating, treatment, effect, and severity. The nurse may ask questions such as how long she has had the pain, if the pain is constant or intermittent, if anything makes it better, and if anything makes it worse. After obtaining that information, the nurse will be better prepared to initiate interventions for pain control.

3. The nurse would hypothesize that the patient's joint pain negatively impacts her quality of life and probably decreases her level of activity. Even though studies have shown improvement in joint pain from arthritis with increased exercise, patients often find that information to be counterintuitive, instead choosing to rest the joints in an effort to improve symptoms.
4. The nurse should perform a functional assessment to gain a better understanding of the patient's ability to perform ADLs. There are several assessments that can be used but it is most likely that the nurse will use the Katz Index of Independence in Activities of Daily Living.
5. The nurse should first relay these findings to the provider. The provider may order medications to better control her osteoarthritis symptoms or initiate a referral to physical or occupational therapy. Additionally, the nurse should offer support and encouragement to the patient, as losing the ability to perform ADLs can have a significant impact on a patient's mental health. The nurse should also connect the patient to other resources, such as support groups for individuals with osteoarthritis or access to companies that provide assistive devices.
6. Findings that would indicate that interventions were effective and optimal outcomes were achieved include improvement in pain level, improved range of motion, and increased ability to perform or assist with ADLs. The patient should also express an understanding of the need for occupational therapy and be an active participant in her plan of care.

## Chapter 24

### Unfolding Case Study

1. The most important cue for the nurse to recognize based on the provided information is the redness on the patient's sacrum. Specifically, the nurse should recognize that the redness is nonblanchable, meaning that it does not turn white when pressed, indicating that it is a stage one pressure injury. It is also important to recognize that the patient has tenderness in that area with sitting, which is consistent with a pressure injury.
2. The nurse should perform a focused skin assessment to confirm the staging of the redness on the sacrum. Based on its nonblanching status, it is likely to be stage one, but the nurse should assess more carefully to confirm. The nurse should also perform a skin assessment to determine the patient's risk for developing pressure injuries. This will allow the nurse to discover potential causes of the skin breakdown and initiate interventions to reduce risk factors.
3. The nurse should recognize that the patient has difficulty moving related to her osteoarthritis. This immobility is likely contributing to the development of the patient's pressure injury. Additionally, the nurse may hypothesize that factors related to the patient's hydration and nutrition status could be contributing as well.
4. The provider ordered a consultation with the wound care team because of the open wound found on the patient's foot. Based on the assessment findings, the wound appears to be infected, warranting more intense care and follow-up that are best provided by a specialized team. The provider has ordered a consultation with the diabetes educator because it is likely that the patient's foot wound is related to her diabetes. The wound has not healed even though it has been a month since the initial accident, indicating poor wound healing, which is consistent with diabetes. Also, the patient reports being unable to feel any pain on her foot, despite obvious signs of infection. This is concerning and likely related to peripheral neuropathy associated with her diabetes, thus indicating the need for more education about her condition. The provider ordered the application of a nonadherent gauze dressing on the foot to protect the wound site and promote optimal healing. Nonadherent gauze dressings are specifically designed to minimize trauma to the wound bed during dressing changes by reducing the likelihood of the dressing sticking to the wound.
5. The priority actions by the nurse include further assessment and documentation of the wound, initiation of ordered specialty consultations, and application of the ordered dressing. The nurse should closely assess the foot wound for size, drainage characteristics, and any other concerning findings. These should all be documented in the patient's chart, along with a picture of the wound to use for comparisons later. The nurse should also initiate the referrals to wound care and the diabetes educator to ensure that the patient receives these services before discharge. Last, the nurse should apply the nonadherent gauze dressing as ordered. This will keep the wound covered, preventing worsening infection, until the wound care team is able to take a look at it.
6. Findings that would indicate success of the interventions include a wound that is improving (as evidenced by

comparison to the original photo taken during the initial assessment), improved redness and swelling, stable vital signs that do not indicate the presence of an infection, and patient understanding of the need to change the dressing often and keep the area clean. Additionally, the patient should express an understanding of any education provided to them by the diabetes educator regarding the prevention of future injuries and delayed wound healing related to peripheral neuropathy.

## Chapter 26

### Unfolding Case Study

1. The most important cue for the nurse to recognize is that the patient is unable to void. This is concerning since the patient has been in the hospital for over six hours at this point.
2. Since the patient was given a diuretic six hours prior, the nurse would have expected the patient to void by now. This is concerning for urinary retention.
3. Patients with urinary retention may be asymptomatic, so it can be difficult to assess for. However, the nurse could assess for bladder distension on palpation, lower abdominal discomfort, and an inability to initiate or sustain a stream of urine.
4. First, the nurse should report the findings to the provider. It is likely the provider will order a bladder scan to measure how much urine is in the bladder. This is done with a bladder scanner (ultrasound) at the bedside by the nurse.
5. The nurse should anticipate that the provider will order a straight catheterization to empty the bladder. The provider might order an indwelling Foley catheter if the patient requires strict input and output documentation, or if the patient's condition worsens.
6. If performing straight catheterization, the nurse would expect to remove 500 mL of urine from the patient. If less is excreted, there may have been a problem with the catheter that warrants follow-up. The patient should also report less abdominal discomfort and lower abdomen distension if the interventions were effective.

## Chapter 30

### Unfolding Case Study

1. The nurse should recognize that the patient is experiencing severe 7/10 back pain. The rest of the patient's vitals are currently stable.
2. To gather subjective information about the patient's pain, the nurse should perform a "PQRSTU" assessment. During this assessment, the nurse can get more information about what makes the pain worse or better, what the pain feels like, where the pain is felt, how severe the pain is, when the pain started, and what the patient thinks is causing the pain. Objective information would be gathered by checking vital signs and assessing for body language that is indicative of pain such as grimacing or moaning.
3. The patient has a history of osteoarthritis, so the nurse might hypothesize that it could be contributing to some of the back pain. Additionally, the patient could be experiencing distress from being in the hospital that is manifesting as physical pain.
4. The rationale for the ketorolac is immediate pain control. Ketorolac is an NSAID that is indicated for the treatment of breakthrough pain and is used to manage moderate to severe pain, such as the pain displayed by the patient in this case study. Physical therapy is ordered to help the patient with exercise and movement that may improve the back pain related to immobility.
5. One of the main side effects of ketorolac is drowsiness, so the nurse should closely monitor for excessive fatigue. The nurse can monitor for this by frequently assessing the patient's level of consciousness and monitoring for changes. Another major adverse effect is GI bleeding. The nurse will monitor the patient closely for early warning signs such as tachycardia or a decrease in hemoglobin. Ketorolac can also cause Steven-Johnson syndrome, so the nurse should stay with the patient for a few minutes after administering the medication to watch for the development of a facial rash.
6. Assessment findings that would indicate effectiveness of the interventions include stable vital signs, lower pain score reported by the patient, and lack of body language cues (e.g., grimacing) that suggest pain.

## Chapter 33

### Unfolding Case Study

1. First, the nurse must recognize the patient's report about being unable to achieve or maintain an erection is significant because sexual dysfunction can negatively impact overall health. The nurse should also recognize the patient is actively being treated for depression and hypertension based on the current medications listed.
2. The nurse should recognize that both antidepressant and antihypertensive medications can contribute to the development of ED and this patient is on both types of medications. The patient also has a history of diabetes, which has been linked to ED. Additionally, the patient is experiencing depression, which may impact his sexual health and well-being.
3. The nurse should gather information about potential psychological and psychosocial factors that may be causing the ED symptoms. The nurse should first ask more about the patient's depression and if he feels that it is being treated effectively. The nurse should also gather information about the patient's body image, stress level, culture, religion, and lifestyle to gain a better understanding of any risk factors that may be present and contributing to his ED symptoms.
4. The nurse should anticipate the provider will want to obtain a more thorough history of the symptoms. Additionally, the nurse should anticipate the provider may suggest a combination of medications and counseling to treat the ED symptoms. The provider may also suggest counseling or support groups for spouses of cancer patients.
5. Because providing education about sexual health topics can be sensitive and difficult, the nurse should first create a safe and supportive environment for the patient to openly discuss his concerns. As an educator, the nurse should provide the patient with factual and easy-to-understand information about the potential causes of ED and what treatments are available. The nurse must employ good communication skills during this discussion, such as by using active listening and nonjudgmental language to create a safe place for the dialogue to occur. The nurse should focus on the facts, ensure that the patient understands that his symptoms are not his fault, and provide him with the education and resources that he needs to make informed decisions about his sexual health.
6. First and foremost, the patient should express an understanding of the provided information. The patient should also feel empowered to take control of his sexual health decisions versus feeling bad that he needs pharmacologic assistance to maintain an erection. Long-term positive outcomes after treatment initiation would include improvement in ED symptoms and less sexual frustration reported by both the patient and his wife.

## Chapter 34

### Unfolding Case Study

1. First, the nurse recognizes the patient's blood pressure and heart rate are both elevated. Additionally, the patient expresses concern about being unable to participate in sexual activity with his wife due to ED symptoms. The nurse should also recognize the patient has been under a lot of stress at work and is experiencing stress related to his wife's cancer diagnosis, which could be contributing to some of his symptoms.
2. When the patient experiences stress, his body releases hormones that activate the "fight-or-flight" response. In some cases, this can be beneficial as a compensatory response, but in this case, it is likely that the patient is experiencing chronic stress, which is no longer compensatory. Chronic stress tends to be responsible for negative physiological responses such as hypertension, gastrointestinal upset, anxiety, and heart failure. This patient is experiencing hypertension and depression, both of which are exacerbated by the chronic stress.
3. Chronic stress can have profound effects on the body, such as those that are reflected in the patient's laboratory results. First, the patient's kidney function is normal, but on the higher end of normal. Chronic stress can negatively affect the kidney's ability to function optimally, so these values could be related to stress. The patient is also experiencing elevated lab values related to his diabetes (e.g., HbA<sub>1c</sub>, glucose), which may be exacerbated by stress. His elevated white blood cell count may indicate that his body is fighting an infection. Individuals who experience chronic stress have an increased risk of infections because the stress weakens their immune system. Last, the patient has elevated lipid levels, which are often associated

with stress.

4. First, the nurse should anticipate the provider will order counseling or other interventions to target the patient's stress levels. Chronic stress can result in many negative physiological symptoms, so treating the underlying stress may help address some of the other health issues the patient is experiencing. The nurse should also anticipate that the provider will order medications or lifestyle changes to address the elevated glucose, hemoglobin A<sub>1C</sub>, and cholesterol levels.
5. One of the main components of Roy's adaptation model is nursing activities, which are equivalent to nursing actions/interventions. This model encompasses a foundation for all aspects of nursing and patient interactions, including the interventions prescribed by the provider. Additionally, this model states that an individual's potential for adaptation is limited to their ability to cope and the body's resources. In this case, another important nursing action would be for the nurse to assess the patient's ability to cope, which would give a better indication as to whether they will be able to adapt from their current stress level.
6. After meeting with the dietitian and making dietary changes, the nurse would recheck laboratory values and hope to see improvements (decreases) in cholesterol and hemoglobin A<sub>1C</sub> over time. The nurse would also assess for improvement in depression symptoms and the patient's ability to cope with stress related to his wife's diagnosis, both of which would indicate a positive patient outcome.

## Chapter 36

### Unfolding Case Study

1. The nurse should recognize that both Mr. and Mrs. Morales are visibly upset by the news. While Mr. Morales appears to be angry, Mrs. Morales is experiencing sadness and disbelief. The nurse should recognize that both feelings are valid and allow them to grieve how they need to in this moment.
2. Mrs. Morales appears to be in the stage of denial based on her comments of disbelief. Mr. Morales, on the other hand, appears to be experiencing anger. He is having an angry outburst about the provider, requesting that they get a second opinion. It is important for the provider to recognize that the anger being directed at them is likely not personal, but a coping mechanism being used by the patient's husband.
3. Based on his questions about what to expect during the dying process, the nurse should anticipate he might like to receive information about physiological changes that might occur during the dying process.
4. The nurse should provide information about the specific stages of death (e.g., early, middle, late) and what symptoms and physiological changes the patient might experience during each. The nurse should also describe physical symptoms to look for, including restlessness, agitation, loss of consciousness, hallucinations, and agonal breathing.
5. The patient has a DNR order in place, so the hospice nurse should not begin CPR. Instead, the nurse should listen to the patient's heart and determine whether or not death has occurred. The nurse should also allow the husband and other family to be with the patient for as long as they need.
6. Everyone grieves death differently, so this could be subjective. However, the nurse would assess for healthy coping mechanisms such as attending support group meetings, spending time with family and loved ones, and showing a gradual improvement in grief symptoms.
